in the de-entrainers for the 241-AZ-702 and the 296-P-16 ventilation system was calculated based on field survey data. Other vent system component loading assumptions are as discussed in Section 3.4.2.2.1.

Bounding values for fiberglass filters are based on information presented in DOE-HDBK-3010-94, *Airborne Release Fractions/Rates and Respirable Fractions for Nonreactor Nuclear Facilities*, for HEPA filters subjected to explosive stresses (e.g., shock, blast, and venting) or thermal stress. The airborne respirable release fraction used to determine the amount of respirable material released from the filter as a result of crushing is 1.0×10^{-2} (DOE-HDBK-3010-94). The cited airborne respirable release fraction for HEPA filters subjected to explosive stresses is considered applicable and conservative for use in this analysis because the fiberglass filters used in tank farm ventilation systems are similar to those empirically evaluated in DOE-HDBK-3010-94.

Consequence Analysis. Appropriate dispersion coefficients and breathing rates are applied to the release amounts to calculate the radiological consequences. Toxicological consequences are calculated using a frequency dependent sum-of-fractions methodology. This analysis presents sum of fractions values based on the assumption that the event falls in the anticipated frequency category.

Table 3.4.2.2-6 summarizes the onsite and offsite radiological and toxicological consequences, without controls for releases from failed ventilation system filters. The consequences associated with the unfiltered release are presented in Section 3.4.2.2.1.

Comparison to Guidelines. Doses calculated for the HEPA filter overpressurization accident are not related to an event frequency nor compared with guidelines limits. This is because the frequencies of the initiating events (e.g., tank bump, etc.) will differ. Thus, different guidelines will apply to each initiating event, since the guidelines are a function of event frequency. The section describing the specific accident scenario will provide such information.

Summary of Safety Structures, Systems, and Components and Technical Safety Requirements Controls.

Safety Structures, Systems, and Components. The safety structures, systems, and components are defined according to the specific accident scenario. Thus, appropriate safety structures, systems, and components are described in the applicable sections discussing the accidents.

Technical Safety Requirements Controls. Technical Safety Requirements controls are developed for specific accident scenarios. Thus, appropriate controls are described in the applicable sections. A Technical Safety Requirement control is established for filter loading (see Table 3.4.2.2-4).

Defense-in-Depth. Additional controls that provide defense-in-depth are determine based on the specific accident scenario that initiates the event (e.g., tank bump, etc.). Thus, appropriate defense-in-depth controls are described in the sections discussing the specific accidents.

Table 3.4.2.2-3. Safety Structures, Systems, and Components for High-Efficiency Particulate Air Filter Failure.

Structures, systems, or components	Safety classification		Safety function	Comments
	SC	SS		
Continuous air monitor-interlock on ventilation system	--	X	Prevents the unfiltered release from occurring for more than 10 minutes	Applies to the 241-A-702 and 241-AZ-702 ventilation systems for Tank 241-AY-102 and the 296-C-006 and 296-P-16 ventilation system for Tank 241-C-106.

SC = Safety-Class.
SS = Safety-Significant.

Table 3.4.2.2-4. Technical Safety Requirement Controls for High-Efficiency Particulate Air Filter Failure.

Control	Safety function	Comments
Ventilation Stack CAM Interlock System	Detects the high radioactivity and shuts off ventilation within 10 minutes for Tank 241-C-106 and Tank 241-AY-102 ventilation systems. This prevents the potential unfiltered release from occurring for more than a short period of time.	The 10 minute period for the 296-P-16 ventilation system comes from the existing analysis in the main text of the BIO (Section 5.3.2.2).
HEPA Filter Control with the following key elements: - Periodic radiation survey to monitor HEPA, HEME, and HEMF filter loading - HEPA filter replacement per change-out criteria, i.e., ≤ 2 mSv/h (200 mrem/h) - 241-AZ-702 HEME replacement per change out criteria (8 mSv/h (800 mrem/h) - Periodic radiation survey to verify that 296-C-006 HEME/HEMF dose contribution is ≤ 1 mSv/h (100 mrem/h) at location of radiation detector that monitors the HEME/HEMF - Replacement of the 241-AZ-702 HEGA before the upstream HEPA filter has been replaced 20 times, or upon indication of degraded HEPA filter performance - Aerosol test upon installation (AWF 241-AZ-702) - Periodic aerosol test (AWF 241-AZ-702)	Reduces consequences from a possible HEPA filter failure by limiting the inventory available. HEPA filter efficiency testing protects the HEGA filter (241-AZ-702) source term assumption in the analysis.	Applies to HEPA filters upstream of the HEGA filters.

CAM = continuous air monitor
HEGA = high-efficiency gas adsorber
HEME = high-efficiency mist eliminator
HEMF = high-efficiency metal filter
HEPA = high-efficiency particulate air (filter)

Table 3.4.2.2-5. Defense-In-Depth Controls for High-Efficiency Particulate Air Filter Failure.

Control	Function	Comments
Low Delta P interlock across the HEPA filters on the ventilation system	Shuts off the ventilation system to prevent unfiltered release	Where provided
High Delta P (across the HEPA filters) alarm (remotely, at a manned facility) on the ventilation system	Directs the operator to have filters replaced	Workers trained in responding properly to all alarms
Testing of filters following installation and annually, thereafter	Ensures the operability of the filters on the ventilation system	Workers trained in testing the filters
Record sampler	Provides quantitative release amounts reported to state (a higher-than-normal amount would indicate that an unfiltered release is occurring)	Record samplers tested periodically
Interlock/alarm on heater over temperature	Shuts down heater on high temperature indication to protect ventilation system	Interlock/alarms tested periodically, where provided
Periodic surveillance of HEPA Delta P and continuous air monitor	Ensures the operability of the HEPA filters and the filtration monitoring system	None
HEPA filter replacement typically performed at 1 mSv/h (100 mrem/h)	Limits inventory available for release and limit dose rate to workers in the vicinity of the filters	None
Flushing of HEME and/or HEMF on the 296-C-006 ventilation system performed at dose rate of 0.2 mSv/h (20 mrem/h)	Limits inventory available for release and limit dose rate to workers in the vicinity of the filters.	None

HEPA = high-efficiency particulate air (filter).

Table 3.4.2.2-6. Summary of Consequences for Filter Failure Due to High Pressure Without Controls.

CONSEQUENCES				
Ventilation System	Radiological (Sv)		Toxicological (SOF)	
	Calculated Dose		Calculated Dose	
	Onsite*	Offsite**	Onsite	Offsite
241-A-702 Release from Filter Failure	1.6 E-02	1.4 E-05	4.0 E+00	5.5 E-03
241-AZ-702 Release from Filter Failure	1.2 E-02	1.0 E-05	2.9 E+00	4.1 E-03
296-P-16 Release from Filter Failure	2.7 E-02	2.3 E-05	3.1 E+00	6.6 E-03
296-C-006 Release from Filter Failure	2.6 E-01	2.2 E-04	3.0 E+01	6.4 E-02

Note: These consequences are not compared to risk guidelines since they are components of the consequences of the overpressure accidents
*Does not include unfiltered release
**24 Hour Release

This page intentionally left blank.

3.4.2.3 Unfiltered Release. This accident category refers to various failures of the WRSS ventilation systems (existing or new systems [Chapter 2.0]) not associated with the failure of HEPA filters analyzed in Section 3.4.2.2. The WRSS unfiltered release accidents identified in the hazard analysis can be grouped according to the following phenomena:

- **Unfiltered Flow (296-C-006 ventilation system)** — A duct breach in the recirculation loop of the 296-C-006 ventilation system could result in the forced release of unfiltered tank headspace gases if recirculation fans continue to operate.

- **Loss of Vacuum and Cooling (241-A-702, 241-AZ-702 and 296-P-16 ventilation systems)** — A duct breach or exhaust fan failure occurs, resulting in a loss of tank vacuum and a loss of tank cooling (no recirculation cooling is available).

- **Overheating** — The ventilation system continues to operate, but does not provide sufficient waste cooling (because of excess heat load in the tank, excess fluffing of waste, or high sluice water temperature.

- **High pressure** — Miscellaneous transient or minor high pressure events occur (e.g., air in slurry distributor line entering Tank 241-AY-102, a nitrogen line break in Tank 241-C-106).

- **Excess Vacuum** — Excess vacuum in tank headspace (caused by ventilation control or alignment error) causes the inlet seal loop to fail. The tank vacuum cannot be maintained after the vent system error is corrected, resulting in an unfiltered release out the failed seal loop.

- **Degraded Filtration** — Degraded filtration caused by the generation of excess aerosols in the tank dome occurs (may be caused by damage or excess flow to the slurry distributor or sluicer).

3.4.2.3.1 Scenario Development. Each of the scenarios listed above is discussed below.

Loss of vacuum and high temperature. The loss of vacuum and high temperature release scenarios are related to excess bulk waste temperatures. By definition, these scenarios do not result in waste overheating that is severe enough to cause a tank bump. Once cooling is lost, the tank waste will heat up and eventually begin to boil. The following assumptions are made for the loss-of-flow and overheating scenarios:

- The tank begins to boil immediately (or was already boiling as the result of excess heat load)

- Steam generated by the boiling tank does not condense, but escapes unfiltered from the inlet risers or failed ventilation ductwork

- The tank heat load is 52 kW (177,400 Btu/h), corresponding to the heat load in Tank 241-AY-102 after transfer of the maximum quantity of Tank 241-C-106 solids (Section 3.4.2.11).

Using these assumptions, the steam generation rate is roughly as follows (assuming supernate has properties of water):

(177,400 Btu/h)/(201 Btu/lb) * (26.8 ft^3/lb) = approx. 400 ft^3/min (11.3 m^3/min)

This steam generation rate is roughly one-tenth the flow assumed for the unfiltered ventilation release accident analyzed in Section 3.4.2.2. It is assumed that the partition fraction used for the Section 3.4.2.2 scenario also applies to the boiling tank. Therefore, the consequences of the unfiltered release scenario caused by a loss of ventilation are bounded by the scenario described in Section 3.4.2.2.

High pressure. Limited high pressure events result in small unfiltered releases caused by excess pressure generated in the tank dome from a release of noncondensible gas from one of the tank components. Consequences of these events also are bounded by the high pressure scenarios in Section 3.4.2 such as tank bump (3.4.2.11) and organic solvent fire (3.4.2.9). The total flow from the operating ventilation system with failed HEPA filters is much higher than the flow expected from limited high pressure events.

Excess Vacuum. An excess tank vacuum scenario has no consequences unless the ventilation system is shut down after the high-vacuum event. If the ventilation system is shut down, unfiltered releases could occur as the result of passive breathing. The releases during passive breathing would be much less than the release from an operating ventilation system with failed HEPA filters.

Degraded Filtration. The degraded filtration scenario is caused by high levels of aerosol flow through a tank ventilation system caused by a failure in the slurry distributor or sluicer. The large aerosol load builds up on the filters, degrading performance and resulting in the release of high levels of emissions out the stack of the affected ventilation system. The degraded filters would still provide some mitigation of the release, so the consequences would be bounded by the unfiltered release scenario developed in Section 3.4.2.2.1.

3.4.2.3.2 Source Term Analysis. The unfiltered effective continuous release amounts listed in Section 3.4.2.2 were based on the ventilation flow rate and calculated by multiplying the nominal volumetric flow rate by a partition factor to convert it to an equivalent outflow of radioactive contaminant. An "agitated tank" partition factor of 1.0×10^{-8} was used. The partition factor cited here is based on experiment results published in RHO-RE-SA-216, *Characterization of Airborne Radionuclide Particulates in Ventilated Liquid Waste Tanks*, for agitated (1.0×10^{-8}) and unagitated (1.0×10^{-10}) tanks under active and passive ventilation.

3.4.2.3.3 Consequence Analysis. The consequences for an unfiltered release are developed in Section 3.4.2.2 and summarized in Tables 3.4.2.2-1 and 3.4.2.2-2.

3.4.2.3.4 Comparison with Guidelines. Refer to Tables 3.4.2.2-1 and 3.4.2.2-2.

3.4.2.3.5 Summary of Safety Classification and Technical Safety Requirement Controls. Controls developed for the Section 3.4.2.2 scenario are directed at controlling an unfiltered release by shutting down the ventilation system and limiting the inventory on the HEPA filters. Controls directed at shutdown of the ventilation system also apply to the unfiltered release scenarios discussed in this section. Controls for high pressure scenarios are applied to the initiating event (e.g., temperature controls to prevent a tank bump). One scenario addressed in this section is unique and will require a TSR control. A control is needed to inspect the recirculation duct on the 296-C-006 ventilation system. This inspection will provide indication of a duct breach that could lead to an unfiltered release. Note that minor transient overpressures were considered to have acceptable consequences, and no special controls were specified for these events.

Safety Structures, Systems, and Components. For the overheating scenarios, the safety-related structures, systems, and components determined for the Section 3.4.2.11 tank bump scenario are also credited here. Section 3.4.2.11 determines that the Tank 241-AY-102 annulus ventilation system and the primary ventilation systems for Tanks 241-AY-102 and 241-C-106 are Safety-Class structures, systems, and components. The safety function is to provide adequate cooling to prevent sludge or supernatant from reaching the local saturation temperature. See Section 3.4.2.11 for further discussion of structures, systems, and components related to the Tank 241-AY-102 annulus ventilation system.

The structures, systems, and components developed for the Section 3.4.2.2 HEPA filter failure scenario also apply to the degraded filtration scenarios. For the HEPA filter failure accident scenario, CAM interlocks on the 241-A-702 (if returned to service), 241-AZ-702, 296-P-16, and 296-C-006 ventilation systems were credited as Safety-Significant. The safety function of these components is to shut down the ventilation system and limit the duration of forced release of unfiltered headspace gases. Table 3.4.2.3-1 provides a reference to the applicable sections of Addendum 1 for safety structures, systems, and components.

Technical Safety Requirement Controls. The TSR controls developed for the Section 3.4.2.11 tank bump scenario are also credited for the overheating accident scenarios. The controls for the tank bump scenario establish tank waste temperature limits, ensure operability of tank waste temperature monitoring instrumentation, and ensure that waste transfers do not create in-tank conditions conducive to overheating. See Section 3.4.2.11 for further discussion of TSRs related to temperature control.

The TSRs developed for the Section 3.4.2.2 HEPA filter failure scenario also apply to the degraded filtration scenarios. The CAM interlock operation controls were also credited as a TSR that mitigates accident consequences. See Section 3.4.2.2 for further discussion regarding these controls.

For the unfiltered-flow and loss-of-vacuum scenarios, a ventilation control program requiring daily visual inspection of the aboveground recirculation ventilation ductwork for Tank 241-C-106 (during sluicing) is credited as a TSR that prevents continued operation of a breached duct found during sluicing (Table 3.4.2.3-2). The ventilation control only applies to the operation of the 296-C-006 ventilation system.

Defense-in-Depth. The Defense-in-Depth controls developed for the Section 3.4.2.2 HEPA filter failure scenario also apply to the degraded filtration scenarios. Table 3.4.2.3-3 summarizes these controls.

For the unfiltered-flow and loss-of-vacuum scenarios, an ignition control for limiting vehicle speed was credited as a Defense-in-Depth feature preventing a vehicle accident from damaging ventilation ductwork.

Another possible cause identified in the hazard analysis for unfiltered flow and loss of vacuum was excessive corrosion of the ventilation ductwork caused by aerosols of the new waste introduced into Tank 241-AY-102. A transfer control that includes waste compatibility controls provides Defense-in-Depth against excessive corrosion caused by adding waste to Tank 241-AY-102.

Table 3.4.2.3-1. Safety Structures, Systems, and Components for Unfiltered Releases.

Safety Structures, Systems, and Components in BIO Addendum 1, Sections 3.4.2.2 (HEPA Filter Failure) and 3.4.2.11 (Tamk bump) apply as safety significant for unfiltered releases.

Table 3.4.2.3-2. Technical Safety Requirement Control for Unfiltered Releases.

Control	Safety function	Comments
Ventilation Controls with the following key elements: - Visual inspection of the aboveground ductwork for Tank 241-C-106 every 24 hours during sluicing (only applies to operation of the 296-C-006 ventilation system).	Prevent continued operation of a damaged ventilation duct (during sluicing)	The recirculation ducts could be breached without affecting the rest of the system, therefore an inspection is required.

Note: TSR controls credited in Sections 3.4.2.2 and 3.4.2.11 also apply.

Table 3.4.2.3-3. Defense-in-Depth Controls for Unfiltered Releases.

Control	Safety function	Comments
Transfer controls with the following key element: - Waste compatibility controls	Prevents excessive corrosion of the ductwork caused by the addition of new waste to Tank 241-AY-102	--
Ignition Controls with the following key element: - Speed limit controls	Prevents damage to exposed ductwork	--

This page intentionally left blank.

3.4.2.4 Fire in Contaminated Area. This accident analysis addresses possible WRSS fire scenarios in contaminated areas. The basis for the scenarios includes the hazards analysis found in Section 3.3, Section 5.3.2.3 in the main text of the BIO and in WHC-SD-WM-CN-056, *Fire in a Contaminated Area.* The WHC-SD-WM-CN-056 analysis bounds fires in contaminated areas by investigating vehicle fuel fires, which is the most severe type of fire. The hazards analysis in Section 3.3 identifies flammable gas deflagrations and propylene glycol fires as additional potential fire scenarios.

3.4.2.4.1 Scenario Development. The three basic scenarios considered in the WRSS fire in a contaminated area analysis are a vehicle fuel pool fire, propylene glycol fire, and flammable gas deflagration.

Vehicle Pool Fire. The vehicle fuel pool fire is the same as discussed in Section 5.3.2.3 of the main text of the BIO.

Propylene Glycol Fire. The possibility of a propylene glycol fire in a contaminated area is not a significant hazard. Propylene glycol is present in two pits that are associated with WRSS sluicing operations, the sluice pump pit and the Tank 241-C-106 ventilation system pit. The two chillers are designed to cool the sluice pump associated with Tank 241-AY-102 and to cool air flowing through the Tank 241-C-106 ventilation system. The propylene glycol in the chillers is present as a solution in water (46% propylene glycol and 54% water) and is not significantly volatile or ignitable. The propylene glycol in the chillers presents little hazard to the potential contamination present in a pit and is, therefore, not addressed further in this analysis.

Flammable Gas Deflagration in a Pit. A fire in a contaminated area in Tank 241-AY-102 or Tank 241-C-106 as a result of flammable gas (e.g., hydrogen) generated within the tank is addressed in Section 3.4.2.8.

Accident Frequency Without Controls. See main text of the BIO, Section 5.3.2.3.

Accident Frequency With Controls. See main text of the BIO, Section 5.3.2.3.

3.4.2.4.2 Source Term Analysis. See main text of the BIO, Section 5.3.2.3.

3.4.2.4.3 Consequence Analysis. The radiological consequences for this analysis are presented in Table 3.4.2.4-1. The consequences shown in the table for the fire are taken directly from WHC-SD-WM-CN-056.

The toxicological consequences for this analysis are presented in Table 3.4.2.4-2. The source terms are taken from the source term analysis and the sum-of-fractions values are taken from Section 3.4.1, excluding headspace gases. Note that the source term for the fire scenario is taken from WHC-SD-WM-CN-056.

3.4.2.4.4 Comparison to Guidelines.

Comparison to Guidelines Without Controls. Table 3.4.2.4-3 compares the calculated consequences to the onsite and offsite evaluation guidelines. As can be seen from Table 3.4.2.4-3, all onsite radiological and toxicological guidelines are exceeded; no offsite guidelines are exceeded.

Comparison to Guidelines With Controls. Because the accident scenarios are prevented as well as mitigated in the scenario with controls, no consequences were calculated, so no comparison to guidelines is possible for the scenario with controls.

3.4.2.4.5 Summary of Safety Structures, Systems, and Components and Technical Safety Requirements.

Safety Structures, Systems, and Components. No safety structures, systems and components have been identified for this event.

Technical Safety Requirement Controls. The TSR controls related to this accident are described in Table 3.4.2.4-4. The TSRs that prevent a vehicle fuel fire from occurring are a multiple control strategy for ignition prevention. This strategy requires a program for protection of the vehicle fuel system, physical barriers, and speed limit controls. The strategy also requires emergency plans to mitigate the consequences of a fire.

Defense-in-Depth. Additional controls that provide Defense-in-Depth are described in Table 3.4.2.4-5. These include a fire protection program, a radiation protection program, a contamination control program, vehicle position spotters, tank farm fences, and a vegetation control program.

Table 3.4.2.4-1. Fire in a Contaminated Area Radiological Consequences.

Case	Source term (L)	Inhalation ULD[c] (Sv/L)	Breathing rate[a] (m^3/s)	Onsite		Offsite	
				χ/Q^a_3 (s/m^3)	Dose[b] Sv (rem)	χ/Q^a_3 (s/m^3)	Dose[b,c] Sv (rem)
Pool fire	0.084[a]	5.6 E+05	3.3 E-04	3.41 E-02	5.3 E-01 (5.3 E+01)	2.83 E-05	4.4 E-04 (4.4 E-02)

[a]Taken from WHC-SD-WM-CN-056, 1996, Fire in a Contaminated Area, Rev. 2, Westinghouse Hanford Company, Richland, Washington.
[b]The dose is calculated as (source term)*(ULD)*(breathing rate)*(χ/Q).
[c]Offsite ingestion doses were taken to be negligible and were excluded.
ULD = unit liter dose.

SOF = sum-of-fractions.

Table 3.4.2.4-4. Technical Safety Requirement Controls for Fire in Contaminated Area.

Control	Safety function	Comments
Ignition Controls with the following key elements: - Vehicle access within the tank farms shall be limited to vehicles whose fuel systems are protected from damage caused by potential collisions with tank structures - Physical barriers shall restrict vehicle access to those aboveground structures outside of tank farm boundaries that can direct liquids into waste tanks. Only vehicles with protected fuel systems will be allowed within barriers - Speed limit controls	Prevent vehicle fuel system damage in the event of collisions with tank structures within the tank farms. Outside the tank farms where vehicle access can not be controlled, prevent vehicle access to tank structures	--
Emergency Preparedness with the following key element: - Response procedures for fire in contaminated area	Mitigates the consequences of a fire in contaminated area	--

Table 3.4.2.4-5. Defense-In-Depth Controls for Potential Fire in Contaminated Area.

Control	Safety function	Comments
Fire protection program	Fire prevention	Program contains a number of provisions that would prevent fires in a pit from causes other than ruptured fuel tanks
Radiation protection program	Facility workers will use masks when working in areas with the potential for airborne contamination	Provides protection for facility workers that would be closest to the accident location
Contamination control program	Survey and cleanup of areas with loose surface contamination	For the scenario analyzed, would reduce the concentration and quantity of contamination in the valve pit
Vehicle positioning spotters	Spotters provide additional level of control in positioning cranes/vehicles	Reduces probability of analyzed accident
Tank farm fences	Provide line of demarcation within which Ignition Control Program key elements related to vehicle fuel systems must be met	Fence gates are typically closed and locked
Vegetation control program	Prevents range fires from impacting Tank Farm facilities	None

3.4.2.5 Caustic Spray Leak. Sodium hydroxide is used to adjust the concentration of hydroxide (OH-) ions in the waste tank contents to minimize corrosion. A pressurized spray leak of caustic solution during a transfer to a waste tank could disperse a significant amount of respirable sodium hydroxide particles. These particles could cause potentially significant onsite or offsite toxicological consequences.

Because quantitative analysis does not exist for overpressurization of a sodium hydroxide carrying cargo tank, qualitative results are presented here and are used as the basis for deriving controls. The qualitative analysis of a pressurized cargo tank rupture and spray leak is presented in HNF-SD-WM-CN-065, *Consequence Analysis of NaOH Solution Spray Release During Addition to Waste Tank*. The main text of the BIO will incorporate this analysis in a future revision. No radioactive materials are associated with this event.

3.4.2.5.1 Scenario Development.

Sequence of Events. Sodium hydroxide is either procured from an offsite vendor and transported in tanker trucks to the tank farms or mixed onsite. The caustic solution may be as strong as 19 M (50 wt%). The solution may be transferred into a given waste tank using a mixer pump or transferred directly through an available riser.

The initiating event is assumed to be a overpressurization of a sodium hydroxide cargo tank. In the worst case scenario, this overpressurization causes the tank to rupture, spraying its contents. Other possible initiators of a spray leak include a crack developing in the cargo tankers and the transfer piping. However, the consequences of the rupture case are assumed to be bounding.

It is important to note that the system analyzed here consists of a pressurized cargo tank, fittings, and flexible polyethylene hose sections. The volume of the analyzed cargo tank is 26,500 L (7,000 gal). This will be the system used to add sodium hydroxide during WRSS operations. The scenario analyzed in Section 5.3.2.9 of the main text of the BIO is another possible system of caustic addition. The main text scenario involves a 208 L (55 gal) drum, a pump, hard piping, and hose.

Accident Scenario Without Controls. For the accident scenario without controls, the sodium hydroxide cargo tank was postulated to rupture after becoming overpressurized, forming an atomizing spray. The pressure inside the cargo tank is assumed to be 862 kPa (125 psi), based on the maximum pressure attainable by the plant air supply, which could be used to pressurize the tank. The vendor could also supply an air compressor, which is assumed to provide less than 862 kPa (125 psi). A rupture of the tanker truck caused by a failure during overpressure was also analyzed.

Accident Frequency Without Controls. The frequency without controls of a cargo tank rupture has not yet been ascertained.

Accident Scenario With Controls. The controls selected for the caustic spray leak are preventive as well as mitigative and are presented in

Section 3.4.2.5.4. These controls prevent overpressurization and leaks, therefore no release scenario is postulated for the case with controls.

Accident Frequency With Controls. With the controls identified for the caustic spray leak in Section 3.4.2.5.4, the accident is prevented although controls are also specified to mitigate the accident.

3.4.2.5.2 Source Term Analysis.

Accident Source Term Without Controls. The main text of the BIO (Section 5.3.2.9) presents the results of the analysis of a spray leak in caustic transfer piping (of the skid system) caused by a crack with a minimum depth of 2.77 mm (0.109 in.) and a maximum length of 25 mm (1 in.). The results of this analysis can be found in HNF-SD-WM-CN-065. The SPRAY Code, Version 3.0, was used to calculate leak rates and small particle fractions for an assumed break in the liquid containment boundary. The crack width was optimized to produce the highest respirable particle fraction using the SPRAY Code (WHC-SD-GN-SWD-200007, *A Model for Predicting Respirable Releases from Pressurized Leaks*).

Particles less than about 10 μm tend to remain suspended in the air for long distances, but particles larger than 10 μm released from a non-elevated source tend to fall out within the first 50 to 100 m (164 to 328 ft) of travel. The size of the liquid particles will decrease in transit by evaporation of the liquid component. Ultimately, only smaller particles of the solid material previously in liquid solution will remain. Therefore, the small particle fraction of the spray release, which is a function of solution concentration and crack width, was determined using the initial diameter of a solution particle (with the given solid fraction) that will shrink to 10 μm by evaporation. The leak rate and atomization efficiency increase with decreasing viscosity and increasing temperature. Therefore, the high end of the temperature range for this liquid (50 °C [122 °F]) was assumed.

A parametric study was then performed using the SPRAY Code to determine the worst case solution concentration within a range of 5% to 50% NaOH to be used for tank additions. The worst case small particle release rate was calculated over a range of NaOH concentrations. These calculations accounted for variation in viscosity and density with concentration. Results of the calculations indicated that a 12% solution was optimal for small particle generation. For this case, the unevaporated particle size range was less than or equal to 20.3 μm and the respirable NaOH release rate was 1.68 g/s. Standard roughness and flow parameters for steel pipe were assumed. For the cases where critical flow developed in the crack, friction factors for laminar flow were assumed for conservatism.

The source term for this accident has been analyzed qualitatively in HNF-SD-WM-CN-065. This analysis shows that a crack in the cargo truck can result in caustic concentrations at the offsite receptor that exceed the risk guidelines. The analysis for tank rupture also shows that caustic concentrations at the offsite receptor can exceed the risk guidelines. In addition, if the offsite guidelines are exceeded, so are onsite guidelines. The caustic spray leak scenario frequency is anticipated (HNF-SD-WM-CN-065).

Accident Source Term with Controls. No source term with controls was derived because the accident controls are preventive as well as mitigative.

3.4.2.5.3 Consequence Analysis. The onsite and offsite toxicological exposures in HNF-SD-WM-CN-065 were determined qualitatively.

Analysis Results.

Consequences Without Controls. The toxicological consequences of the rupture release are qualitatively presented in Table 3.4.2.5-1. A quantitative analysis has not yet been performed (HNF-SD-WM-CN-065).

Consequences With Controls. No consequences with controls were derived because the accident controls are preventive as well as mitigative.

3.4.2.5.4 Comparison to Guidelines. Table 3.4.2.5-1 compares caustic spray leak consequences to risk guidelines. The criterion is exceeded at the onsite receptor location and the offsite receptor location.

3.4.2.5.5 Summary of Safety Structures, Systems, and Components and Technical Safety Requirement Controls.

Safety Structures, Systems, and Components. No safety structures, systems, and components are required.

Technical Safety Requirement Controls. The TSR controls for the caustic spray leak accident analysis are listed in Table 3.4.2.5-2.

Defense-in-Depth. Defense-in-Depth controls for the caustic spray leak accident are listed in Table 3.4.2.5-3.

Table 3.4.2.5-1. Qualitative Consequences of a Caustic Spray Leak Assuming No Controls.

Accident	Consequences								Frequency
	Radiological, Sv (rem)				Toxicological				
	Onsite		Offsite		Onsite		Offsite		
	Calculated dose	Risk guideline	Calculated dose	Risk guideline	Calculated SOF	Risk guideline	Calculated SOF	Risk guideline	
Caustic Spray Leak from the Tanker Truck	N/A	N/A	N/A	N/A	Above guidelines	1	Above guidelines	1	Anticipated
Caustic Release from Rupture of the Tanker Truck	N/A	N/A	N/A	N/A	Above guidelines	1	Above guidelines	1	Anticipated

N/A = not applicable.
SOF = sum-of-fractions.

Table 3.4.2.5-2. Technical Safety Requirement Control* for Caustic Spray Leak.

Control	Safety function	Comments
Caustic Transfer Controls with the following key elements:		
- Plastic sleeving around delivery piping	Prevents or mitigates the consequences of a spray leak	Sleeving shall have a thickness ≥ 4 mil
- Caustic delivery system pressure ≤ 125 psig or below sodium hydroxide cargo tanks specified maximum allowable operating pressure, whichever is lower	Reduces the consequences of a leak by reducing the leak rate. Ensures that sodium hydroxide tanks will not be subject to overpressurization	Overpressurization of sodium hydroxide cargo tanks could result in tank rupture
- Steel pipe shall be Schedule 10 or heavier wall thickness; polyethylene hose or other delivery pipe shall be designed for appropriate pressure delivery. Caustic transfer piping will have a wall thickness of ≥ 0.109 in	Prevents or mitigates the consequences of a leak by reducing the leak rate	A thinner walled pipe would have worse consequences
- Vendors will be required to provide documentation that the sodium hydroxide cargo tanks to be used for caustic transfers meet Department of Transportation Specifications	Ensures that tank relief valves are operable, ensures that minimum wall thickness is at least 0.100 in., and provides for inspections of cargo tanks. This prevents or mitigates release from cracks or ruptures of the tank	
- Traffic barriers shall surround the cargo tank (e.g., traffic cones or stanchions and chains)	Reduces the probability of a caustic leak	

*Note: Controls analyzed are for a skid system and for a cargo tank system, as applicable (e.g., the cargo tank truck does not use steel pipe).

Table 3.4.2.5-3. Defense-in-Depth Controls for Caustic Spray Leaks.

Control	Safety function	Comments
Operator training	Prevents or minimizes the effects of a leak	The operating procedures contain a number of checks to ensure that piping connections are secure and equipment functioning properly. Regular instrument checks during transfers minimize consequences of a leak
TWRS Hazardous Material Protection Program	Prevents or minimizes consequences to a worker from a hazardous material release	The TWRS HMP program is a collection of industrial hygiene programs designed to protect workers against the type and magnitude of hazards identified in Chapter 5.0, "Safety Analysis." See Chapter 4.0, "Safety Management," for a discussion of the HMP program
Emergency response plans and procedures	Mitigates the consequences of leaks or spills	Emergency response plans and procedures are in place to respond to and mitigate the consequences of accidental leaks or spills of hazardous material. See Chapter 4.0, "Safety Management," for a discussion of the emergency preparedness program

HMP = Hazardous Material Protection.
TWRS = Tank Waste Remediation System.

3.4.2.6 **Tank Failure Caused by Excessive Loads.** This accident category refers to structural failures of Tank 241-AY-102 or Tank 241-C-106 caused by the excess loads discussed in the following paragraphs. The load drop accident scenario analyzed here is analogous to the scenario analyzed in Section 5.3.2.13 of the main text of the BIO. It is argued that the mixer pump used in the main text load drop analysis causes more damage than the heavy equipment specific to WRSS. However, the main text consequence analysis was modified to account for the possibility that aging waste solids could be aerosolized in the hypothetical accident. The main text analyzed consequences of a load drop using non-AWF double-shell tank solids.

Load Drop. A load drop could occur during a crane lift of heavy equipment that is being installed or removed from Tank 241-AY-102 or Tank 241-C-106. The following equipment is of concern for the WRSS:

- Concrete cover blocks (several types, all under 14,514 kg [32,000 lb])
- Two booster pumps (1,814 kg [4,000 lb] each)
- One sluicer assembly (771 kg [1,700 lb])
- One winch pump assembly (3,016 kg [6,650 lb]).

The consequences of dropping these pieces of equipment are bounded by the consequences of dropping the 101-SY mixer pump (9,100 kg [20,000 lb]) vertically into a tank pump pit from the maximum crane lift height (for further details on the mixer pump drop, see discussion in the scenario development section). The mixer pump represents the combination of large total mass with a small cross-sectional area of impact that would produce maximum damage to the tank dome. Concrete cover blocks dropped from a similar height would not penetrate the dome because of their large cross-sectional area (see further discussion in the scenario development section). The booster pumps also have a large cross-sectional area and would cause much less damage than the cover blocks because they weigh much less. The sluicer assembly and winch pump assembly have cross-sectional areas comparable to the mixer pump, but have much less mass and would generate a smaller source term even if it is assumed that they could penetrate the tank dome if dropped.

3.4.2.6.1 **Scenario Development.** Load drops will cause localized structural damage to a riser pit floor and the tank dome if drop heights are great enough and if the items dropped are rigid enough. The failure mode for equipment drops at heights > 6.1 m (20 ft) is the result of excess local shear stresses in the dome. A load drop event can occur as a result of the following:

- Drop of the load as the result of cable failure, brake failure, or operator error
- Drop of the boom (with or without the load) as the result of boom or boom cable failure.

The load can drop onto the soil cover over Tank 241-AY-102 or Tank 241-C-106, onto the pits over the tank, primarily the pump pit, or onto a riser. The worst case is a load drop into a pump pit because, of all the possible drop locations that could result in the load reaching the tank waste, the pump pit is structurally the weakest.

All load drop accidents are bounded by the consequences of a mixer pump drop. Although a mixer pump will not be used for WRSS operations, a mixer pump drop was used in the analysis to provide an upper bound on the consequences of dropping the heavy equipment that will be used in the project sluicing operations. The WRSS accident scenario assumes that a 9,100 kg (20,000 lb) mixer pump (the weight of the lifting hardware is ignored) is dropped into the pump pit of Tank 241-AY-102 or Tank 241-C-106. Although some cover blocks are heavier than mixer pumps, the cover block drop height necessary to damage the dome is at least 10 times greater (WHC-SD-WM-TI-775, *Structural Assessment of Accident Loads*) than for a mixer pump. The factor of 10 is directly related to the impact area. The impact area for the cover block is 0.13 m^2 (200 in^2); for the pump the impact area is 0.023 m^2 (36 in^2). Another reason the mixer pump drop is considered to be the worst case drop is the orientation of the equipment during the lift. The pump would be lifted so that the axis is vertical. The cover block would be lifted flat.

Accident Scenario Without Controls. See main text of the BIO, Section 5.3.2.13.

Accident Frequency Without Controls. Because the pumps and heavy equipment assemblies are already installed in Tank 241-AY-102 and Tank 241-C-106, pump replacement is not planned during WRSS operations unless a pump unit fails during sluicing operations. However, as a worst case or upper bound on the load drop frequency, it is assumed that both the sluicer and winch pump assemblies must be replaced annually because of operator error or a delay in the start of the WRSS operations.

Installation of large loads in the tank requires several critical lifts. Replacing a pump assembly requires removal of the cover blocks, booster pump, and sluicer or winch pump assembly, then replacement with the new parts. A drop of the cover blocks or booster pumps will not penetrate the tank dome because of the relatively large surface area of impact. This leaves four critical lifts that may penetrate the tank dome during replacement of the sluicer and winch pump assemblies. Thus, the upper bound on the dome penetration frequency (per year) is four times the probability of dropping an object during a critical lift.

The frequency of a heavy load drop for the WRSS operations is in the "unlikely" category, as in Section 5.3.2.13 of the main BIO text.

Accident Scenario With Controls. See main text of the BIO, Section 5.3.2.13.

Accident Frequency With Controls. See main text of the BIO, Section 5.3.2.13.

3.4.2.6.2 Source Term Analysis. This section quantifies the material released should a load drop occur.

Source Term Without Controls. As discussed in the main text of the BIO, the total waste made respirable is 0.51 L (0.126 gal). After accounting for the amount that is suspended and the amount that is removed from the tank, a total of 0.005 L of respirable material is released.

Source Term With Controls. Because the accident is prevented with controls in place, there is no source term with controls.

3.4.2.6.3 Consequence Analysis. The consequences of the load drop scenario were calculated in accordance with the methodology presented in Section 3.4.1.

The radiological consequences are based on the unit liter dose for aging waste facility tank solids. As previously discussed, use of the dry salt cake source term with the unit liter dose for aging waste facility tank solids does not realistically represent an object drop into sludge or slurry in Tank 241-AY-102 or Tank 241-C-106. Rather, the aging waste facility tank unit liter dose source term should be interpreted as an upper bound on the more realistic source term from a drop into liquid.

Consequences Without Controls. Table 3.4.2.6-1 summarizes the radiological and toxicological consequences of the load drop scenario without controls. The doses were calculated using the bounding χ/Q' values.

$$EDE_{onsite} = (0.005\ L)\left(3.41 \times 10^{-2}\ \frac{s}{m^3}\right)\left(3.3 \times 10^{-4}\ \frac{m^3}{s}\right)\left(1.7 \times 10^{6}\ \frac{Sv}{L}\right)$$

$$= 0.096\ Sv$$

$$\approx 0.1\ Sv$$

$$EDE_{offsite} = (0.005\ L)\left(2.83 \times 10^{-5}\ \frac{s}{m^3}\right)\left(3.3 \times 10^{-4}\ \frac{m^3}{s}\right)\left(1.7 \times 10^{6}\ \frac{Sv}{L}\right)$$

$$+ (0.005\ L)\left(2.83 \times 10^{-5}\ \frac{s}{m^3}\right)\left(8.1\ \frac{Sv \cdot m^3}{s \cdot L}\right)$$

$$= 8.1 \times 10^{-5}\ Sv$$

The "all solids" toxicological sum-of-fractions was chosen to bound the toxicological consequences (see Section 5.3.1 of the main text of the BIO). The accident happens in a short period of time, so the sum-of-fractions for a puff release is assumed. The frequency of this event is in the "unlikely" category as discussed above.

$$T_{onsite} = (0.005\ L)\left(6.6 \times 10^{3}\ \frac{1}{L}\right)$$

$$= 33$$

$$T_{offsite} = (0.005\ L)\left(1.7 \times 10^{-7}\ \frac{1}{L}\right)$$

$$= 8.5 \times 10^{-4}$$

Consequences With Controls. Because the accident is prevented with controls, there are no consequences with controls.

Sensitivity of the Results to Key Parameters and Assumptions. See BIO, Section 5.3.2.13.

3.4.2.6.4 Comparison with Guidelines. The onsite radiological consequences without controls of 0.1 Sv (10 rem) is above the onsite evaluation guidelines of 0.05 Sv (5 rem) for an "unlikely" event (Table 3.4.2.6-1). The offsite guidelines of 0.005 Sv (0.5 rem) are easily met. The onsite toxicological consequences without controls of 33 exceed the onsite guidelines of 1.0. The offsite guidelines are met.

With controls, the event is prevented; therefore no consequences are calculated.

3.4.2.6.5 Summary of Safety Structures, Systems, and Components and Technical Safety Requirement Controls. The following paragraphs present safety classification and TSR controls for the load drop accident. They also cover Safety-Class SSCs and TSR controls for uniform and concentrated load scenarios.

Safety Structures, Systems, and Components. No Safety-Class or Safety-Significant equipment is specified for this accident. Instead, the controls focus on TSRs that prevent the accident.

Technical Safety Requirement Controls. Table 3.4.2.6-2 summarizes the TSR controls. The TSR control chosen for the load drop event is an administrative control that states the height to which a load is raised shall not exceed the critical height of 6.1 m (20 ft) above the soil at grade or the floor of the pits. Justification for a 6.1 m (20 ft) drop is provided in WHC-SD-WM-TI-782, *Load Drop Evaluation*. The pit floors are chosen because the cover blocks over the pits do not provide much resistance to a load drop. The numerical value of the critical height is based on the lack of penetration of the worst case hypothetical load (the Tank 241-SY-101 mixer pump) dropped onto the weakest point that could result in dome penetration (the pump pit). Details are in the load drop calculations presented in WHC-SD-WM-TI-782. Load drops from the critical height will not result in penetration of the dome.

Another element of the Technical Safety Requirement requires use of DOE/RL-92-36, *Hanford Site Hoisting and Rigging Manual*, which provides guidelines for inspection, personnel qualification, training, equipment to be used, and critical lift procedures for lifts over all TWRS facilities.

It has previously been demonstrated that dome or roof collapse caused by excessive loads is not credible. However, because different cranes can be brought to the Site, a control is required to protect the assumption. The maximum loads above which the dome or roof could fail are presented in WHC-SD-WM-TI-775 and WHC-SD-TWR-RPT-002, *Structural Integrity and Potential Failure Modes of the Hanford High-Level Waste Tanks.* The Technical Safety Requirement load limits must be set well below the failure loads because the stresses caused by the loads must meet code allowables.

The concentrated load shall not exceed 90,800 kg (100 tons) over Tank 241-AY-102 or Tank 241-C-106 either permanently or temporarily (WHC-SD-WM-TI-775).

Defense-in-Depth. Defense-in-Depth features are those operational practices that also serve to prevent an accident or mitigate its consequences (Table 3.4.2.6-3). The load drop event has six Defense-in-Depth features including a radiation protection program, a facility Health and Safety Plan, a Job Control System, operator training, operating procedures, and emergency response plans/procedures.

Table 3.4.2.6-1. Consequences of a Load Drop Assuming No Controls.

Table 3.4.2.6-2. Technical Safety Requirement Control for Load Drops.

Control	Safety function	Comment
Dome Loading Control with the following key elements:		Critical lifts are defined in the Hanford Site Hoisting and Rigging Manual
- For critical lifts over SSTs and DSTs:		
• Hanford Site Hoisting and Rigging Manual requirements shall be met	Prevents load drop accidents (i.e., reduces the frequency of load drops)	The cover blocks offer little resistance to load drops due to their failure at low bending moments and are not considered in determining compliance with the (6.1 m) 20 ft limit. The (6.1 m) 20 ft limit considers the largest mixer pump (9,100 kg [20,000 lbs]) and cover blocks as the limiting loads
• Height of the bottom of the load shall not exceed 6.1 m (20 ft) over the soil or pit floor	Limits load handling over a tank so that in the event the load is dropped the tank dome would not collapse	
- External load on the tank dome:	Prevents exceeding external loads that may cause tank dome failure	
• SST uniform load shall not be modified		
• DST uniform loads shall be below 2.5 m (8.3 ft) of soil (AY and AZ tank farms, and 2.3 m (7.5 ft) of soil (SY, AW, AN, AP tank farms)		
• 100 series SST and DST concentrated load shall not exceed 90,800 kg (100 tons) on a temporary or permanent basis		

DOE/RL-92-36, 1996, Hanford Site Hoisting and Rigging Manual, U.S. Department of Energy, Richland Operations Office, Richland, Washington.

DST = double-shell tank.
SST = single-shell tank.

3.4.2.7 Tank Failure Caused by Excessive Vacuum. This accident category refers to structural failures of Tank 241-AY-102 or Tank 241-C-106 caused by excess vacuum in the tank headspace. The excess vacuum hazards discussed are analogous to those analyzed in Section 5.3.2.13 of the main text of the BIO. Excess vacuum events specific to the WRSS have been identified in the WRSS hazard analysis. Special consideration has been given to the new ventilation systems that will be installed in the tanks before the WRSS starts up. This accident scenario is bounded by the analysis in Section 3.4.2.6.

Tank failure refers to loads or conditions that could result in dome or roof collapse; dome or roof settling (wall failure); or dome, roof, wall, or bottom perforation that can result in the release of radioactive waste to the environment through openings in the walls, the bottom, or the dome of a tank. The following accidents were identified in the WRSS hazard analysis as those that could lead to structural failure as the result of excessive vacuum in the tank headspace (Section 3.2).

- Fan controller failure or operator error increases fan speed
- Inlet ventilation damper accidentally closes
- Inlet ventilation plugged by ice (as the result of chiller malfunction or weather) or ash
- Incorrect ventilation system alignment reduces inflow
- Cold water spray into tank causes condensation in headspace
- Cool down of tank headspace after an in-tank fire.

The analysis in WHC-SD-TWR-RPT-002 for high internal vacuum states that single-shell and double-shell tanks can withstand -55 kPa (-8 psig) of vacuum. Vacuum due to fire, existing ventilation system failure (i.e., exhaust fan with all flow paths blocked), and vacuum cooling the dome space due to water spray cannot reach -55 kPa (-8 psig).

The new ventilation systems that will be installed in Tank 241-AY-102 and Tank 241-C-106 before startup of WRSS sluicing operations also cannot create a vacuum approaching -55 kPa (-8 psig). Assuming that all infiltration pathways into the tank headspace are blocked, the greatest vacuum that can be created with the new exhaust fans running at maximum design speed in either Tank 241-AY-102 or Tank 241-C-106 is less than 14 kPa (2 psig), as discussed in Chapter 2.0. Higher than design fan speeds would require some failure in the fan motor controller system (combined with blocked inlet pathways). To reach motor speeds much higher than the design speed, the overcurrent protection on the fan motor also would have to fail. Even if all the preceding controller failures occurred, the fan motor could not credibly reach speeds required to generate a vacuum of -55 kPa (-8 psig) before the motor circuits failed as the result of excess current.

Although structural failure is not deemed credible, an excessive vacuum event could result in failure of the ventilation system seal loops and small unfiltered releases because of inability to maintain tank headspace vacuum at nominal flow rates. Unfiltered release events resulting from excess vacuum are analyzed in Section 3.4.2.3 of this addendum.

3.4.2.7.1 Scenario Development. No credible tank failure resulting from an excessive vacuum scenario has been identified.

3.4.2.7.2 Source Term Analysis. Not applicable.

3.4.2.7.3 Consequence Analysis. Not applicable.

3.4.2.7.4 Comparison with Guidelines. Not applicable.

3.4.2.7.5 Summary of Safety Structures, Systems, and Components and Technical Safety Requirement Controls. Safety structures, systems, and components and TSR controls need not be designated because excess vacuum cannot cause tank failure leading to an airborne release of radioactive material.

3.4.2.8 Flammable Gas Deflagration. This analysis addresses the hazards and controls associated with the generation, storage, release, and postulated combustion of flammable gases in Tank 241-AY-102, a double-shell AWF tank; Tank 241-C-106, a SST; and the associated transfer systems. This hazard was first identified as an unreviewed safety question (USQ) in 1990. This USQ was updated on November 1, 1996 (TF-96-0433, *Consolidation of Flammable Gas/Slurry Growth Unreviewed Safety Question Issues*) to account for increased understanding of the nature of the hazard and the affected facilities. The updated USQ addresses potential flammable gas hazards in the AWF tanks. The flammable gas USQ remains open for the facilities associated with WRSS operations as of this writing.

This BIO Addendum affirms the applicability of the U.S. Department of Energy, Richland Operations Office approved controls for the performance of WRSS operations (HNF-SD-WM-TSR-006, *Tank Waste Remediation System Technical Safety Requirements*). This affirmation is required for several reasons.

- The ventilation system on Tank 241-C-106 is being modified in a manner that will reduce flow rate from a nominal 67.9 m^3/min (2400 ft^3/min) to 10.2 m^3/min (360 ft^3/min). The reduction in ventilation flow rate will result in an increase in the flammable gas concentration in the tank headspace.

- The sluicing of the sludge in Tank 241-C-106 has the potential to release the flammable gas that has accumulated in the waste matrix and is trapped beneath the waste surface.

- The addition of Tank 241-C-106 sludge to Tank 241-AY-102 will increase the gas generation rate in this tank. This results in an increase in the chronic (or "steady state") gas release rate to the tank vapor space, and thus an increase in the gas concentration.

- The gas retention and release behavior of the sludge may be changed after it is moved from Tank 241-C-106 to Tank 241-AY-102. This may result from changes in gas generation rates, waste sludge rheology, and waste configuration where the sludge will be stored under a large amount of supernatant liquids in Tank 241-AY-102, whereas little supernate is currently contained in Tank 241-C-106. These changes may result in an increased likelihood of a buoyant displacement gas release event (GRE).

Evaluation Methodology. The sluicing and transfer of sludge from Tank 241-C-106 to Tank 241-AY-102 and subsequent storage of the sludge in Tank 241-AY-102 is evaluated by determining the impact of this sluicing and subsequent storage on key flammable gas phenomena as described in the main text of the BIO. Controls specified for current operations and storage are justified as being adequate or are modified to be adequate for the sluicing and subsequent storage conditions.

Radioactive waste generates hydrogen through the radiolysis of water, thermolytic decomposition of organic compounds, and corrosion of the tank's carbon steel walls. Radiolysis and thermolytic decomposition also generate ammonia. Additional flammable gases (such as methane) and an oxidizer

(e.g., nitrous oxide) are generated by chemical reactions between various degradation products of organic chemicals originally present in the tank. Volatile or semi-volatile organic chemicals also produce organic vapors.

The gas generated through these processes may be released continually to the tank vapor spaces (historically referred to as steady state flammable gas generation) or be retained by the tank's waste matrix, potentially resulting in an episodic GRE. Steady state flammable gas generation from radiolysis, chemical decomposition, and corrosion is expected from all of the wastes in the Hanford Site underground storage tanks. With a GRE, gas is retained in the tank's waste matrix until it is spontaneously released or a release is induced during waste disturbing activities, such as waste sluicing operations.

An accident scenario for a representative flammable gas deflagration resulting from a GRE in an AWF tank is provided in the BIO, Section 5.3.2.14. The representative GRE accident analysis assumes the release and ignition of sufficient trapped gas such that the resulting energy creates unfiltered release paths, but is insufficient to collapse the tank dome. A gas release of this size has never been observed, and is not expected for the current waste contents of either Tank 241-C-106 or Tank 241-AY-102. Therefore, the energy associated with the deflagration of such a release is considered bounding for these two tanks with their current waste contents.

The source terms selected for the representative GRE accident analysis in the BIO are based on the current waste storage conditions. Changes to the source term may occur as a result of WRSS operations including: (1) bringing AWF waste slurries into Tank 241-C-106 via the sluicing line and (2) creating a slurry in Tank 241-AY-102 as a result of slurry transfer from Tank 241-C-106. The analysis in the main text of the BIO assumes that the material released from an SST has a source term consistent with SST solids. The analysis in the BIO assumes that the material released from an AWF tank has a source term consistent with AWF liquids. As seen in WHC-SD-WM-SARR-016, *Tank Waste Compositions and Atmospheric Dispersion Coefficients for use in Safety Analysis Consequence Assessments*, release of AWF slurries (a combination of liquids and solids) from Tank 241-C-106 rather than the assumed SST solid wastes could result in an increased radiological dose at the receptor locations. Additionally, the existence of a solids component in the material released from Tank 241-AY-102 would also result in an increased radiological dose over that when only AWF liquids are assumed to be released. Determination of the fraction of liquid versus solids that may be entrained in the release is an additional uncertainty associated with this event that is not associated with the flammable gas USQ.

As indicated in the BIO, the consequence analysis for the representative GRE is not considered bounding. However, at this point in the resolution process of the open USQ, the analysis serves to indicate the need for an authorization basis control strategy. As provided in the BIO, Appendix E, the control strategy is prevention. Controls related to monitoring and ignition sources are assigned to specific facilities and tanks on the basis of observed and estimated gas release behavior. These controls are not specifically derived from GRE consequence analysis, and would not be changed by variations in the magnitude of the calculated consequences presented in the BIO. The BIO

analysis results are discussed in detail in Section 5.3.2.14 and summarized in Table 5.3.2.14-1 of the BIO main text. The results of the consequence analysis are not tabulated in this addendum.

Applicability of Flammable Gas Controls. The specific monitoring and ignition source controls applicable to the sluicing operation in Tank 241-C-106 are driven by assignment of this tank to flammable gas Facility Group 3 (BIO, Appendix E) and the nature of activities and operations performed. The sluicing operation does not alter the assignment of Tank 241-C-106 to Facility Group 3. In addition, performance of the sluicing operation falls within the authorization basis definitions for the nature and location of activities and operations. Therefore, with respect to GRE behavior that may be associated with operation of the WRSS, the existing authorization basis monitoring and ignition source controls continue to apply.

The specific monitoring and ignition source controls applicable to the use of supernatant liquids from Tank 241-AY-102 as the sluicing fluid and the transfer and storage of sludge from Tank 241-C-106 to Tank 241-AY-102 are driven by assignment of Tank 241-AY-102 to flammable gas Facility Group 2 (main text of the BIO, Appendix E) and the nature of activities and operations performed. The sluicing operation does not alter the assignment of Tank 241-AY-102 to Facility Group 2. In addition, performance of the sluicing operation falls within the authorization basis definitions for the nature and location of activities and operations. Therefore, with respect to GRE behavior that may be associated with the sluicing operation, the existing authorization basis monitoring and ignition source controls continue to apply. The impact of storing additional sludge in Tank 241-AY-102 on the flammable gas Facility Group assignment is discussed in the Gas Release Event evaluation section which follows.

The strategy to prevent or mitigate potential hazards associated with flammable gas in Tank 241-C-106 and Tank 241-AY-102 during the performance of the sluicing operation involves implementation of the controls detailed in the BIO TSR (HNF-SD-WM-TSR-006). The BIO, Appendix E strategy is to expeditiously implement achievable and practical controls to manage postulated flammable gas risks. While doing so, progress towards safety issue resolution and USQ closure will continue to concentrate on remaining uncertainties regarding the quantification of risk and effectiveness of control strategies.

The controls are aimed primarily at prevention of ignition of flammable gas (although certain aspects of the control strategy are mitigative in nature). Provisions for ventilation serve to prevent accumulation of chronically released gases and possibly reduce the time at risk assuming the occurrence of a spontaneous or induced gas release. Flammable gas monitoring requirements serve to validate ventilation effectiveness as well as prevent or halt manned activities when margin of safety is considered to be insufficient (i.e., conditions are such that the flammable gases exist in concentrations greater than 25% of the lower flammability limit [LFL]). Ignition controls related to work practices and equipment requirements serve to eliminate, to the greatest extent practical, ignition sources.

This three-pronged control strategy (ventilation, monitoring, and ignition source control) is effective in preventing the accumulation of flammable gases where ignition sources may be present or to eliminate ignition sources where flammable gases may potentially be present. Neither the BIO nor this addendum present analysis results that quantitatively demonstrate the effectiveness of these controls to prevent flammable gas deflagrations. Quantitative demonstration of the effectiveness of controls will be accomplished as part of the flammable gas USQ closure process.

3.4.2.8.1 Steady State Generation.

Tank 241-C-106. Sluicing operations in Tank 241-C-106 will not increase the steady state generation of flammable gases. Steady state flammable gas generation is dependent on several parameters including waste volume, decay heat load, waste temperature, organic complexant chemical concentrations, and nitrate/nitrite concentration. Removing sludge from Tank 241-C-106 will decrease the gas generation rate.

Implementation of WRSS operations, however, does include modifications to the ventilation system provided to Tank 241-C-106. These modifications result in a ventilation flow rate reduction from a nominal 67.9 m^3/min (2400 ft^3/min) to 10.2 m^3/min (360 ft^3/min). Currently, Tank 241-C-106 is estimated to be generating and releasing hydrogen at a best estimate rate of 0.18 m^3/day (6.5 ft^3/day) (HNF-SD-WM-CN-114, *Project W-320 Primary Ventilation Air Flow Requirements for Mitigation of Steady State Flammable Gas Concentrations in the Headspaces of Tanks 241-C-106 and 241-AY-102*). This release rate requires 5.0×10^{-3} m^3/min (0.18 ft^3/min) ventilation flow rate to keep the headspace below 100% of the LFL, and 2.0×10^{-2} m^3/min (0.7 ft^3/min) ventilation flow rate to keep the headspace below 25% of the LFL. Using an upper bound hydrogen generation rate of 0.19 m^3/day (6.7 ft^3/day), the required ventilation flow rates are 5.1×10^{-3} and 2.1×10^{-2} m^3/min (0.18 and 0.74 ft^3/min) to keep the headspace below 100% and 25% of the LFL, respectively. If active ventilation were completely lost, the 2690 m^3 (95,000 ft^3) headspace of Tank 241-C-106 would reach 25% of the LFL in 117 days using the best estimate hydrogen generation rate and 113 days using the upper bound rate (HNF-SD-WM-CN-114).

Based on gas concentration measurements taken under high flow rate conditions, the current ventilation system is proven to provide adequate ventilation to sweep out the steady state generated gases. The new system has no operational history upon which to base the claim it will also provide adequate ventilation. However, analysis of the steady state hydrogen concentration in the headspace of Tank 241-C-106 indicates that only 2.1×10^{-2} m^3/min (0.74 ft^3/min) of ventilation airflow is needed to ensure that the flammable gas concentration in the headspace remains less than 25% of the LFL (HNF-SD-WM-CN-114). To confirm this, flammable gas monitoring will be used for a short time after full startup (steady state conditions attained) of the new ventilation system to confirm the system's ability to keep flammable gas concentrations below 25% of the LFL. As a backup, the higher capacity system will be maintained in an available condition until the monitoring is complete.

Tank 241-AY-102. Adding sludge to Tank 241-AY-102 will increase the gas generation rate in this tank. The implementation of the BIO, Appendix E control strategy to Tank 241-AY-102 during and following WRSS operations, provides ventilation to prevent accumulation resulting from a steady state gas release. However, the safety margin provided by compliance with the ventilation requirements of the BIO TSRs (HNF-SD-WM-TSR-006) may be decreased as a result of the sludge addition. This is due to the expected increases in waste volume, decay heat load, and waste temperature resulting from the added high heat load waste.

In order to provide some degree of confidence that the ventilation flow and AWF TSRs for ventilation restoration are adequate to prevent a flammable gas deflagration resulting from the increased gas generation rate, available gas monitoring and ventilation data were reviewed and a scoping analysis was performed via an engineering Calculation Note (HNF-SD-WM-CN-114).

This calculation note determined that Tank 241-AY-102 is generating and releasing hydrogen at the best estimate rate of 0.39 m^3/day (14 ft^3/day) (HNF-SD-WM-CN-114). The upper bound hydrogen generation rate is 0.57 m^3/day (20 ft^3/day). If all the waste in Tank 241-C-106 is transferred to Tank 241-AY-102, a best estimate is that Tank 241-AY-102 would generate 0.58 m^3/day (20.5 ft^3/day) hydrogen, with an upper bound of 0.75 m^3/day (26.7 ft^3/day) (HNF-SD-WM-CN-114). A second conservative assumption is that the headspace volume of Tank 241-AY-102 is limiting at 930 m^3 (33,000 ft^3) (HNF-SD-WM-CN-114).

Under the upper bound hydrogen generation rate conditions, a ventilation flow rate of 8.3 x 10^{-2} m^3/min (2.95 ft^3/min) is sufficient to ensure the headspace remains below 25% LFL. The minimum design flow rate provided by the upgraded AY/AZ vent system (241-AZ-702), 2.8 m^3/min (100 ft^3/min) per tank, exceeds the 25% LFL ventilation requirement by an order of magnitude. This evaluation provides some confidence in the adequacy of the ventilation system to prevent the steady state accumulation of flammable gas to levels above the LFL since the minimum ventilation flow rate provided by the existing 241-A-702 ventilation system ranges from approximately 11.3 to 17.0 m^3/min (400 to 600 ft^3/min) and the minimum ventilation flow rate provided by the 241-AZ-702 ventilation system is approximately 2.8 m^3/min (100 ft^3/min). To confirm this, flammable gas monitoring will be used for a short time after completing the sludge transfer to Tank 241-AY-102 (steady state conditions attained) to confirm the system's ability to keep flammable gas concentrations below 25% of the LFL. The risk of this approach is low since the calculations show a large margin between what is required (6.8 x 10^{-2} m^3/min) and what is provided (at least 2.8 m^3/min).

The scoping analysis then determined the flammable gas concentration increase transient, assuming a loss of forced ventilation. Based on the estimated gas generation rate after the addition of Tank 241-C-106 sludge, the amount of time with no forced ventilation flow before the dome space concentration would exceed 25% of the LFL is approximately 7.7 days, using upper bound generation rates (HNF-SD-WM-CN-114). In addition, the amount of time with no ventilation flow before exceeding the LFL is more than 33 days. This evaluation provides some confidence in the adequacy of the BIO TSRs

(HNF-SD-WM-TSR-006) to prevent the steady state accumulation of flammable gas to levels above the LFL because ventilation restoration is required immediately, and gas monitoring is required to be initiated within 72 hours.

The implementation of the main text of the BIO, Appendix E control strategy in conjunction with the application of the BIO TSRs (HNF-SD-WM-TSR-006) provides adequate controls to prevent a flammable gas deflagration as a result of steady state flammable gas generation.

3.4.2.8.2 Gas Release Event.

Gas Release Events in Tank 241-C-106. The sluicing operation disturbs the waste sludge which could potentially result in a GRE. Sluicing is conservatively defined as a globally waste disturbing operation (BIO, Appendix E). Waste disturbing activities represent the primary means of releasing gas retained in the waste matrix resulting in a GRE.

The controls required by BIO TSRs (HNF-SD-WM-TSR-006) are graded based on the tank Facility Group assignment and the nature of the operation or activity. Tank 241-C-106 is assigned Facility Group 3 status. This facility assignment means that GRE controls are focused on waste intrusive regions during normal storage when no waste disturbing operations are being performed. Gas release event controls are extended to the dome space intrusive regions during waste disturbing operations. Controls are <u>not</u> extended to ex-tank intrusive regions during globally waste disturbing operations (as would be the case for tanks assigned to Facility Group 2). The sluicing operation involves mobilizing portions of the sludge with a jet of liquid waste and pumping the resultant slurry out of the tank. This operation, therefore, is waste disturbing and GRE controls are required in the dome intrusive region during operation of the WRSS.

The equipment, materials, and work practices associated with the equipment used in Tank 241-C-106 for WRSS operations have been evaluated by the Flammable Gas Equipment Advisory Board (FGEAB) to verify that they are in compliance with the Ignition Source Control Sets #1 and #2 as detailed in BIO TSR AC 5.10 (HNF-SD-WM-TSR-006). The FGEAB evaluation of the equipment, materials, and work practices associated with this project determined that the applicable Ignition Source Control Sets could be satisfied in all cases by implementing several design modifications. The required design modification will be verified to have been implemented during Operational Readiness Review.

Comprehensive compliance with the applicable Ignition Source Control Sets minimizes the potential for an ignition source in regions that could be flammable as a result of a small induced GRE. This control implementation is adequate for the performance of WRSS operations as a large GRE is not expected or postulated. These expectations are based on the following information.

- Small amounts of retained gas (WHC-SD-WM-ER-526, *Evaluation of Hanford Tanks for Trapped Gas*)

- Slurry growth and GRE behavior are associated with tanks that contain large quantities of organic complexants. Although Tank 241-C-106 might have contained organic complexant waste in the

past, samples indicate that almost all the complexants have decomposed to oxalate.

- No supernate to drive buoyant displacement GREs.

Thus, the implementation of the main text of the BIO, Appendix E control strategy during sluicing in Tank 241-C-106 provides adequate control to prevent a flammable gas deflagration as a result of a GRE.

Gas Release Events in Tank 241-AY-102. Gas release events are postulated to occur in DST and AWF tanks spontaneously or as a result of waste disturbing operations and activities. The controls required by the BIO TSRs (HNF-SD-WM-TSR-006) are graded based on the tank Facility Group assignment and the nature of the operation or activity. Tank 241-AY-102 is assigned Facility Group 2 status. This facility assignment means that GRE controls are focused on dome space intrusive and waste intrusive regions during non-waste disturbing or locally waste disturbing operations. Controls are extended to ex-tank intrusive regions during global waste disturbing operations. WRSS involves waste addition/removals or transfers in Tank 241-AY-102 which are defined as global waste disturbing operations. Therefore, the expanded controls are required during WRSS transfers.

The assignment of Facility Group 2 is based on consideration for future use of the tanks rather than current waste inventory or current observation of GRE behavior. All DST and AWF tanks are assigned to Facility Group 2 unless they have observed large spontaneous GRE behavior, in which case they are assigned Facility Group 1 status. The DSTs and AWFs are within their design life and are integral to the safe waste storage and disposal mission. They will receive new waste from other Hanford Site facilities and will undergo liquid reductions, waste consolidation, multiple transfers, and mixing.

Procedures are in place to minimize the likelihood that these operations would create conditions resulting in large spontaneous gas release behavior. However, it is recognized that some operations may result in increased gas generation and retention. Therefore, it is appropriate to categorize these facilities in Facility Group 2 or higher. In the unlikely event that significant GRE behavior develops in Facility Group 2 tanks, they will be moved to Facility Group 1 (main text of the BIO, Appendix E). Therefore, Tank 241-AY-102 will remain assigned to Facility Group 2 unless large spontaneous GRE behavior is observed as a result of WRSS or any other waste transfers to this tank. If large spontaneous GRE behavior is anticipated or observed, the GRE behavior can be at least partially mitigated by removal of the supernatant liquid. Removal of the supernatant liquid mitigates GREs by reducing waste buoyant displacements and increases the tank dome space available for dilution of the released gas.

The equipment, materials, and work practices associated with this project were evaluated by the FGEAB to verify that the equipment and materials used in and around Tank 241-AY-102 are in compliance with the Ignition Source Control Sets #1 and #2 as detailed in BIO TSR AC 5.10 (HNF-SD-WM-TSR-006). The FGEAB evaluation of the equipment, materials, and work practices associated with this project determined that the applicable Ignition Source Control Sets could

be satisfied in all cases by implementing several design modifications. The required design modification will be verified to have been implemented during Operational Readiness Review.

Comprehensive compliance with the applicable Ignition Source Control Sets not only minimizes the potential for an ignition source following a steady state gas release, but also minimizes the potential for an ignition source following a GRE. This control implementation provides an additional level of safety in order to prevent a flammable gas deflagration even if a large GRE were to occur. However, a large GRE is not expected to occur during or following WRSS operation. These expectations are based on the following information.

- LA-UR-97-1330, *Discussion of Flammable Gas Issues for Project W-320*, states that since Tank 241-AY-102 does not contain any organic complexants and is very dilute in terms of nitrates and nitrites, the volume of retained gas in the sludge following the transfer should be small (retained gas void fraction is estimated to be less in Tank 241-AY-102 than currently exists in Tank 241-C-106).

- Because the retained gas void fraction is expected to be low, and the neutral-buoyancy void fraction is estimated to be > 20%, episodic releases (rollovers) are not expected in Tank 241-AY-102 (LA-UR-97-1330, Appendix B).

- Because the makeup of Tank 241-AY-102 will be principally Tank 241-C-106 sludge and GRE behavior is not observed in Tank 241-C-106, GRE behavior is not anticipated in Tank 241-AY-102.

The implementation of the main text of the BIO, Appendix E control strategy during WRSS operation in Tank 241-AY-102 provides adequate control to prevent a flammable gas deflagration as a result of a GRE, even though a GRE is not expected to occur.

3.4.2.8.3 Controls. This section summarizes the adequacy of existing controls for the implementation of WRSS operations, and summarizes any required new controls.

Safety Structures, Systems, and Components. Because of the open status of the USQ and the technical uncertainties associated with the flammable gas safety issue, it is assumed that installed equipment that performs a critical safety function to prevent or mitigate risk from flammable gas deflagrations merits a safety class designation. Additional analysis provided by the final safety analysis report or in support of safety issue resolution and USQ closure may provide refinement to this approach. As indicated in the BIO, the ventilation safety function is designated as Safety Class. The new ventilation system to be utilized on Tank 241-C-106, therefore, is designated safety class. There are no unique new safety functions needed or provided by WRSS operations, and therefore the safety SSCs as stated in the main text of the BIO remain applicable. The SSCs credited with managing risk from flammable gas deflagrations are repeated in Table 3.2.4.8-1.

Technical Safety Requirement Controls. The fundamental control strategy for all affected facilities is contained in the BIO TSRs (HNF-SD-WM-TSR-006). WRSS operations relies on these TSRs for management of flammable gas hazards. There are no unique new safety requirements needed for, or provided by, WRSS operations, and therefore the BIO TSRs remain applicable. The TSRs credited in the BIO for managing risk from flammable gas deflagrations are repeated in Table 3.4.2.8-2.

Defense in Depth. There are unique and specific Defense-in-Depth measures that apply to the risk management of the flammable gas hazard for WRSS operations. These are included in the Process Control Plan, which is described in Section 2.5. Key Defense-in-Depth items are listed in Table 3.4.2.8-3.

Relative to managing risk from GREs in Tank 241-C-106 during sluicing, the Process Control Plan includes monitoring the headspace concentrations in Tank 241-C-106 and stopping sluicing if concentrations exceed 25% of the LFL.

Relative to managing risk from the ignition of GREs during operation of the WRSS, flammable gas concentrations will be monitored in Tank 241-AY-102 and WRSS will be stopped if concentrations exceed 25% of the LFL.

Relative to managing future GRE behavior in Tank 241-AY-102, the Process Control Plan collects data in order to avoid making Tank 241-AY-102 into a tank that experiences large episodic releases of flammable gas. The Process Control Plan requires baseline hydrogen concentration data from both tanks, and a series of stages where a transfer of waste is made. Monitoring occurs during a waiting period and a decision is made about whether another transfer stage should be done. In addition, a step-by-step contingency plan to remove the supernate out of Tank 241-AY-102 is included to mitigate GRE behavior if retained gas void fractions are estimated to approach neutral-buoyant void fractions.

Table 3.4.2.8-1. Safety Structures, Systems, and Components for Flammable Gas Deflagrations.

Structures, systems, or components	Safety classification		Safety function	Comments
	SC	SS		
Active ventilation	X	--	Maintains flammable gas concentrations in tank dome spaces, due to steady state releases, below 25% of the LFL	Applies to Tanks 241-C-106 and 241-AY-102
Primary tank leak detection system	X	--	Provides indication that corrective action is required to avoid accumulation and deflagration of waste gas in the annulus space	--

LFL = lower flammability limit.
SC = Safety-Class.
SS = Safety-Significant.

Table 3.4.2.8-2. Technical Safety Requirement Controls for Flammable Gas Deflagrations.

Control	Safety function	Comments
DST and AWF Tank Ventilation Systems	Prevents the accumulation of flammable gases due to steady-state releases and reduce the time at risk due to a gas release event	Flow must be verified OR flow monitoring must be performed OR pressure monitoring must occur
SST Ventilation Systems - Active	Applies to Tank 241-C-106 during transfer operations because an active ventilation system is required to remove accumulations of flammable gases produced during activities	Flow must be verified OR flow monitoring must be performed OR pressure monitoring must occur
Primary Tank Leak Detection System	Provides indication that corrective action is required to avoid accumulation and deflagration of waste gas in the annulus space	--
Flammability controls	A program will be established, implemented, and maintained to manage flammable gas hazards	During the performance of WRSS transfer operations there is the possibility of flammable conditions developing as a result of waste disturbing activities
Ignition controls	A program will be established, implemented, and maintained to manage potential ignition sources that can initiate a fire or flammable gas deflagration	Ignition controls for the annulus includes leak detection systems
Flammable gas monitoring	A program will be established, implemented, and maintained to monitor flammable gas concentrations to prevent deflagrations	
Emergency Preparedness - Response procedures	A program will be established, implemented, and maintained to ensure that emergency response plans are developed to direct facility actions in the event of a deflagration/detonation	--
HEPA filter controls - Periodic radiation surveillance - Replacement based on accumulation	Reduce consequences from a possible HEPA filter failure by limiting the inventory available for release.	--

AWF = aging waste facility.
DST = double-shell tank.
HEPA = high-efficiency particulate air (filter).
LFL = lower flammability limit.
SST = single-shell tank.
TWRS = Tank Waste Remediation System.
WRSS = Waste retrieval sluicing system.

Table 3.4.2.8-3. Defense-in-Depth Controls for Flammable Gas Deflagrations.

Control	Safety function	Comments
Monitor dome pressure in Tank 241-C-106 and Tank 241-AY-102 during sluicing	To determine if gas release events are occurring	A positive pressure increase indicates a release
Periodic video monitoring of the waste in Tank 241-AY-102	Foaming can cause enhanced retention of flammable gases. In addition, the foam could cause the high-level detector to function introducing an intermittent spark source	--
Measure background concentrations in both tanks for 3-4 weeks prior to sluicing	To determine the baseline generation rates and types of flammable gases in the tanks	Supports the Process Control Plan
Monitor the ventilation flow rates in both tanks during and after sluicing	This is used to help determine how much flammable gas is released versus how much gas is retained	Supports the Process Control Plan
Monitor level growth and use barometric pressure evaluation after sluicing	This determines whether Tank 241-AY-102 will become a tank that undergoes gas release events (often called rollovers)	Supports a decision on whether the contingency plan for removal of supernate from Tank 241-AY-102 if evaluation of conditions indicates a potential for rollover needs to be implemented
Flammable gas monitoring during sluicing	Determines if release events are occurring and provides evidence of gas retention	Stopping transfer activities between Tank 241-C-106 and Tank 241-AY-102 immediately if the concentration of flammable gas is > 25% of the LFL and transfer operations are in progress provides protection for the worker, minimizes activities that can produce an ignition source, and ensures the sluicing operation remains safe
HEPA filter replacement typically performed at 1 mSv/h (100 mrem/h)	Limit inventory available for release and limit dose rate to workers in the vicinity of the filters	--

HEPA = high-efficiency particulate air (filter)
LFL = lower flammability limit.

3.4.2.9 Organic Solvent Fire. This section evaluates risks associated with the presence of separable-phase organic solvents in Tank 241-AY-102 and Tank 241-C-106 during and after WRSS operations. Both tanks have been identified as potentially containing a separate organic solvent phase capable of sustained burning (WHC-SD-WM-CN-032, *Analysis of Consequences of Postulated Solvent Fires in Hanford Site Waste Tanks*). If a separable organic liquid phase exists or is created by sluicing and is subsequently ignited, energy sufficient to release hazardous materials from the tanks could be liberated.

The analysis for an organic solvent fire contained in WHC-SD-WM-CN-032 is almost entirely applicable to Tank 241-AY-102 and Tank 241-C-106. The ventilation rate considered is 0.047 m^3/s (100 cfm). Therefore, the following sections are based on the analysis in WHC-SD-WM-CN-032 with modifications only to the extent necessary for their application to sluicing of Tank 241-C-106. The type of organic material involved in this accident is bis(2-ethylhexyl) phosphate instead of the tri-butyl phosphate (TBP) and normal paraffin hydrocarbon analyzed in the main text.

This analysis also closely follows that found in Section 5.3.2.15 of the main text. When the discussions between Section 5.3.2.15 of the BIO overlap with the discussions in this analysis, only a summary is presented here.

WHC-SD-WM-CN-032 evaluates the frequency and consequences of the following three basic fire scenarios.

- **Pool Fires**—Pools are a layer of solvent floating on top of liquid waste or a layer that is trapped in a depression on top of solid waste. Neither Tank 241-AY-102 nor Tank 241-C-106 currently has a solid layer on top of the waste, but the analysis bounds such a possibility. The solids layer might occur on top of the waste if, for example, Tank 241-C-106 were to lose water and expose the solids at the bottom of the tank. The organic solvent pool has an area greater than 1 m^2 (10.8 ft^2).

- **Puddle Fires**—Puddles are 1 m^2 (10.8 ft^2) or less in area and would exist only in a depression in a solid waste surface. A puddle could occur in Tank 241-C-106 if the water layer were lost.

- **Wick-Stabilized Fires**—A wick-stabilized fire configuration would be a sludge or salt cake permeated with solvent. As the solvent burned, the sludge or salt cake would act as a wick. This case applies only to Tank 241-C-106 if the water layer in the tank were lost.

In addition to the accident scenarios identified in WHC-SD-WM-CN-032, the hazards analysis documented in Section 3.3 identifies several accident sequences specific to Tank 241-AY-102, Tank 241-C-106, and WRSS operations. The dominant sequences include the creation of a separable organics phase as a result of pumping and sluicing operations and subsequent ignition of the separated organic solvent. Less likely event sequences include inadvertently allowing the solids to become exposed and the organic components subsequently igniting.

The possibility of an organic solvent pool resulting in significant headspace flammability concerns is addressed in WHC-SD-WM-CN-032. The conclusion from WHC-SD-WM-CN-032 is that the low-volatility compounds in the waste pose little flammable vapor hazard, even if a separable organics phase forms. The organophosphates found in Tank 241-C-106 are bounded, in terms of volatility, by the organophosphates assumed in WHC-SD-WM-CN-032. Therefore, a flammable vapor deflagration resulting from formation of a separable organics phase in Tank 241-AY-102 or Tank 241-C-106 is not evaluated as a separate event.

3.4.2.9.1 Scenario Development. Four cases from WHC-SD-WM-CN-032 were found to bound organic solvent fires for sluicing operations.

- **Case G**—Bounding radiological accident for a single-shell tank fire (Tank 241-C-106).
- **Case K**—Bounding radiological accident for a double-shell tank fire (Tank 241-AY-102).
- **Case H**—Bounding toxicological accident for a single-shell tank fire (Tank 241-C-106).
- **Case L**—Bounding toxicological accident for a double-shell tank fire (Tank 241-AY-102).

The letter designator for each "case" is taken from the spreadsheet calculations in WHC-SD-WM-CN-032. The designators are maintained throughout this analysis to ease cross-referencing to the source document.

Scenarios Without Controls

- **Initiators**—An evaluation of potential initiators, including results from testing laboratories, is given in WHC-SD-WM-CN-032. For the cases involving pool and puddle fires, the only initiators with sufficient energy to cause ignition are lightning strikes and vehicle fuel fires. However, a wick-stabilized fire was found to require less energy to initiate and less energy to maintain the necessary conditions for combustion. For a wick-stabilized fire, initiators include hot metal from cutting torches, but not sparks or slag from welding; lightning strikes; and vehicle fuel fires.

  A flammable gas deflagration is also a potential initiator to an organic solvent fire in a tank. However, the consequences of a flammable gas deflagration (Section 3.4.2.8) are evaluated as a separate accident and applicable controls have already been developed for them.

- **Bounding Radiological and Toxicological Wick-Stabilized Fire in Single-Shell Tank, Case Q** WHC-SD-WM-CN-032 indicates that solvent could intrude into the underlying sludge or salt cake in a single-shell tank following salt well pumping of drainable liquids from a tank. This condition also applies to Tank 241-C-106 during sluicing operations if the water is inadvertently drained from the tank by the slurry pump, or makeup cooling water is not provided. Exposed solids saturated with solvent could burn like a candle using the solids as a wick. The burning surface would slowly increase and could eventually cover approximately 40 m^2 (431 ft^2).

- **Bounding Radiological Single-Shell Tank Fire, Case G** WHC-SD-WM-CN-032 indicates that in this scenario a pool of solvent is postulated to burn on the waste surface of an actively ventilated single-shell tank. The active ventilation system results in more radioactive material being exhausted from the tank, even after the fire is extinguished, and applies to Tank 241-C-106.

- **Bounding Radiological Double-Shell Tank Fire, Case K** WHC-SD-WM-CN-032 indicates that a puddle fire (1 m^2 [10.8 ft^2]) is bounding for radiological releases from double-shell tanks (e.g., Tank 241-AY-102). A puddle fire assumes that the solvent collects in a small area on a solids surface. Tank 241-AY-102 does not have a known solids layer on top of the liquid layer, but the supernate in Tank 241-AY-102 could be almost completely removed following cessation of WRSS operations. In that case, inadvertent exposure of the solids in Tank 241-AY-102 would be more likely. Therefore, Case K is retained as the bounding case for Tank 241-AY-102.

- **Bounding Toxicological Single-Shell Tank Fire, Case H** WHC-SD-WM-CN-032 indicates that this case is a passively ventilated pool fire with the large vent path model (9.5cm [3.75in.]) orifice and a 1.27m (50in.) orifice. The large vent path results in the toxic material in the headspace being rapidly ejected from the tank. Because toxicological guidelines are based on concentration, this case produces the largest toxicological consequence.

- **Bounding Toxicological Double-Shell Tank Fire, Case L** WHC-SD-WM-CN-032 indicates that a pool fire (210 m^2 [2,260 ft^2]), an active ventilation system, and a large vent path (1.27m [50in.]) orifice and a 0.24m (9.6in.) orifice is bounding for this case. This case applies to all double-shell tanks, including Tank 241-AY-102. The large vent path results in the toxic material in the headspace being rapidly ejected from the tank. Because toxicological guidelines are based on concentration, this case produces the largest toxicological consequence.

Accident Frequencies Without Controls. The accident frequency without controls is assigned based on the frequency of the initiating event. For an organic solvent fire in Tank 241-AY-102 or Tank 241-C-106, the accident frequency is the sum of the frequencies of lightning strikes, vehicle fuel

fires, and the presence of hot metal from cutting torches. WHC-SD-WM-CN-032 shows that these are the only potential ignition sources that also have sufficient energy to start a fire.

- **Lightning**—The frequency of lightning strikes is determined in WHC-SD-WM-CN-032 as 3×10^{-5} per year per tank. This frequency applies directly to WRSS operations.

- **Vehicle Fuel Fire**—WHC-SD-WM-CN-032 determined that the frequency of a vehicle collision with an aboveground structure is 7×10^{-5} per tank per year. This frequency applies directly to WRSS sluicing operations.

- **Flame or Torch Cutting**—Flame or torch cutting on a tank or its attachments (i.e., a riser or a ventilation duct) where hot chunks of metal could fall to the waste surface is not a common activity. For the sluicing operations, no more than five flame or torch cutting operations per year per tank are expected, excluding the initial facility modifications. The basic human error probability of 1×10^{-2} is assumed in estimating the likelihood of dropping hot metal into a tank during a cutting operation. The resulting frequency of an event during a cutting activity is then

  $$(5) \times (1 \times 10^{-2}) = 5 \times 10^{-2} \text{ per year per tank.}$$

  The only case where hot metal from a cutting operation could initiate a fire is for the wick-stabilized condition. The probability of igniting solvent-permeated sludge is estimated at 1×10^{-1} (WHC-SD-WM-CN-032). The probability of draining Tank 241-C-106 to obtain an exposed solids layer is taken to be 1×10^{-2} for human error to inadvertently drain the tank and not correct the loss of water condition. Therefore, the overall frequency without controls of having a wick-stabilized solvent fire resulting from torch cutting is

  $$(5 \times 10^{-2}) \times (1 \times 10^{-1}) \times (1 \times 10^{-2}) = 5 \times 10^{-5} \text{ per year per tank.}$$

  Although WHC-SD-WM-CN-032 indicates that hot metal from cutting torches would not initiate a fire in a double-shell tank (Tank 241-AY-102), the possibility of exposing the solids layer in Tank 241-AY-102 must be considered. The supernate in Tank 241-AY-102 could be substantially reduced following cessation of sluicing operations. This configuration increases the likelihood of inadvertently exposing the solids layer. Furthermore, inclusion of the frequency of hot metal as an initiator does not alter the conclusions of the frequency analysis. The frequency category is the same with or without the frequency of the hot metal initiator.

- **Overall Frequencies**—For Tank 241-AY-102 and Tank 241-C-106, the sum of the frequencies for lightning, vehicle fuel fire, and torch cutting scenarios is the overall frequency of an organic solvent fire. This frequency is $(3 \times 10^{-5}) + (7 \times 10^{-5}) + (5 \times 10^{-5}) = 1.5 \times 10^{-4}$ per tank per year, times one tank (241-AY-102 or 241-C-106), for a frequency of

1.5 x 10^{-4} per year for either tank. These frequencies fall into the range of "unlikely" (10^{-4} to 10^{-2} per year) for determining risk evaluation guidelines.

Note that if the torch-cutting scenario is excluded from the frequency for Tank 241-AY-102, the overall frequency would be 1 x 10^{-4} per year, which still falls within the "unlikely" category.

Scenarios With Controls. The controls specified in this analysis eliminate two of the three possible initiators: vehicle fuel spills and flame cutting. The scenario with controls is, therefore, an organic solvent fire initiated by a lightning strike.

Frequencies With Controls. The frequency bin for the accidents without controls is "unlikely." The multiple control strategy for protection of fuel and prevention of ignition sources eliminates vehicle fuel fires and flame cutting as initiators. Failure of these controls is considered a beyond design basis event. Only lightning remains, with an initiating event frequency of 3 x 10^{-5} per year. For both tanks this results in a frequency designation of "extremely unlikely" for the accident scenarios with controls.

3.4.2.9.2 Source Term Development. The source terms from an organic solvent fire in Tank 241-AY-102 or Tank 241-C-106 are based on the source term models developed in WHC-SD-WM-CN-032.

The radiological material inventory for ventilation system components is summarized in HNF-SD-WM-CN-099. Of the three material inventories from the fire, only the HEPA filter source term is different than that calculated in WHC-SD-WM-CN-032. The different material inventory for the HEPA filters is discussed below.

HNF-SD-WM-CN-099 also lists the toxicological material inventory. Of the toxicological material inventories, only phosphorous pentoxide (P_2O_5) differs from that calculated in WHC-SD-WM-CN-032. Because of recent test data on the organic content of Tank 241-C-106, the assumptions pertaining to the types and quantities of organophosphates are different from those in WHC-SD-WM-CN-032. The material inventory calculations (emission factor) for the solvent smoke in this analysis address the new P_2O_5 inventory.

Filters. The air filter material inventories for the bounding ventilation systems for Tanks 241-AY-102 and 241-C-106 are taken from HNF-SD-WM-CN-099. The values in WHC-SD-WM-CN-032 are not appropriate because the difference in ULDs results in different filter loadings. The filter loadings are calculated from radiation readings near the surface of the filter housings (based on the filter change-out requirements), and different ULDs comprise different mixtures of isotopes. Selecting different ULDs results in altering the isotopic distribution on the filters and, subsequently, the radiological loadings on the filters.

HNF-SD-WM-CN-099 reports air filter loadings and subsequent inventory released following an overpressure event for both tanks and the various possible ventilation configurations.

The bounding HEPA filter material releases (based on the liquid/solid split discussed in Section 3.4.1) from HNF-SD-WM-CN-099 are as follows:

- Tank 241-C-106, 1.91×10^{-1} L; 296-C-006 system
- Tank 241-AY-102, 3.66×10^{-2} L; 241-A-702 system.

These releases are based on pressure failure of the filters, which bounds temperature failure (HNF-SD-WM-CN-099). These inventories are used in Table 3.4.2.9-1 to calculate dose consequences.

Solvent Smoke. The inventories arising from the solvent smoke (combustion products) are taken from WHC-SD-WM-CN-032. The radiological inventories are as follows:

- Case G, Tank 241-C-106; 4.38 kg (9.66 lb) of Tank 241-C-106 tank waste
- Case K, Tank 241-AY-102; 13.2 kg (29.1 lb) of Tank 241-AY-102 tank waste.

These inventories are used in Table 3.4.2.9-1 to calculate dose consequences.

The toxic materials produced by the organic solvent fire are modeled in WHC-SD-WM-CN-032 as CO, NO_2, and P_2O_5. These materials represent the predominant combustion species that can be expected to form when hydrocarbon liquids and organophosphates are burned.

The inventories for CO and NO_2 are appropriate for a fire in either Tank 241-C-106 or Tank 241-AY-102 and are used from WHC-SD-WM-CN-032 without modification. The inventory for P_2O_5 in WHC-SD-WM-CN-032 is based on the combustion, and subsequent emission factor, of TBP found in Tank 241-C-103. Recent test data documented in HNF-SD-WM-TI-756, *Chemical and Chemically Related Issues Associated with Sluicing Tank C-106 Waste to Tank AY-102*, indicates that Tank 241-C-106 contains a significant amount of bis(2-ethylhexyl) phosphate. Therefore, a new emission factor must be calculated for the P_2O_5. The method used to calculate the new emission factor is identical to that used in WHC-SD-WM-CN-032.

The stoichiometry for the oxidation of bis(2-ethylhexyl) phosphate is

$$C_{16}H_{35}O_4P + 24\ O_2 = 16\ CO_2 + 17.5\ H_2O + 0.5\ P_2O_5.$$

Using molecular weights of 322.48 g/mol for bis(2-ethylhexyl) phosphate and 142 g/mol for P_2O_5, the mass ratio of P_2O_5 to bis(2-ethylhexyl) phosphate is 0.22. HNF-SD-WM-TI-756 indicates that a minimum of 82% (by mass) of the solvent is made up of organophosphate compounds, but does not list the composition of the remaining 18%. Because the remaining 18% of the solvent could be organophosphate compounds, it is assumed that 100% by mass of the solvent is organophosphates. While this assumption seems overly conservative, a reduction of 18% in the calculated toxicological consequences has no impact on the conclusions reached in this analysis. The emission factor is, therefore, 0.22 kg P_2O_5 formed per kilogram of solvent burned.

The emission factor calculated based on the Tank 241-C-106 waste is bounding for Tank 241-AY-102 because few organophosphate hazards are expected from Tank 241-AY-102 waste.

Aqueous Boil-Off. The radiological inventory arising from the aqueous waste are taken from WHC-SD-WM-CN-032 for the bounding cases and are as follows:

- Case G, Tank 241-C-106; 0.368 kg (0.81 lb) of Tank 241-C-106 tank waste
- Case K, Tank 241-AY-102; 0.333 kg (0.73 lb) of Tank 241-AY-102 tank waste.

These inventories are used in Table 3.4.2.9-1 to calculate dose consequences. The toxicological inventories from the aqueous boil-off and tank headspace are used as modeled in WHC-SD-WM-CN-032.

3.4.2.9.3 Consequence Analysis. The consequence analysis is taken from WHC-SD-WM-CN-032 except for modifications for the ULDs, waste densities, and new P_2O_5 emission factor.

The different ULDs arise from the difference between the operations used as the basis of WHC-SD-WM-CN-032 and those to be performed in sluicing. In WHC-SD-WM-CN-032, it was assumed that no mixing occurred and that the tanks are in essentially a quiescent or static condition. This is not true for sluicing operations, where active mobilization and transport of Tank 241-C-106 solids and potential mobilization and transport of Tank 241-AY-102 solids will occur. Therefore, the ULDs listed in Section 3.4.1 are used in this analysis.

WHC-SD-WM-CN-032 also assumed a waste density of 1 kg/L when multiplying inventories (mass) by ULDs (dose per unit volume). The wastes in Tank 241-C-106 and Tank 241-AY-102 have a density of greater than 1 kg/L. The waste densities of 1.27 kg/L (10% solids and 90% liquids) and 1.41 kg/L (33% solids and 66% liquids) are used in this analysis for fires in Tank 241-AY-102 and Tank 241-C-106, respectively. These densities are used to convert the appropriate ULDs to a mass basis.

Table 3.4.2.9-1 shows the consequences for the cases without controls. Consequences with controls are shown in Table 3.4.2.9-2. The case without controls corresponds to the worst-case frequencies of the bounding fire. The case with controls corresponds to a frequency reduction to "extremely unlikely." The values presented in Table 3.4.2.9-2 are validated in HNF-SD-WM-CN-099, Attachment 6.

The remaining parameters, the breathing rate, and the onsite and offsite atmospheric dispersion factors are taken from WHC-SD-WM-CN-032.

3.4.2.9.4 Comparison with Guidelines. Tables 3.4.2.9-1 and 3.4.2.9-2 compare the accident consequences (without and with controls) to the appropriate risk evaluation guidelines. As can be seen from Tables 3.4.2.9-1 and 3.4.2.9-2, all offsite consequences (radiological and toxicological with

and without controls) are below offsite evaluation guidelines. The table also shows that all onsite consequences (radiological and toxicological with and without controls) are above the onsite evaluation guidelines.

3.4.2.9.5 Summary of Safety Structures, Systems, and Components and Technical Safety Requirements.

Safety Structures, Systems, and Components. No Safety-Class or Safety-Significant structures, systems, and components have been identified in this analysis.

Technical Safety Requirement Controls. Controls that act to prevent (reducing the likelihood) or mitigate the consequences of an organic solvent fire are provided in Table 3.4.2.9-3. The TSRs include ignition controls to prevent igniting an organic pool, transfer controls, emergency preparedness, and HEPA filter controls.

Defense-in-Depth. Defense-in-Depth controls are identified in Table 3.4.2.9-4. These include vehicle positioning spotters, tank farm fences, and HEPA filter replacement.

Table 3.4.2.9-1. Summary of Consequences and Frequencies for Organic Solvent Fire Without Controls.

Accident	Consequences								Frequency
	Radiological, Sv (rem)				Toxicological

Table 3.4.2.9-3. Technical Safety Requirement Controls for Organic Solvent Fires. (2 sheets)

Control	Safety function	Comments
Ignition Controls with the following key elements: - Vehicle access within the tank farms shall be limited to vehicles whose fuel systems are protected from damage caused by potential collisions with tank structures - Physical barriers shall restrict vehicle access to those aboveground structures outside of tank farm boundaries that can direct liquids into waste tanks. Only vehicles with protected fuel systems shall be allowed within barriers - Speed limit controls - Stop intrusive activities in Tank 241-AY-102 and 241-C-106 when lightning is identified within a 80.5 km (50-mile) radius of the tank farm - Secure equipment in lowest position (e.g., lay down equipment elevated above the tanks and lower crane boom) if lightning is identified within 80.5 km (50 miles) of the tank farm - If flame cutting is performed in a location where debris from the cutting could fall on the waste surface in a tank, a device that is capable of catching and holding hot metal debris from the cutting shall be inserted between the cutting operation and the waste surface. This does not apply to sparks or slag from welding	Prevents vehicle fuel system damage in the event of collisions with tank structures within the tank farms. Outside the tank farms where vehicle access can not be controlled, prevent vehicle access to tank structures Pieces of hot metal from flame cutting may be capable of igniting salt cake or sludge that has entrained organic solvent in it	--
Transfer Controls with the following key elements: - All waste transfers shall be evaluated to ensure that the waste transfer does not create an organic solvent hazard outside the BIO safety envelope	Ensures that waste transfers do not create an organic solvent hazard outside the safety envelope established by the BIO (i.e., prevent creation of a new tank with an organic solvent hazard unless the required organic solvent controls are extended to the tank)	--
Emergency Preparedness with the following key element: - Response procedures	Mitigates the consequences of a fire	--

Table 3.4.2.9-3. Technical Safety Requirement Controls for Organic Solvent Fires. (2 sheets)

Control	Safety function	Comments
HEPA Filter Controls with the following key elements: - Periodic radiation survey to monitor HEPA filter loading - HEPA filter replacement per change-out criteria (i.e., ≤ 2 mSv/h [200 mrem/h]) - 241-AZ-702 HEME replacement per change-out criteria (8 mSv/h (800 mrem/h) - Periodic radiation survey to verify that 296-C-006 HEME/HEMF dose contribution is ≤ 1 mSv/h (100 mrem/h) at location of radiation detector that monitors the HEME/HEMF - Replacement of the 241-AZ-702 HEGA before the upstream HEPA filter has been replaced 20 times, or upon indication of degraded HEPA filter performance	Reduces consequences from a possible HEPA filter failure by limiting the inventory available	Applies to all HEPA filters and prefilters in the ventilation system
- Aerosol test upon installation (AWF 241-AZ-702) - Periodic aerosol test (AWF 241-AZ-702)	HEPA filter efficiency testing protects the HEGA filter source term assumption in the analysis	Applies to HEPA filters upstream of the HEGA filters

HEGA = high-efficiency gas adsorber
HEME = high-efficiency mist eliminator
HEMF = high-efficiency metal filter
HEPA = high-efficiency particulate air (filter).

Table 3.4.2.9-4. Defense-in-Depth Controls for Organic Solvent Fire.

Control	Safety function	Comments
Vehicle positioning spotters	Spotters provide additional level of control in positioning cranes/vehicles	Reduces probability of analyzed accident
Tank farm fences	Provide line of demarcation within which Ignition Control Program key elements related to vehicle fuel systems must be met	Fence gates are typically closed and locked
HEPA filter replacement typically performed at 1 mSv/h (100 mrem/h)	Limits inventory available for release, limits dose rate to workers in vicinity of the filters	Doses from HEPA filters were minimal compared to the overall doses

HEPA = high-efficiency particulate air (filter).

This page intentionally left blank.

3.4.2.10 In-Tank Fuel Fire/Deflagration. This accident addresses the possibility that a combustible fuel is inadvertently added to either Tank 241-AY-102 or Tank 241-C-106 during or after sluicing operations. This scenario is the same as in Section 5.3.2.16 of the main text of the BIO except that the material risk can include AWF solids. Even though increased consequences could occur, the control strategy is prevention. The controls are not specifically derived from the consequences and would not be changed by variations in the magnitude of the calculated consequences.

3.4.2.10.1 Scenario Development. In assessing the results of fuel spills into tanks, two possible scenarios are considered. The first scenario is a pool fire in which the fuel burns on the surface of the waste (Section 3.4.2.9, Organic Solvent Fire). The second scenario is a headspace deflagration in which vaporized fuel causes the headspace volume to reach the lower flammability limit, and the vaporized fuel is ignited (Section 3.4.2.8, Flammable Gas Deflagration). The difference between the two scenarios is the physical state of the fuel when ignition occurs.

Accident Scenarios Without Controls. The fuel spills are initiated by vehicle accidents and by propylene glycol spills into the tank. The vehicle accident would be an impact into an above grade structure (e.g., a riser) and the subsequent spill of the vehicle fuel into the structure. Because many of the aboveground tank structures have penetrations into the tank, the fuel is assumed to leak into the tank and also spill into the pits. The case where the spill is contained (and catches fire) in the aboveground structure is addressed in Section 3.4.2.4 (Fire in Contaminated Area). The maximum amount of vehicle fuel available in an accident is 227 L (60 gal) (i.e., the capacity of the largest fuel tank on any vehicle that enters the tank farms). Some of the spilled fuel could enter the waste tank through the damaged structure, while some of the fuel would vaporize as the fuel drained into the tank. Section 5.3.2.16 of the main text of the BIO describes the vehicle accident scenario.

The propylene glycol spills could be initiated by a failure associated with either the pit or process chiller. The pit chiller is associated with the Tank 241-AY-102 pump pit and is designed to provide cool air to the pit to remove heat generated by the pump. The process chiller is associated with the ventilation systems of Tank 241-C-106. Before sluicing, the process chiller will be used to precool the waste and minimize the possibility of releasing steam from the waste after sluicing operations begin. After sluicing operations have begun, the process chiller will be used on the recirculation line of the new ventilation system as part of the moisture removal system to prevent the formation of fog in the tank.

The propylene glycol from either chiller would not present a significant fire or deflagration hazard in the tank. Propylene glycol is present in the chillers as a solution in water (46% propylene glycol and 54% water). Therefore, the possibility that a propylene glycol spill results in a fire inside either Tank 241-AY-102 or Tank 241-C-106 is not addressed further.

Accident Frequency Without Controls. The frequency category assigned is "extremely unlikely" based on the analysis in Section 3.4.2.4.

Accident Scenario With Controls. The multiple control strategy specified in Section 3.4.2.10.5 prevents the accident by controlling the fuel and ignition sources. Because the accident is prevented by the specified controls, no release scenarios are postulated for the case with controls. The failure of the multiple control strategy is considered a beyond design basis event.

Accident Frequency With Controls. No release scenarios are postulated assuming success of the credited controls. Therefore, no accident frequency is developed for this case.

3.4.2.10.2 Source Term Analysis.

Accident Source Term Without Controls. The source term for the vehicle fuel pool fire is bounded by the source term calculated for the organic solvent pool fire in Section 3.4.2.9 and is not repeated here.

Accident Source Term With Controls. No release scenarios are postulated assuming success of the credited controls; therefore, no source term is developed for this case.

3.4.2.10.3 Consequence Analysis. As discussed in the scenario development, the potential radiological and toxicological consequences associated with a vehicle fuel spill into a tank are bounded by the consequences of an organic solvent pool fire consequences presented in Section 3.4.2.9 and are outlined in Tables 3.4.2.9-1 and 3.4.2.9-2.

3.4.2.10.4 Comparison with Guidelines. It can be seen from Table 3.4.2.9-2 that the consequences of a pool fire are outside all onsite evaluation guidelines. However, the pool fire is within all offsite evaluation guidelines.

3.4.2.10.5 Summary of Safety Structures, Systems, and Components and Technical Safety Requirements.

Safety Structures, Systems, and Components. No Safety-Class or Safety-Significant structures, systems, and components have been identified to prevent or mitigate this accident.

Technical Safety Requirement Controls. Because the potential consequences identified for this accident exceed evaluation guidelines, TSR controls have been developed. The controls specified in Section 3.4.2.9.5 for the organic solvent fire are designed to prevent the inadvertent spill of vehicle fuel into a tank, provide emergency response if necessary, and limit the release from the high-efficiency particulate air filters. These controls apply to both a fuel fire and deflagration.

To avoid repeating controls and possible inconsistencies, the reader is referred to Section 3.4.2.9.5 for the TSR controls for this accident.

Defense-in-Depth. As with the TSR controls, several features that provide Defense-in-Depth are listed in Section 3.4.2.9.5.

3.4.2.11 Tank Bump. A tank bump could occur if operations related to the tanks produce any of the following conditions without compensating measures being taken.

- Removal of supernate from a tank and the resulting reduction in liquid level will reduce the hydrostatic pressure in the sludge layer and consequently decrease the saturation temperature of the interstitial solution (primarily concerns Tank 241-C-106).
- Increasing the heat load in a tank by adding insoluble solids to Tank 241-AY-102 and/or operating high power pumps.
- Increase of the sludge layer thickness either by fluffing of the current sludge or adding additional sludge (concerns Tank 241-AY-102).
- Inadequately cooling the tank for an extended period (concerns both tanks).

The first three conditions may occur during the WRSS transfer of material from Tank 241-C-106 to Tank 241-AY-102. The fourth condition could occur as the result of ventilation system failure or operational error. The presence of an organic oil film on the top of the supernate layer, due to mobilization of the organics currently dispersed in the waste, could impede evaporative cooling of the tank.

Tank 241-C-106 is one of several SSTs with the proper initial conditions conducive to a tank bump. Tank 241-C-106 contains 746,000 L (197,000 gal) (about 1.75 m [69 in.]) of soft sludge with a total heat load estimated at 38.8 kW (132,400 Btu/h) (as of June 1994) (HNF-SD-W320-ER-004, *Project W-320 SAR and Process Control Thermal Analysis*). The total heat load and the heat load distribution determine the peak temperature in the sludge. If this peak sludge temperature exceeds the local saturation temperature, the potential for a tank bump will increase. Tank 241-C-106 is on the High Heat Watch List and must receive periodic water additions to maintain the waste temperatures within allowable limits. Currently, forced ventilation with added water to promote thermal conductivity and evaporative cooling is used for heat removal.

Tank 241-AY-102, a double-shell tank, contains 121,000 L (30,000 gal) (about 305 mm [12 in.]) of sludge and 3.1 million L (812,000 gal) of supernate for a total waste depth of about 9.1 m (30.0 ft). The estimated heat load of Tank 241-AY-102 is 13.2 kW (45,000 Btu/h) (HNF-SD-W320-ER-004).

The waste transferred into Tank 241-AY-102 will add to that tank's heat load and cause an increase in the sludge temperatures. In addition, the sludge from Tank 241-C-106 will probably not settle back immediately to its original volume, but will initially remain "fluffed" to some greater volume and depth. This increased volume will increase the distance over which heat transfer must take place and further increase the temperature in the sludge. The amount of fluffing (the fluff factor) to be expected is uncertain. A fluff factor of 2 is being assumed as bounding (HNF-SD-W320-ER-004). Thermal analyses have been performed for waste addition to Tank 241-AY-102 to confirm adequate heat removal capability. Analysis results indicate that

waste temperatures will remain below saturation for waste transfers of up to 0.6 m (2 ft). The analysis assumes 4.3 m^3/min (150 ft^3/min) flow to the cooling channels under the tank floor, and operable primary ventilation (these assumptions are valid for both 241-A-702 and 241-AZ-702). After the first campaign to transfer 0.6 m (2 ft) of sludge from Tank 241-C-106, temperatures will not reach their new steady-state values for some time (about 300 days for 0.6 m (2 ft) of sludge transfer) (HNF-SD-W320-ER-004). Real-time temperature data on the tank contents will be entered into a thermal model in the form of an initial temperature history to project thermal response of the sludge. The results will be used to calibrate the model, establish hold times between transfers, and further evaluate cooling requirements for sludge transfers.

The analysis presented here uses a mixture of AWF solids and AWF liquids to develop consequences. A similar mixture of SST solids and SST liquids would have a much lower ULD, thus consequences from an SST tank bump are bounded by the tank bump in Tank 241-AY-102. Therefore, for purposes of establishing the need for controls, only analysis specific to Tank 241-AY-102 is performed.

3.4.2.11.1 Scenario Development. The WRSS accident scenario assumes that heat removal is insufficient to maintain acceptable operating temperatures and that saturation temperature has been reached. This condition is postulated to have been reached as a result of any one or a combination of the four conditions discussed in Section 3.4.2.11.

The analysis uses the following assumptions. Details of the analysis and scenario choice are described in HNF-SD-WM-CN-098, *Consequences of a Postulated Tank Bump Related to Project W-320.*

- In the tank bump analysis (WHC-SD-WM-CN-022), 1.45 m (4.75 ft) of sludge was assumed to have been transferred from Tank 241-C-106 to Tank 241-AY-102, producing a total sludge depth of 3.35 m (11 ft) in Tank 241-AY-102 (fluff factor of 2). The total pool depth was assumed to be maintained at 9.1 m (30 ft).

- For loss of ventilation, a "best estimate" temperature profile (corresponding to the thermal model for 1.45 m [4.75 ft] of sludge and a fluffing factor of 2) was assumed for the sludge layer corresponding to conditions leading to an initial bump caused by inadequate cooling (loss of primary and annulus ventilation) for the heat load over an extended period.

- Only saturated sludge becomes involved in a tank bump. Therefore, the severity of the tank bump is directly related to the volume of saturated sludge. The tank sludge is expected to first reach saturation temperature in the bottom center of the tank. The fraction of sludge that is saturated in this situation is much less than 1. In this case, where the tank is a subject of ongoing operations and is constantly monitored, a tank bump is assumed to be initiated when such a temperature profile exists.

- The vent path configuration that allowed the greatest aerosol release and therefore produced the greatest consequence to onsite and offsite receptors was used.

- No credit was taken for condensation of steam in the supernate layer overlying the sludge.

Accident Scenario Without Controls. For the accident scenario without controls, it was postulated that active ventilation would be lost for an indefinite period. The temperature of the tank waste near the bottom of the tank was modeled to exceed local saturation temperature.

Accident Frequency Without Controls. The frequency of a tank bump without controls was categorized as "anticipated."

Accident Scenario With Controls. The controls selected for the tank bump scenario are preventive and are presented in Section 3.4.2.11.5. The controls prevent tank waste from reaching saturation temperatures, thereby precluding a tank bump.

Accident Frequency With Controls. With the controls identified in Section 3.4.2.11.5, the accident is assumed to be prevented.

3.4.2.11.2 Source Term Analysis. The Tank 241-AY-102 waste conditions were modeled with the GOTH thermal hydraulics computer code, a transient computer program used to model multi-phase flow (WHC-SD-WM-CN-022). The GOTH code presented the mass of waste released (the release fraction and inventory at risk are included in the code). The waste types assumed for radiological dose consequence calculations were AWF tank liquids and solids. The waste types assumed for toxicological consequences were double-shell tank liquids (the toxicological sum-of-fractions for double-shell tank liquids includes AWF liquids) and double-shell tank solids (the toxicological sum-of-fractions for double-shell tank solids includes AWF solids). These are bounding assumptions for a release due to a steam bump in either Tank 241-AY-102 or Tank 241-C-106.

Accident Source Term Without Controls. GOTH model estimates showed that for the worst case tank vent configuration, a tank bump in Tank 241-AY-102 would eject 35.4 kg (78 lbm) of solids and 280 kg (620 lbm) of liquids directly out of the pit drains along with 180 kg (400 lbm) of steam over about 3 seconds (WHC-SD-WM-CN-022). Because this is such a short-duration release, the steam release would initially form a cloud over the release point with the waste material suspended as an aerosol. The loading of this much waste material in this amount of steam would amount to more than a kilogram per cubic meter. Even with some turbulent mixing with air, this is far too great a load to be sustained for even a short time. The material would rapidly fall out of the cloud until the air loading decreased to some short-term sustainable value. The GOTH simulation also shows 770 kg (1700 lbm) of steam issuing from the tank vent at the same time the release from the pit occurs. This magnitude of pressure pulse will easily blow out the filters (HEPA, HEGA and HEME) in the ventilation system. No credit was taken for cover blocks being in place because they would have little effect on the material released.

The maximum sustainable loading of an aerosol mist in air is normally assumed to be 100 mg/m^3 (6.23x10^{-6} lb/ft^3) (ANSI N46.1, *American National Standard - Guidance for Defining Safety-Related Features of Nuclear Fuel Cycle Facilities*). However, because the air loading here is for a fast transient condition until turbulent mixing with the surrounding air and enough evaporation of the water portion of the liquid release can occur, 10 times this value (1 g/m^3) (6.23x10^{-5} lb/ft^3) is assumed for conservatism. For the WRSS accident, all the transportable aerosol that could affect a downwind receptor is assumed to be carried by the released steam at a transient loading of 1 g/m^3 (6.23x10^{-5} lb/ft^3).

The maximum total steam release for any scenario considered was 950 kg (2100 lbm). Assuming the liquid-solid ratio described above (280 kg [620 lbm] liquid and 35.4 kg [78 lbm] solids), the net transportable releases are 9.63 x 10^{-2} L (2.54 x 10^{-3} gal) of solids and 1.17 L (0.31 gal) of liquids (HNF-SD-WM-CN-098). The 1 g/m^3 (6.23x10^{-6} lb/ft^3)initial loading includes the water portion of the liquid waste component that would rapidly evaporate during transport leaving only the dissolved solids. Therefore, in this case, the usual maximum air loading of 100 mg/m^3 (6.23x10^{-6} lb/ft^3) at the receptor cannot be used to assume additional fallout.

The analysis showed the tank headspace pressure to reach a peak of about 28 kPa gauge (4.1 psig) in Tank 241-AY-102 (WHC-SD-WM-CN-022). More available headspace and lower hydrostatic head would result in a lower peak pressure in Tank 241-C-106 than Tank 241-AY-102.

The pressure pulse of 28 Kpa gauge (4.1 psig) is approximately 10 times the minimum pressure required for high-efficiency particulate air filter blow out. Therefore, the filters (HEPA, HEME, and HEGA) in the AY/AZ farm ventilation systems should be expected to fail during a tank bump. Thus, the consequences of the tank bump are increased by the dose contribution from filter blow out and subsequent unfiltered release. However, the dose contribution of filter blow out and unfiltered release is insignificant compared to the dose consequences of the tank bump itself. For example, the 241-A-702 ventilation system represents the bounding case for Tank 241-AY-102 (refer to Sections 3.4.2.2 and 3.4.2.3). For the 241-A-702 system, the combined onsite consequence of 2.1 E-02 Sv for the filter failure and unfiltered release is two orders of magnitude lower than the 1.9 Sv onsite consequences of a tank bump. In addition, the initial headspace air with its normal loading of waste material is assumed to be displaced out of the tank by the steam release. The dose contribution resulting from this effect is negligible compared to the dose consequences of the bump itself (WHC-SD-WM-CN-043, *Tank Bump Consequence Analysis*).

Accident Source Term With Controls. No source term with controls was derived because the accident controls are preventative.

3.4.2.11.3 Consequence Analysis. The onsite and offsite dose consequences and toxicological exposures were determined using the method discussed in Section 3.4.1.

Analysis Results.

Consequences Without Controls. The radiological and toxicological consequences of this release are presented in Table 3.4.2.11-1.

Consequences With Controls. No consequences with controls were derived because the accident controls are preventative.

3.4.2.11.4 Comparison to Guidelines. Table 3.4.2.11-1 compares the tank bump consequences to risk guidelines. Onsite consequences without controls for both radiological and toxicological exposure are above risk guidelines. Offsite radiological consequences are also above risk guidelines. Therefore, to protect the onsite worker and members of the public from both radiological and toxicological hazards of a tank bump, the event must be controlled.

Note that increasing the amount of sludge transferred beyond the 1.45 m (4.75 ft) assumed in the bump simulation from WHC-SD-WM-CN-022 that was used as the basis of this analysis would increase the severity of the bump and the consequent releases. The scenario analyzed here already produces consequences above the onsite and offsite boundary risk guidelines. Increasing the amount of sludge transferred and hence increasing the potential severity of the accident would, therefore, have no effect on the conclusions.

3.4.2.11.5 Summary of Safety Structures, Systems, and Components and Technical Safety Requirement Controls.

Safety Structures, Systems, and Components. Because both the onsite and offsite guidelines are exceeded, Safety-Class structures, systems, and components are required (Table 3.4.2.11-2).

The primary and annulus ventilation systems for Tank 241-AY-102 remove a major portion of the heat generated in the primary tank. The safety function provides the means to maintain tank waste below local steam saturation temperature. The safety function of both these systems is to maintain the tank waste temperatures below the saturation temperature. The ventilation system for Tank 241-C-106 removes heat from the waste and its safety function is also to maintain the tank waste temperatures below the saturation temperature.

Technical Safety Requirement Controls. The TSR controls selected to prevent tank bumps are listed in Table 3.4.2.11-3. These controls establish tank waste temperature limits, and ensure that waste transfers do not create in-tank conditions conducive to bump initiation.

Tank 241-C-106. Tank waste temperature limits are set for Tank 241-C-106 to prevent the waste in the tank from reaching saturation temperatures. The temperature limits will be lowered as WRSS operations proceed, since the hydraulic head, and thus the saturation temperature, is reduced from waste transfer.

The liquid level in Tank 241-C-106 will be maintained at a pre-determined level for the first two increments (defined as 0.3 m of sludge) of waste transfer, to avoid affecting the sub-cooling provided by the hydraulic head of

the liquid in the tank. The control of the liquid level in Tank 241-C-106 can not be monitored using the ENRAF liquid level instrument because this instrument will be shut down during sluicing operations to avoid damage by the sluice stream. Therefore, the control uses the lower liquid level sensor on the submersible slurry pump. The minimum liquid cover/hydraulic head control requirement will be eliminated after the first sluicing campaign as discussed in HNF-SD-W320-ER-004.

Tank 241-AY-102. To prevent the transfer of heat generating sludge to Tank 241-AY-102 beyond its cooling capacity, a step-wise transfer of waste is required. Waste will be transferred in three campaigns, each consisting of two transfer increments of 0.3 m (1 ft.). Each transfer increment will be followed by a hold period to monitor waste parameters and thermal response. Transfer increments can comprise one or several batches of waste. The sluicing batch durations will be limited by two factors: (1) the mass flow meter totalizer reading (estimated volume of sludge transferred), and (2) a maximum time duration established based on mass flow meter instrument detection level. These two values will be established in the WRSS process control plan. The values may be subsequently modified based on WRSS operational experience.

During the monitoring period between transfer increments, the volume of Tank 241-C-106 sludge transferred to Tank 241-AY-102 will be calculated using ENRAF densitometer density profile data and Tank 241-AY-102 grab samples analysis results. This estimate will be compared with the mass flow meter totalizer readings. The monitoring period duration may also be extended until adequate confidence is established in the estimated sludge volume/heat load transferred.

The sludge volume transferred from Tank 241-C-106 to Tank 241-AY-102 is monitored in real time using the mass flow meter located in pit 241-AY-02A. This solids volume transferred is used to estimate the approximate heat load transferred. After each sluicing campaign, the heat load transfer monitoring is accomplished by performing a heat balance on each of the two tanks to refine the thermal analysis baseline and verify that subsequent sluicing operations can be accomplished safely.

Defense-in-Depth. Existing prevention and mitigation features support Defense-in-Depth as shown in Table 3.4.2.11-4.

Table 3.4.2.11-1. Consequences of a Tank Bump Assuming No Controls.

Accident	Consequences								Frequency

Control	Safety classification		Safety function	Comments
	SC	SS		
Tank 241-AY-102 primary ventilation system	X	--	Provides the means to maintain tank waste below local saturation temperature	If saturation temperatures are reached a tank bump could occur
Tank 241-AY-102 annulus ventilation system	X	--	Prevents Tank 241-AY-102 from reaching the saturation temperature	If saturation temperatures are reached a tank bump could occur
Tank 241-C-106 ventilation system	X	--	Provides the means to maintain tank waste below local saturation temperature	If saturation temperatures are reached a tank bump could occur

SC = Safety-Class.
SS = Safety-Significant.

Table 3.4.2.11-3. Technical Safety Requirement Controls for Tank Bumps. (2 sheets)

Control	Safety function	Comments
SST Waste Temperature Controls with the following tank waste temperature limit: For Tank 241-C-106, ≤ 205 °F (96 °C)	Ensures that tank waste temperatures at which a tank bump or steam release event could occur are not reached	The specific waste temperature limit for Tank 241-C-106 applies prior to sluicing operations
DST and AWF Tank Waste Temperature Controls with the following tank waste temperature limits: For Tank 241-AY-102, ≤ 195 °F (91 °C), for all waste levels OR ≤ 195 °F (91 °C) in the top 4.6 m (15 ft) of the waste AND ≤ 215 °F (102 °C) in the waste below 4.6 m (15 ft)	Ensures that tank waste temperatures at which a tank bump or steam release event could occur are not reached	The specific waste temperature limits for Tank 241-AY-102 applies prior to, during, and after sluicing operations
Tank 241-AY-102 Annulus Ventilation System - Operability	Ensures operability of the Tank 241-AY-102 annulus ventilation system	Applies to Tank 241-AY-102 after 0.6 m (2 ft) of sludge from Tank 241-C-106 has been transferred
Transfer Controls with the following key elements: - Incremental waste transfer with material balance after each sluicing batch of 12 hours maximum duration during transfer operations, including total material transferred and solids loading calculation - All waste transfers shall be evaluated to ensure that the waste transfer does not create a tank bump hazard outside the BIO safety envelope	Ensures that conditions in Tank 241-AY-102 remain within analyzed envelope at all times Ensures that the waste transfer does not create a tank bump hazard outside the safety envelope (i.e., prevent creation of a new tank with a tank bump hazard unless the required tank bump controls are extended to the tank)	During the monitoring period, volume of Tank 241-C-106 transferred will be calculated using the ENRAF densitometer and Tank 241-AY-102 grab samples analysis results The sludge transferred from Tank 241-C-106 is monitored real time using the mass flow meter on the transfer line
Process Instrumentation and Measuring and Test Equipment with the following key element: - Equipment must be calibrated and properly maintained	Ensures instrumentation used to monitor temperature, tank levels, and transfer line flow is maintained	--
Ventilation Controls with the following key element: - Provide adequate cooling capacity for Tank 241-AY-102, through the primary and annulus ventilation systems, after 0.6 m (2 ft.) of sludge is transferred into the tank	Ensures that adequate cooling capacity is available to keep waste in Tank-241-AY-102 from reaching saturation temperature for each sluicing campaign	--

Table 3.4.2.11-3. Technical Safety Requirement Controls for Tank Bumps. (2 sheets)

Control	Safety function	Comments
Tank 241-AY-102 Primary Ventilation System	Provides adequate cooling capacity in Tank 241-AY-102 in conjunction with Annulus Ventilation System	Applies to Tank 241-AY-102 after 0.6 m (2 ft) of sludge from Tank 241-C-106 has been transferred
Tank 241-C-106 Waste Temperature Controls: - Predict saturation temperatures at the bottom of Tank 241-C-106. Use predicted height of the waste throughout the incremental transfer and periodically monitor the waste temperature	Ensures that tank waste temperatures at which a tank bump or steam release event could occur are not reached	--
- During the first two 0.3 m (1.0 ft) transfer increments, the liquid level established before start of each sluicing increment will be maintained throughout the increment	Prevents a steam flash in Tank 241-C-106 resulting from loss of hydraulic head	

AWF = aging waste facility.
DST = double-shell tank.
SST = single-shell tank.
TSR = Technical Safety Requirement.

Table 3.4.2.11-4. Defense-in-Depth Controls for Tank Bumps.

Control	Safety function	Comments
The airlift circulators in Tank 241-AY-102 will be disabled prior to the start of sluicing operations	Prevents inadvertent transfer of heat generating materials to Tank 241-C-106 and prevents ALC initiation of tank bump in Tank 241-AY-102	Transfer of large amounts of sludge to Tank 241-C-106 via the sluice line could increase the heat load in Tank 241-C-106 to greater than the analyzed range, possibly causing a tank bump in Tank 241-C-106
Communications between the Tank 241-C-106 and Tank 241-AY-102 control trailers will be maintained during sluicing operations	Coordinates operations at the two tanks and to detect flow imbalances or other unexpected conditions	--
Pump pit and sluice pit cover blocks (including removable plugs) will be in place prior to any sluicing operations and prior to enabling of the sluice or slurry pumps	Provides containment and confinement function in the event of a tank bump or spray leak within the pit, and limit onsite and offsite radiological and toxicological exposures	Camera installation through the cover plug camera port is allowed
The transfer pumps associated with the sluice and slurry lines must be administratively locked out except as necessary for actual sluicing operations and maintenance	Prevents inadvertent initiation of sluice or slurry flow which could result in a sludge configuration leading to tank bump conditions	Unexpected operation of a transfer pump when the transfer system is not in a proper lineup for sluicing operations could lead to an accidental release or injury to personnel
Emergency response plan/procedures	Protects onsite personnel and facility workers from unnecessary radiological and toxicological exposure in the event of a tank bump	--

ALC = air lift circulator.

3.4.2.12 Liner Breach Caused by Steam Between the Steel Liner and Concrete Shell in Tank 241-C-106. A liner breach caused by steam under the liner can cause a rapid steam pressurization of the tank headspace, similar to that caused by a tank bump. A liner breach is a safety concern because of the potential for a release of aerosolized waste into the environment and/or an insult to the environment from tank leakage.

Water could get between the steel liner of Tank 241-C-106 and the concrete shell by four methods. These include water in the concrete itself, spillage during liner filling, rainfall during construction, or a leak. Water from the concrete, from spillage, or from rainfall, is assumed to have vaporized in the 1970s, when the tank temperatures were at their highest.

During sluicing operations, a stream of supernate may be directed at the carbon steel tank liner. This supernate jet could strike an area of the tank liner that has been weakened by corrosion, thus causing a leak. Other leak possibilities exist (they are listed in the WRSS hazard analysis [see Section 3.2]), but the same consequences are yielded. Raw water or supernate could leak under the bottom of the liner and the grout that covers the asphalt layer over the concrete base of the tank. This liquid could become trapped if the liner were to expand during a temperature increase. The heated asphalt under the liner provides another method of entrapment.

The current measured temperature in Tank 241-C-106 is about 63 °C (145 °F). Thermal modeling indicates that the maximum temperature in the bottom center of Tank 241-C-106 is about 109 °C (228 °F). Before sluicing, the tank will be chilled to about 107 °C (224 °F) (HNF-SD-W320-ER-004). The saturation temperature of water is pressure dependent. Hydrostatic head (i.e., the pressure caused by the weight of the waste) for the total waste height (including sludge) increases local pressure and, therefore, local saturation temperature. At the current level of waste, the saturation temperature needed under the liner to create steam is about 110 °C (230 °F). The saturation temperature of water at atmospheric pressure is 100 °C (212 °F). Waste temperature rising above the saturation temperature would create a steam bubble between the liner and the concrete base of the tank. A sufficiently energetic steam bubble could breach the liner and possibly initiate a tank bump. This liner breach would eject steam containing contamination into both the atmosphere and the soil.

The tank bump scenario is specifically addressed in Section 3.4.2.11; the supporting documents for that analysis are WHC-SD-WM-CN-022 and WHC-SD-WM-CN-043. The tank bump scenario covers the response of steam travelling through waste in more detail. The response of steam created by a liner breach would be similar to the bump.

Drying waste will experience a temperature peak caused by decreased conductivity, but the waste will eventually cool down as radioactive isotopes decay. If enough waste is removed, the remaining waste temperatures will remain below the saturation temperature of water, eliminating the possibility of a liner breach.

Water entrapment under the liner is only a concern in single-shell tanks. Tank 241-C-106 is a SST containing 746,000 L (197,000 gal) (about 1.75 m [69 in.]) of soft sludge with a total heat load estimated at 38.8 kW (132,400 Btu/h) as of June 1994. This tank is on the high heat watch list and must have periodic water additions to maintain the waste temperatures within allowable limits by means of evaporative cooling using active ventilation.

On January 28, 1965, a steam release event occurred in Tank 241-A-105. After the event, it was determined that the bottom of the steel liner was displaced from the concrete pad and bulged upward to a maximum of 2.6 m (8.5 ft). It was determined that the cause of the event was an amount of liquid between the liner and concrete reached the saturation temperature, converted to steam, and pushed the liner upward. Subsequently, this displacement caused the liner to fail and leak some amount of waste to the space between the liner and the concrete (Bander et al. 1994, *Assessment of Possibility of Deformation of the Bottom Steel Liner of Tank 241-C-106*).

3.4.2.12.1 Scenario Development. Engineered heat removal methods are implemented when heat removal by natural conduction to the soil is insufficient to maintain acceptable operating temperatures. The most common heat removal method is active ventilation of the tank headspace. An initiating event is the result of equipment failures or operational errors that result in impaired heat transfer from the sludge to the supernate or heat transfer from the supernate to the tank ventilation system. The other initiating event is operational errors that increase the heat generation capacity of the waste to above the heat removal capacity of the tank.

Tank waste temperature begins to rise when the engineered heat removal mechanism (e.g., active ventilation) is lost or certain operational errors occur. The rate of the temperature increase depends on the heat generation rate and the quantity of waste involved.

The following assumptions were made to ensure conservative results (HNF-SD-W320-CN-004, *Consequence Analysis of a Liner Breach Due to Steam Under the Liner*).

1. A total of 1.25 m (4.1 ft) of sludge has been transferred from Tank 241-C-106 to Tank 241-AY-102 with a total sludge depth of 0.79 m (2.6 ft) left in Tank 241-C-106. This value was chosen based on analysis discussed in HNF-SD-W320-ER-004, which shows that without ventilation, 0.79 m (2.6 ft) of dry waste in Tank 241-C-106 will result in temperatures above saturation. Less remaining waste would result in lower temperatures; however, temperature models would be necessary to determine what level of waste would yield temperatures below saturation.

2. A small amount of liquid (just under 26.5 L [7 gal]) is trapped under the liner, turns to steam, and expands the liner until just before breaching. If the steam cools, a 1400 ft^3 void is created under the liner (Bander et al. 1994).

3. Water fills the void completely.

4. The tank reaches the saturation temperature of water and the trapped water under the liner turns to steam and breaches the liner. A differential pressure of 22.1 kPa (3.2 psi) will breach the liner. This pressure differential could be created by the presence of about 26.5 L (7 gal) of water under the liner that is converted to steam (Bander, et al. 1994).

5. The liner breach causes a pressure drop. Saturation temperatures drop with the pressure drop and a certain amount of liquid under the liner flashes to steam and is released out of the liner breach. This amount can be determined using energy conservation.

6. All steam released is assumed to be involved in the accident, with no effect from condensation. Condensation would have a minimal effect because the supernate is at approximately the same temperature as the sludge.

7. If a liner breach occurred during sluicing or before dry-out of the waste, the consequences would be lower than if the event happens after sluicing is finished and the remaining waste material has dried out. This is because the moist waste would have a greater density, and consequently the source term would be lowered.

8. The worst case source term is 100% dry solids, with the maximum amount of water trapped under the liner. The waste moisture content and level have little effect on the consequences.

Accident Scenario Without Controls. For the accident scenario without controls, the temperature of water trapped under the liner of Tank 241-C-106 was postulated to rise above local saturation.

Accident Frequency Without Controls. The frequency without controls of a liner breach was categorized as "anticipated" in the hazards analysis.

Accident Scenario With Controls. The controls selected for the liner breach scenario are preventive and are presented in Section 3.4.2.12.5. These controls prevent the water trapped beneath the liner of Tank 241-C-106 from reaching saturation temperatures, thereby precluding the liner breach event. Should a rising temperature trend be detected, potential heat sources (e.g., pumps) would be eliminated and waste cooling techniques (e.g., ventilation, water addition) would be restored or initiated.

Accident Frequency With Controls. With the controls identified for the liner breach scenario in Section 3.4.2.12.5, the accident is prevented.

3.4.2.12.2 Source Term Analysis. The amount of steam released into Tank 241-C-106 during both the liner breach and the resultant steam flash was calculated to find the entrained waste release. The waste types assumed for radiological dose consequence calculations were single-shell tank solids. The waste types assumed for toxicological consequences were SST solids.

Accident Source Term Without Controls. A liner breach in Tank 241-C-106 would release 0.47 L (0.12 gal) of respirable solids (HNF-SD-W320-CN-004). The entire volume of steam created is assumed to be released during the event.

As noted previously, the release of steam from under the liner is similar to a tank bump event. Therefore, the source term model used in HNF-SD-W320-CN-004 is based on the tank bump calculations in WHC-SD-WM-CN-043 and WHC-SD-WM-CN-022 (Section 3.4.2.11).

Damage to the ventilation system filters should be expected during a liner breach event. The dose contributions of filter blow out and subsequent unfiltered release are added to the dose consequences of the steam release itself. The contribution of the filter blow out and unfiltered release are included in the consequences presented in Table 3.4.2.12-1, and are quantified in Section 3.4.2.2. and 3.4.2.3.

Accident Source Term With Controls. No source term with controls was derived because the accident controls are preventive.

3.4.2.12.3 Consequence Analysis. The onsite and offsite dose consequences and toxicological exposures were taken from HNF-SD-W320-CN-004.

Analysis Results.

Consequences Without Controls. The radiological and toxicological consequences of this release are presented in Table 3.4.2.12-1.

Consequences With Controls. No consequences with controls were derived because the accident controls are preventive.

Key Parameters and Assumptions. A major assumption includes the transportable and respirable releases. The transportable (able to reach a receptor at least 100 m downwind) and respirable source term for this accident was formulated by assuming all the steam issuing from the tank to be carrying a short-term transient air loading (1 g/m^3) of waste material (HNF-SD-W320-CN-004).

3.4.2.12.4 Comparison to Guidelines. Table 3.4.2.12-1 compares liner breach consequences to risk guidelines. Onsite consequences without controls for both radiological and toxicological exposure are above risk guidelines. Offsite radiological consequences are also above risk guidelines. To protect the onsite worker from both radiological and toxicological hazards of a liner breach, the event must be controlled.

3.4.2.12.5 Summary of Safety Structures, Systems, and Components and Technical Safety Requirement Controls.

Safety Structures, Systems, and Components. No safety structures, systems, and components were identified in this analysis.

Technical Safety Requirement Controls. The TSR controls selected to prevent a liner breach are listed in Table 3.4.2.12-2. These controls establish tank waste temperature limits, ensure operability of tank waste

temperature monitoring instrumentation, and ensure that waste transfers do not create in-tank conditions conducive to liner breach initiation. It should be noted that AC 5.26 provides a more restrictive temperature control on Tank 241-C-106 than is imposed by LCO 3.3.1. This is primarily because the sluicing operation will lower the local saturation temperature through removal of hydraulic head. In addition, an element has been added to the Administrative Controls (AC 5.26) to require a recovery plan if the temperature is exceeded.

Defense-in-Depth. Existing prevention and mitigation features support Defense-in-Depth, as shown in Table 3.4.2.12-3.

Table 3.4.2.12-1. Consequences of a Liner Breach Assuming No Controls.

Accident	Consequences								Frequency
	Radiological, Sv (rem)				Toxicological				
	Onsite		Offsite		Onsite		Offsite		
	Calculated dose*	Risk guideline	Calculated dose*	Risk guideline	Calculated SOF*	Risk guideline	Calculated SOF*	Risk guideline	
Liner Breach	5.4 E+00 (5.4 E+02)	5.0 E-03 (5.0 E-01)	4.4 E-03 4.4 E-01	1.0 E-03 (1.0 E-01)	2.6 E+04	1	8.2 E-01	1	Anticipated

SOF = sum-of-fractions.

* Note: The radiological and toxicological dose is based on consequences identified in 98-TWR-025, Contract No. DE-AC06-96RL13200 - Addendum To Safety Evaluation Report (SER) For Project W-320, Tank 241-C-106 Sluicing (Letter from J. D. Wagoner, RL, to R. D. Hanson, FDH), dated September 25, 1998.

Table 3.4.2.12-2. Technical Safety Requirement Controls for Liner Breaches.

Control	Safety function	Comments
SST Waste Temperature Controls with the following key element (prior to start of sluicing): - Temperature ≤ 205°F	Ensures that tank waste temperature monitoring system is operable and that temperatures at which a liner breach event could occur are not reached	Temperatures must be maintained below those that could result in creation of steam under the liner
Tank 241-C-106 Waste Temperature Controls with the following key element: - Establish temperature controls that are < T_{sat} for existing tank conditions (during and after sluicing)	Ensures that tank waste temperature monitoring system is operable and that temperatures at which a liner breach event could occur are not reached	The specific waste temperature limits will depend on the amount of waste remaining in Tank 241-C-106, since T_{sat} under the liner varies with pressure. Temperatures must be maintained below those that could result in creation of steam under the liner
Transfer Controls with the following key element: - All waste transfers will be evaluated to ensure that the waste transfer does not create a liner breach hazard outside the BIO safety envelope	Ensures that waste transfers do not create a liner breach hazard outside the safety envelope established by the BIO (i.e., prevent creation of a new tank with a liner breach hazard unless the required liner breach controls are extended to the tank)	--
Process Instrumentation and Measuring and Test Equipment with the following key element: - Equipment must be calibrated and properly maintained	Ensures instrumentation used to monitor temperature, tank levels, and transfer line flow is maintained	--

AWF = Aging Waste Facility.
DST = double-shell tank.
SST = single-shell tank.
TSR = Technical Safety Requirement.

Table 3.4.2.12-3. Defense-in-Depth Controls for Liner Breaches.

Control	Safety function	Comments
Active ventilation or other heat removal mechanisms will be maintained	Maintains sludge and supernatant temperatures below the required control levels for tanks with a potential for a liner breach	--
Pump pit and sluice pit cover blocks (including removable plugs) will be in place whenever the conditions for initiation of a liner breach are present (i.e., known leaking liner, active ventilation system down indefinitely)	Provides containment and confinement function in the event of a liner breach	WHC-SD-WM-CN-043 quantifies the reduction of a tank bump, similar to a liner breach, in consequences provided by cover blocks
Emergency response plan/ procedures	Protects onsite personnel and facility workers from unnecessary radiological and toxicological exposure in the event of a liner breach	--
A material balance will be performed after each sluicing batch of 12 hours maximum duration during transfer operations, including total material transferred and solids loading calculation	Ensures that the introduction of tank solids into the sluice line is ≤ 10%	An inadvertent deviation of Tank 241-C-106 conditions outside the analyzed envelope could result in a liner breach
Syphon protection is provided on the slurry distributor and the submersible sluice pump discharge line within Tank 241-AY-102	Prevents establishing a syphon when slurry pumps or sluice pumps are shut down	A syphon, if established, could drain back from Tank 241-AY-102 to Tank 241-C-106 and could result in overfilling Tank 241-C-106, allowing liquid to leak under the liner
Material balance including level monitoring to identify leakage into the liner	Tank 241-AY-102 level measurement and slurry line mass flow measurement	--
Raw water is metered	Used in coordination with material balance and 241-AY-102 level monitoring, detects large raw water leakages	--
Communication between Tank 241-C-106 and Tank 241-AY-102 control trailers will be maintained during sluicing operations	Coordinates operations at the two tanks and detects flow imbalances or other unexpected conditions (e.g., power failure)	--
Sluicing controls	Sluicing controls are in the process control plan. During the early stages of sluicing, the sluice stream will not be directed at the waste near the walls	During the later stages of sluicing, the sluice stream will be directed toward the wall to ensure effective recovery of the Tank 241-C-106 waste
Design feature - The stiff hose is engineered to maintain integrity	Prevents sluicer hose from breaking off and causing liner breach	--
Design feature - Positive mechanical stops are provided to limit nozzle travel to less than 25° above horizontal	Prevents the sluice stream from impinging on an area above the steel liner. Prevents sluice from leaking into the liner from top of liner	--

WHC-SD-WM-CN-043, 1996, Tank Bump Consequence Analysis, Rev. 2, Westinghouse Hanford Company, Richland, Washington.

3.4.2.13 Subsurface Leak Remaining Subsurface. This accident category refers to low-energy subsurface leaks that remain subsurface and are not visually detected. A subsurface leak that forms a surface pool and is visually detectable is analyzed in Section 3.4.2.14. The analyzed leak is similar to the subsurface leak remaining subsurface scenario analyzed in the main text of the BIO. However, the presence of the berm over the transfer lines in the WRSS makes the worst case leak geometry different from that described in Section 5.3.2.7 of the main text of the BIO. The direct dose from waste in the berm is much larger than the direct doses for below ground waste calculated in the main text, which is primarily caused by the long path through the soil that attenuates the direct radiation. The shielding provided by the soil is not as great as in the WRSS analysis. Secondary factors that also changed doses compared to those in the main text were a larger transfer flow rate for WRSS and a different waste for the source term for WRSS (Section 3.4.1).

Possible causes of a subsurface leak identified in the hazard analysis include the following:

- Failure of an encased transfer line during sluicing operations (caused by corrosion or aging)
- Excavation accident that damages a waste transfer line
- Leak from a cracked or broken pump or valve or a related transfer pit failure
- Structural failure of a tank wall or bottom.

Tank structural failure could result in a large subsurface leak, but the subsurface plume would have no immediate consequences to facility workers or offsite receptors because of the large amount of soil shielding above the liquid in the tanks; therefore, this scenario was not analyzed. Leaks into a transfer pit are analyzed in Section 3.4.2.16. Excavation accidents are analyzed in Section 3.4.2.17. Therefore, failure of an encased waste transfer line was chosen as the worst case subsurface leak and is analyzed in the following subsections.

3.4.2.13.1 Scenario Development. The worst case subsurface leak remaining subsurface accident scenario is a subsurface leak from a waste transfer line during WRSS operations. The following assumptions are used to calculate dose consequences for the scenario with and without controls.

- The leak occurs in the slurry line because the heavy solid loading will make doses higher in the slurry line than in the sluicing line.
- The burial depth of the slurry transfer line varies depending on location, but the worst consequences are obtained if the leak occurs near Tank 241-C-106 where the line is buried just below the surface and is bermed.
- The berm near Tank 241-C-106 is 0.76 m (2.5 ft) high and 2.44 m (8 ft) wide.

- The leak remains below the surface (not visually detectable) and no airborne radioactive or toxic materials are released.
- The total radiological dose to the onsite receptor is comprised of direct (line of sight), skyshine, and associated bremstrahlung radiation components for 12 hours, which is consistent with the method presented in the main text of the BIO (Section 5.3.1.1.1).
- Uncontaminated soil cover of 152.4 mm (6 in.) remains as shielding over the leak area.
- Leaking waste completely saturates a region of the soil around the leak site.
- The soil void fraction is 40%.
- The soil density is 1.6 g/cm^3 (100 lb/ft^3).
- The slurry line waste density is 1.4 g/cm^3 (87 lb/ft^3).
- The worst case leak geometry is a disk representing a leak into the soil under the berm or a rectangular region saturating a section of the berm to within 152.4 mm (6 in.) of the surface.

Accident Scenario Without Controls. The following parameters were used in the accident scenario without controls.

- The transfer line flow rate is 28.4 L/s (450 gpm).
- A leak rate of 5% of the total flow (a higher leak rate would become the subsurface leak resulting in a pool [Section 3.4.2.14] or the spray leak from an underground waste transfer line [Section 3.4.2.17]).
- The duration of the leak is assumed to be 12 hours (maximum sluicing batch duration).
- The source term is two parts AWF tank liquids and one part AWF tank solids (Section 3.4.1 for the radionuclide composition of these sources) corresponding to the worst case slurry line source term discussed in Section 3.4.1.

Accident Frequency Without Controls. The frequency category for a subsurface leak accident without controls is "anticipated." Pipeline failures occurred during earlier operations and are documented in the Hanford Site occurrence reporting database.

Accident Scenario With Controls. The accident scenario with controls is the same as that without controls except that the solids loading in the source term is assumed to be 90% solids from Tank 241-C-106 (instead of 100% solids from Tank 241-AY-102). The source term is 2 parts SST liquid, 18 parts AWF tank liquid, 9 parts SST solid, and 1 part AWF tank solid. (See Section 3.4.1 for a discussion of the mitigated [or with controls] source term.)

Accident Frequency With Controls. The frequency of a pipe failure resulting from aging or corrosion is reduced to "unlikely" by taking credit for the encasement as a second and independent barrier to corrosion or aging induced failure. The failure rate for the primary transfer line is estimated to be 3.3×10^{-9} leaks/m/h (1×10^{-9} leaks/ft/h) (WHC-IP-0690, *Safety Analysis and Regulation Manual*). The length of transfer pipe is 0.5 km (0.3 mi). This gives a 1.4×10^{-2}/yr failure rate for the primary pipe. The failure rate for both primary and secondary pipes is assumed to be lowered to place the overall frequency in the "unlikely" category.

3.4.2.13.2 Source Term Analysis. The source term calculations for this event are documented in HNF-SD-WM-CN-104, *Calculation Notes for an Underground Leak which Remains Underground*.

Source Term Without Controls. The total volume of material released in the assumed 12-hour leak is 60,570 L (16,000 gal). The worst case geometry was found to be a saturated length of the berm because of the increased direct dose from waste in the berm compared to an underground "disk" model. The mixture of isotopes present in the release without controls is presented in HNF-SD-WM-CN-104. No airborne radioactive or toxic materials are released because the leak is subsurface.

Source Term With Controls. The total volume of material released and worst case geometry in the scenario with controls is the same as for the scenario without controls. The mixture of isotopes present in the release with controls is discussed in HNF-SD-WM-CN-104 and reflects a smaller percentage of AWF tank solids loading, as discussed in Section 3.4.1.

3.4.2.13.3 Consequence Analysis. This section presents the dose consequences associated with the radiation field created by the subsurface leak. For each assumed geometry, radiation dose rates are calculated for the onsite receptor (a receptor located at 100 m [328 ft] from the leak point). Line-of-sight and bremstrahlung and skyshine dose rate contributions were calculated using the ISO-PC (WHC-SD-WM-UM-030, *ISO-PC Version 1.98 - User's Guide*) and MICROSKYSHINE (Grove 1987, *MICROSKYSHINE*) computer codes, respectively. Details of the calculations are presented in HNF-SD-WM-CN-104. The worst case geometry with controls and without controls was found to be a saturated section of the berm. The receptor dose starts after the full subsurface plume has been created. The dose to the offsite receptor is insignificant because of the large distance between the source and receptor.

Consequence Without Controls. Dose to the onsite receptor is 0.011 Sv (1.1 rem) in the scenario without controls. No significant toxicological consequences or offsite radiological consequences would occur (Table 3.4.2.13-1).

Consequences With Controls. Dose to the onsite receptor in the accident scenario with controls is 0.01 Sv (1.0 rem). No significant toxicological consequences or offsite radiological consequences would occur (Table 3.4.2.13-2).

3.4.2.13.4 Comparison With Guidelines. The dose to the onsite receptor in the scenario without controls, 0.011 Sv (1.1 rem), is above the onsite risk

guideline (0.005 Sv [0.5 rem]) for an "anticipated" event. The dose to the onsite receptor with controls, 0.01 Sv (1.0 rem), is below the onsite risk guideline (0.05 Sv [5 rem]) for an "unlikely" event. No significant toxicological consequences or offsite radiological consequences would occur.

3.4.2.13.5 Summary of Safety Classification and Technical Safety Requirement Controls. Safety classification, TSR controls, and Defense-in-Depth features for the subsurface leak accident are summarized in the following paragraphs.

Safety Structures, Systems, and Components. The secondary piping is credited as a Safety-Significant component that provides a redundant leak barrier that reduces the likelihood of a leak resulting from corrosion or aging. The transfer leak detection systems and tank level detection systems (shown in Table 3.4.2.13-3) have also been designated as Safety-Significant for protection of the facility worker.

Technical Safety Requirement Controls. Technical Safety Requirement controls are in place to prevent or mitigate a subsurface leak. Table 3.4.2.13-4 summarizes these controls. The TSRs include excavation controls, transfer controls, encasement seal loop controls, transfer leak detection systems, and transfer pump administrative lock controls.

Defense-in-Depth. Table 3.4.2.13-5 summarizes the Defense-in-Depth features applicable to the subsurface leak accident. Defense-in-Depth controls include pressure/leak testing, operator training, operating procedures, seismic shutdown switches and emergency response.

Table 3.4.2.13-1. Summary Consequences and Frequencies for a Subsurface Leak Remaining Subsurface Without Controls.

Accident	Consequences								Frequency
	Radiological, Sv (rem)				Toxicological				
	Onsite		Offsite		Onsite		Offsite		
	Calculated dose	Risk guideline	Calculated dose	Risk guideline	Calculated SOF	Risk guideline	Calculated SOF	Risk guideline	
Subsurface Leak Remaining Subsurface	1.1 E-02 (1.1 E+00)	5.0 E-03 (5.0 E-01)	N/A	1.0 E-03 (1.0 E-01)	N/A	1	N/A	1	Anticipated

N/A = not applicable.
SOF = sum-of-fractions.

Table 3.4.2.13-2. Summary Consequences and Frequencies for a Subsurface Leak Remaining Subsurface With Controls.

Accident	Consequences								Frequency
	Radiological, Sv (rem)				Toxicological				
	Onsite		Offsite		Onsite		Offsite		
	Calculated dose	Risk guideline	Calculated dose	Risk guideline	Calculated SOF	Risk guideline	Calculated SOF	Risk guideline

N/A = not applicable.
SOF = sum-of-fractions.

Table 3.4.2.13-3. Safety Structures, Systems, and Components for Subsurface Leaks Remaining Subsurface.

Structure, system, or component	Safety classification		Safety function	Comments
	SC	SS		
Waste transfer pipe-in-pipe encasement	--	X	Ensure that a leak in the primary waste transfer system piping is directed to a waste transfer-associated structure	Mitigates frequency of leaks
Transfer leak detection systems	--	X	Detects leaks in transfer-associated structures and activates an alarm, leading to operator shutdown of the transfer	Prevents/mitigates significant facility worker hazard
Tank level detection systems	--	X	Provide indication of tank waste level to support performance of periodic material balance during waste transfers to detect leaks or misroutes	Prevents/mitigates significant facility worker hazard

SC = Safety-Class.
SS = Safety-Significant.

Table 3.4.2.13-4. Technical Safety Requirement Controls for Potential Subsurface Leaks Remaining Subsurface.

Control	Safety function	Comments
Transfer Leak Detection Systems	Detects leaks in transfer-associated structures and activates an alarm, leading to operator shutdown of the transfer	Ensure leak detector alarms are operable during transfer
Transfer Controls with the following key elements: - Material Balance after each sluicing batch of 12 hours maximum duration during transfer operations, including total material transferred and solids loading calculation - Configuration management: control of jumper and valve configuration - Establish communications between 241-C-106 and 241-AY-102 control room during sluicing operations - Transfer path verification - independent route verification during transfer setup	Prevent/mitigate significant facility worker hazard	--
Encasement Seal Loop Controls with the following key element: - Ensure the encasement seal loop valves are not in the closed position	Ensure that if the primary pipe leaks during waste transfer, the encasement will drain to the waste transfer-associated structure	--
Excavation control	Prevents pipe rupture caused by excavation activities	See Section 3.4.2.17
Transfer Pump Administrative Lock Controls	Eliminate motive force for unplanned transfers	--

Table 3.4.2.13-5. Defense-in-Depth Controls for Subsurface Leaks Remaining Subsurface.

Control	Function	Comments
Pressure/leak testing of transfer route before material transfer	Provides a greater level of assurance of transfer line integrity before actual transfer of waste	Enhanced NDE used for final welds
Operator training	Operations of facilities are performed by Hanford Site experienced crews with specific training in these activities	--
Operating procedures	Operations are performed to approved plant operating procedures	--
Emergency response plan/ procedures	Plans and procedures are in place to respond to emergency conditions	--
Seismic shutdown switches	Shut down transfer pumps upon detection of a seismic event	--

NDE = nondestructive examination.

3.4.2.14 Subsurface Leak Resulting in a Pool. A subsurface leak resulting in a pool accident is analyzed in Section 5.3.2.19 of the BIO main text. This analysis is different than that presented in the main text of the BIO because the flow rate of the WRSS pumps is greater than the flow rate used in the BIO, and the waste composition is different.

The specific hazardous conditions that can result in waste leaks directly to the soil surface are identified in the hazard analysis. A leak from the transfer line could result in washing away of the soil berm and the formation of a pool. The line could be uncovered by localized flooding and subsequently failed by corrosion or stress. In addition, an excavation accident could result in a break of a line and the formation of a pool.

3.4.2.14.1 Scenario Development. A breach of the slurry transfer line was selected as the bounding, representative accident for detailed analysis. Because an unconstrained pipe break permits waste to flow at 41 L/s (650 gpm), the scenario produces the largest surface pool. Local flooding is assumed to uncover the line during transfer operations, the line is breached, and the waste spills directly on the ground.

The unmitigated scenario assumes that the leak is detected after 7 hours, any onsite personnel are evacuated immediately, and the leak cannot be stopped until the pumping is terminated after 12 hours. This accident scenario was qualitatively assigned a frequency of "anticipated" (1 to 10^{-2}/year). The frequency was based on the tank farms operational history. The occurrence reporting database has documented previous related pipe failures.

The mitigated accident scenario assumes that the spilled slurry content is different from the unmitigated slurry because it more realistically reflects the average mixed content of Tank 241-AY-102 (Section 3.4.1). The operator more promptly detects the leak, the pump is turned off, and any onsite personnel are immediately evacuated. The frequency of the mitigated accident scenario is taken to be the same as the unmitigated accident scenario.

3.4.2.14.2 Source Term Analysis. The composition, ULD, and sum-of-fractions for the slurry mixtures used in this analysis are detailed in Section 3.4.1. Details of the supporting source term calculations are documented in HNF-SD-WM-CN-110, *Consequences of a Radioactive Surface Pool Resulting From Waste Transfer Operations Between Tanks 241-C-106 and 241-AY-102*.

The waste is assumed to flow onto the ground at the maximum capacity of the pump, 41 L/s (650 gpm). Therefore, in 12 hours, 12 x 60 x 60 x 41 = 1,771,600 L (468,000 gal) are spilled onto the ground. Soil conditions are assumed to be such that the growing pool remains a free-standing liquid for 12 hours. This maximizes the spread of the pool and creates the largest surface area available for aerodynamic resuspension by the wind. A "spreading factor" (i.e., surface area of soil affected divided by the spill volume) equal to 8.7 per linear foot is used in this analysis, consistent with WHC-SD-WM-CN-049, *Calculation Notes for Surface Leak Resulting in Pool, TWRS FSAR Accident Analysis.* A final pool size of 127 m (417 ft) radius and area of 5.06 x 10^4 m^2 (5.45 x 10^5 ft^2) is calculated to form.

A resuspension flux (from DOE-HDBK-3010-94, equal to 2×10^{-10} kg/m^2) is used to estimate the rate that aerosols are generated by the wind. The waste density is 1.4 kg/L, so 1.4×10^{-10} L/m^2-s is generated by the wind while the pool is liquid. The unmitigated aerosol amount released during these 12 hours is 0.156 L. The peak release rate, 7.2×10^{-6} (L/s), occurs at the end of pool formation.

After the transfer pump is shut off, the waste will soak into the soil, leaving entrained salts and entrained solids behind as surface contamination. The contaminated soil is assumed to be immediately available as dry soil for resuspension by the wind. The respirable release fraction, 8.4×10^{-5}, is taken from Section 3.2.4.4 in DOE-HDBK-3010-94. This release takes place in the 12- to 24-hour period. The unmitigated amount of contaminated soil that is resuspended during these 12 hours is 148.7 L (39 gal). The peak release rate, 2×10^{-3} (L/s), occurs at the onset of soil resuspension. Note that the offsite consequences will be dominated by the material resuspended from the contaminated soil phase.

As a limiting case to determine the maximum available operator response time, without consequences exceeding risk guidelines, a detection time of 43 minutes was used to calculate mitigated consequences. This corresponds to 106,000 L (28,000 gal) of material released. Actual operator response time is expected to be significantly less than 43 minutes. In this case, the pool only grows to a radius of 31 m (102 ft) and reaches a final surface area of 3.03×10^3 m^2. The amount of material released during pool formation is limited to 3.4×10^{-2} L at a peak rate of 4.3×10^{-7} (L/s). The amount of material released as contaminated soil is less than 0.9 L (0.2 gal), at a peak rate of 1.2×10^{-5} (L/s).

3.4.2.14.3 Consequence Analysis. Table 3.4.2.14-1 summarizes the consequences of spills without control and Table 3.4.2.14-2 summarizes the consequences of spills with controls. The unmitigated scenario at a worst case composition has a ULD equal to 5.6×10^5 Sv/L, a sum-of-fractions multiplier (onsite) equal to 1.3×10^4 s/L, and a sum-of-fractions multiplier (offsite) equal to 68 s/L. The mitigated scenario uses a reasonable mixture of the liquid and solid source terms in Tank 241-C-106 and Tank 241-AY-102 and has a smaller ULD equal to 1.2×10^5 Sv/L, a sum-of-fractions multiplier (onsite) equal to 1.9×10^4 s/L, and a sum-of-fractions (offsite) multiplier equal to 40 s/L.

The radiological dose consequences without controls are 3.0 Sv (3.0×10^2 rem) for the onsite receptor, which includes shine from the growing pool, and 8.0×10^{-1} Sv (8.0×10^1 rem) for the offsite receptor. The toxicological sum-of-fractions are 0.09 and 0.13 for the onsite and offsite receptors, respectively.

The radiological dose consequences with controls are 1.3×10^{-2} Sv (1.3 rem) for the onsite receptor, which includes shine from the growing pool, and 1.0×10^{-3} Sv (1.0×10^{-1} rem) for the offsite receptor. The toxicological sum-of-fractions are 8.3×10^{-3} and 5.0×10^{-4} for the onsite and offsite receptors, respectively.

3.4.2.14.4 Comparison to Guidelines. Table 3.4.2.14-1 provides the radiological and toxicological consequences of the accident scenario without controls. The radiological onsite and offsite consequences without controls are well above the risk guidelines. The toxicological sum-of-fractions for the risk guidelines is less than 1 (within risk guidelines) for both the onsite and offsite receptors.

Table 3.4.2.14-2 shows the results of the accident scenario with controls. The radiological onsite dose consequence is above the risk guideline; however, the offsite dose consequence meets the risk guideline. The toxicological sum-of-fractions for the risk guidelines is less than 1 (within risk guidelines) for both the onsite and offsite receptors.

3.4.2.14.5 Summary of Safety Structures, Systems, and Components and Technical Safety Requirement Controls. Tables 3.4.2.14-3 and 3.4.2.14-4 summarize the safety structures, systems, and components and TSR controls selected to prevent and mitigate subsurface leaks from the transfer lines used in the operations involving Tank 241-C-106 and Tank 241-AY-102. For each control, the safety function required is described. Clarifying comments are provided as necessary.

Safety Structures, Systems, and Components. For pipe-in-pipe encased transfer lines, the encasements were designated Safety-Class. The safety function of the encasements is to contain and route waste leaked from the primary line back to transfer structures (e.g., process pits). The transfer line leak detection system has been designated as Safety-Class to prevent pit overflows during transfers. The system prevents pit overflows by alarming and alerting operators to shut down the transfer pump.

Tank level detection systems were designated as Safety-Significant to support the performance of periodic material balances during transfers. Material balances are important to back up leak detectors and limit the amount of waste that can be released to the environment.

Technical Safety Requirement Controls. A transfer leak detection system control is required to stop the transfer if a leak is found, and to prevent transfer-associated structures from overflowing.

A waste transfer control program was developed to limit the potential consequences of leaks from subsurface transfer lines. Material balances are required as part of the transfer control program to limit the volume of waste potentially leaked to the soil column (without surfacing) as a backup detection for leaks into encased lines that drain back to transfer structures containing Safety-Class pit leak detectors. Material balances are required to be performed after each sluicing batch of 12 hours maximum duration during the transfer. The material balances are especially important; over an extended period, the skyshine from pools smaller than those analyzed in the representative accident can give integrated doses approaching the evaluation guideline for the onsite receptor. Other key elements of the waste transfer control program include configuration management and independent route verification during transfer. These key elements are required to prevent misroutes into potentially compromised transfer lines.

Establishing communication between the Tank 241-C-106 and Tank 241-AY-102 control rooms during transfers is another key element of the transfer control. Detection of a leak allows for the transfer to be stopped to minimize the amount of leakage. Table 3.4.2.14-4 describes the TSR controls for subsurface leaks resulting in pools.

A TSR control also is necessary to ensure that the appropriate emergency response procedures are implemented when a surface waste pool is detected. Emergency response plans for a waste leak shall include response procedures with a graded approach based on the magnitude of the leak to protect the offsite public, onsite worker, and facility worker (e.g., transfer termination, leakage containment and removal, and site evacuation).

Defense-in-Depth. Table 3.4.2.14-5 summarizes hardware and existing tank farm procedures that provide Defense-in-Depth protection against leaks from buried or bermed transfer lines. These include a walkdown of the transfer lines, encasement leak detectors, seismic shutdown switches, and flow rate monitoring.

Table 3.4.2.14-1. Summary of Consequences and Frequencies for Subsurface Leak Resulting in a Pool without Controls.

Accident	Consequences								Frequency
	Radiological, Sv (rem)				Toxicological

Control	Safety function	Comments
Walkdowns are performed once/shift to detect surface leaks from transfer line	Provides backup to material balance for leaks that might surface	--
WRSS pipe-encased transfer lines are equipped with encasement leak detectors	Detect leak during transfer, provide backup to pit leak detection	Can also be used as Safety-Class substitute for pit leak detection
Monitor flow rate	Provides evidence of a leak. If flow data indicates leakage, stop the transfer and determine the cause	Necessary for material balance
Seismic shutdown switches	Shut down transfer pumps upon detection of a seismic event	

WRSS = Waste retrieval sluicing system.

3.4.2.15 Surface Leak Resulting in a Pool. A subsurface leak resulting in a pool is analyzed in Section 5.3.2.18 of the BIO main text. This analysis is different than that analyzed in the BIO main text because the pump flow rate of the WRSS pumps is higher than that used in the BIO, and the waste composition is different. The consequences of this accident are bounded by the subsurface leak resulting in a pool analyzed in Section 3.4.2.14 of this addendum.

3.4.2.15.1 Scenario Development. The breach of the slurry transfer line was selected as the bounding representative accident for detailed analysis of surface pools. Because an unconstrained pipe break permits waste to flow at 41 L/s (650 gpm), the subsurface-originating leak produces the largest surface pool in 12 hours (Section 3.4.2.14).

Surface-originating leaks, such as an overflow of the pit with its cover block on, would constrain the waste flow to less than 28.4 L/s (450 gpm) and a smaller surface pool would form within the 12 hours.

The frequency category of the accident without controls is determined on the basis of the likelihood of the initiating event. Tank farm operating experience indicates that waste leaks into process pits are "anticipated" events. Between 1972 and 1996, the occurrence reporting database includes five accounts of waste being misrouted through compromised transfer paths into process pits. The frequency of the accident with controls is the same as the accident without controls.

3.4.2.15.2 Source Term Analysis. See Section 3.4.2.14.2.

3.4.2.15.3 Consequence Analysis. Surface leak consequences are bounded by the consequences postulated for subsurface leaks (Section 3.4.2.14.3).

3.4.2.15.4 Comparison to Guidelines. See Table 3.4.2.14-1 in Section 3.4.2.14.

3.4.2.15.5 Summary of Safety Structures, Systems, and Components and Technical Safety Requirement Controls. Tables 3.4.2.15-1 and 3.4.2.15-2 summarize the safety structures, systems, and components and TSR controls selected to prevent or mitigate surface pool leaks throughout the TWRS. For each safety structure, system, and component and TSR control, the safety function required is described in Chapter 4.0 of this addendum.

Technical Safety Requirement Controls. Technical safety requirement controls are listed in Table 3.4.2.15-2 and detail relating to their safety function are listed in HNF-SD-WM-TSR-006, *Tank Waste Remediation System Technical Safety Requirements*, and Section 5 of this addendum. A key element for communications between the control locations for Tank 241-AY-102 and Tank 241-C-106 was added to AC 5.12, Transfer Controls, to mitigate this accident.

Defense-in-Depth Controls. Table 3.4.2.15-3 identifies the Defense-in-Depth controls.

Table 3.4.2.15-1. Safety Structures, Systems, and Components for Surface Leak Resulting in Pool.

Control	Safety classification		Safety function	Comments
	SC	SS		
Transfer leak detection system	X	--	Detects leaks in transfer-associated structures and activates an alarm, leading to operator shutdown of the transfer	Ensure leak detector alarms are operable during transfers
Transfer System Covers	--	X	Limit release of aerosols generated by splatter inside the pit*; limit shine and skyshine dose to onsite receptor	Pit structure and covers provide confinement safety function. Pit structure also required to support the pit covers
Tank level detection systems	--	X	Supports periodic material balances during transfers	See material balance TSR AC (next table)
Primary tank leak detection system	X		Provides indication of infiltration into the annulus of Tank 241-AY-102	--
Transfer line pipe in pipe encasement	X	--	Provide secondary confinement for leaks from primary line; route leak from primary line back to process pit*	--
Back flow preventers	--	X	Prevent back flow of waste	Safety significant to prevent general contamination of service water supply systems, e.g., the tanker truck

* Includes valve pits, central and feed pump pits, sluice pits, leak detection pits, annulus pump pits, flush pits, catch tank pump pits, diversion boxes, vault pits, vent station nozzle pit.

AC = Administrative Control.
SC = Safety-Class.
SS = Safety-Significant.
SST = single-shell tank.
TSR = Technical Safety Requirement.

Table 3.4.2.15-2. Technical Safety Requirement Controls for Surface Leak Resulting in Pool.

Control	Safety function	Comments
Transfer system covers	Limit release of aerosols generated by splatter inside the pit; limit shine and skyshine dose to onsite receptor	Ensures pits physically connected to transfer route are covered during transfers
Transfer Leak Detection Systems	Detects leaks in transfer-associated structures and activates an alarm, leading to operator shutdown of the transfer	Ensure leak detector alarms are operable during transfers
Primary Tank Leak Detection System	Ensures primary tank leak detection systems on tanks physically connected to the transfer route are operable to detect misroutes into the annulus of Tank 241-AY-102	--
Transfer Controls with the following key elements: - Material balance after each sluicing batch of 12 hours maximum duration during transfer operations, including total material transferred and solids loading calculation - Configuration management: control of jumper and valve configuration - Establish communications between 241-C-106 and 241-AY-102 control room during sluicing operations - Cap/blank nozzles when not in use - Vehicle restrictions around transfer lines	Provides confirmation of analysis assumptions Prevents misroutes of waste and prevents jumpers from being grossly misaligned or from falling off during transfers Detects a waste transfer line leak; limits volume of waste leaked Prevents leak through open nozzles Ensures that the transfer line is protected from vehicle collisions that could result in a loss of integrity of the primary and encasement pipes	High flow rate leaks into pits can overflow the pits before transfer pumps can be manually shut down after leak detector alarm activates (if pit drain plugged)
Emergency Preparedness with the following key element: - Response procedures	Provides response procedures to mitigate structure overflow.	--
Excavation Control Program	Prevents pipe rupture caused by excavation activities.	See Section 3.4.2.17
Transfer Pump Administrative Lock Controls with the following key element: - The administrative lock of a waste transfer pump is demonstrated by removing and securing the motive force from the pump (e.g., electrical power, steam, water, or air)	Eliminate motive force for unplanned transfers	--
Transfer System Cover Removal Controls	Ensure structures physically connected to the transfer route are covered during transfers and provide compensatory measures for cover removal during transfers	--

Table 3.4.2.15-3. Defense-in-Depth Controls for Surface Leak Resulting in Pool.

Control	Safety function	Comments
Tank farms are visually surveyed by operators at least once a day	Surveys are performed to check for general problems (e.g., animal or water intrusion, etc.)	Surveys will detect surface pools of waste due to all causes. Surveys provide backup detection to leak detectors and material balances of water
Pit drains, where open	Allow leak to drain back to storage or catch tank; prevents overflow of pit to soil surface	High capacity pit drains are designed to accommodate maximum flow from the line
Encasement leak detectors	Detect leaks from primary line; limit leak volume	Redundant to interfacing pit leak detectors
Backflow preventers	Prevent backflow	--
Material balance after each sluicing batch of 12 hours maximum duration during transfer operations, including total material transferred and solids loading calculation	Limit duration of pool release	Material balances are typically performed by comparing level changes in the source and receipt tanks. The material balances will eventually discover the discrepancy caused by the pool leak
Seismic Shutdown switches	Shut down transfer pumps upon detection of a seismic event	--

3.4.2.16 Spray Leak from Structure. Only one spray leak accident related to WRSS operations has not been previously considered in the safety documentation for the main text of the BIO that is needed for WRSS analysis. This is an accident associated with the sluice line and slurry line flush connections located in pits over Tank 241-AY-102 (the highest elevation in the system). These connections are 5.1 cm (2 in.) diameter (nominal) pipes directed vertically upward under removable plugs in the pit cover blocks. The flush connections are normally closed by blanked jumper-type connectors. The flush line spray leak without controls assumes that the blank connector and the removable plug in the pit cover block have been removed so that the maximum system flow is directed vertically out the open 5.1 cm (2 in.) line into the air above the pit. The spray scenario with controls assumes that the removable plug is in place and the flow is directed against the underside of the pit cover block. Analysis has shown that maximum flow from the connection is not sufficient to lift the 159 kg (350 lb) removable plug.

3.4.2.16.1 Scenario Development. Two bounding accident scenarios have been chosen to represent the range of flush connector spray leaks that could occur in the sluice and pump pits over Tank 241-AY-102 during WRSS operations. These scenarios were analyzed for both the sluice line (high flow rate, low solids content) and the slurry return line (lower flow, high solids content) to determine worst case radiological and toxicological consequences. Details of the scenario development and analysis can be found in HNF-SD-WM-CN-102, *Radiological and Toxicological Consequences of a Worst-Case Spray Leak Related To Project W-320*.

Accident Scenario Without Controls. For the accident scenario without controls, the pit cover plug over the flush connection was assumed to be removed and the stream was assumed to be directed vertically upward. A slurry line release from pump pit 241-AY-02A and a sluice line release from sluice pit 241-AY-02E were evaluated to determine the worst case. Both flush connections are nominal 5.1 cm (2 in.) Schedule 40 pipe with an inside diameter of 5.25 cm (2.067 in.). In the case of the sluice line, the pump was assumed to be very close to the open flush connection and to be running at maximum speed (3056 rpm) with no discharge head. The maximum flow rate under these conditions is 41.0 L/s (650 gpm) with a discharge velocity of 19.9 m/s (65.3 ft/s) at the flush connection.

For the slurry line returning from Tank 241-C-106, the flush connection was assumed to be elevated 10.7 m (35.10 ft) higher than the slurry pump and the material was assumed to traverse about 600 m (656 yd) of pipe run. The flush connection actually is very close to but at a higher elevation than the slurry distribution nozzles in Tank 241-AY-102. The flow from the flush connection is therefore expected to be about the same as the normal 22.1 L/s (350 gpm) flow rate for the slurry line. For this analysis, however, the flow was conservatively assumed to be 28.4 L/s (450 gpm), or about 6.3 L/s (100 gpm) above the expected flow rate. The corresponding flow velocity from the flush connection was estimated to be 13.8 m/s (45.3 ft/s). Consistent with previous spray release analyses in the main text, the flush connection release was assumed to continue unabated for 24 hours.

Accident Frequency Without Controls. The accident frequency without controls is assigned based on the frequency of the initiating event. In this case, the initiating event is the failure or absence of the blank connector that closes off the flush connection. This causes a pressurized spray release during a transfer. The initiating event frequency is considered to be "anticipated" (1 event/year - 1.0×10^{-2} events/year) consistent with Section 5.3.2.20 of the main text of the BIO.

Accident Scenario With Controls. The conditions for the release scenario with controls are the same as assumed for the scenario without controls except that the removable plug in the pit cover block over the flush connection was assumed to be in place. A slurry line release in pump pit 241-AY-02A and a sluice line release in sluice pit 241-AY-02E were evaluated to determine the worst case. Consistent with WHC-SD-WM-CN-048, *Calculation Notes in Support of TWRS FSAR Spray Leak Accident Analysis*, the impact of the stream on the underside of the pit cover was assumed to saturate the air in the pit to the maximum sustainable air loading of 100 mg/m^3 (ANSI N46.1). The direct aerosol release was then assumed to be carried with the air displaced from the pit while the pit fills with slurry.

After the pit fills, the spray release ends and the slurry spreads over the ground above the pit as a pool. Pool releases are covered in Sections 3.4.2.14 and 3.4.2.15 and are outside the scope of this scenario. Pits 241-AY-02A and 241-AY-02E are equipped with 152mm (6in.) high-capacity drains emptying directly into Tank 241-AY-102. These drains are designed to handle the maximum flow from an open transfer line. In addition, both pits are equipped with leak detectors that alarm before the liquid reaches the levels of the high-capacity drains. For purposes of this bounding analysis, the high-capacity drains were assumed to be blocked and no credit was taken for the leak detectors. Because a negative pressure is maintained in the pits via the drains to Tank 241-AY-102, the consequences with the drains open would be far less severe.

Accident Frequency With Controls. The accident with controls frequency category is "anticipated." No safety structures, systems, and components or TSR controls are credited with reducing the likelihood of the initiating event.

3.4.2.16.2 Source Term Analysis. The method and detailed calculations used to determine the airborne aerosol release volumes in the accident analyses without and with controls are documented in HNF-SD-WM-CN-102. The following sections summarize the source term analyses.

Source Term Without Controls. Based on the total solids and liquids in both tanks, the solid and liquid components of the slurry circulating in both directions between Tank 241-C-106 and Tank 241-AY-102 in the sluice line and slurry line were determined to have the following best estimate compositions:

- **Liquids**—10% SST liquids and 90% AWF tank liquids
- **Solids**—90% SST solids and 10% AWF tank solids.

The sluice supernate being pumped from Tank 241-AY-102 to Tank 241-C-106 was assumed to contain 10% solids and 90% liquids, while the slurry being pumped back from Tank 241-C-106 was assumed to contain 33% solids and 67% liquids.

Two sources of aerosolization were evaluated: direct production by edge shear during slurry flow out of the nozzle and instability/shear stress at the surface of the liquid during the fall from its maximum height and impact on the ground (assumed to be a hard surface). The passage of the falling material through the air creates airflow patterns and turbulence that aid in suspension of the slurry. The sluice supernate and slurry return flows were investigated to determine the worst case.

The direct spray releases from the nozzle and from the pool formed on the ground were found to be negligible compared to the respirable releases produced by the fall and impact of the stream after reaching maximum height above the pit cover. The respirable aerosol release produced by the fall and impact of the liquid stream was calculated using the method recommended in DOE-HDBK-3010-94. Neglecting effects of air resistance, a vertical stream with an initial velocity of 19.9 m/s (65.3 ft/s) can reach a height of 20.2 m (66.3 ft). The airborne release fraction of slurry falling and impacting on a hard surface from a height of 20.2 m (66.3 ft) was determined to be 1.18×10^{-3}. As recommended in DOE-HDBK-3010-94 for this type of release, the respirable fraction was assumed to be one. The resulting respirable release rate is 4.84×10^{-2} L/s (0.77 gpm). The corresponding 12- and 24-hour respirable releases are 2.09×10^{3} L (552 gal) and 4.18×10^{3} L (1,100 gal).

Source Term With Controls. In the accident with controls, the pit cover provides an impaction surface that prevents aerosols from jetting directly into the atmosphere. The covers also create a relatively stagnant air volume that fosters agglomeration and rainout of aerosols within the pit. Aerosol removal also occurs as the result of condensation on the pit walls and the underside of the cover blocks. Aerosol is further removed from any air expelled from the pit through the cover block gaps because the leakage paths are tortuous and provide additional surfaces for impingement and condensation.

It was assumed (consistent with WHC-SD-WM-CN-048) that the impact of the stream on the underside of the pit cover saturates the air in the pit to the maximum sustainable air loading of 100 mg/m^3 (ANSI N46.1). The direct aerosol release is then carried with the air displaced from the pit as the pit fills with slurry. No credit was taken in this bounding analysis for the leak detectors or the 1.5 cm (6 in.) diameter high-capacity drains in the pits. Note that once the pit fills and overflows, the slurry will form a pool on the ground above. The releases from such a pool are addressed in Sections 3.4.2.14 and 3.4.2.15.

The sluice line flush connection is in pit 241-AY-02E with inside dimensions of 2.4 m x 1.8 m x 2.1 m (8 ft x 6 ft x 7 ft) giving an interior volume of 9.5 m^3 (336 ft^3). The total volume displaced while the pit is filling with slurry is this volume plus an additional 35% from heating of the air in the pit and addition of water vapor up to 100% relative humidity (WHC-SD-WM-CN-048). The total air volume displaced from the pit through crevices and small openings is then 12.8 m^3 (452 ft^3), implying a slurry aerosol release of 1.28 g (2.82×10^{-3} lbm). Using the sluice supernate

density (1.27 g/cm^3 [75.5 lbm/ft^3]) the equivalent slurry volume was calculated to be 1.01 x 10^{-3} L (2.67 x 10^{-4} gal). At a slurry addition rate of 41.0 L/s (65.2 gpm) or 4.10 x 10^{-2} m^3/s (1.45 ft^3/s), the pit will fill in 232 seconds or 3.86 minutes. No credit was taken for pit volume occupied by piping and machinery. The slurry aerosol release rate resulting from volume displacement is then 4.35 x 10^{-6} L/s (6.92 x 10^{-5} gpm).

The slurry line flush connection is in pit 241-AY-02A, which has inside dimensions of 3.7 m x 2.4 m x 1.5 m (12 ft x 8 ft x 5 ft) giving an interior volume of 13.6 m^3 (480 ft^3). The total volume displaced while the pit is filling with slurry is this volume plus an additional 35% from heating of the air in the pit and addition of water vapor up to 100% relative humidity (WHC-SD-WM-CN-048). The total air volume displaced out of the pit through crevices and small openings is 18.4 m^3 (650 ft^3), implying a slurry aerosol release of 1.84 g (4.06 x 10^{-3} lbm). Using the return slurry density (1.41 g/cm^3 [88.0 lbm/ft^3]), the equivalent slurry volume was calculated to be 1.30 x 10^{-3} L (3.43 x 10^{-4} gal). At a slurry addition rate of 28.4 L/s (452 gpm) or 2.84 x 10^{-2} m^3/s (1.00 ft^3/s), the pit will fill in 479 seconds or 7.98 minutes. No credit was taken for pit volume occupied by piping and machinery. The slurry aerosol release rate resulting from volume displacement is then 2.71 x 10^{-6} L/s.

3.4.2.16.3 Consequence Analysis. The onsite and offsite inhalation dose consequences and toxicological exposures were determined using the method discussed in Section 3.4.1. (See HNF-SD-WM-CN-102 for the detailed dose calculations.) The radiological and toxicological consequences for the accident scenarios without and with controls are summarized in Tables 3.4.2.16-1 and 3.4.2.16-2, respectively.

For the flush connection spray leak without controls, the sluice line release was found to be more limiting with the dose to the onsite receptor determined to be 150 Sv (15,000 rem) (50-year committed effective dose equivalent). The dose to the offsite receptor was found to be 0.21 Sv (21 rem). The toxicological sum-of-fractions for the onsite and offsite receptors were found to be 620 and 0.87, respectively.

For the flush connection spray leak with controls, the slurry return line release was found to be more limiting with the dose to the onsite receptor determined to be 1.8 x 10^{-3} Sv (0.18 rem). The dose to the offsite receptor was found to be 1.6 x 10^{-6} Sv (1.6 x 10^{-4} rem). The toxicological sum-of-fractions for the onsite and offsite receptors were found to be 5.8 x 10^{-2} and 1.1 x 10^{-4}, respectively.

Key Parameters and Assumptions—Accident Analysis Without Controls. The consequences for the accident scenario assuming no controls were calculated conservatively. The sensitivity of the analysis results to key parameters and assumptions used in the analyses are addressed in this section.

1. **Waste Flow Rate**—Maximum flow rate from the sluice line with the flush connection open was assumed to be 41.0 L/s (650 gpm) (maximum pump flow with no discharge head). Maximum flow rate from the slurry line with the flush connection open was assumed to be 28.4 L/s (450 gpm) (normal flow rate plus 6.29 L/s [100 gpm]). This

flow rate is considered to be very conservative for the slurry line because of the elevation of the flush connection above the slurry pump and the much longer run of pipe involved. The flow rate from the flush connection determines the upward flow velocity, hence the height to which the stream of liquid will rise before falling back to earth. The dominant release mechanism here is the aerosolization of the slurry by instability/shear stress at the surface of the liquid during the fall from maximum height and the effects of ground impact (assumed to be on a hard surface).

2. **Slurry Mixes and Unit Liter Doses**—Based on the amounts of the various waste components in Tank 241-C-106 and Tank 241-AY-102, the radiological ULDs and toxicological unit sum-of-fractions were based on a best estimate composition for the liquid and solid components of the sludge being circulated between the two tanks. In the sluice stream or the slurry stream, the liquid component was assumed to be 10% SST liquid and 90% AWF tank liquid while the solid component was assumed to be 90% SST solids and 10% AWF tank solids. The sluice stream from Tank 241-AY-102 to Tank 241-C-106 was assumed to be 10% solids and 90% liquids, while the slurry stream from Tank 241-C-106 to Tank 241-AY-102 was assumed to be 33% solids and 67% liquids. These are both maximum expected values for the amount of solids. Based on the sluice line composition (limiting from a release consequence point of view), using the ULD for pure AWF tank components increases the consequences by about a factor of 4. This would not be realistic, however, because uniformly mixing the contents of Tank 241-AY-102 would produce a slurry with only about 4% AWF tank solids.

3. **Release Mechanisms**—The dominant release mechanisms for the scenario without controls are the processes associated with the fall and impact of the slurry from the maximum height reached by the liquid stream issuing from the flush connection. These processes were modelled as recommended in DOE-HDBK-3010-94. Also as recommended, the respirable fraction for the aerosol release was assumed to be one. Releases from direct aerosolization at the exit nozzle were found to be negligible.

4. **Accident Duration**—The spray leak accident without controls is assumed to continue undetected for 24 hours. The total respirable aerosol release is directly proportional to the assumed accident duration. However, changing wind direction, wind speed, and atmospheric stability results in a logarithmically decreasing χ/Q' as a function of time. The decreasing χ/Q' value somewhat offsets the increase in release quantity over increasing accident durations. Therefore, the 24-hour dose to the offsite receptor was found to be only a factor of 2.6 times larger than for a 2-hour release at the same leak rate. The onsite receptor is assumed in the accident analysis to be exposed during the first 12 hours of the accident. The 12-hour onsite dose was found to be only 66% larger than the dose for a 2-hour exposure.

Key Parameters and Assumptions—Accident Analysis With Controls. The analysis with controls has the same sensitivities to accident duration and assumed solids content as the analysis without controls. Key parameters to which the analysis with controls is sensitive are discussed as follows.

- **Aerosol concentration of air expelled from the pit**—In the accident analysis with controls, the air displaced from the pit is assumed to be limited in aerosol concentration to a value of 100 mg/m^3 (6.24×10^{-6} lbm/ft^3), comparable to fog. The fog value provides an upper bound for the analysis. The dose is proportional to the assumed aerosol concentration.

- **Temperature and humidity change**—The analysis assuming controls estimates an initial volumetric expansion of the pit air based on a temperature and humidity change from -1 °C (30 °F), 15% relative humidity to 49 °C (120 °F), 100% relative humidity. From psychrometric charts, the volume expansion results in a pit air exchange equal to 35% of the pit volume. This volume expansion is conservative because the initial temperature of the pit at the start of the spray leak would normally be much higher than -1 °C (30 °F) and the final pit air temperature was set equal to the maximum expected waste temperature (i.e., no heat transfer into the walls of the pit was assumed).

- **Leak flow rate**—For this type of release, the covered pit would fill very quickly, limiting the total spray release to the waste entrained in the air displaced from the pit. The direct radiological consequences of the spray release are therefore independent of the leak flow rate. The maximum release rate, and therefore the toxicological consequences are proportional to the leak flow rate. In the scenario with controls, the slurry stream would normally be expected to return to Tank 241-AY-102 via the high capacity 15.2 cm (6 in.) drain in the pit producing very little release. For this analysis, however, the pit drain was assumed to become plugged. Once the pit fills and runs over, the accident becomes a surface pool release (analyzed in Section 3.4.2.17).

3.4.2.16.4 Comparison with Guidelines. The accident doses and toxicological exposures without and with controls are compared with the offsite and onsite risk guidelines in Tables 3.4.2.16-1 and 3.4.2.16-2. The accident radiological doses without controls are above both the offsite and onsite evaluation guidelines. Both offsite and onsite doses from the spray leak assuming controls are shown to be well below the risk guidelines.

The toxicological sum-of-fractions is well over one for the accident without controls at the onsite receptor location. The toxicological consequences therefore exceed the onsite risk guidelines. The offsite toxicological consequences for the accident without controls are below risk evaluation guidelines. The toxicological sum-of-fractions for the accident with controls is well below one, hence well below the risk guidelines, for both the onsite and offsite receptors.

3.4.2.16.5 Summary of Safety Structures, Systems, and Components and Technical Safety Requirement Controls. No changes in Safety structures, systems, and components and no new TSR controls are required for this accident (Tables 3.4.2.16-3 through 3.4.2.16-5).

Safety Structures, Systems, and Components. Table 3.4.2.16-3 summarizes the safety structures, systems, and components selected to prevent or mitigate the spray leak from a structure. These include the transfer system covers, backflow preventers, the pipe-in-pipe encasements, and the stack CAM and interlock.

Technical Safety Requirement Controls. The TSRs selected to prevent or mitigate the spray leak from a structure include the transfer system cover controls; the ventilation stack CAM interlock system on 241-A-702, 241-AZ-702, 296-P-16, and 296-C-006 Ventilation Systems; transfer controls; the encasement seal loop controls; the transfer pump administrative lock controls; and the transfer system cover removal controls.

Defense-in-Depth. The Defense-in-Depth controls to prevent or mitigate the spray leak from a structure encompass service testing of repositioned jumpers, process pit and vault pit leak detectors, material balance, encasement leak detectors, isolation valves, seismic shutdown switches, and backflow preventers.

Table 3.4.2.16-1. Summary of Consequences and Frequencies Without Controls.

Accident	Consequences								Frequency
	Radiological, Sv (rem)				Toxicological				
	Onsite		Offsite		Onsite		Offsite		
	Calculated dose	Risk guideline	Calculated dose	Risk guideline	Calculated SOF	Risk guideline	Calculated SOF	Risk guideline	
Spray leak from flush connection	1.5 E+02 (1.5 E+04)	5.0 E-03 (5.0 E-01)	2.1 E-01 (2.1 E+01)	1.0 E-03 (1.0 E-01)	620	1	0.87	1	Anticipated

SOF = sum-of-fractions.

Table 3.4.2.16-2. Summary of Consequences and Frequencies With Controls.

Accident	Consequences								Frequency
	Radiological, Sv (rem)				Toxicological				
	Onsite		Offsite		Onsite		Offsite		
	Calculated dose	Risk guideline	Calculated dose	Risk guideline	Calculated SOF	Risk guideline	Calculated SOF	Risk guideline	
Spray leak from waste transfer system	1.8 E-03 (1.8 E-01)	5.0 E-03 (5.0 E-01)	1.6 E-06 (1.6 E-04)	1.0 E-03 (1.0 E-01)	0.052	1	1.1 E-04	1	Anticipated

SOF = sum-of-fractions.

Table 3.4.2.16-3. Safety Structures, Systems, and Components for Spray Leaks.

Control	Safety classification		Safety function	Comments
	SC	SS		
Transfer system covers	X	--	Knockdown spray, limit release of aerosols to the atmosphere	Waste transfer-associated structure covers are also a mitigative feature for other accidents and provide radiation protection (i.e., shielding) for facility workers
Backflow preventers in service water system connections to the waste transfer system	--	X	Prevent contamination of the service water system, e.g., the tanker truck, via backflow of waste into service water line, e.g., the hose	The hazardous condition of concern is a spray leak, a rupture of the tanker truck, or simply exposure of the workers
Transfer line pipe-in-pipe encasement	X	--	Confine leak from the primary piping and ensure that a leak is directed to the encasement leak detection system	The pipe-in-pipe encasement shall be designed to withstand the design basis earthquake and high wind
Stack CAM and interlock to exhaust fan (241-A-702, 241-AZ-702, 296-P-16, and 296-C-006 Ventilation Systems)	X	--	Ensure exhaust fan is shut down should exhaust HEPA filters break through (Prevent unfiltered release from occurring for more than 10 minutes)	Aerosol-laden air could eventually saturate the HEPA filters, resulting in their failure

CAM = continuous air monitor.
HEPA = high-efficiency particulate air (filter).

Table 3.4.2.16-4. Technical Safety Requirement Controls for Spray Leaks.

Control	Safety function	Comments
Transfer system covers	Operable covers mitigate spray leak by knocking down/confining the spray. This control ensures covers are operable when the waste transfer-associated structure is physically connected to the waste transfer piping during waste transfer	An exception is allowed if the waste transfer-associated structure is separated by two locked valves and continuous monitoring for spray leaks is provided
Ventilation stack CAM interlock system	Ensures interlock is operable during transfers out of the facility and during tank farm transfers through routes physically connected to the unloading facility	--
Transfer Controls with the following key elements: - Configuration management shall be applied to waste transfer routes - The waste transfer route configuration shall be independently verified prior to transfers - Use of vehicle restrictions around transfer lines	 Configuration management and independent verification of waste transfer routes serves to prevent mistransfers Ensure that the transfer line is protected from vehicle collisions that could result in a loss of integrity of the primary and encasement pipes	--
Encasement Seal Loop Controls with the following key element: - Encasement valve on encasement drain line will not be closed	Ensure that if the primary pipe leaks during waste transfer, the encasement will drain to the waste transfer-associated structure	Control prevents pressurizing encasement risers which could result in abovegrade spray release
Transfer Pump Administrative Lock Controls	Eliminate motive force for unplanned transfers	To address spray leaks that may occur during inadvertent waste transfer pump starts, either the waste transfer-associated covers will be operable or the waste transfer pump(s) physically connected to waste transfer-associated structures will be locked out
Transfer System Cover Removal Controls	Provide compensatory measures for cover removal during transfers	--

Table 3.4.2.16-5. Defense-in-Depth Controls for Transfer System Spray Leaks.*

Control	Safety function	Comments
Repositioned jumpers are in service tested during initial sluicing. Cameras lowered through penetrations in the cover block are used to verify initial jumper integrity during the leak test	Reduce the likelihood of a spray leak from a failed or misaligned jumper	--
Process pit and vault pit leak detectors	Limit duration of spray release. The liquid fraction of the release will drain past the leak detector	Leaks that produce low flow rates of liquid may not be detected
Material balance after each sluicing batch of 12 hours maximum duration during transfer operations, including total material transferred and solids loading calculation	Limit duration of spray release	Material balances are typically performed by comparing level changes in the source and receipt tanks and adjusting for line holdup. The material balances will eventually discover the discrepancy caused by the spray leak
Encasement leak detectors	Ensure transfer pump is shutdown upon detection of leak from primary transfer pipe. Prevents pressurization and potential spray leak from test riser	--
Isolation valves; manual valve is closed to isolate the flush system when not in use	Prevent backflow of waste into the raw water supply	Isolation valves are not effective at preventing backflows during flushing operations as the valves will be open
Backflow preventers	Prevent backflow of waste into the raw water supply	--
Seismic shutdown switches	Shut down transfer pumps upon detection of a seismic event	

*Some of the controls in this list may be determined to be Safety-Class or Safety-Significant for other accidents.
CAM = continuous air monitor.

3.4.2.17 Spray Leak from an Underground Waste Transfer Line. This analysis addresses the potential of WRSS operations to break an underground transfer line before or during sluicing operations. This accident is different than that analyzed in Section 5.3.2.21 of the main text of the BIO because the pump flow rate of the WRSS pumps is higher than that used in the BIO and the waste composition is different. Although the consequences of an underground transfer line failure are developed in other WRSS accident analyses, unique event sequences are identified in this analysis. The need for controls applicable to these unique event sequences is also identified.

3.4.2.17.1 Scenario Development. The accident scenarios for spray leaks from an underground transfer line are described in the main text of the BIO.

Other event initiators identified in the hazard analysis in Section 3.3 include a seismic event and light aircraft crash. The excavation activity is the dominant initiator because the consequence analyses are already bounding and the likelihood of an excavation error is greater than a seismic event or an aircraft crash.

An impact to a transfer line could result in two basic release scenarios: a spray leak and formation of a surface pool. The formation of a surface pool is addressed in Sections 3.4.2.14 and 3.4.2.15, and spray leaks are addressed in Section 3.4.2.16. The source terms and consequences in those sections are bounding for the possible releases postulated in this event. Comparing the consequences of (and recovery from) a surface pool and a spray leak shows that the spray leak is bounding over the surface pool. Therefore, the consequences in this analysis are taken from the consequences of a spray leak from an aboveground structure. The possible formation of a surface pool is not considered further.

The bounding frequency category assigned to this event is "anticipated." This frequency is assigned in the main text of the BIO to excavation impacts to underground waste transfer lines and applies to the transfer lines associated with Tank 241-C-106 sluicing operations.

3.4.2.17.2 Source Term Analysis. The source term for this event is bounded by the source term calculated in the main text and in Section 3.4.2.16.

3.4.2.17.3 Consequence Analysis. The consequences for this event are bounded by the consequences calculated in the main text and in Section 3.4.2.16. The consequences are mitigated or prevented for the scenario with controls.

3.4.2.17.4 Comparison to Guidelines. The consequences calculated in the main text and in Section 3.4.2.16 for a spray leak without controls exceed the onsite and offsite radiological risk guidelines and the onsite toxicological risk guidelines, and require controls. The consequences are mitigated or prevented for the scenario with controls.

3.4.2.17.5 Summary of Safety-Class Structures, Systems, and Components and Technical Safety Requirements.

Safety Structures, Systems, and Components. No safety structures, systems, and components have been identified for this event.

Technical Safety Requirement Controls. Table 3.4.2.17-1 lists the controls relied on to prevent impacts to the underground transfer lines. In addition to the preventive controls, a mitigative control is listed as a key element in Table 3.4.2.17-1. The TSRs selected are excavation controls to prevent damaging the transfer line and transfer controls to protect the transfer line integrity.

Defense-in-Depth. The Defense-in-Depth controls for this event are listed in Table 3.4.2.17-2. The Defense-in-Depth controls are barriers to restrict access to the transfer line, seismic shutdown switches, and transfer controls.

Table 3.4.2.17-1. Technical Safety Requirement Controls for Spray Leak from Underground Waste Transfer Lines.

Control	Safety function	Comments
Excavation Controls with the following key elements: - An excavation permit shall be required when excavating in areas where waste transfer lines exist	Prevents leaks in waste transfer lines caused by excavation activities by ensuring: • Excavation activities are not inadvertently performed near waste transfer lines • Excavation activities are carefully controlled when required near waste transfer lines	--
- Waste transfers are prohibited through lines uncovered by excavation activities unless compensatory controls are established	Prevents transfers through waste transfer lines that are uncovered by excavation activities that could cause worker radiation doses exceeding limits established by the radiation protection program	
- Waste transfers shall not be conducted in transfer lines located within approximately 5 m (15 ft) of ongoing excavation activities	Prevents leaks in waste transfer lines caused by excavation activities by ensuring that excavation activities are not performed near waste transfer lines during waste transfers	
- Prior to initiation of an excavation activity, identify emergency response actions and establish communications between the excavation site and operations personnel to ensure immediate shutdown of waste transfers when leakage is indicated.	Mitigates waste transfer leaks caused by excavation activities by prompt shutdown of the waste transfer pump	
- Encased pipe outside of the tank farm boundaries shall be identified with permanent aboveground labels	Prevents leaks in waste transfer lines caused by excavation activities by ensuring that excavation activities are not inadvertently performed near waste transfer lines outside of tank farms	

Table 3.4.2.17-2. Defense-in-Depth Controls for Spray Leak from Underground Waste Transfer Lines.

Control	Safety function	Comments
T-bars and chains	Restrict access to transfer lines	--
Material balance after each sluicing batch of 12 hours maximum duration during transfer operations, including total material transferred and solids loading calculation	Prevents a leak from a transfer line by monitoring the flow through the lines	A small leak, such as a spray leak, is difficult to detect by the material balance equipment
Seismic shutdown switches	Shut down transfer pumps upon detection of a seismic event	

3.4.2.18 Natural Phenomena. The following natural phenomena events were identified in the hazard analysis: seismic events, ice storms, rainfall, local flooding, volcanic activity, and high winds/dust devils. These phenomena are initiators for several of the accidents analyzed in detail in Section 3.4.2. They do not pose any unique accident scenarios different from those in Section 3.4.2 or the main text of the BIO.

This page intentionally left blank.

3.4.3 Beyond Evaluation Basis Accidents

The results of an assessment of beyond evaluation basis accidents analyzed to provide a perspective of the residual risk associated with tank farm operations (including WRSS) is provided in the main text of the BIO. Beyond valuation basis accidents are not analyzed specific to WRSS.

4.0 SAFETY STRUCTURES, SYSTEMS, AND COMPONENTS

4.1 INTRODUCTION

The purpose of this chapter is to provide details on structures, systems, and components (SSCs) utilized by Project W-320 that are necessary for Waste Retrieval Sluicing System (WRSS) activities to satisfy accident consequence guidelines, provide Defense-in-Depth, and aid in ensuring worker safety. Descriptions of the attributes required (1) to support the safety functions identified in the hazard and accident analyses, and (2) to support subsequent derivation of the Technical Safety Requirements (TSRs), are provided.

4.2 REQUIREMENTS

The following lists the current standards, regulations, and U.S. Department of Energy (DOE) orders that establish the requirements in support of safety analysis and design.

- DOE 5480.28, *Natural Phenomena Hazard Mitigation*[1] (1994)
- DOE 6430.1A, *General Design Criteria*[2] (1989)
- HP-SDC-4.1, *Standard Architectural-Civil Design Criteria*[3] (1988)

The existing WRSS SSCs that are designated as Safety-Class and Safety-Significant in this addendum, were not designed and constructed to meet Safety-Class criteria.

An engineering analysis was performed for each Safety Class and Safety Significant system of the WRSS to ensure that it is able to perform its safety function. The results of this evaluation are provided in HNF-2050, *Project W-320 Safety Class and Safety Significant Equipment Engineering Evaluation.* The engineering analysis defined the project strategy for meeting the system safety functions(s) and evaluated the system compliance with safety design requirements. The evaluation includes failure modes and effects analysis, allowed outage times and operational attributes and critical characteristics. The evaluation discusses the results of the reliability analyses for the Tank 241-AY-102 primary and annulus ventilation systems and Tank 241-C-106

---

[1] DOE 5480.28 was canceled by DOE N 251.4 and DOE O 420.1. As of July 2, 1996, the new orders were not transmitted for compliance; therefore, compliance with DOE 5480.28 is required by clause 1-97(a).

[2] Non safety-related portions of DOE 6430.1A will be phased out/canceled upon meeting the implementation conditions of DOE O 430.1. The portions of DOE 6430.1A related to nuclear safety for nonreactor nuclear facilities are canceled by DOE O 420.1. As of July 2, 1996, the new orders were not transmitted for compliance; therefore, compliance with DOE 6430.1A is required.

[3] Refer to Appendix F, "Site-wide Controlled Manual Cross Reference Table," of the BIO for cross-walk between Site-wide controlled manuals (e.g., WHC-CM-X-XX) superseded by Fluor Daniel Hanford, Inc., FDH Procedures (e.g., HNF-PRO-XXX).

primary ventilation system. The evaluation provides the basis for establishing the spare parts requirements for the Safety Class and Safety Significant systems. Acceptance and operational testing is underway, and will demonstrate, where practical, that safety functions and requirements can be met.

4.3 SAFETY-CLASS STRUCTURES, SYSTEMS, AND COMPONENTS

This section provides information about the Safety-Class SSCs identified in Chapter 3.0 "Hazard Evaluations and Accident Analyses." Table 4-1 provides a summary list of those SSCs. Details of each Safety-Class SSC correlating to the information in Table 4-1 follow.

4.3.1 Annulus Ventilation System (Tank 241-AY-102)

The annulus ventilation system of Tank 241-AY-102 is identified as a Safety-Class SSC for the tank bump (Section 3.4.2.11 "Tank Bump") accident scenario and is credited as Safety Significant for the unfiltered release (Section 3.4.2.3 "Unfiltered Release") accident scenario.

4.3.1.1 Safety Function. The safety function of the Tank 241-AY-102 annulus ventilation system is to provide adequate cooling to prevent the sludge or supernate in the tank from reaching the local saturation temperature in the scenarios of Sections 3.4.2.3 and 3.4.2.11.

4.3.1.2 System Description. The Tank 241-AY-102 annulus ventilation system draws outside air into the tank annulus area, where heat being conducted through the tank inner liner is absorbed, before the air is filtered and exhausted to the environment.

The annulus space in Tank 241-AY-102 is ventilated by a dedicated, independent ventilation system. A portion of the annulus ventilation system has been blocked to increase the under-floor flow rate. If needed, any combination of an increased vacuum exhaust fan, an inlet system blower, and an inlet system chiller may be installed to enhance the cooling capacity of the annulus ventilation system and meet the cooling requirements of the tank. Cooling requirements depend on thermal analysis of the actual transferred waste conditions (i.e., volume, fluffing factor, and tank temperature response). A supporting SSC is the electrical system that supplies power to the ventilation fans.

4.3.1.3 **Functional Requirements.** The annulus ventilation system shall maintain a flow rate to control tank waste temperature within the following limits:

≤195 °F (91 °C), for all waste levels

OR

≤195 °F (91 °C) in the top 4.6 m (15 ft) of the waste

AND

≤215 °F (102 °C) in the waste below 4.6 m (15 ft)

Tank waste temperatures must be controlled below those temperatures that could lead to waste boiling, steam generation, overpressurization conditions, and unfiltered releases.

4.3.1.4 **System Evaluation.**

Performance Criteria: To meet its safety function, the annulus ventilation system must provide the sufficient cooling capacity to maintain waste temperatures below the limits described above. Under analyzed base case conditions, the system will require a flow rate capability of 61 m^3/min (2150 ft^3/min) and provision of 4 °C (40 °F) inlet air (HNF-SD-W320-ER-004, *Project W-320 SAR and Process Control Thermal Analysis*). Final determination will be made based on data from the first sluicing campaign.

Analytical results (HNF-SD-W320-ER-004) for worst-case thermal transients indicate that the maximum allowable outage time of this system is 25 days.

System Evaluation: The Tank 241-AY-102 annulus ventilation system is existing and operational. This system was evaluated, as described in Section 4.2, to determine any needed functional upgrades and/or requirements for spares. The system may be upgraded, as described in Section 4.3.1.2, if required for increased cooling capacity. Designs for new equipment upgrades will be performed to DOE 6430.1A criteria.

During WRSS operations, the operability of the annulus ventilation systems shall be verified at a surveillance frequency of 10 days.

4.3.1.5 **Controls (TSRs).**

The assumption in the analyses presented in Sections 3.4.2.3 and 3.4.2.11 is that the annulus ventilation system provides adequate cooling capacity to ensure that the Tank 241-AY-102 waste saturation temperatures are not exceeded for the potential tank bump and unfiltered release.

4.3.2 **Primary Tank Ventilation System (241-AY-102 & 241-C-106)**

The primary ventilation systems of Tanks 241-AY-102 and 241-C-106 are identified as Safety-Class SSCs for the flammable gas deflagration

(Section 3.4.2.8) accident scenario, and the tank bump (3.4.2.11) accident scenario and are credited as Safety-Significant for the unfiltered release (3.4.2.3) accident scenario.

4.3.2.1 Safety Function. The safety functions of the primary ventilation systems of Tanks 241-AY-102 and 241-C-106 are to (1) dilute gases released from the waste in a chronic (steady state) manner such that flammable gas concentrations in tank dome spaces remain below 25% of the lower flammability limit (LFL) and (2) to help remove heat to maintain the tank waste temperatures below the saturation temperature. Another safety function of the Tank 241-C-106 primary system is to cool the tank and prevent a steam release by eliminating thermal saturation zones.

4.3.2.2 System Description. The primary ventilation systems of Tanks 241-AY-102 and 241-C-106 draw outside air into the tanks, mixing and displacing the flammable gases produced by the waste. The air/gas mixture is then removed from the tanks, filtered to remove radioactive particulates, and exhausted to the environment.

Specifically, the Tank 241-C-106 ventilation system (296-C-006) is a combination recirculation and exhaust system. The ventilation system serves to (1) cool the tank, and (2) dilute flammable gas generated in the sludge, which discharges a thoroughly decontaminated ventilation stream to the atmosphere. The recirculation portion of the system is used to provide the needed cooling. The exhaust portion of the system maintains headspace below flammable conditions.

An older heating, ventilating, and air-conditioning (HVAC) system (296-P-16) also serves Tank 241-C-106. The older system will be maintained in an operational standby status as a backup system for cooling Tank 241-C-106. Its main function, however, will be to subcool Tank 241-C-106 waste before initiation of sluicing to reduce the potential for a steam release event during the retrieval activity and to provide a high flow exhaust system to support Tank 241-C-106 open riser maintenance activities.

The primary ventilation system (241-A-702) of Tank 241-AY-102, serves to (1) cool the tank, (2) maintain the tank at a negative pressure while discharging a decontaminated ventilation stream to the atmosphere, and (3) dilute flammable gas generated in the sludge. A backup ventilation system is also available for the 241-A-702 ventilation system. The supporting SSC is the electrical system that provides power to the ventilation fans.

The 241-AZ-702 ventilation system, which will replace the 241-A-702 system, uses separate systems for cooling and/or confinement and for exhausting (Figure 2-9). However, 241-AZ-702 and the existing ventilation system (241-A-702) both rely on evaporative cooling to maintain waste temperatures. The exhaust system contains HEPA filtration and stacks similar to the existing design. A separate recirculating system is added for cooling and confinement. This additional system greatly reduces the amount of air vented out the stack. The 241-AZ-702 system will have three operating modes available: recirculation, high heat, and by-pass.

4.3.2.3 Functional Requirements. The active primary ventilation systems of Tanks 241-AY-102 and 241-C-106 shall prevent the accumulation of flammable gases from steady-state releases by (1) providing a minimum flow rate, and (2) limiting a loss of ventilation upset to a timeframe where gases cannot build to more than the LFL. Definition of 25% LFL is provided in Appendix E, "Flammable Gas/Slurry Growth Unreviewed Safety Question: Justification for Continued Operation for the Tank Farms at the Hanford Site," of the BIO main text.

The primary active ventilation system on Tank-C-106 (296-C-006 or 296-P-16) must also provide sufficient cooling capacity to maintain the waste below 96 °C (205 °F).

4.3.2.4 System Evaluation.

Performance Criteria: To meet its safety function, the primary ventilation system must maintain flammable gas concentrations in tank dome spaces below 25% of the LFL. The minimum flow rate to maintain the headspace below 25% of the LFL has been evaluated in (HNF-SD-WM-CN-114) *Calculation Note: Project W-320 Primary Ventilation Air Flow Requirements for Mitigation of Steady State Flammable Gas Concentrations in the Headspaces of Tanks 241-C-106 and 241-AY-102* for both tanks. For Tank 241-C-106, this flow rate is 2.7E-02 m^3/min (0.74 ft^3/min), using an upper bound hydrogen generation rate of 0.19 m^3/day (6.7 ft^3/day). For Tank 241-AY-102, this flow rate is 8.3E-02 m^3/min (2.95 ft^3/min), using an upper bound hydrogen generation rate of 0.75 m^3/day (26.9 ft^3/day).

The 296-P-16 system must provide 4 °C (40 °F) inlet air through the air inlet station to pre-cool the waste below saturation temperatures (HNF-SD-W320-ER-004).

The Tank 241-AY-102 system must provide 14.2 m^3/min (500 ft^3/min) at 24 °C (76 °F), as noted in HNF-SD-W320-ER-004.

Following sluicing, the 296-P-16 system must maintain any remaining waste in Tank 241-C-106 below saturation temperature (Section 3.4.2.12, "Liner Breach Due to Steam Between the Steel Liner and Concrete Shell in Tank 241-C-106"). This function may not be required if enough waste material is removed from the tank.

System Evaluation: The Tank 241-AY-102 primary ventilation system is existing and operational. This system will be evaluated, as described in Section 4.2 above, to determine any needed functional upgrades and/or requirements for spares. The nominal flow rate of the 241-A-702 system, 17 m^3/min (600 ft^3/min), is more than adequate to maintain the headspace below 25% of the LFL. There is an existing backup ventilation system available for use in the event of a ventilation outage.

The 241-AZ-702 system has been constructed, but not yet operational. This system will also be evaluated, as described in Section 4.2. The nominal flow rate of the 241-AZ-702 system, 2.8 m^3/min (100 ft^3/min), is also more than adequate to maintain the headspace of Tank 241-AY-102 below 25% of the LFL.

The existing Tank 241-C-106 primary ventilation system (296-P-16) is operational. This system has been upgraded to meet flammable gas ignition control requirements (BIO Appendix E). This system will be evaluated as described in Section 4.2. The nominal flow rate of the 296-P-16 system, 68 m^3/min (2400 ft^3/min), is more than adequate to maintain the headspace of Tank 241-C-106 below 25% of the LFL.

The new Tank 241-C-106 primary ventilation system (296-C-006) has been designed, constructed, and installed, but is not yet operational. This system was evaluated as described in Section 4.2. The nominal flow rate of the 296-C-006 system, 5.7 m^3/min (200 ft^3/min), is also more than adequate to maintain the headspace of Tank 241-C-106 below 25% of the LFL. When this system is operational, the 296-P-16 system will serve as a back-up system for both cooling and flammable gas dilution functions.

4.3.2.5 Controls (TSR). The assumption in the Sections 3.4.2.3, 3.4.2.8, and 3.4.2.11 accident analyses is that the ventilation systems are operable and operating during WRSS operations. The operability assumption includes (1) monitoring of the differential pressure across the ventilation system's HEPA filters, or (2) monitoring of the tank pressures, or (3) verification of the flow.

4.3.3 Primary Tank Leak Detection System (241-AY-102)

The primary tank leak detection system for Tank 241-AY-102 is identified as a Safety-Class SSC for the flammable gas deflagration accident (Section 3.4.2.8) and the surface leak resulting in pool accident (Section 3.4.2.15).

4.3.3.1 Safety Function. The safety function of the primary tank leak detection system is to provide an indication of leakage of waste to the annulus space of Tank 241-AY-102.

4.3.3.2 System Description. The primary tank leak detection system includes (1) conductivity probes that detect the presence of liquid in the tank annulus, and (2) a CAM that detects the presence of airborne radionuclides in the annulus ventilation exhaust stream.

4.3.3.3 Functional Requirements. The annulus conductivity probes must be able to detect a specified depth of waste in the bottom of the annulus, and must provide an audible alarm signal and an annunciator panel light upon the detection of waste.

If the conductivity probe is not in service, the annulus ventilation system's CAMs must operate continuously while the annulus ventilation system is operating, and must alarm when radiation levels exceeding a preset level are detected.

4.3.3.4 System Evaluation.

Performance Criteria: To meet their safety function, the primary tank leak detectors must be continuously operational or fail in a fail-safe mode (alarming). Liquid waste contact with the annulus leak detector will activate alarms and annunciator panel lights. The CAM will alarm if the radiation level exceeds a preset level. Failure of the CAMs will activate audible and visible alarms.

System Evaluation: The primary leak detectors on Tank 241-AY-102 are in place, and are operational, and were evaluated as described in Section 4.2. The operability of the liquid waste detectors must be verified by a system functional test prior to WRSS operations.

4.3.3.5 Controls (TSRs). The assumption in the Sections 3.4.2.8, "Flammable Gas Deflagration," and 3.4.2.15, "Surface Leak Resulting in a Pool," analyses is that the annulus liquid waste detectors are operable.

4.3.4 Transfer Line Pipe-in-Pipe Encasement

The transfer line pipe-in-pipe system, and specifically the encasement, has been designated as Safety-Class SSC for the subsurface leak resulting in a pool (Section 3.4.2.14), surface leak resulting in a pool (Section 3.4.2.15), and spray leak from structure (Section 3.4.2.16) scenarios, and is credited as Safety-Significant for the subsurface leak remaining subsurface (Section 3.4.2.13)scenario.

4.3.4.1 Safety Function. The safety function of the transfer line pipe-in-pipe system is to ensure that a leak in the primary waste transfer system piping will be contained and directed to a waste transfer-associated structure, where the leak will be detected, subsequently resulting in operator shutdown of the transfer operation.

4.3.4.2 System Description. The transfer line pipe is fabricated as a pipe within a pipe, with an inner or primary pipe that is surrounded by an encasement or secondary pipe. The encasement pipe forms a sloped annular drain channel, and any leaked waste from a primary pipe will flow by gravity from the leak site along this annular channel to a detector.

4.3.4.3 Functional Requirements. The transfer line pipe-in-pipe system shall contain and route the waste leaked from the primary pipe to a structure at which the leak can be detected. The encasement shall provide an unobstructed flow path to the structure.

4.3.4.4 System Evaluation.

Performance Criteria: To meet its safety function, the transfer lines must be capable of withstanding maximum system pressures, temperatures, and transients. It must withstand credible natural phenomena (i.e., high winds, earthquakes) and must not fail by corrosion for the life of the project.

System Evaluation: The WRSS transfer lines have been constructed and are ready for operation. The transfer lines are designed to Safety-Significant requirements per the U.S. Department of Energy, Richland Operations Office (RL), approved (HNF-SD-W320-FDC-001, *Functional Design Criteria for Tank 241-C-106 Waste Retrieval, Project W-320*). The encased lines are provided with cathodic protection to reduce the possibility of corrosion failure, as well as seismic switches to trip the pumping systems in the event of a significant earthquake (0.1 g). The lines will only be used a total of 10-20 days over a 1-year period.

The transfer line leak accidents analyzed in Section 3.4.2 rely primarily on leak detection and operator shutdown of the transfer pumps to mitigate potential accident consequences. The transfer lines are assumed to fail in both the unmitigated and mitigated accident scenarios. An additional margin of safety is provided by the seismic shutdown switches which are credited as Defense-in-Depth. The seismic trip system will have setpoints that shut down the slurry pump, sluice pump, and booster pumps at ground accelerations less than the current Safety-Significant design seismic loads for the pipe-in-pipe system. If such an event were to occur, the pipe-in-pipe system would require engineering inspection and structural reanalysis prior to further use.

Considering the design of the system and its limited use, it is judged to meet its safety function. The drain path into the pit(s) from the annulus of the encased piping system shall be verified to be free of obstructions prior to the start of a waste transfer.

4.3.4.5 Controls (TSRs). The accident analyses presented in Sections 3.4.2.13, "Subsurface Leak Remaining Subsurface," through 3.4.2.16, "Spray Leak from Structure," assume that the encasement is unobstructed and operable before a waste transfer and remains operable throughout the WRSS operation. The operability assumption includes that the encasement seal loop valves are in their operating position.

4.3.5 Transfer Leak Detection Systems

The transfer leak detection systems, including leak detectors in interfacing pits and their alarms are identified as Safety-Class SSCs for the Subsurface Leak Resulting in a Pool (Section 3.4.2.14) and "Surface Leak Resulting in a Pool," Section 3.4.2.15 accident scenarios, and are credited as Safety-Significant for the "Subsurface Leak Remaining Subsurface" (Section 3.4.2.13) scenario.

4.3.5.1 Safety Function. The safety function of the transfer line leak detection system, and specifically the leak detectors in the pits, is to provide warning of liquid within the transfer line encasement, and routine waste accumulation to prevent transfer pits from overflowing as the result of equipment leaks.

4.3.5.2 System Description. The pits and transfer line encasements are provided with leak detectors located in the lowest part of the structures. The leak detectors have electrodes, at different electrical potentials, which are short-circuited by a conductive medium (i.e., liquid waste) and cause a

change in state of the monitoring circuitry. When liquid waste short-circuits the leak detector electrodes, an alarm is generated.

4.3.5.3 Functional Requirements. A leak detector must be capable of detecting a predetermined depth of liquid accumulation. The leak detection system is required to activate an alarm when a leak is detected.

4.3.5.4 System Evaluation.

Performance Criteria: To meet their safety function, leak detectors must be continuously operational or fail in a fail-safe mode (alarming). When the detectors are contacted by liquid waste, an alarm will activate, leading to operator shutdown of the transfer system.

System Evaluation: The leak detectors associated with the WRSS are installed and operational. These leak detectors have been modified to meet flammable gas ignition control requirements (BIO Appendix E) and provide fail-safe alarm capability. The leak detectors were evaluated as described in Section 4.2. The operation of the leak detector and the associated alarm shall be verified prior to WRSS operations.

4.3.5.5 Controls (TSRs). The assumption in Sections 3.4.2.13, 3.4.2.14, and 3.4.2.15 is that the leak detector systems will be operable and operating during WRSS operations. The operability assumptions include ensuring (1) that the leak detection system is operational, and (2) that the alarm and control functions activated by the leak detector are routinely verified. The specific bases and controls protecting the operability assumptions are developed in Chapter 5.0.

4.3.6 Transfer System Covers

The transfer system covers are identified as Safety-Class SSCs for the spray leak from structure (Section 3.4.2.16) accident scenario, and are credited as Safety-Significant for the surface leak resulting in a pool (Section 3.4.2.15) scenario.

4.3.6.1 Safety Function. The safety function of the transfer system covers is to mitigate the effects of a spray release (i.e., knock down the spray) from the pressurized transfer line and limit the release of aerosols to the atmosphere. Transfer system covers also limit shine and skyshine dose to the onsite receptor.

4.3.6.2 System Description. The transfer system covers are concrete and have been positioned over the pits to form a barrier.

4.3.6.3 Functional Requirements. The transfer system covers must be capable of limiting the splatter of a spray release and mitigating the release of aerosols, as well as limiting shine and skyshine dose to the onsite receptor.

4.3.6.4 System Evaluation.

Performance Criteria: To meet their safety function, the transfer system covers must be in place, must be structurally sound for their design life, and must cover the pit openings such that an undiverted spray to the atmosphere is not possible.

System Evaluation: The transfer system covers are all currently installed and were evaluated as described in Section 4.2. The 241-C-06A and 241-C-06C cover blocks were recently upgraded due to structural concerns, and the 241-AY-02A pit cover block was designed to DOE 6430.1A criteria. The covers shall be verified to be in place during transfers.

4.3.6.5 Controls (TSRs). The Sections 3.4.2.15 and 3.4.2.16 accident analyses assume that the covers and cover assemblies will be operable prior to WRSS operations and will remain operable throughout the WRSS operation to provide a tortuous leak path for a spray leak.

Each time a transfer system cover is opened, the pit structure and its covers shall be visually inspected for damage and/or degradation in structural integrity. The exterior of the transfer system covers shall be visually inspected prior to WRSS operation to ensure that (1) covers are installed and operable, and (2) cover plugs are installed and operable.

4.3.7 Stack Continuous Air Monitor and Interlock to Exhaust Fan

The primary exhaust stack CAM, and interlock to the exhaust fan are identified as a Safety-Class SSC for the spray leak from structure (Section 3.4.2.16) accident scenario.

4.3.7.1 Safety Function. The safety function of the stack CAM interlock to the exhaust fan is to ensure that the fan will be shut down in the event of HEPA exhaust filters break through.

4.3.7.2 System Description. If the stack CAMs on the ventilation exhaust stack detect a predetermined radiation level, the interlock signals an alarm and transmits a signal to a relay that interrupts the electrical power to the exhaust fan motor.

Supporting SSCs include the electrical power for the CAM, the interlock, the alarm, any instrument cabinet heaters, and freeze protection for the CAM gas tubing.

4.3.7.3 Functional Requirements. The stack CAM must operate continuously while the exhaust systems are operating and must be capable of alarming and shutting down the exhaust fan when radiation levels above background are detected in the stack.

4.3.7.4 System Evaluation.

Performance Criteria: The stack CAMs shall operate continuously during ventilation system operation and shall actuate the alarm on failure. Interlocks shall be operational at all times the system is functional.

System Evaluation: The stack CAMs and interlocks are existing and operational on the operating exhausters associated with the WRSS. All WRSS-related stack CAMs and interlocks have been upgraded to meet flammable gas ignition control requirements (BIO Appendix E). CAMs and interlocks will be evaluated as described in Section 4.2. The CAMs and interlocks shall be calibrated and verified to be operable prior to waste transfers. The interlocks must be ensured operable during transfers out of the facility and during tank farm transfers through routes physically connected to the unloading facility.

4.3.7.5 Controls (TSRs). The assumptions in the Section 3.4.2.16 accident analysis are that the CAMs with interlocks are provided on all ventilation stacks, and that the CAMs and their associated alarms and interlocks are operable and operating during and following a spray leak from the structure that results in damage to the HEPA filters. The operability function includes (1) the vacuum pump operates as designed, (2) isokinetic sampling conditions are maintained, (3) the CAMs accurately measure radionuclide levels in the sample, (4) the CAMs are properly set to actuate interlocks when high radionuclide levels are detected, (5) the interlocks perform as required, and (6) local and remote alarms, both visual and audible, are actuated by failure of the CAMs.

4.4 SAFETY-SIGNIFICANT STRUCTURES, SYSTEMS, AND COMPONENTS

This section provides information about the Safety-Significant SSCs identified in Chapter 3.0. Refer to Section 4.3 for the description of Safety-Significant SSCs that are also designated as Safety-Class SSCs with a common safety function. Table 4-2 provides a summary list of the Safety-Significant SSCs. Details of each unique Safety-Significant SSC, correlating to the information in Table 4-2, follow.

4.4.1 Stack Continuous Air Monitor Interlocks

The stack CAM interlocks are designated as Safety-Significant for the "HEPA Filter Failure Due to Exposure to High Pressure or High Temperature," Section 3.4.2.2 and "Unfiltered Release" (Section 3.4.2.3) accident scenarios.

4.4.1.1 Safety Function. The safety function of the stack CAM interlock systems for the accident scenarios presented in Sections 3.4.2.2 and 3.4.2.3 is to prevent the unfiltered ventilation system release from occurring for more than 10 minutes for the 241-A-702 (if returned to service), and 241-AZ-702 ventilation systems on Tank 241-AY-102, and for more than 10 minutes for the 296-C-006 and 296-P-16 ventilation systems on Tank 241-C-106.

4.4.1.2 System Description. The stack CAMs continuously monitor the exhaust air while the ventilation systems are in operation. The CAMs measure the radiation level in the exhaust stream and shut down (through an interlock) the appropriate ventilation system when a predetermined level is reached. The CAMs shall also activate an alarm or shut down the exhaust system in the event of CAM failure.

Supporting SSCs include the electrical power for the CAM, the interlock, the alarm, any instrument cabinet heaters, and freeze protection for the CAM gas tubing.

4.4.1.3 Functional Requirements. The stack CAMs must operate continuously while the exhaust systems are operating. The CAM interlocks are located some distance downstream of the filter location and are expected to be unaffected by the initiator of the HEPA filter failure. The ventilation stack CAMs shall be interlocked to the fans to ensure ventilation system shut-off within 10 minutes for the Tank 241-AY-102 and Tank 241-C-106 ventilation systems.

4.4.1.4 System Evaluation. The stack CAMs shall be calibrated prior to WRSS operations and periodically as required.

4.4.1.5 Controls (TSRs). The assumptions in the HEPA filter failure accident described in Section 3.4.2.2 and credited in Section 3.4.2.3 are that the CAMs are provided on all exhaust stacks, and that the CAMs and their associated alarms and interlocks are operable and operating. The operability assumptions include (1) vacuum pumps operate as designed, (2) isokinetic sampling conditions are maintained, (3) CAMs accurately measure radionuclides in the sample, (4) CAMs are properly set to actuate interlocks when high radionuclide levels are detected, (5) interlocks perform as required, and (6) local and remote alarms, both visual and audible, are actuated by failure of the CAMs.

4.4.2 Tank Level Detection System

The primary tank level detection systems are designated as Safety-Significant SSCs for the subsurface leak remaining subsurface (Section 3.4.2.13), subsurface leak resulting in a pool (Section 3.4.2.14), and surface leak resulting in a pool (Section 3.4.2.15) accident scenarios.

4.4.2.1 Safety Function. The safety function of the tank (primary) level measurement system is to provide measurements used in the performance of material balance calculations between transfer batches. The calculations are used to detect discrepancies during transfers to detect leaks or misroutes.

4.4.2.2 System Description. Each system includes at least one level detector, which may be a manual tape, an FIC gauge, an ENRAF gauge, or a set of dip tubes.

4.4.2.3 Functional Requirements. The level detection systems are required to measure tank waste levels and to transmit the data to local and/or remote level indicators.

4.4.2.4 System Evaluation. Tank level detection systems shall measure waste levels with an accuracy of ±1.3 cm (±0.5 in.) and will be verified operable prior to WRSS operations.

4.4.2.5 Controls (TSRs). The assumption in the Chapter 3.0 accident analyses is that the level monitoring systems will be operable and operating when they are needed to perform their safety function. The operability assumption includes (1) calibration of level detection instruments and indicators is properly performed and is kept current, and (2) level readings are taken and/or recorded at intervals that will allow early detection of leaks or misroutes into Tanks 241-C-106 and 241-AY-102. NOTE: The level detection system for Tank 241-C-106 will be raised during this operation.

4.4.3 Backflow Preventers

The backflow preventers for the slurry from Tank 241-AY-102 are identified as Safety-Significant SSCs for the surface leak resulting in a pool (Section 3.4.2.15) and spray leak from structure (Section 3.4.2.16) accident scenarios.

4.4.3.1 Safety Function. The safety function of the backflow prevention devices is to prevent back flow of waste into the service water system (e.g., tankers, trucks).

4.4.3.2 System Description. The backflow preventer consists of two valves that prevent backflow into the service water system. At the AY Farm, a temporary manual valve and check valve are added to the connection.

4.4.3.3 Functional Requirements. Backflow prevention devices shall be installed in accordance with the manufacturer's instructions. The rated pressure of the backflow preventer shall exceed the maximum pressure of the system in which it is installed.

4.4.3.4 System Evaluation. They shall be operated within their design limits (e.g., maximum operating pressure) as certified by the manufacturer.

4.4.3.5 Controls (TSRs). TSR controls are not required to ensure the functionality of backflow preventers (Section 5.3.3.3).

Table 4-1. Safety-Class Structures, Systems, and Components.

SSC	Accident(s)	Safety Functions	Functional Requirements	Operability criteria for TSRs
Annulus ventilation system (Tank 241-AY-102)	Tank Bump, Section 3.4.2.11.	Provides waste temperature cooling ability to maintain tank waste temperatures below local saturation temperature.	Provide annulus space ventilation flow for cooling of the waste in Tank 241-AY-102.	The operability of the annulus ventilation system shall be verified prior to sluicing and periodically thereafter.
Primary tank ventilation systems (Tank 241-C-106/ 241-AY-102)	Flammable Gas Deflagration, Section 3.4.2.8; Tank Bump, Section 3.4.2.11.	Maintain flammable gas concentrations below 25% of the LFL. Provides waste temperature cooling ability to maintain tank waste temperatures below local saturation temperature.	Maintain the ventilation flow rates as required by operational procedures. Provide ventilation flow for cooling.	Operability must be verified prior to WRSS operations.
Primary tank leak detection system	Flammable Gas Deflagration, Section 3.4.2.8; Surface Leak Resulting in a Pool, Section 3.4.2.15.	Provides indication that waste has leaked into the annulus space.	Detect a specified depth of waste in the annulus area and provide an audible alarm signal and annunciator panel light.	Operability must be verified prior to WRSS operations.
Transfer line pipe-in-pipe encasement	Subsurface Leak Resulting in a Pool, Section 3.4.2.14; Surface Leak Resulting in a Pool, Section 3.4.2.15; Spray Leak from Structure, Section 3.4.2.16.	Ensures that a leak in the primary waste transfer system piping is contained and directed to a waste transfer-associated structure.	Route the waste from the leaking primary pipe to the pit.	Shall be verified operable prior to WRSS operations.
Transfer leak detection system	Subsurface Leak Resulting in a Pool, Section 3.4.2.14;Surface Leak Resulting in a Pool, Section 3.4.2.15.	Detect leaks in transfer associated structures (pits).	Shall be capable of detecting leak and activating an alarm leading to operator shutdown of the transfer	Shall be verified operable prior to WRSS operations.
Transfer system covers	Spray Release from Structure, Section 3.4.2.16.	Mitigate the effect of a spray leak within the transfer pits. Limit release of aerosols generated by splatter inside the pit; limit shine and skyshine dose to onsite receptor.	The covers must be capable of limiting the splatter of a spray release and mitigating the release of aerosols.	Transfer system covers must be installed during waste transfers.
Stack CAM and interlock to exhaust fan 241-A-702/ 241-AZ-702 296-P-16/296-C-006)	Spray Leak From Structure, Section 3.4.2.16.	Shut down exhaust fan should exhaust HEPA filters break through.	Shall be capable of detecting a predetermined level of radiation in the exhaust stream and shut down the ventilation system.	Shall be calibrated and verified operable prior to WRSS operations.

CAM = continuous air monitor. HEPA = high-efficiency particulate air (filter). TSR = Technical Safety Requirement. WRSS = Waste Retrieval Sluicing System.

Table 4-2. Safety-Significant Structures, Systems, and Components. (2 sheets)

SSC	Accident(s)	Safety Functions	Functional Requirements	Operability Criteria for TSRs
Annulus ventilation system (Tank 241-AY-102)	Unfiltered release 3.4.2.3	Provides waste temperature cooling ability to maintain tank waste temperatures below local saturation temperature.	Provide annulus space ventilation flow for cooling of the waste in Tank 241-AY-102.	The operability of the annulus ventilation system shall be verified prior to sluicing and periodically thereafter.
Primary tank ventilation systems (Tank 241-C-106/ 241-AY-102)	Unfiltered Release 3.4.2.3	Provides waste temperature cooling ability to maintain tank waste temperatures below local saturation temperature.	Maintain the ventilation flow rates as required by operational procedures Provide ventilation flow for cooling	Operability must be verified prior to WRSS operations
CAM interlocks on ventilation systems (241-A-702/ 241-AZ-702/ 296-P-16/ 296-C-006)	HEPA Filter Failure, Section 3.4.2.2; Unfiltered Release, Section 3.4.2.3.	Shut down the ventilation system in the event that a HEPA filter fails, and prevent an unfiltered release to the atmosphere for more than a specified time.	Continuously monitor exhaust air while the ventilation system is in operation. Measure the radiation level in the exhaust stream and shut down the ventilation system when a predetermined level is reached. The CAMs shall also activate an alarm or shut down the exhaust system in the event of CAM failure.	CAMs shall be inspected and tested in accordance with existing Hanford Site procedures.
Tank level detection systems	Subsurface Leak Remaining Subsurface, Section 3.4.2.13; Subsurface Leak Resulting in a Pool, Section 3.4.2.14; Surface Leak Resulting in a Pool, Section 3.4.2.15.	Provide tank level indication to support material balance calculations between transfer batches.	Provide level readouts within a specified tolerance.	Shall be verified operable prior to WRSS operations.
Transfer leak detection systems	Subsurface Leak Remaining Subsurface, Section 3.4.2.13	Detect leaks in transfer associated structures (pits).	Shall be capable of detecting leak, and activating an alarm, leading to operator shutdown of the transfer.	Shall be verified operable prior to WRSS operations.
Transfer line pipe-in-pipe encasement	Subsurface Leak Remaining Subsurface, Section 3.4.2.13	Ensures that a leak in the primary waste transfer system piping is contained and directed to a waste transfer-associated structure.	Route the waste from the leaking primary pipe to the pit.	Shall be verified operable prior to WRSS operations.
Transfer system covers	Surface Leak Resulting in a Pool, Section 3.4.2.15	Limit release of aerosols generated by splatter inside the pit; limit shine and skyshine dose to onsite receptor	Pit structures and covers provide a mitigative safety function to limit releases.	Shall be in place during WRSS operations.

Table 4-2. Safety-Significant Structures, Systems, and Components. (2 sheets)

SSC	Accident(s)	Safety Functions	Functional Requirements	Operability Criteria for TSRs
Backflow preventers	Surface Leak Resulting in a Pool, Section 3.4.2.15; Spray Leak from Structure Section 3.4.2.16.	Safety-Significant to prevent general contamination of service water supply systems.	Backflow prevention devices shall be installed in accordance with the manufacturer's instructions. The rated pressure of the backflow preventer shall exceed the maximum pressure of the system in which it is installed.	Backflow prevention devices shall be functionally tested and shall be verified to be operating correctly.

CAM = continuous air monitor.
HEPA = high-efficiency particulate air (filter).
SSC = structure, system, and component.
TSR = Technical safety requirement.
WRSS = Waste Retrieval Sluicing System.

5.0 DERIVATION OF TECHNICAL SAFETY REQUIREMENTS

5.1 INTRODUCTION

The necessary preventive and mitigative features determined to be essential for the Waste Retrieval and Sluicing System (WRSS) in Chapter 3.0 and from the designation of Safety-Class and Safety-Significant features in Chapter 4.0 of this Addendum are identified in this chapter. Information necessary for preparing the separate Technical Safety Requirement (TSR) document (HNF-SD-WM-TSR-006, *Tank Waste Remediation System Technical Safety Requirements*) required by DOE 5480.22, *Technical Safety Requirements*, is also provided in this chapter.

TSRs define acceptable conditions, safe boundaries, and management or Administrative Controls (ACs) that ensure safe operation of a nuclear facility and reduce the potential risk to the public and onsite workers from uncontrolled releases of radioactive or other hazardous material or from radiation exposures caused by inadvertent criticality (DOE 5480.22).

This chapter consists of summaries and references to pertinent sections of the main text of the BIO and this Addendum that describe design and Administrative Control (AC) features needed to prevent or reduce the consequences of an accident specific to the WRSS. The Safety Limits (SLs), Limiting Control Settings (LCSs), Limiting Conditions for Operation (LCOs), Surveillance Requirements, ACs, and Design Features form the basis of the TSR document and provide the logical link between the TSRs and the main text of the BIO and this Addendum.

This chapter includes the following:

- Qualitative and quantitative TSR selection criteria
- Operational modes that designate distinguishable facility configurations
- Derivation of minimum staffing levels for each operational mode
- Derivation discussion of the TSR controls selected
- A list of design features not covered by the TSRs
- Identification of TSR interfaces with other Tank Waste Remediation System (TWRS) and Hanford Site facilities and the controls
- Tables that link the hazard and accident analyses and the TSRs
- A table that provides cross-references to other chapters in this Addendum

5.2 REQUIREMENTS

The primary requirements specific for this chapter, the hazard and accident analyses, and the TSR document are included in DOE 5480.22 and DOE 5480.23, *Nuclear Safety Analysis Reports*.

5.3 TECHNICAL SAFETY REQUIREMENTS COVERAGE

5.3.1 Summary

The suite of TSRs for analyzed hazards/accidents for the WRSS operations is summarized in Table 5-1. This table lists TSR controls per the accident analyses in Chapter 3.0 and the evaluation of safety structures, systems, and components (SSCs) in Chapter 4.0, "Safety Structures, Systems, and Components," of this Addendum. It also provides a brief derivation basis for each control related to the specific accident. Table 5-1 is written to provide a road-map to the respective accident analysis section or to Section 5.5, "Technical Safety Requirement Derivation," where derivation details are arranged by TSR control.

The required TSR controls for the WRSS are necessary and prudent for public safety, significant Defense-in-Depth, significant worker safety, and for preventing and mitigating radiological and toxicological consequences.

Worker safety for the WRSS is covered by integrated safety management programs (e.g., HNF-SD-WM-HSP-002 *Tank Farms Health and Safety Plan* [HASP]). These safety programs described in the HASP reduce the likelihood and potential impacts of events and are covered by their respective regulatory and contractual systems of basic requirements. Therefore, these programs are not repeated as AC programs in the TSR document. A cross-reference to the other chapters in this Addendum is provided in Table 5-2. DOE 5480.22 requires the TSR document to include AC programs for nuclear criticality safety, organization and management (including minimum staffing), and occurrence reporting at a minimum.

5.3.2 Criteria

The Executive Summary and other appropriate sections of the BIO main text discuss the control selection process from initial hazard analysis identification to selection of hardware or administrative programs for controls. The section below outlines the criteria that were considered in control selection. These criteria were also used for the WRSS.

5.3.2.1 Control Selection Criteria. The following elements were considered in selection of controls for the WRSS to the extent practical.

- **Contractor Management Directives, Policies, and Procedures**—Controls were not selected for environmental-only hazards unless the radiological or toxicological consequences exceed offsite or onsite

risk guidelines. Environmental controls for the WRSS are, however, discussed in Section 3.3.2.3.4 and listed in Table C-4 of this Addendum.

- **Analysis Assumptions**—Controls were selected to protect major assumptions that could be affected by an operating activity or equipment operation.
- **Sensitivity Analysis**—Controls were selected for less significant analysis assumptions if variability of the assumption significantly affected consequences.
- **Reliability**—Controls were selected for equipment systems that have demonstrated high reliability in the tank farm environment.
- **Optimization**—Controls were selected that could address multiple accidents to minimize implementation costs.
- **Priorities**—Controls were selected first, to prevent, then to mitigate; first, to involve passive systems, then actively engineered systems; and first, to use engineered controls, then administrative programs.
- **Practical Safety-Class/Safety-Significant Designation**—Controls were selected that would have value in being designated Safety-Class or Safety-Significant.
- **Risk Guidelines**—Controls were identified that would bring the frequency or consequences within acceptable risk guideline values when possible; the process was iterative and may require more than one control.
- **Conservatism**—Controls were selected to drive consequences further below risk guidelines for additional risk reduction.
- **Facility Worker Safety**—Controls were selected that would not significantly increase radiological or toxicological exposures to the facility worker.
- **Significant Defense-in-Depth**—Controls were selected from the suite of Defense-in-Depth items if they significantly minimized risk.
- **Operational Flexibility**—Controls were selected that minimized the need for additional operators or maintenance personnel.
- **Procedure Minimization**—Controls were selected that minimized the need for new or significantly modified operational or ACs.
- **Existing Hardware**—Controls were selected primarily for equipment systems that were in place.
- **Cost/Benefit**—Controls were selected, when new systems were needed, that minimized costs on a qualitative basis.

- **Impacts on TWRS Mission**—Controls were selected that minimized impact to characterization and stabilization activities.

- **Applicability/Consistency**—Controls were selected if they mirrored activities already in progress in the field.

5.3.3 Safety Structures, Systems, and Components Not Provided With Explicit Technical Safety Requirement Coverage

The Safety-Class and Safety-Significant SSCs for the WRSS that have not been provided with explicit TSR coverage include the WRSS Transfer System level detection, and backflow prevention. All other safety SSCs are provided with TSR coverage with an LCO or are included in an AC program. The bases for not providing TSR coverage are provided in the following paragraphs.

5.3.3.1 WRSS Transfer System. The WRSS transfer encasements are Safety-Class SSCs. There are no TSR controls for these safety SSCs, because they are passive Design Features, and their safety function is managed by configuration control processes. These SSCs were not credited as a control in the analysis but were identified as a key assumption in maintaining their encasements, directing leakage to leak detection systems. Leak detection systems are managed by the TSR control LCO 3.1.3, "Transfer Leak Detection Systems."

5.3.3.2 Tank Level Detection Systems. Tank level detection systems are Safety-Significant SSCs. There are no TSR controls for these safety SSCs because the accident analyses identified these as being needed only to support performance of material balance calculations during waste transfers according to AC 5.12, "Transfer Controls." Process and measuring and test equipment are further managed by AC 5.19, "Process Instrumentation and Measuring and Test Equipment."

5.3.3.3 Backflow Prevention. Backflow prevention devices are Safety-Significant. Requirements for backflow prevention devices are implemented by the Industrial Hygiene Program described in Chapter 8.0, "Hazardous Material Protection."

5.4 DERIVATION OF FACILITY MODES

5.4.1 Operational Modes

The operational modes (Operation and Limited) for TWRS facilities are included in the TSR document (HNF-SD-WM-TSR-006). The modes for Tank 241-C-106 and Tank 241-AY-102 during WRSS operations are the same as other single-shell and Aging Waste Facility (AWF) tanks and are defined as follows:

- **Operation**—Waste is being stored. Waste transfers to or from any tank are authorized. Routine operational and maintenance activities may be performed.

- **Limited**—Waste is being stored. Waste transfers to or from any tank are not authorized except in accordance with an approved recovery plan. Routine operational and maintenance activities may be performed.

A mode is the state of an individual tank at a given time. A particular support system may provide services for several individual tanks, with each tank operating in a different mode. Under these circumstances, the applicable mode for the support system is the most restrictive mode applicable to any of the tanks being provided with supporting services.

5.4.2 Minimum Staffing Levels

The minimum operations shift complement in the Operation and Limited Modes for TWRS facilities are included in the TSR document. They are one shift manager/operational engineer, five nuclear operators, two Radiological Control Technicians, and the Emergency Control Center staff. This minimum staff in each mode is considered adequate to perform the minimum safety functions necessary to protect the health and safety of the public, onsite workers, and the environment during normal operations, and abnormal and emergency conditions. The minimum staff does not include individuals necessary to support WRSS operations, therefore additional staff is required. Additional staff is necessary to establish continuous communications between the control rooms for Tanks 241-C-106 and 241-AY-102 during WRSS activities. During sluicing operations in accordance with AC requirements additional staff are required to perform additional surveillances in support of AC 5.18.

5.5 TECHNICAL SAFETY REQUIREMENT DERIVATION

This section details the level of control and derivation bases for the TSRs organized by control for WRSS. It can be used as an interface to link the accident analyses and the TSRs. It defines why WRSS controls were chosen.

Tables 5-1 and 5-2 provide road maps to controls or accident summaries depending on starting points. Table 5-1 is applicable if starting from accidents or Chapter 3.0 of this Addendum. Table 5-2 is applicable if starting from an overall summary of the remaining BIO Addendum chapters.

All controls are discussed below except for ACs 5.1 through 5.6. Sections AC 5.1, "Purpose," AC 5.2, "Contractor Responsibility," and AC 5.3, "Compliance," define the need for the following AC provisions, and clarify responsibility per good management practice. These three controls could be rewritten as a preface to the AC section, but they were included in this format because they are recognizable to Operations personnel from past Operational Safety Requirements (OSRs). Sections AC 5.4, "Technical Safety Requirement Violation," AC 5.5, "Occurrence Reporting," and AC 5.6, "Organization," satisfy the requirements of DOE 5480.22, Section 9.3.(5). This DOE order section requires ACs for reporting deviations and identifying staffing requirements.

5.5.1 Level of Control Criteria

The section below outlines the criteria for determining the level of control; for example, when an AC is chosen over a Limiting Condition for Operation control. Generalized criteria may be found in U.S. Department of Energy (DOE) orders. The following criteria, while considered to meet the generalized order criteria, reflect an interpretive base determined by coordination with other DOE Site TSR writing personnel, a DOE-sponsored TSR training course, contractor procedures, reactor standard technical specifications (NUREG 1431, *Standard Technical Specifications, Westinghouse Plants*), the proposed TSR rule, and Site expertise. The criteria were used for the BIO TSRs and for the WRSS TSRs.

5.5.1.1 Safety Limits/Limiting Control Settings. There are no additional SLs for WRSS specific accidents. The criteria for selection of the SLs are:

- A primary passive barrier failed (e.g., tank, piping).
- Passive barrier failure was the direct result of exceeding a physical parameter.
- This physical parameter can be directly measured by field personnel.
- Radiological or toxicological consequences without controls exceeded offsite and onsite risk guidelines.

LCSs are setpoints on safety systems that control process variables to prevent exceeding SLs. The specific setpoints are chosen so that, if exceeded, sufficient time is available to automatically or manually correct the condition before exceeding SLs. The LCSs are usually combined with their respective LCOs. By combining the LCSs with the LCOs, the LCS setpoint becomes part of the operability of the system. Furthermore, placing the applicability, actions, and surveillances for a system in a single location enhances safety and reduces the complexity of the TSR document.

5.5.1.2 Limiting Conditions for Operation Versus Administrative Controls. Accidents/hazards exceeding offsite or onsite risk guidelines, that are not candidates for SLs per the criteria listed above, are candidates for either LCOs or ACs. ACs are considered as important to the control philosophy as LCOs; they are not treated as less meaningful controls for safety. An AC is selected over an LCO if the control is better controlled by a program than a direct measurement and ensuing action. The following comparison identifies the process used in determining the proper type of control for reduction of risk. This approach is consistent with the guidance in DOE-STD-3009-94, *Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports*, which states: "The decision as to whether an operating limit (such as an LCO) or a TSR AC is more appropriate is left to the judgment of the SAR Preparer."

- Parameter Measurement

  LCO—A process parameter or hardware is available for measurement by field operating or maintenance personnel and is available in real time or near to real time.

  AC—The control involves several parameters required for the accident to occur, or requires an analysis of field parameters by engineering or management personnel, or involves a parameter obtainable only by physical sampling requiring analytical delay time, or no measurement equipment is available.

- Control of Field Condition

  LCO—Hazard/accident results solely from exceeding a physically monitored parameter (e.g., continuous air monitor [CAM] interlock actuation).

  AC—Hazard/accident does not occur as a result of exceeding a physically monitored parameter but requires a combination of conditions to occur. Examples are: noncompliance with procedures, involvement of multiple organizations or personnel, or involving solely the corroboration of field information to protect accident analysis assumptions, or programmatic deficiencies.

- Response Action

  LCO—Exceeding a specific parameter requires immediate actions to reduce risk that are achievable through field personnel and resulting operating or maintenance procedures.

  AC—Exceeding parameter or condition either requires no immediate applicable actions to reduce risk, or actions are complex requiring evaluation and possible further data gathering, or actions solely involve emergency response personnel for mitigation.

- Surveillances

  LCO—Equipment or instrumentation is required to monitor a specific parameter, and it is appropriate to have surveillances to demonstrate operability.

  AC—Conditions leading to accident either cannot be measured by instrumentation; or surveillance intervals may be long because parameter of concern changes slowly; or a condition does not require immediate action, and sufficient recovery time exists to permit response action.

- Prior Control Method

  LCO—Hazard is currently controlled by an LCO or a lower-tiered control involving system(s) measurement and response.

  AC—Hazard is currently managed by an AC or other program.

5.5.2 LCO 3.1.1—Transfer System Covers and Entry Doors

5.5.2.1 Purpose. This control to ensure Transfer System Covers and Entry Doors operability is derived from the "Surface Leak Resulting in a Pool" accident in Section 3.4.2.15, and "Spray Leak from Structure accident in Section 3.4.2.16, for WRSS. The release of radioactive material without controls exceeds offsite and onsite radiological risk guidelines for both accidents. The release of toxicological material without controls exceeds the onsite risk guidelines for the spray leak from structure accident. Ensuring that transfer system covers are placed correctly over their associated structures (and the removable plugs are installed), in conjunction with the other controls selected, reduces the offsite consequences to meet or be within risk guidelines for both accidents and reduces the onsite consequences to within risk guidelines for the spray leak from structure by containing sprayed/splashed materials within the transfer system structure. The analysis in Sections 3.4.2.15 and 3.4.2.16 takes specific credit for the Transfer System Covers and Entry Doors when calculating consequences with controls.

This control is closely associated with "Transfer Pump Administrative Lock Controls" (AC 5.20) and "Transfer System Cover Removal Controls" (AC 5.22). Since surface leaks and spray leaks are improbable when their motive force is removed via administrative locks on pumps, as outlined within AC 5.20, Transfer System Cover operability controls are relaxed (i.e., not applicable) under these conditions. Surface leaks and spray leaks are likewise improbable when multiple isolation valves separate the transfer path and the structure of concern. In this situation, an alternate (and less stringent) control, as outlined within AC 5.22, is allowed in lieu of the Transfer System Cover and Entry Doors control.

5.5.2.2 Derivation Criteria. This control was selected because it takes advantage of existing hardware; Transfer system covers are already an integral part of transfer structure design. In addition, implementation of this control minimizes modifications needed to administrative procedures, as the process for the inspection of Transfer system covers associated with planned transfers is already a part of existing procedures.

5.5.3 LCO 3.1.3—Transfer Leak Detection Systems

5.5.3.1 Purpose. This control is required for the "Subsurface Leak Remaining Subsurface," Section 3.4.2.13, the "Subsurface Leak Resulting in Pool," Section 3.4.2.14 and the "Surface Leak Resulting in a Pool," Section 3.4.2.15 accidents for WRSS. Ensuring that transfer leak detection systems are operable reduces offsite consequences of the surface leak accident to meet the risk guidelines by limiting the amount of waste material released. This is

accomplished by a combination of alarm and operator response to shut down associated transfer pumps, thus removing the motive force behind the leak and limiting further leakage. The onsite consequences still remain above risk guidelines for the surface leak resulting in a pool. This control reduces the consequences to below the onsite radiological risk guidelines for the subsurface leaks.

This control is closely associated with the "Transfer Pump Administrative Lock Controls" (AC 5.20). Since subsurface leaks and surface leaks are improbable when their motive force is removed via administrative locks on pumps, as outlined within AC 5.20, transfer leak detection system operability controls are relaxed (i.e., not applicable) under these conditions.

5.5.3.2 Derivation Criteria. This control was selected because it protects the analysis assumptions and uses existing hardware. Transfer leak detection systems are already installed in all transfer-related structures.

5.5.4 LCO 3.1.4—Ventilation Stack Continuous Air Monitor Interlock Systems

5.5.4.1 Purpose. This control applies to the following accident scenarios: (1) spray leak from structure in Section 3.4.2.16; (2) high-efficiency particulate air (HEPA) filter failure—exposure to high temperature or pressure in Section 3.4.2.2; and (3) unfiltered release in Section 3.4.2.3. Based on the results of the spray leak analysis, the release of radioactive material without controls could exceed offsite and onsite risk guidelines and the onsite risk guidelines for the release of toxicological material. The ventilation stack CAM interlock to the ventilation system exhaust fan is credited in the analysis with stopping the ventilation system thereby terminating an unfiltered release. This control applies to spray leaks inside actively ventilated tanks. This action reduces the potential consequences of a pressurized spray leak event during transfers to maintain radiological consequences below risk guidelines.

Based on the results of the HEPA filter failure analysis and the unfiltered release analysis, the release of radioactive material without controls could exceed onsite risk guidelines. The ventilation stack CAM interlock that detects potential HEPA filter failure and unfiltered release and shuts off the ventilation system exhaust fan within 10 minutes for Tank 241-C-106 is credited in the analysis with stopping the ventilation system and terminating an unfiltered release. This action reduces the potential consequences of an unfiltered release to maintain radiological consequences equal to or below risk guidelines when a HEPA filter fire occurs or a high-pressure event occurs that impacts the HEPA filter.

A related control is AC 5.18, "HEPA Filter Controls." It requires verification that the HEPA filter and prefilter housing radiation levels are less than or equal to 200 mrem/h. This control also requires verification that the radiological dose contribution of the 296-C-006 HEME and HEMF is below 100 mrem/h, requires the 241-AZ-702 system HEGA filters to be changed before the upstream HEPA filter in the associated filter train has been replaced 20 times, or upon indication of degraded HEPA filter performance, and

requires efficiency testing of the HEPA filters upstream of the HEGA filters. This protects a key accident analysis assumption used to calculate the quantity of waste material accumulated on the filters based on the radionuclide content, thereby limiting the inventory on the filters available for release.

5.5.4.2 Derivation Criteria. The ventilation stack CAM interlock systems were selected as the controls because the analysis with controls assumes the ventilation system shuts off within 10 minutes, thereby terminating the unfiltered release. Based on human factor considerations, it is not feasible to have operator monitoring and subsequent response actions within 10 minutes, therefore, it was necessary to rely on an automatic feature to shutdown the ventilation flow through an unfiltered pathway. The CAM interlock was selected because it exists for the majority of applications where the control is required or could be installed where only a CAM alarm currently is available.

Although the accident analysis did not assume a specific setpoint for CAM interlock actuation it did assume that the CAM interlock will actuate on increasing radiation level. The functional requirement is that the CAM activates an interlock after detecting a radiation level that exceeds the preset level based on normal operating practices. Since a specific setpoint was not identified in the analysis, a setpoint of 10,000 cpm was selected, based on normal operating practice and to allow flexibility in adjustment of the setpoint based on radon decay products. Normal setpoint ranges are 4,000-6,000 cpm to allow activation just above background.

5.5.5 LCO 3.2.1—Double-Shell Tank and Aging Waste Facility Tank Ventilation Systems

5.5.5.1 Purpose. This control derives from the flammable gas deflagrations accident in Section 3.4.2.8 for the WRSS and the main text of the BIO. The release of radioactive material without controls could exceed onsite risk guidelines and offsite risk guidelines for certain scenarios. Maintaining the 241-AY-102 primary tank ventilation system in conjunction with the "Primary Tank Leak Detection Systems" (LCO 3.2.6), "Flammability Controls" (AC 5.9), "Ignition Controls" (AC 5.10), "Flammable Gas Monitoring Controls" (AC 5.11), and "Emergency Preparedness" (AC 5.14) reduces the risk from the steady state release, accumulation and ignition of flammable gases. Due to technical uncertainties related to this hazard, and the nature of the analysis contained in the main text of the TWRS BIO, the risk reduction in unquantified. In addition, for "Tank Bump" accident (Section 3.4.2.11) and "Unfiltered Release" accident (Section 3.4.2.3), primary tank ventilation provides adequate cooling capacity in Tank 241-AY-102 in conjunction with the LCO 3.3.3, "Tank 241-AY-102 Annulus Ventilation System" and AC 5.25, "Ventilation Controls." Maintaining temperature below local saturation temperature prevents the tank bump and unfiltered release accidents.

5.5.5.2 Derivation Criteria. Although the historical requirements related to active ventilation of the primary tanks were not established to control flammable gases, available gas sample results indicate that flammable gas concentration in all sampled tanks are less than 5% of the lower flammability

limit (LFL). These controls require near constant operation of the exhausters for the primary tank ventilation system for DSTs and AWF tanks. Therefore, one of the key elements of the flammable gas control strategy is the use of currently installed active ventilation systems on the primary tanks to dilute and remove flammable gases that are continuously released from stored waste. The DST and AWF tank ventilation systems were selected because the existing systems have demonstrated the necessary operational performance. The ventilation system is credited with providing a flow rate in the headspace that maintains the steady-state flammable gas concentration well below the LFL.

5.5.6 LCO 3.2.2—Single-Shell Tank Ventilation Systems-Active

5.5.6.1 Purpose. This control applies to the flammable gas deflagrations accident in Section 3.4.2.8 for the WRSS. The release of radioactive material without controls could exceed onsite risk guidelines and offsite risk guidelines for certain scenarios. Maintaining the active SST ventilation systems in conjunction with "Flammability Controls" (AC 5.9), "Ignition Controls" (AC 5.10), "Flammable Gas Monitoring Controls" (AC 5.11), and "Emergency Preparedness" (AC 5.14) reduces the risk of a flammable gas deflagration, but due to the technical uncertainties related to this hazard, and the nature of the analysis contained in the main text of the BIO, the risk reduction is unquantified. In addition, for "Tank Bump" accident (Section 3.4.2.11) and "Unfiltered Release" accident (Section 3.4.2.3), Tank 241-C-106 Ventilation System provides cooling capacity in conjunction with AC 5.26, "Tank 241-C-106 Waste Temperature Controls."

5.5.6.2 Derivation Criteria. This control was selected because it took credit for an existing system that had demonstrated the necessary operational performance. Although the historical requirements related to active ventilation of the SSTs with active ventilation systems were not established to control flammable gases, available gas sample results indicate that flammable gas concentrations in all sampled tanks are less than 5% of the LFL. These controls require near-constant operation of the exhausters for the SSTs with active ventilation systems. Therefore, one of the key elements of the flammable gas control strategy is the use of currently installed active ventilation systems on the tanks to dilute and remove flammable gases that are continuously released from stored waste. The ventilation system is credited with maintaining the steady-state flammable gas concentration well below the LFL.

5.5.7 LCO 3.2.6—Primary Tank Leak Detection Systems

5.5.7.1 Purpose. This control is applicable to two accident scenarios: flammable gas deflagrations in Section 3.4.2.8, and surface leak resulting in a pool in Section 3.4.2.15 for the WRSS. For flammability scenarios the release of radioactive material without controls could exceed onsite risk guidelines and offsite risk guidelines for certain scenarios. Maintaining the primary tank leak detection systems in conjunction with the "DST and AWF Tank

Ventilation Systems" (LCO 3.2.1), "Flammability Controls" (AC 5.9), "Ignition Controls" (AC 5.10), "Flammable Gas Monitoring Controls" (AC 5.11), and "Emergency Preparedness" (AC 5.14) reduces risk but due to technical uncertainties related to this hazard, and the nature of the analysis contained in the main text of the BIO, the risk reduction is unquantified.

Based on the results of the analysis for the surface leak resulting in a pool, the release of radioactive material without controls could exceed the offsite and onsite radiological risk guidelines. Maintaining the primary tank leak detection systems in conjunction with the "Transfer Controls" (AC 5.12), "Transfer System Covers and Entry Doors" (LCO 3.1.1), "Transfer Leak Detection Systems" (LCO 3.1.3), "Emergency Preparedness" (AC 5.14), "Excavation Controls" (AC 5.17), "Transfer Pump Administrative Lock Controls" (AC 5.20), and "Transfer System Cover Removal Controls" (AC 5.22) reduces the consequences to meet the risk guidelines for offsite, and the onsite radiological consequences are still above the risk guidelines. Primary tank leakage detection controls are credited in the analysis to provide operators information on potential waste accumulation in the annulus from a transfer system leak. This allows termination of the transfer before the annulus overflows to produce a surface pool.

5.5.7.2 Derivation Criteria. The primary tank leak detection systems were selected as the controls because they took credit for an existing system that had demonstrated the necessary operational performance. The primary tank leak detection system consists of either a CAM that detects the presence of airborne radionuclides in the annulus ventilation exhaust stream or a conductivity probe leak detection system installed in the annulus between the primary and secondary tanks on DSTs and AWF tanks. The primary tank leak detection system will detect primary tank leakage as well as waste infiltration to the annulus.

5.5.8 LCS/LCO 3.3.1—Single-Shell Tank Waste Temperature Controls

5.5.8.1 Purpose. These controls for Tank 241-C-106 are required based on the accident analysis for a tank bump in Section 3.4.2.11, liner breach caused by steam between the liner and concrete shell in Tank 241-C-106 accident scenario in Section 3.4.2.12, and unfiltered release in Section 3.4.2.3. For the tank bump and liner breach accidents, consequences could exceed offsite and onsite radiological risk guidelines and exceed onsite toxicological guidelines. For the unfiltered release accident, consequences could exceed onsite radiological risk guidelines. Temperature controls for Tank 241-C-106 during and after WRSS operations to prevent an unfiltered release or a liner breach due to steam between the steel liner and concrete shell are included in AC 5.26, "Tank 241-C-106 Waste Temperature Controls." A liner breach because of steam under the liner could cause a rapid steam pressurization of the tank headspace. AC 5.26 establishes a new saturation temperature during and after WRSS operations to prevent a liner breach. An unfiltered release could occur because of overheating of the tank. Ventilation controls to inspect portions of the ventilation ductwork on Tank 241-C-106, to prevent an unfiltered release, are included in AC 5.25, Ventilation Controls."

The controls for waste temperature prevent exceeding temperatures at which tank bumps (including steam release events) could occur. Temperature controls reduce the probability of the accident. The waste temperature controls consist of waste temperature limits and monitoring. The monitoring systems provide operators with information on waste temperatures in tanks susceptible to a tank bump, and alert them to take actions necessary to prevent exceeding temperatures at which tank bumps can occur. Programmatic controls for the temperature monitoring systems in AC 5.19 are discussed in Section 5.5.21.

This control is closely associated with "SST Ventilation Systems-Active" (LCO 3.2.2). The active ventilation system for Tank 241-C-106 is one method to control waste temperature by removing heat from the tank headspace.

This control is also associated with "Transfer Controls" (AC 5.12). Transfer controls are imposed during WRSS operations to ensure that planned transfer parameters such as level and heat generation rate are consistent with existing tank conditions.

5.5.8.2 Derivation Criteria. Waste temperature controls were selected because temperature is the parameter of concern, is under the control of operations, and is monitored with existing systems. In addition, implementation of temperature controls minimizes modifications needed to administrative procedures, as the process for monitoring temperatures is already a part of existing procedures. Temperature can be controlled by a variety of methods (e.g., ventilation, engineered heat removal, limiting activities in the tank).

5.5.9 LCS/LCO 3.3.2—Double-Shell Tank and Aging Waste Facility Tank Waste Temperature Controls

5.5.9.1 Purpose. These controls for Tank 241-AY-102 are required based on the accident analyses for a tank bump in Section 3.4.2.11 (in this addendum) and unfiltered release in Section 3.4.2.3 (in this addendum). For the tank bump accident, consequences could exceed offsite and onsite radiological risk guidelines and onsite toxicological risk guidelines. For the unfiltered release accident, consequences could exceed onsite risk guidelines. An unfiltered release could occur because of overheating of the tank. Ventilation controls for Tank 241-AY-102 to prevent a tank bump (and unfiltered release) are included in AC 5.25, "Ventilation Controls."

The controls for waste temperature prevent exceeding temperatures at which tank bumps (including steam release events) could occur. Temperature controls reduce the probability of the accident. The waste temperature controls consist of waste temperature limits and monitoring. The monitoring systems provide operators information on waste temperatures in tanks susceptible to a tank bump, and alert them to take actions necessary to prevent exceeding temperatures at which tank bumps can occur. Programmatic controls for the temperature monitoring systems in AC 5.19 are discussed in Section 5.5.21.

This control is closely associated with "DST and AWF Tank Ventilation Systems" (LCO 3.2.1), and "Tank 241-AY-102 Annulus Ventilation System" (LCO 3.3.3). The active ventilation systems for Tank 241-AY-102 are the primary method to control waste temperature by removing heat from the tank headspace, sides, and bottom.

This control is also associated with "Transfer Controls" (AC 5.12). Transfer controls are imposed during WRSS operations to ensure that planned transfer parameters such as level and heat generation rate are consistent with existing tank conditions.

5.5.9.2 Derivation Criteria. Waste temperature controls were selected because temperature is the parameter of concern, is under the control of operations, and is monitored with existing systems. In addition, implementation of temperature controls minimizes modifications needed to administrative procedures, as the process for monitoring temperatures is already a part of existing procedures. Temperature can be controlled by a variety of methods (e.g., ventilation, engineered heat removal, limiting activities in the tank).

5.5.10 LCO 3.3.3-Tank 241-AY-102 Annulus Ventilation System

5.5.10.1 Purpose. This control for tank 241-AY-102 is required based on the accident analyses for a tank bump in Section 3.4.2.11 and unfiltered release in Section 3.4.2.3. For the tank bump accident, consequences could exceed offsite and onsite radiological risk guidelines and onsite toxicological risk guidelines. For the unfiltered release accident, consequences could exceed onsite radiological risk guidelines. An unfiltered release could occur because of overheating of the tank. Ventilation controls for Tank 241-AY-102 to prevent a tank bump (and unfiltered release) are included in AC 5.25, "Ventilation Controls."

The controls for waste temperature (LCO 3.3.2) prevent exceeding temperatures at which tank bumps (including steam release events) could occur. Temperature controls reduce the probability of the accident to within acceptable offsite and onsite risk guidelines. The waste temperature controls consist of waste temperature limits and monitoring. The annulus ventilation system provides a means to control waste temperature. The monitoring systems provide operators information on waste temperatures in tanks susceptible to a tank bump, and alert them to take actions necessary to prevent exceeding tank bump, and alert them to take actions necessary to prevent exceeding temperatures at which tank bumps can occur. Programmatic controls for the temperature monitoring systems in AC 5.19 are discussed in Section 5.5.21.

This control is closely associated with "DST and AWF Tank Ventilation Systems" (LCO 3.2.1). The active ventilation systems for Tank 241-AY-102 are the primary method to control waste temperature by removing heat from the tank headspace, sides, and bottom.

This control is also associated with "Transfer Controls" (AC 5.12). Transfer controls are imposed during WRSS operations to ensure that planned transfer parameters such as level and heat generation rate are consistent with existing tank conditions.

5.5.10.2 Derivation Criteria. This control is selected because the annulus ventilation system is used to control the temperature of the waste in Tank 241-AY-102. Temperature is the parameter of concern, is under the control of operations, and is monitored with existing systems. Temperature can be controlled by a variety of methods (e.g., ventilation, engineered heat removal, limiting activities in the tank).

5.5.11 AC 5.7—Nuclear Criticality Safety

5.5.11.1 Purpose. This control protects the accident analysis assumptions of the nuclear criticality accident in Section 3.4.2.1 for the WRSS. The bounding nuclear criticality accident is considered beyond extremely unlikely, therefore a quantitative accident analysis was not performed. Initial assumptions that were key to this conclusion were identified. The controls protect these initial condition assumptions.

5.5.11.2 Derivation Criteria. Several initial conditions were noted in the accident analysis. The controls included in the TSR represent those initial conditions necessary to protect key analysis assumptions, specifically, plutonium concentration subcriticality limit. An AC was appropriate because the controls apply to documenting criticality limits and controls in Criticality Safety Evaluation Reports and implementation in Criticality Prevention Specifications and procedures which are not under the direct control of the tank farm operator.

A nuclear criticality program is also required per DOE 5480.22, Section 9.e.(5) as one of the standard ACs. This control meets the intent of that requirement.

5.5.12 AC 5.9—Flammability Controls

5.5.12.1 Purpose. This control is required for the flammable gas deflagration accident in Section 3.4.2.8 for the WRSS. However, no change to this BIO control was identified as a result of the WRSS accident analysis. Based on the results of the analysis for the flammable gas deflagrations in DSTs, the release of radioactive material without controls could exceed onsite risk guidelines and offsite risk guidelines for certain scenarios. Maintaining the flammability controls in conjunction with the "DST and AWF Tank Ventilation Systems" (LCO 3.2.1), "Primary Tank Leak Detection Systems" (LCO 3.2.6), "Ignition Controls" (AC 5.10), "Flammable Gas Monitoring Controls" (AC 5.11), and "Emergency Preparedness" (AC 5.14) reduces risk but due to technical uncertainties related to this hazard, and the nature of the analysis contained in the main text of the BIO, the risk reduction is unquantified.

Based on the results of the analysis for the flammable gas deflagrations in SSTs, the release of radioactive material without controls could exceed onsite risk guidelines and offsite risk guidelines for certain scenarios. Maintaining the flammability controls in conjunction with the active SST ventilation systems (LCO 3.2.2), "Ignition Controls" (AC 5.10), "Flammable Gas Monitoring Controls" (AC 5.11), and "Emergency Preparedness" (AC 5.14) reduces risk but due to technical uncertainties related to this hazard, and the nature of the analysis contained in the main text of the BIO, the risk reduction is unquantified.

5.5.12.2 Derivation Criteria. The administrative program for flammability controls is credited in the reduction of frequency of a flammable gas deflagration. This control identifies flammable gas Facility Group assignments for Tank 241-AY-102 and Tank 241-C-106.

5.5.13 AC 5.10—Ignition Controls

5.5.13.1 Purpose. This control applies to several WRSS accidents: fire in contaminated area in Section 3.4.2.4, flammable gas deflagrations in Section 3.4.2.8, organic solvent fire in Section 3.4.2.9, and in-tank fuel fire/deflagration in Section 3.4.2.10.

Based on the results of the analysis for the fire in contaminated area, the release of radioactive and toxic material without controls could exceed onsite risk guidelines. Maintaining the ignition controls in conjunction with "Emergency Preparedness" (AC 5.14) reduces the accident frequency below the risk guidelines.

Based on the results of the analysis for the flammable gas deflagrations, the release of radioactive material without controls could exceed onsite and offsite risk guidelines for most cases. Maintaining the ignition controls in conjunction with the "DST and AWF Tank Ventilation Systems" (LCO 3.2.1), the active SST ventilation systems (LCO 3.2.2), "Primary Tank Leak Detection Systems" (LCO 3.2.6), "Flammability Controls" (AC 5.9), "Flammable Gas Monitoring Controls" (AC 5.11), and "Emergency Preparedness" (AC 5.14) reduces risk but due to technical uncertainties related to this hazard, and the nature of the analysis contained in the main text of the BIO, the risk reduction is unquantified.

Based on the results of the organic solvent fire analysis, the release of radioactive and toxic materials without controls could exceed onsite risk guidelines. Maintaining the ignition controls in conjunction with "Transfer Controls" (AC 5.12), "Emergency Preparedness" (AC 5.14), and "HEPA Filter Controls" (AC 5.18) does not reduce the accident frequency or consequences below the risk guidelines for all scenarios.

Based on the results of the analysis for the in-tank fuel fire/ deflagration, the release of radioactive and toxic materials without controls could exceed onsite risk guidelines. Maintaining the ignition controls in conjunction with Transfer Controls" (AC 5.12), "Emergency Preparedness" (AC 5.14), and "HEPA Filter Controls" (AC 5.18) does not reduce the frequency or consequences of the event to within risk guidelines.

5.5.13.2 Derivation Criteria. The administrative program to control ignition sources is credited primarily in the reduction of frequency of the accident scenarios for which the control was selected. The controls apply to fire in contaminated area, reducing the frequency to within risk guidelines; to flammable gas deflagrations, reducing the frequency; to organic solvent fire, reducing the frequency and protecting the facility worker with significant Defense-in-Depth key elements; and to in-tank fuel fire/deflagration, reducing the frequency and protecting the facility worker with significant Defense-in-Depth key elements.

5.5.14 AC 5.11—Flammable Gas Monitoring Controls

5.5.14.1 Purpose. This control applies to the flammable gas deflagration accident analysis presented in Section 3.4.2.8. The results of the analysis for the flammable gas deflagrations in DSTs indicate that the release of radioactive material without controls could exceed onsite risk guidelines and offsite risk guidelines for certain scenarios. Maintaining the flammable gas monitoring controls in conjunction with the "DST and AWF Tank Ventilation Systems" (LCO 3.2.1), "Primary Tank Leak Detection Systems" (LCO 3.2.6), "Ignition Controls" (AC 5.10), "Flammability Controls" (AC 5.9), and "Emergency Preparedness" (AC 5.14) reduces risk but due to technical uncertainties related to this hazard, and the nature of the analysis contained in the main text of the BIO, the risk reduction is unquantified.

Based on the results of the analysis for the flammable gas deflagrations in SSTs, the release of radioactive material without controls could exceed onsite risk guidelines and offsite risk guidelines for certain scenarios. Maintaining the flammable gas monitoring controls in conjunction with the active SST ventilation systems (LCO 3.2.2), "Ignition Controls" (AC 5.10), "Flammability Controls" (AC 5.9), and "Emergency Preparedness" (AC 5.14) reduces risk but due to technical uncertainties related to this hazard, and the nature of the analysis contained in the main text of the BIO, the risk reduction is unquantified.

5.5.14.2 Derivation Criteria. Flammable gas monitoring is used as part of the flammable gas hazard management strategy. These controls prevent the introduction of an uncontrolled or errant spark source into a location when and where flammable gas concentrations are above a level of concern for a fire, deflagration, or detonation. Therefore, flammable gas monitoring is required during manned activities, during certain unmanned activities, and upon loss of ventilation. These controls are credited in reducing the frequency of the flammable gas deflagration scenario and represents activities currently in progress in the tank farms.

The applicable key elements of AC 5.11 for WRSS are (a), (b) and (c). Key element (d) protects a key assumption associated with double-contained receiver tanks and does not apply to WRSS.

Key element (e) represents ignition control methodologies specific for WRSS operations. These actions are added because of the continued potential significant consequences of the flammable gas deflagration accident. The actions specified do not quantitatively control the consequences to below risk guidelines, but enhance facility worker protection.

5.5.15 AC 5.12–Transfer Controls

5.5.15.1 Purpose. This control applies to several WRSS accidents. The controls apply to organic solvent fire in Section 3.4.2.9, in-tank fuel fire in Section 3.4.2.10, tank bump in Section 3.4.2.11, liner breach due to steam between steel liner and concrete shell in Tank 241-C-106 in Section 3.4.2.12, subsurface leak remaining subsurface in Section 3.3.2.13, subsurface leak resulting in pool in Section 3.4.2.14, surface leak resulting in a pool in Section 3.4.2.15, and spray leak from structure in Section 3.4.2.16.

Based on the results of the in tank fuel fire and organic solvent fire analyses, the release of radioactive and toxic materials without controls could exceed onsite risk guidelines. Maintaining the transfer controls in conjunction with "Ignition Controls" (AC 5.10), "Emergency Preparedness" (AC 5.14), and "HEPA Filter Controls" (AC 5.18) does not reduce the accident frequency or consequences below the risk guidelines for all scenarios. The transfer controls include a compatibility evaluation to minimize the potential for introducing organic solvents into tanks.

Based on the results of the tank bump analysis, the release of radioactive material without controls could exceed onsite risk guidelines and offsite radiological risk guidelines. Maintaining the transfer controls (which require compatibility analysis and periodic evaluation of the amount of the heat-generating material transferred) in conjunction with "DST and AWF Ventilation Systems" (LCO 3.2.1), "SST Waste Temperature Controls" (LCO 3.3.1), "DST and AWF Tank Waste Temperature Controls" (LCO 3.3.2), "Tank 241-AY-102 Annulus Ventilation System" (LCO 3.3.3), "Ventilation Controls" (AC 5.25), "Process Instrumentation and Measuring and Test Equipment" (AC 5.19), and "Tank 241-C-106 Waste Temperature Controls" (AC 5.26) prevents the accident. The transfer controls include a compatibility evaluation to ensure that transfers do not produce conditions in a tank (e.g., high-sludge level and high heat load) so that, if tank cooling were inoperable, there would be a possibility of creating a tank bump before cooling was restored. The transfer controls also include a material balance after each sluicing batch of 12 hours maximum duration during sluicing to ensure that planned transfer parameters, such as level and heat generation rate, are consistent with existing tank conditions.

Based on the results of the liner breach due to steam between steel liner and concrete shell in Tank 241-C-106 accident, the consequences without controls could exceed onsite and offsite radiological risk guidelines and onsite toxicological risk guidelines. Maintaining transfer controls in conjunction with the "SST Waste Temperature Controls" (LCO 3.3.1), "Process Instrumentation and Measuring and Test Equipment" (AC 5.19), and

"Tank 241-C-106 Waste Temperature Controls" (AC 5.26) reduces the consequences below the risk guidelines. The transfer controls include a requirement to ensure that the final tank state is within analyzed conditions.

Based on the results of the subsurface leak remaining subsurface analysis, the release of radioactive material without controls exceeds onsite radiological risk guidelines. Maintaining the transfer controls in conjunction with "Transfer Leak Detection Systems" (LCO 3.1.3), "Encasement Seal Loop Controls" (AC 5.13) and "Transfer Pump Administrative Lock Controls" (AC 5.20), "Excavation Controls" (AC 5.17), and the design feature of the double-encased pipe reduce the consequences below the risk guidelines. The transfer controls include material balances, configuration management, independent route verification, and establishing communications between the control rooms for Tanks 241-C-106 and 241-AY-102. These controls minimize the potential for a misrouting and facilitate the detection of leakage.

Based on the results of the subsurface leak resulting in a pool analysis, the release of radioactive material without controls could exceed the offsite and onsite radiological risk guidelines. Maintaining the transfer controls in conjunction with "Transfer Leak Detection System," (LCO 3.1.3) and "Emergency Preparedness" (AC 5.14) reduces the consequences to meet the risk guidelines for offsite, and the onsite radiological consequences are still above the risk guidelines. The transfer controls include material balances, configuration management, independent route verification, and establishing communications between the control rooms for Tanks 241-C-106 and 241-AY-102. These controls minimize the potential for a misrouting and facilitate the detection of leakage.

Based on the results of the analysis for the surface leak resulting in a pool, the release of radioactive material without controls could exceed the offsite and onsite radiological risk guidelines. Maintaining the transfer controls in conjunction with the "Transfer System Covers and Entry Doors" (LCO 3.1.1), "Transfer Leak Detection Systems" (LCO 3.1.3), "Primary Tank Leak Detection Systems" (LCO 3.2.6), "Emergency Preparedness" (AC 5.14), "Excavation Controls" (AC 5.17), "Transfer Pump Administrative Lock Controls" (AC 5.20), and "Transfer System Cover Removal Controls" (AC 5.22) reduces the consequences to meet the risk guidelines for offsite, and the onsite radiological consequences are still above the risk guidelines. The transfer controls include material balances, configuration management, vehicle restrictions, cap/blanks on open nozzles, and establishing communications between the control rooms for Tanks 241-C-106 and 241-AY-102. These controls minimize the potential for a misrouting, overflows from a misrouting, and facilitate the detection of leakage.

Based on the results of the spray leak from structure analysis, the release of radioactive material without controls exceeds the offsite and onsite radiological risk guidelines and onsite toxicological risk guidelines. Maintaining the transfer controls in conjunction with the "Transfer System Covers and Entry Doors" (LCO 3.1.1), "Ventilation Stack CAM Interlock Systems" (LCO 3.1.4), "Encasement Seal Loop Controls" (AC 5.13), "Transfer Pump Administrative Lock Controls" (AC 5.20), and "Transfer System Cover Removal Controls" (AC 5.22) reduces the consequences below the risk guidelines. The transfer controls include configuration management, vehicle restrictions, and

independent route verification. These controls minimize the potential for a misrouting, facilitate the detection of leakage and protect the transfer lines from vehicle damage.

5.5.15.2 Derivation Criteria. The transfer controls were selected to reduce consequences below risk guidelines where possible, reflect current operational practices, protect the analysis assumptions, and use existing systems to the maximum extent possible.

5.5.16 AC 5.13—Encasement Seal Loop Controls

5.5.16.1 Purpose. This reduces the consequences of a leak in the primary piping by ensuring that material is directed into the pit and activates transfer leak detection. This protects key assumptions in the following two accidents: subsurface leak remaining subsurface (Section 3.4.2.13) and spray leak from structure (Section 3.4.2.16). This control ensures that if a leak occurred in primary piping it would be directed toward pit leak detection, and would not pressurize the encasement, causing a spray through abovegrade encasement test riser extensions or WRSS transfer system extensions.

5.5.16.2 Derivation Criteria. Leak detection, cover blocks, and transfer controls are the primary controls for the noted accidents. This control is specific since it protects a key assumption of plant configuration in the analysis; namely, that leaked material will be detected or that it will not cause pressurized conditions.

5.5.17 AC 5.14—Emergency Preparedness

5.5.17.1 Purpose. This control is required to respond to leaks on the surface to limit pool sizes per the subsurface leak resulting in a pool accident as specified in Section 3.4.2.14. This is the only accident where emergency response is required to reduce consequences. This control works together with LCO 3.1.3, "Transfer Leak Detection Systems" and AC 5.12, "Transfer Controls," to ensure minimal pool size and proper emergency response.

The control also represents a significant Defense-in-Depth item that is justifiably elevated to control status for mitigating the following pool and fire accidents: "Fire in Contaminated Area" (Section 3.4.2.4), "Flammable Gas Deflagrations" (Section 3.4.2.8), "Organic Solvent Fire" (Section 3.4.2.9), "In-Tank Fuel Fire/Deflagration" (Section 3.4.2.10), and "Surface Leak Resulting in a Pool" (Section 3.4.2.15). Because this control was originally a Defense-in-Depth item for these accidents, actual mitigation results are not quantified in the analyses.

5.5.17.2 Derivation Criteria. The subsurface leak resulting in a pool accident takes credit for evacuation of personnel from the vicinity of the pool. This activity is a programmatic response rather than an operator-directed event. It involves the coordination of several operational organizations and maintenance crafts, thus making emergency preparedness a logical programmatic control.

This control is also applied to those accidents where site conditions and controls degrade. Fire is an example of a situation where emergency responses activate facility worker protection controls (e.g., safety equipment) and protect Site personnel through fire-fighting and evacuation procedures. This control was selected for all of the fire-related accidents because, in a fire event, it is necessary to protect personnel before attempting to determine cause and subsequent actions. Likewise, for waste leak pools on the surface, this control helps isolate personnel to minimize exposures to radioactive and hazardous material. Lastly, this control requires the development of responses to earthquakes, thus ensuring proper protection of personnel and property and the public when earthquakes produce indeterminate damage or disrupt normal communications and safety controls.

5.5.18 AC 5.16–Dome Loading Controls

5.5.18.1 Purpose. This control minimizes the risk of dropping objects through pit floors and tank domes. This relates to the tank failure due to excessive loads (Section 3.4.2.6). Based on the results of the tank failure due to excessive loads analysis, the release would exceed the onsite radiological and toxicological guidelines without controls. The dome loading controls prevent the accident scenario from occurring.

5.5.18.2 Derivation Criteria. The controlling of lifted loads was detailed as an AC because the varied methodologies for control are limited to the use of streamers (tag lines), temporary barriers to restrict lift height, and the need for restrictions over certain vessels. Because the control requires several parameters, and because of the conservatisms in the analysis, exceeding 6 m (20-ft) does not directly cause the accident (e.g., no credit taken for piping or pumps within the pit). This is consistent with several of the criteria noted in Section 5.3.2.1. This control was chosen because of its minimal impact on operational activities.

The dome loading controls in AC 5.16 are a realistic summary. For example, there are no specific controls on snow or ash loading because these were noted in the analysis as being insignificant. Of great value for the analysis, however, is the requirement for baselining and managing changing loads. This detail protects the assumptions of the analysis.

5.5.19 AC 5.17–Excavation Controls

5.5.19.1 Purpose. This control protects the facility worker, as well as onsite and offsite personnel, from spray or pool consequences while excavating piping systems during a transfer. The WRSS accidents related to this control are subsurface leak remaining subsurface (Section 3.4.2.13), surface leak resulting in a pool (Section 3.4.2.15) and spray leak from an underground waste transfer line (Section 3.4.2.17). This accident is associated with the spray and pool scenarios, and the control strategy is preventive to minimize the probability of the excavation accident and mitigative to reduce consequences below risk guidelines.

5.5.19.2 Derivation Criteria. The control represents a broad selection of current operational activities to cover the varied contingencies during excavation activities. It does not rely solely upon an excavation permit process, since transfers could be initiated after proper completion of permitting. These activities involve a variety of field personnel and include several activities prior to actual excavation, thus qualifying this control as administrative.

5.5.20 AC 5.18—High-Efficiency Particulate Air Filter Controls

5.5.20.1 Purpose. These controls apply to several accidents for the WRSS. The controls apply to HEPA filter failure-exposure to high temperature or pressure (Section 3.4.2.2), unfiltered release (Section 3.4.2.3), flammable deflagrations (Section 3.4.2.8), organic solvent fire (Section 3.4.2.9) and in-tank fuel fire/deflagration (Section 3.4.2.10) to limit the radioactive inventory available for release from the HEPA filters that is assumed in the accident analysis.

Based on the results of the HEPA filter failure analysis and unfiltered release analysis, the release of radioactive material without controls could exceed onsite risk guidelines for DSTs and SSTs with active ventilation. The consequences are reduced by: (1) maintaining the HEPA filter and prefilter housing contact dose radiation level at less than or equal to 200 mrem/h; verifying that the radiological dose contribution of the 296-C-006 HEME and HEMF is below 100 mrem/h; requiring the 241-AZ-702 system HEGA filters to be changed before the upstream HEPA filter in the associated filter train has been replaced 20 times, or upon indication of degraded HEPA filter performance; and performing efficiency testing of the HEPA filters upstream of the HEGA filters, and (2) an operable CAM interlock, per LCO 3.1.4, that stops the ventilation system.

Based on the results of the organic solvent fire analysis and in-tank fuel fire/deflagration analysis, the release of radioactive material without controls could exceed onsite risk guidelines. Monitoring the ventilation system filter dose rates in conjunction with "Ignition Controls" (AC 5.10), "Transfer Controls" (AC 5.12), and "Emergency Preparedness" (AC 5.14) does not reduce the accident frequency or consequences below the risk guidelines for all scenarios.

5.5.20.2 Derivation Criteria. The HEPA filter control on radioactive loading was selected because it was a key analysis assumption and reflected current practices for filter monitoring and replacement. The control also applied to multiple accidents and reduced the consequence to within acceptable risk guidelines where possible.

5.5.21 AC 5.19—Process Instrumentation and Measuring and Test Equipment

5.5.21.1 Purpose. This provides a support control for the process instrumentation and measuring and test equipment used to verify that process

parameters comply with the TSRs when specific instrumentation and associated surveillances are not included in the TSR for the WRSS. This provides controls for the instrumentation used to monitor temperatures to comply with the tank bump analysis (Section 3.4.2.11), unfiltered release (Section 3.4.2.3) and the liner breach due to steam between steel liner and concrete shell in Tank 241-C-106 (Section 3.4.2.12), as well as instrumentation used to verify process parameters for the ACs in the TSR. This control on the process instrumentation and measuring and test equipment ensures that process parameters are properly monitored.

5.5.21.2 Derivation Criteria. This control was included because for some process parameters included in the TSR, it is not essential to specify the particular instrumentation or measuring equipment to demonstrate compliance with the process parameter, provided the instrumentation or equipment used to monitor the parameter is maintained. If the analysis credits a specific process parameter (e.g., temperature) but does not require specific instrumentation (e.g., credit is not taken for interlock actuation upon reaching the setpoint), then any instrumentation or measuring equipment can be used, provided it has the capability to monitor the required parameter. This support control was selected because it provides operational flexibility to use various instrumentation and equipment to measure TSR parameters, provided it complies with requirements of AC 5.19 while ensuring the safety functions assumed in the accident analysis are met.

5.5.22 AC 5.20—Transfer Pump Administrative Lock Controls

5.5.22.1 Purpose. The control to establish a program for administrative lock controls on waste transfer pumps is prompted by the WRSS accident analysis for a subsurface leak remaining subsurface (Section 3.4.2.13), surface leak resulting in a pool (Section 3.4.2.15), and spray leak from structure (Section 3.4.2.16).

When active transfer pumps are under administrative lock, the potential for pressurizing the transfer system is significantly decreased. This greatly reduces the risk of all three accidents identified above, as the motive force behind the accidents (i.e., a pressurized system) is eliminated.

This control is closely associated with a number of other controls: "Transfer System Covers" (LCO 3.1.1), and "Transfer Leak Detection Systems" (LCO 3.1.3). These controls are established based on the potential for leaks caused by the pressurization of the waste transfer system. Since leaks are improbable when their motive force is removed, these controls are relaxed (i.e., not applicable) when all physically connected transfer pumps are administratively locked per AC 5.20.

5.5.22.2 Derivation Criteria. An AC was selected because it is applicable to multiple accident scenarios, and is implemented and monitored similar to other lock programs onsite. This control reduces implementation costs, and allows operational flexibility, because implementation of this control allows relaxation of other transfer system leak-related controls while transfer pumps are administratively locked.

5.5.23 AC 5.22—Transfer System Cover Removal Controls

5.5.23.1 Purpose. The Transfer System Cover removal controls program is applicable to a surface leak resulting in a pool (Section 3.4.2.15), and spray leak from structure (Section 3.4.2.16). Without controls, the surface leak resulting in a pool and the spray leak have unacceptable onsite and offsite consequences.

When two or more closed valves in series separate the waste transfer route and a transfer system structure, the potential for waste leakage through the valves with sufficient pressurization of the piping to cause significant leakage within the structure is minimal. This greatly reduces the probability of the accidents identified above from occurring within the structure. In this situation, an alternative (and less stringent) control, using the Transfer System Cover removal control program, is allowed in lieu of the Transfer System Cover control.

5.5.23.2 Derivation Criteria. This control was selected because it allows operational flexibility through the relaxation of Transfer System Cover operability controls when a minimum of two closed valves in series separates the transfer route and the structure of concern. Because it involves monitoring of varied configurations rather than strict operability (though this is the prime definition for transfer cover operability), an AC format was selected.

5.5.24 AC 5.23—Caustic Transfer Controls

5.5.24.1 Purpose. This control minimizes the risk of a caustic spray leak. The caustic spray leak program is applicable to the accident analysis for a caustic spray leak (Section 3.4.2.5) for the WRSS. The caustic spray leak, when not controlled by TSR controls, is assumed to have onsite and offsite toxicological consequences.

Requiring sodium hydroxide cargo tanks to provide proof of DOT specification and restricting the operating pressure will decrease the potential for the cargo tank to rupture due to overpressurization. This reduces the probability of the accident occurring. Requiring traffic barriers also reduces the probability of the accident occurring.

5.5.24.2 Derivation Criteria. This control was selected because it represents a minimal cost to implement and it does not involve the installation of new equipment.

5.5.25 AC 5.25—Ventilation Controls

5.5.25.1 Purpose. The ventilation controls program is derived from the accident analyses for an unfiltered release (Section 3.4.2.3), and tank bump (Section 3.4.2.11) for the WRSS. Without controls, the unfiltered release exceeds the onsite radiological evaluation guidelines, and the tank bump

exceeds the onsite and offsite radiological evaluation guidelines and onsite toxicological evaluation guidelines.

With a visual inspection of aboveground recirculation ventilation ductwork for Tank 241-C-106 every 24 hours during sluicing, the potential for an unfiltered release through damaged ductwork is minimal. This greatly reduces the probability of the unfiltered release accident from occurring. In this situation, the control prevents continued operation of a breached duct found during sluicing. This control applies only after the new Tank 241-C-106 ventilation system (296-C-006) is installed.

With the periodic determination of the cooling capacity requirements for Tank 241-AY-102 and provision of the necessary cooling capability, the potential for a tank bump due to exceeding the saturation temperature of the waste is prevented. This greatly reduces the probability of the tank bump accident from occurring. In this situation, the control protects the temperature limits in LCS/LCO 3.3.2, "DST and AWF Tank WASTE Temperature Controls," which prevents the saturation temperature of the waste from being reached because the necessary cooling to maintain temperatures below the saturation temperature is being provided. This control is applicable only to Tank 241-AY-102 after 0.61 m (2 ft) of waste have been added to the tank by the WRSS.

5.5.25.2 Derivation Criteria. The ventilation inspection control was selected because it took credit for an existing program that demonstrates the necessary operational performance. The visual inspection of the ventilation ductwork will identify damage or leaks (e.g., condensate dripping) so that WRSS operations can be stopped by preventing continued use of a breached duct found during sluicing. This control applies only to Tank 241-C-106 after the 296-C-006 ventilation system is installed and sluicing is in progress.

The cooling capacity control was selected because it allows for determination of the cooling requirements for Tank 241-AY-102 based on the heat generation rate conditions determined in the tank and then provides the necessary cooling requirements. The annulus ventilation system will typically provide the necessary cooling but, based on the heat generation rate determined, it is anticipated that operation of the annulus ventilation system will only be required when more than 2 ft of waste has been transferred to Tank 241-AY-102.

5.5.26 AC 5.26—Tank 241-C-106 Waste Temperature Controls

5.5.26.1 Purpose. The controls for SST waste temperature during WRSS operations are required based on the WRSS accident analysis for liner breach due to steam between the steel liner and the concrete shell in Tank 241-C-106 (Section 3.4.2.12) and the unfiltered release due to overheating (Section 3.4.2.3). This control also applies to Tank 241-C-106 for WRSS tank bump (Section 3.4.2.11) during and after sluicing. The bounding accidents for tank bump and liner breach exceeded both onsite and offsite radiological risk guidelines, and consequences were above onsite radiological risk guidelines for unfiltered release. Also, the tank bump and liner breach bounding accidents exceeded onsite toxicological risk guidelines.

5.5.26.2 Derivation Criteria. AC 5.26 replaces LCS/LCO 3.3.1 during and after sluicing operations. This control is designed to protect a more restrictive temperature limit for saturation conditions, to prevent a liner breach scenario. This limit varies with the hydrostatic head due to waste, therefore an AC program was determined to be most appropriate.

Waste temperature controls were selected because temperature, the parameter of concern, is under the control of operations and is monitored with existing systems. In addition, implementation of temperature controls minimizes modifications needed to administrative procedures, as the process for monitoring temperatures is already a part of existing procedures. Temperature can be controlled by a variety of methods (e.g., ventilation, engineered heat removal). The monitored temperatures can then be modelled to determine the maximum tank bottom temperatures.

Level monitoring is also under the control of operations and is observed with existing systems. Using the level detection system, the pressure at the tank bottom can be found, in order to determine the local saturation temperature of water.

5.6 DESIGN FEATURES

Design Features are those features not covered elsewhere in the TSRs and which, if altered or modified, would have a significant effect on safety. Design Features are normally permanently built-in features that do not require, or infrequently require, maintenance or surveillance and are normally not subject to change by Operations personnel. The categories of design features to be addressed in accordance with DOE 5480.22 include the following:

- Vital passive components, such as piping, vessels, supports, confinement structures, and containers
- Configuration and physical arrangement of the facility where safety is a concern including site characteristics, such as the locations of public access roads, collocated facilities, facility area boundaries, site boundaries, and distances to the nearest residences
- Building materials, if the safe operation of the facility depends on any component being constructed of a particular material.

Changes to Design Features are considered significant modifications. The unreviewed safety question process ensures that changes to Design Features are appropriately analyzed and controlled so that they do not adversely affect safe operation of the facility. The configuration management system that controls changes to Design Features is discussed in the main text of Section 4.15, "Configuration Management," of this BIO.

Design Features for TWRS facilities are included in the TSR document. Unique Design Features for the WRSS that, if altered or modified, would have a significant effect on safe operation are listed below. Descriptions of these Design Features are provided in Chapter 2.0 of this Addendum. Based on the criteria for Design Features in DOE 5480.22, passive features that are only

for environmental protection are not listed. Environmental features are, however, discussed in Chapter 3.0 of this Addendum. Radioactive and hazardous waste management control features are discussed in the main text of Section 4.6, "Radioactive and Hazardous Material Waste Management," of the BIO.

5.6.1 Waste Retrieval Sluicing System

Design Features for the WRSS include the following:

- Positive mechanical stops are provided on the remotely operated, hydraulically controlled sluicer in Tank 241-C-106 to limit nozzle travel to 115° vertically (0° reference is the nozzle pointed straight down). This prevents the sluice stream from impinging on an area above the tank liner and leaking into the liner from the top of the liner.

- Syphon protection (holes) is provided on the slurry distributor and the submersible sluice pump discharge lines within Tank 241-AY-102 to prevent a syphon when the slurry pumps or sluice pumps are shut down.

- The sluicer hose in Tank 241-C-106 is engineered to maintain structural integrity to prevent the hose from breaking off and causing a liner breach.

- The WASTE transfer pipe-in-pipe encasement confines leaks from the primary piping and channels waste leaked from the primary pipe to a transfer-associated structure where the leak can be detected. The encasement also provides outside protection against corrosion of the inside pipe.

- The weight of the removable plugs in cover blocks for the sluice slurry line flush connection pits on Tank 241-A4-102 exceeds the maximum lifting force caused by waste discharged from the open flush nozzle.

5.7 INTERFACES WITH TECHNICAL SAFETY REQUIREMENTS FROM OTHER FACILITIES

The TWRS Facility interfaces with other Hanford facilities are identified and discussed in Appendix B, "Facility and Process Description," of this BIO. TWRS programs are in place and are adequate to ensure that interactions with other facilities and their safety requirements do not affect the TWRS safety basis, and do not exceed the safety analyses requirements. There are no interface requirements that affect the WRSS safety basis.

Table 5-1. Hazard and Accident Analyses and Technical Safety Requirement Cross-Reference. (7 sheets)

Analyzed accident and BIO Addendum section	Technical Safety Requirement	Control basis
Nuclear Criticality (3.4.2.1)	AC 5.7 Nuclear Criticality Safety - Establish CPSs based on CSERs - Recovery actions if limits exceeded - Criticality training program	AC 5.7 provides for a criticality safety program as required by DOE 5480.22, Section 9.e.(5). Implementation of these controls protects the assumptions in the accident analysis to prevent a criticality from occurring Criticality limits and controls are documented in CSERs and implemented in CPSs through procedures. Criticality safety training is provided and procedures identify the recovery actions in the event the CPS requirements are not met
HEPA Filter Failure-Exposure to High Temperature or Pressure (3.4.2.2)	LCO 3.1.4 Ventilation Stack CAM Interlock Systems AC 5.18 HEPA Filter Controls - Periodic radiation surveillance - Replacement based on accumulation - Aerosol test upon installation (AWF 241-AZ-702) - Periodic aerosol test (AWF 241-AZ-702)	LCO 3.1.4 controls consequences of accident to meet onsite radiological risk guidelines. CAM interlock detects increasing radiological effluent releases and stops the ventilation exhaust fan within 10 minutes AC 5.18 protects radioactive loading assumptions on ventilation system filters in accident analysis
Unfiltered Release (3.4.2.3)	AC 5.25 Ventilation Controls - Visual inspection of aboveground recirculation ventilation ductwork for Tank 241-C-106 every 24 hours during sluicing (only applies after the 296-C-006 ventilation system is installed) TSR controls in BIO Addendum 1, Section 3.4.2.2 (HEPA Filter Failure) and 3.4.2.11 (Tank Bump) also apply	AC 5.25 prevents continued operation of a damaged recirculation ventilation duct on Tank 241-C-106 (only applies after the 296-C-006 ventilation system is installed)

Table 5-1. Hazard and Accident Analyses and Technical Safety Requirement Cross-Reference. (7 sheets)

Analyzed accident and BIO Addendum section	Technical Safety Requirement	Control basis
Fire in Contaminated Area (3.4.2.4)	AC 5.10 Ignition Controls - Vehicle fuel system protection - Physical barriers outside tank farms - Speed limit controls AC 5.14 Emergency Preparedness - Response procedures	AC 5.10 provides controls to lessen the probability of the accident. Vehicle controls prevent the rupture of a vehicle fuel system which may result in a fire in a contaminated area (e.g., open pit) AC 5.14 represents a significant Defense-in-Depth control that has been elevated to a TSR. It provides direction for fire response and recovery activities
Caustic Spray Leak (3.4.2.5)	AC 5.23 Caustic Transfer Controls - Plastic sleeving around delivery piping - Caustic delivery system transfer pressure ≤ 125 psig or below sodium hydroxide cargo tanks specified maximum allowable operating pressure whichever is lower - Piping thickness - Sodium hydroxide cargo tanks meet applicable DOT specifications - Traffic barriers shall surround the cargo tank (e.g., traffic cones or stanchions and chains)	AC 5.23 provides controls to reduce the consequences and probability of the accident TSR controls are established for plastic sleeving around delivery piping (≥ 4 mil thickness) to prevent or mitigate the consequences of a spray leak. The limitations on the caustic delivery system pressure and piping thickness for caustic delivery reduces the consequences of a leak by reducing the leak rate. NaOH cargo tanks must meet applicable DOT inspections to minimize the potential for a tanker leak. Traffic barriers reduce the probability of a caustic leak
Tank Failure Due to Excessive Loads (3.4.2.6)	AC 5.16 Dome Loading Controls - Limits on load height - Hanford Site Hoisting and Rigging Manual for critical lifts - Uniform and concentrated load limits	AC 5.16 provides controls to prevent the accident and protect the onsite worker These controls limit the potential for a load damaging a waste retaining structure, resulting in an uncontrolled release
Tank Failure Due to Excessive Vacuum (3.4.2.7)	None	No credible tank failure and collapse due to an excessive vacuum scenario has been identified
Flammable Gas Deflagrations (3.4.2.8)	LCO 3.2.1 DST and AWF Tank Ventilation Systems LCO 3.2.2 SST Ventilation Systems - Active LCO 3.2.6 Primary Tank Leak Detection Systems AC 5.9 Flammability Controls AC 5.10 Ignition Controls AC 5.11 Flammable Gas Monitoring Controls AC 5.14 Emergency Preparedness - Response procedures AC 5.18 HEPA Filter Controls - Periodic radiation surveillance - Replacement based on accumulation	LCO 3.2.1, LCO 3.2.2, LCO 3.2.6, AC 5.9, AC 5.10,and AC 5.11 provide controls to lessen the probability of accident AC 5.14 represents a significant Defense-in-Depth control that has been elevated to a TSR. It provides direction for fire response and recovery activities AC 51.8 protects radioactive loading assumptions on ventilation system filters in accident analysis

Table 5-1. Hazard and Accident Analyses and Technical Safety Requirement Cross-Reference. (7 sheets)

Analyzed accident and BIO Addendum section	Technical Safety Requirement	Control basis
Organic Solvent Fire (3.4.2.9)	AC 5.10 Ignition Controls - Lightning (stop intrusive work, secure elevated equipment) - Barrier for hot metal during flame cutting - Vehicle fuel system protection - Physical barriers outside tank farms - Speed limit controls AC 5.12 Transfer Controls - Evaluate impact on organic solvent transfer AC 5.14 Emergency Preparedness - Response procedures AC 5.18 HEPA Filter Controls - Periodic radiation surveillance - Replacement based on accumulation - Aerosol test upon installation (AWF 241-AZ-702) - Periodic aerosol test (AWF 241-AZ-702)	AC 5.10 and AC 5.12 provide controls to lessen probability of accident, and AC 5.10 protects the facility worker with significant Defense-in-Depth key elements Ignition controls minimize the initiators (lightning, hot metal, and vehicle fuel fire) with sufficient energy to ignite an organic solvent fire AC 5.14 represents a significant Defense-in-Depth control that has been elevated to a TSR. It provides direction for fire response and recovery activities AC 5.18 protects radioactive loading assumptions on ventilation system filters in accident analysis
In-Tank Fuel Fire/Deflagration (3.4.2.10)	Note: This accident credits the same controls as the Organic Solvent Fire (3.4.2.9) above.	--

6.0 PREVENTION OF INADVERTENT CRITICALITY

This chapter contains information relevant to prevention of inadvertent criticality at Tank Waste Remediation System facilities as a result of the activities associated with the Waste Retrieval Sluicing System (WRSS).

6.1 REQUIREMENTS

See the main text of HNF-SD-WM-BIO-001, *Tank Waste Remediation System Basis for Interim Operation* (BIO) for requirements.

6.2 FACILITY IMPLEMENTATION

See the main text of the BIO for facility implementation.

6.3 CRITICALITY CONCERNS

HNF-SD-W320-CSA-001, *Criticality Safety Assessment of Tank 241-C-106 Remediation*, concludes that an inadvertent criticality as a result of the activities associated with WRSS is not considered possible for the plutonium concentration determined to be in tank waste and the WRSS process to be applied to the tank waste.

6.4 CRITICALITY CONTROLS

See the main text of the BIO for criticality concerns.

6.5 CRITICALITY PROTECTION PROGRAM

See the main text of the BIO for details of the criticality protection program.

6.6 CRITICALITY INSTRUMENTATION

See the main text of the BIO for criticality discussion.

7.0 RADIATION PROTECTION

7.1 INTRODUCTION

This chapter identifies the requirements for radiation protection for Tank Waste Remediation System Waste Retrieval Sluicing System facilities and operations and the implementing program documents. Implementation of these programmatic requirements by the Waste Retrieval Sluicing System assures that the appropriate radiation protection standards are incorporated in project design and construction.

7.2 REQUIREMENTS

Section 4.4, "Radiological Protection," of the main text of HNF-SD-WM-BIO-001, *Tank Waste Remediation System Basis for Interim Operation*, provides the radiation protection requirements and facility implementation for the Waste Retrieval Sluicing System.

7.3 PROJECT IMPLEMENTATION

The radiation dose and dose rate design limits for Waste Retrieval Sluicing System activities are delineated in HNF-SD-W320-FDC-001, *Functional Design Criteria for Tank 241-C-106 Waste Retrieval, Project W-320.* Design details required to comply with the criteria are verified in calculations completed by the architect-engineer/constructor. Programmatic elements of radiation protection are governed by existing Site and facility programs. Descriptions of radiation monitoring and instrumentation are given in the system description in Chapter 2.0, "Facility Description." No requirements above those identified in the programmatic documents were required for the Waste Retrieval Sluicing System.

8.1 INTRODUCTION

Hazardous material protection requirements for this facility are fully defined in Section 4.5, "Hazardous Material Protection," in the main text of HNF-SD-WM-BIO-001, *Tank Waste Remediation System Basis for Interim Operation.* No specific requirements related to occupational hazardous material protection above those specified in the main text are required for Waste Retrieval Sluicing System activities.

8.2 PROJECT IMPLEMENTATION

No specific requirements related to occupational hazardous material protection were identified for Waste Retrieval Sluicing System activities; therefore, no specific requirements related to occupational hazardous material protection above those identified in the programmatic documents are required.

10.0 INITIAL TESTING, IN-SERVICE SURVEILLANCE, AND MAINTENANCE

10.1 INTRODUCTION

This section identifies the requirements for initial testing, in-service surveillance, and maintenance of Tank Waste Remediation System (TWRS) Waste Retrieval Sluicing System (WRSS) safety structures, systems, and components (SSCs).

10.2 REQUIREMENTS

Initial testing, in-service surveillance, and maintenance policies and programs addressed in this section are regulated by the following U.S. Department of Energy orders:

- DOE 4330.4B, *Maintenance Management Program* (1994)[1]
- DOE 4700.1, *Project Management System*, Change 1 (1992)[1]
- DOE 5480.19, *Conduct of Operations Requirements for DOE Facilities*, Change 1 (1992)
- DOE 5480.23, *Nuclear Safety Analysis Reports*, Change 1 (1994)
- DOE-76-45/1, *Occupancy/Use Readiness Manual* (1992)

TWRS implementation of the initial testing, in-service surveillance, and maintenance program requirements is documented in the following:

- WHC-CM-1-8[2], *Work Management* (1996)
- WHC-CM-4-2[2], *Quality Assurance Manual* (1996)
- HNF-IP-0842, *TWRS Administration* (1996)
- WHC-SP-0850, *Maintenance Implementation Plan* (1994)

---

[1]DOE 4330.4B and DOE 4700.1 will be phased out/canceled upon meeting implementation conditions of DOE O 430.1.

[2]Refer to Appendix F, "Site-wide Controlled Manual Cross Reference Table," of the BIO for cross-walk between Site-wide controlled manuals (e.g., WHC-CM-X-XX) superseded by Fluor Daniel Hanford, Inc., FDH Procedures (e.g., HNF-PRO-XXX).

10.3 TESTING PROGRAM

The W320 Project is responsible for testing prior to Official Acceptance of Constructions (OAC) section II (HNF-CM-6-2, *Project Management*). Subsequent to OAC section II East Tank Farms Operations is responsible for testing. Testing will be performed following a graded approach with more extensive testing conducted on Safety-Class components, components included as Defense-in-Depth items and components not readily accessible following installation. Note: Testing was conducted based on the safety classification of the components in place at the time of the testing.

HNF-SD-W320-TP-001, *Project W-320, Tank 241-C Waste Retrieval Sluicing System Testing Plan*, was prepared to support test planning and define test controls for acceptance testing and operational testing of the Project W-320 equipment.

10.3.1 Acceptance Testing

To facilitate operational testing and phased turnover, the WRSS was broken into subsystems. Many of the WRSS subsystems are relatively simple systems consisting of standard structures, off the shelf components or non-electromechanical systems. These subsystems will be placed in service following acceptance testing and will not be subjected to operational testing.

The majority of acceptance testing was performed either by the equipment vendors or the construction contractor. Once acceptance testing is verified as complete, subsystems of the WRSS may be turned over to East Tank Farm Operations and placed into service.

Acceptance testing will be performed by Project W-320 on all WRSS equipment and component to demonstrate fabrication, assembly, installation, and construction requirements specified in design documents were met. Acceptance testing includes fabrication and cleanliness inspections; wire continuity checks and adjustment of electrical protective devices; adjustment of torque-limiting devices; instrument calibration; testing instrumentation loops; and adjustment of controllers, limit switches, and other similar devices. Acceptance testing may also include equipment mock up and run-in tests, conducted both prior to and following installation.

Project W-320 acceptance testing includes three basic types of tests: vendor factory acceptance tests; general construction acceptance tests; and final acceptance tests. All acceptance testing will be the responsibility of the construction contractor and will be successfully completed prior to turnover of a WRSS subsystem or component to Projects.

Some WRSS subsystems will be placed in service following acceptance testing and will not be subjected to operational testing. These subsystems are:

- 241-C-106 Electrical Power Supply System
- 241-AY-102 Electrical Power Supply System

- Air and Water Service System
- Fire Protection System
- 241-Air Intake Chiller System.

10.3.2 Pre-Operational Testing

Preoperational testing will be conducted by performing Operational Test Procedures (OTPs) on the sluicing, ventilation, and instrumentation systems after turnover to Tank Farms operations. These integrated OTPs test the overall operability of the systems and procedures, except that no waste is actually transferred. Any test exceptions are documented and resolved. It is important to note that this Safety Assessment envelopes the consequences of accidents during the planned preoperational test activities. During operational testing, components of the WRSS will be operated at defined parameters to ensure they are ready for full operational testing. At the completion of preoperational testing, conditions and test results will be evaluated by the test director and a determination will be made to proceed with operational testing.

10.4 PROCEDURES

Prior to Project turnover, test procedures will be developed, reviewed and approved in accordance with the W-320 Test Plan. After turnover, test procedures will be developed, reviewed, and approved in accordance with HNF-IP-0842.

10.5 IN-SERVICE SURVEILLANCE PROGRAM

In-service surveillance and inspections at TWRS WRSS will be performed according to DOE 4330.4B using a graded approach. Program requirements include periodic inspections to ensure that proper conditions, cleanliness, and housekeeping are maintained to support safe and reliable facility operations.

The surveillance program is conducted in conjunction with the maintenance and testing program. Together, these programs ensure continued operation of Safety-Class and Safety-Significant SSCs at TWRS WRSS.

10.5.1 Provisions for Testing and Calibrations

The TWRS program for surveillance, inspection, and testing activities ensures that equipment needed for safe, reliable facility operation performs as required and that the program responds to the requirements of DOE 4330.4B. At TWRS the design authority is responsible for planning and documenting surveillance tests and other tests as discussed in Chapter 17.0.

10.5.2 Control and Calibration of Measuring and Test Equipment

The control and calibration of measuring and test equipment shall follow the guidelines of DOE 4330.4B and HNF-IP-0842, Volume V, "Maintenance/Production Control."

10.5.3 Training of Personnel Performing Surveillance

Training of maintenance personnel shall follow the guidelines and procedures of HNF-IP-0842, Volume III, Section 10.6, "Maintenance Training," which include references to DOE 4330.4B and also apply to training used for in-service surveillance personnel.

10.6 MAINTENANCE PROGRAM

The TWRS operations manager has overall responsibility for operation and maintenance of the WRSS. The scope of the TWRS WRSS is discussed in Chapter 2.0. The TWRS WRSS maintenance program is conducted according to DOE 4330.4B, which provides general policy and objectives for establishing cost-effective maintenance and repairs.

11.0 OPERATIONAL SAFETY

11.1 INTRODUCTION

This chapter identifies requirements and implementing program documents for the Waste Retrieval Sluicing System (WRSS) operational safety and fire protection.

11.2 REQUIREMENTS

Operational safety requirements are defined for this facility in Section 4.8, "Conduct of Operations;" Section 4.9, "Work Control;" and Section 4.10, "Fire Protection Program" in the main text of HNF-SD-WM-BIO-001, *Tank Waste Remediation System Basis for Interim Operation* and in the HNF-SD-WM-TSR-006, *Tank Waste Remediation System Technical Safety Requirements*. Specific requirements for Waste Retrieval Sluicing System activities related to fire protection above those specified in the main text are noted in the following subsections.

11.3 PROJECT IMPLEMENTATION

A fire hazards analysis was performed by Columbia Energy and Environment Services Inc., for Waste Retrieval Sluicing System activities (WHC-SD-W320-FHA-001, *Fire Hazard Analysis for Project W-320 Tank 241-C-106 Waste Retrieval*). The conclusion from this analysis is described in the following paragraphs.

The fire hazards analysis comprehensively assessed the risk from fire at Waste Retrieval Sluicing System facilities to determine (1) the potential for the occurrence of fire is minimized; (2) fire will not cause an onsite or offsite release of radiological and other hazardous materials that will threaten the public health and safety or the environment; (3) requirements that will provide an acceptable degree of life safety to U.S. Department of Energy and contractor personnel are in place and there are no undue hazards to the public from fire and its effects on U.S. Department of Energy facilities; and (4) safety systems will not be damaged by fire. The following discussion summarizes the conclusions from the fire hazards analysis.

There are no fixed fire protection systems protecting the equipment and structures in Tank Farm 241-C. A fire involving a trailer in this area is not likely to be controlled or extinguished without the use of hose streams flowing significant quantities of water. Fire hydrants within the vicinity of Tank 241-C-106 equipment and in accordance with the applicable requirements of DOE 6430.1A, *General Design Criteria*, were installed.

The Safety-Class equipment is designed with redundancy. It has been concluded that an accidental fire will not result in a loss of the capability of the Safety-Class system to accomplish its required safety function.

Accumulation of tumbleweeds and other transient combustibles is likely to occur periodically in and around Waste Retrieval Sluicing System equipment and structures. In keeping with Fluor Daniel Hanford policy to limit combustibles to a level As Low as Reasonably Achievable, there is a procedure to ensure periodic removal of tumbleweeds and other unwanted transient combustibles from TWRS facilities.

DOE 6430.1A, Section 1530.99.0, stipulates that automatic water sprinkler coverage be provided throughout nonreactor nuclear facilities. Automatic sprinkler protection is not expected to prevent or reduce any subsequent loss that may result from a fire in the Process Building. Based on the evaluation of combustibles and processes planned for Waste Retrieval Sluicing System activities, a deviation from the DOE 6430.1A requirement for full automatic water sprinkler protection has been made.

12.0 PROCEDURES AND TRAINING

12.1 INTRODUCTION

Procedures and training requirements are defined in Section 4.11, "Training and Procedures," in the main text of HNF-SD-WM-BIO-001, *Tank Waste Remediation System Basis for Interim Operation*. Specific requirements for Waste Retrieval Sluicing System operations related to procedures and training above those specified in the main text are noted as follows.

12.2 PROJECT IMPLEMENTATION

Responsibility for training on the new systems prior to commencement of operations is defined in HNF-IP-0842, *TWRS Administration*. Training and procedure development is to be conducted per existing Site and facility requirements. Procedures and training requirements for areas specifically related to Waste Retrieval Sluicing System activities will be developed in accordance with DOE 5480.19, *Conduct of Operations Requirements for DOE Facilities*, and with the results of the accident analysis (Chapter 3.0).

13.0 HUMAN FACTORS

13.1 REQUIREMENTS

Human factors requirements are defined in Section 4.18, "Human Factors," in the main text of HNF-SD-WM-BIO-001, *Tank Waste Remediation System Basis for Interim Operation.*

13.2 PROJECT IMPLEMENTATION

The application of human factors is graded on project risk, complexity, and level of involvement of the operator at the facility. With the Tank Waste Remediation System, human factors are considered in the development of procedures and controls; staffing; interface with safety structures, systems, and components; surveillance; maintenance; and safety analyses.

14.0 QUALITY ASSURANCE

14.1 INTRODUCTION

The quality assurance requirements and provisions during the procurement, design, and construction phases of project W-320 are defined in the Tank Waste Remediation System (TWRS) general project plan WHC-SD-WM-QAPP-018, *Tank Waste Projects Quality Assurance Program Plan*, and the project specific quality assurance program plan (QAPP) WHC-SD-W320-QAPP-001, *Project Specific Quality Assurance Plan*.

The quality assurance requirements and provisions for the TWRS operations, including the sluicing of Tank 241-C-106, are outlined in WHC-SP-1131, *Westinghouse Hanford Company Quality Assurance Program and Implementation Plan*, the Project Hanford Management Contract (PHMC)-adopted and the Department of Energy (DOE)-approved document required under the Part 10 Code of Federal Regulations, Section 830.120, "Quality Assurance." Specific operating procedures applicable to the project W-320 sluicing operation are contained in the TWRS Procedures Manual, most current revision.

The details of the quality assurance program for the project and the operation are contained in the above mentioned documents. The following sections of this chapter provide a summary of the quality assurance processes employed during the project and to be employed during the course of the sluicing operation.

14.2 REQUIREMENTS

The controlling requirements for the design and construction phases of the project are those applicable requirements found in DOE Order 6430.1A, *General Design Criteria*. Quality assurance requirements related to the design, procurement, and construction phases of the project are identified in the project specific QAPP. Quality assurance requirements for the operation of 241-C-106 sluicing activities are bounded by the QA requirements contained and referenced in the TWRS Project Procedures Manual.

14.3 TANK WASTE REMEDIATION SYSTEM QUALITY ASSURANCE PROGRAM AND ORGANIZATION

The quality assurance program implementation is outlined in the WHC-SP-1131 document identified earlier. Specific TWRS QA organizational structure and processes are contained in the adopted WHC-CM-6-34[1], *TWRS Quality Management Plan*, and WHC-CM-6-50, *TWRS Quality Assurance*.

[1]Refer to Appendix F, "Site-wide Controlled Manual Cross Reference Table," of the BIO for cross-walk between Site-wide controlled manuals (e.g., WHC-CM-X-XX) superseded by Fluor Daniel Hanford, Inc., FDH Procedures (e.g., HNF-PRO-XXX).

14.4 QUALITY IMPROVEMENT

Safety-Class/approval designators are identified on all procurement documents. The designators provide a key to the level of receipt inspection required to be conducted upon receipt of items. Special inspection plans are written for items requiring special or unique receipt inspections. Processes used during the W-320 project for receipt inspections and the filing and resolution of nonconformance reports are identified in the project specific QAPP.

TWRS operational quality improvement processes are outlined and referenced in the TWRS Project Procedures Manual (CM manuals 6-34 and 6-50). These procedures bound the 241-C-106 sluicing activities by requiring that all activities conducted within the TWRS project adhere to requirements contained within the Manual.

14.5 DOCUMENTS AND RECORDS

Documents and records maintained within the quality system include but are not limited to: certified vendor information, instrument/equipment calibration records, adverse assessment results until they are corrected. Project design media (e.g. certified vendor information) are retained in project files until project completion and then turned over to operations. Operational media (e.g. calibration records) are retained in auditable files until archived. Improvement media (e.g. assessment findings and selected observations) are retained on electronic data bases until corrected or resolved. Specific details of document and record processes are contained in the TWRS Project Procedures Manual.

14.6 QUALITY ASSURANCE PERFORMANCE

14.6.1 Work Processes

The PHMC adopted QA Program and Implementation Plan requires that all work be conducted in accordance with approved policies, procedures, or instructions. TWRS operations work procedures are contained in the Project Procedures Manual. When an activity is needed that is not covered by existing procedures, documents (justification for continued operation [JCO], recovery plan, work plan, procedure, etc.) are prepared and approved prior to conducting the activity. The requirements for producing these activity documents are currently contained in the TWRS Procedures Manual.

14.6.2 Design

One of the initial documents produced following conceptual design is the project specific quality assurance project plan (QAPP). The QAPP defines the quality assurance measures required during the course of project including subsequent design, procurement, and construction. The QAPP specific to

project W-320 is the HNF-SD-W320-QAPP-001 document mentioned earlier in this chapter.

14.6.3 Procurement

Quality assurance requirements for procurements are contained in the project specific quality assurance plan. Vendors/Sellers are evaluated to determine their capability to produce the desired item at the specified level of quality. Also, each procurement item is required to have a "Safety-Class/approval" designator derived from the safety analysis. This designator acts as a key to aid in defining the necessary and sufficient set of quality requirements that is included in the procurement package. Quality clauses and/or specific quality requirements are included in the procurement package to assure that the desired function, form, and fit derived by the analyses is communicated to the Seller. Specific requirements for procurement during the W-320 project are outlined in the project specific QAPP.

14.6.4 Inspection and Testing for Acceptance

Quality control inspections are defined during the procurement phase based on the importance of the item as determined by analyses conducted during the design phase. Inspections can take the form of visual examinations, non-destructive testing, and in limited cases, destructive testing of a small sample of items. Specific inspection requirements are based on the particular item and its application/needed function. The requirements for inspection and testing are outlined in the project specific QAPP.

14.6.5 Independent and Management Assessment

The conduct of assessments during the operational phase within the TWRS project is defined and controlled by requirements outlined and referenced in the TWRS Project Procedures Manual. During the conduct of the project, assessments were conducted in the form of surveillances conducted internal and external to the W-320 project. In both cases, plans for the assessments are required to be developed at the beginning of each year. If a problem is noted or develops during the course of the year, special assessments can be conducted to gain insights and/or information needed by management to effect corrective actions.

14.6.6 Training and Qualifications

Project personnel (craft, engineers, supervisors) undergo performance-based training according to specific qualification and training programs for their respective areas of responsibility. National standards provide the training and qualification requirements for the various crafts. Site and/or facility specific needs (e.g., radiological, toxicological, emergency preparedness, etc. specific to TWRS) are provided on the Hanford reservation through annual training in both general and facility specific areas.

Qualification and training requirements for nuclear operators are outlined in the DOE Order 5480.20A, *Personnel Selection, Qualification, and Training Requirements for DOE Nuclear Facilities*. TWRS operating personnel are trained and qualified in accordance with the applicable requirements contained within this DOE Order.

15.0 EMERGENCY PREPAREDNESS PROGRAM

Emergency preparedness program requirements are fully defined in Section 4.13, "Emergency Preparedness," in the main text of HNF-SD-WM-BIO-001, *Tank Waste Remediation System Basis for Interim Operations*. No additional project-specific requirements related to emergency preparedness are required beyond those identified as appropriate for Waste Retrieval Sluicing System activities in Sections 3.0, 4.0, and 5.0.

16.0 PROVISIONS FOR DECONTAMINATION AND DECOMMISSIONING

16.1 INTRODUCTION

This section describes provisions that facilitate the decontamination and decommissioning of facilities associated with Waste Retrieval Sluicing System activities.

16.2 REQUIREMENTS

The Tank Waste Remediation System does not have a formal decontamination and decommissioning plan. The main text of the BIO contains provisions for decontamination and decommissioning. Detailed plans will be prepared as required to support the decontamination and decommissioning of the Waste Retrieval Sluicing System.

DOE 5820.2A, *Radioactive Waste Management*, contains the primary requirements for decontamination and decommissioning activities. The current regulatory basis for decontamination and decommissioning activities is minimal. Some definitions of technical requirements for decontamination and decommissioning are listed in DOE 5400.5, *Radiation Protection of the Public and the Environment*.

16.3 DESCRIPTION OF CONCEPTUAL PLANS

The design of the Waste Retrieval Sluicing System shall facilitate decontamination per HNF-SD-W320-FDC-001, *Functional Design Criteria for Tank 241-C-106 Waste Retrieval, Project W-320*, so the facility can be decommissioned at a future date. Guidance for retrieval equipment design to facilitate eventual decommissioning shall be obtained from ANSI N300-1975, *Design Criteria for Decommissioning of Nuclear Fuel Reprocessing Plants*, and DOE 6430.1A, *General Design Criteria*, Sections 1300-11.2 and 1321-7.

The following principles shall be employed to the extent practicable.

- Modular, separable confinements shall be used for radioactive and other hazardous materials to preclude contamination of fixed portions of the structure.
- Filtration components of the ventilation systems shall be located at or near individual enclosures and as close as practical to the sources of contamination to minimize long runs of internally contaminated ducts.
- Areas subject to contamination shall be designed to facilitate decontamination. Liners and coatings shall be selected to withstand decontaminating agents and radiation degradation throughout the life of the facility. Surfaces should be free of crevices, ledges, and/or protrusions that could collect radioactive material.

- Penetrations shall be designed to minimize technical and construction problems in the structural closing and sealing of these penetrations at the time of decommissioning.
- Penetrations shall be waterproofed for protection during decontamination efforts.
- Fixtures and outlets shall be sealed.
- Drains and similar piping shall have physical provisions for cleaning.
- Piping systems shall be sloped and free of traps except as required for retrieval process isolation.
- Adequate clearance shall be provided for transfer of equipment.
- Lifting lugs shall be used on large tanks or equipment.
- Modular radiation shielding shall be used in lieu of, or in addition to, monolithic shielding walls.

17.0 MANAGEMENT, ORGANIZATION, AND INSTITUTIONAL SAFETY PROVISIONS

17.1 INTRODUCTION

The Waste Retrieval Sluicing System design and operations will be in accordance with the Tank Waste Remediation System organization structures, policies, and programs that ensure safety is the fundamental principle guiding all Tank Waste Remediation System operations.

17.2 REQUIREMENTS

The requirements for management, organization, and institutional safety provisions are contained in the main text of HNF-SD-WM-BIO-001, *Tank Waste Remediation System Basis for Interim Operation.*

17.3 PROJECT IMPLEMENTATION

There are no project-specific requirements related to management, organization, and institutional safety provisions for the Waste Retrieval Sluicing System activities.

ACCIDENT NUMBER 1 - Nuclear Criticality: WRSS Specific Analysis								
RP	W320-BCD-TRANS01	Tank 241-C-106 Plutonium Inventory	Release of ionizing radiation and radioactive gas from Tank 241-C-106 due to a criticality event in the tank pump vortices	1. Natural occurrence if conditions are met	F1	S2	A04	01
ACCIDENT NUMBER 2 - HEPA Filter Failure: WRSS Specific Analysis								
B-1-a	W320-D-ALL01	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol through failed filters from Tank 241-AY-102 due to a steam bump	1. Human error 2. Communications error with other workers using the tank 3. IOSRs require activation of ALCs in event temperature above limit	F3	S2	D14	02
ACCIDENT NUMBER 3 - Unfiltered Release: WRSS Specific Analysis								
C-1-a	W320-D-VENT07	Tank Dome Space Inventory	Release of low energy radioactive aerosol from Tank 241-C-105/ Tank 241-C-106 ventilation system due to failure to determine ventilation leak during sluicing.	1. Ducting corrosion 2. Seal deterioration	F3	S2	D14	03
ACCIDENT NUMBER 4 - Fire in Contaminated Area: BIO Analysis Bounding								
A-1-a	W320-ABCD-TRANS11	Tank Inventory	Release of energetic radioactive aerosol release from line break due to flammable gas ignition in pit with cover block falling onto piping.	1. Chimney through deep drop legs 2. 6 in. high capacity drain to dome space 3. Pit sealed to minimize inleakage	F2	S3	B08	04
ACCIDENT NUMBER 5 - Caustic Spray Leak: BIO Analysis Bounding								
	Covered by the analysis in Section 3.4.2.5 which will be incorporated into the main text of the TWRS BIO in a future revision							05
ACCIDENT NUMBER 6 - Tank Failure - Due to Excessive Loads: WRSS Specific Analysis								
A-1-a	W320-ABCD-ALL01	Tank Inventory	Release of energetic radioactive aerosol from damaged tank due to flooding on top of Tank 241-C-106 dome	1. Raw water line rupture 2. Heavy rainfall	F1	S3	C19	06A
A-1-a	W320-ABCD-ALL02	Tank Inventory	Release of energetic radioactive aerosol from damaged tank due to flooding on top of Tank 241-AY-102 dome	1. Raw water line rupture 2. Heavy rainfall	F1	S3	C19	06B

Table B-1. Representative Hazards of Analyzed Accidents. (4 sheets)

Bin	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	Rep Acc
ACCIDENT NUMBER 7 - Tank Failure - Due to Excessive Vacuum: WRSS Specific Analysis, bounded by 6, above								
B-1-a	W320-BCD-ALL03	Tank Inventory	Release of energetic radioactive aerosol from damaged Tank 241-C-106 due to excessive vacuum resulting from ventilation system fan over speed and failure of tank loop seal failure.	1. Rotameter valve to controller fault 2. Operator error in adjusting rotameter or inadvertent adjustment	F1	S3	C11	07A
A-1-a	W320-BCD-ALL02	Tank Inventory	Release of energetic radioactive aerosol from collapsed Tank 241-AY-102 due to excessive vacuum resulting from W030 ventilation system inlet damper closing and failure of PCV fails to relieve vacuum.	1. Rotameter valve to controller fault 2. Operator error in adjusting rotameter or inadvertent adjustment	F0	S3	C11	07B
ACCIDENT NUMBER 8 - Flammable Gas Deflagrations - DST/SST: BIO analysis adopted (qualitatively)								
A-1-a	W320-D-ALL07	Tank Inventory	Release of energetic radioactive aerosol from damaged double shell Tank 241-AY-102 due to seismic event which releases flammable gas from the waste and after shocks cause mechanical sparks which ignites the flammable gas mixture.	1. Natural Phenomena	F2	S3	B18	08A
A-1-a	W320-BCD-PUMP04	Tank 241-AY-102 Inventory	Release of energetic radioactive aerosol to atmosphere due to submersible pump being raised too high in Tank 241-AY-102, winch lifting strap breaking, pump falling into waste resulting in a flammable gas release which is ignited by broken electrical cables.	1. Operator error in positioning direction 2. Inadvertent or accidental actuation 3. Winch controller fault	F0	S3	B08	08B
A-1-a	W320-A-TRANS05	Tank 241-C-106 inventory	Release of energetic radioactive aerosol to atmosphere due to temperature out of specification resulting in steam bump when Tank 241-C-106 level is lowered which induces a release of a flammable gas plume and then is ignited.	1. Operator mistake 2. Temperature measurement fault	F0	S3	B08	08C

Table B-1. Representative Hazards of Analyzed Accidents. (4 sheets)

Bin	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	Rep Acc
ACCIDENT NUMBER 9 - Organic Solvent Fire: WRSS Specific Analysis, different organic solvent than BIO								
A-1-a	W320-B-ALL09	Tank Inventory and Filter Burden	Release of energetic radioactive aerosol from damaged tank due to formation of organic layer in Tank 241-AY-102 during slurry distribution and subsequent ignition of organics.	1. Sluicing causes organic separation	F1	S3	B04	09A
A-1-a	W320-B-ALL10	Tank Inventory and Filter Burden	Release of energetic radioactive aerosol from damaged tank due to formation of organic layer in Tank 241-C-106 during sluicing and subsequent ignition of organics.	1. Sluicing causes organic separation	F1	S3	B04	09B
ACCIDENT NUMBER 10 - In-Tank Fuel Fire/Deflagration: Consequences bounded by accident 9 above								
A-1-a	W320-D-CHILL01	Tank Inventory and Filter Burden	Release of energetic radioactive aerosol from damaged tank due to a leak and ignition of propylene glycol from pit chiller into Tank 241-C-106.	1. Piping or tubing leak	F0	S3	B12	10
ACCIDENT NUMBER 11 - Steam Bump: WRSS Specific Analysis								
C-1-a	W320-D-TRANS08	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol through failed filters due to excessive fluffing of waste in Tank 241-AY-102 resulting in large steam bump and unfiltered release.	1. Inadequate prediction of waste behavior	F1	S2	D01	11
ACCIDENT NUMBER 12 - Steam Explosion between Steel Liner and Concrete Shell: WRSS Specific Analysis								
B-1-a	W320-ABCD-TRANS01	Tank Inventory	Release of liquid waste due to sluicer nozzle jet being directed at and breaching Tank 241-C-106 wall resulting in water leaking into liner gap where steam vapor forms and breaches tank bottom.	1. Unavoidable operator action	F3	S2	D04	12
ACCIDENT NUMBER 13 - Subsurface Leak Remaining Subsurface: WRSS Specific Analysis								
C-3-b	W320-B-TRANS19	Transfer Line Inventory	Release of radioactive liquid from breached transfer line due to a leak from primary transfer line and a defective secondary line resulting in an underground spill.	1. Line corrosion 2. ground movement 3. Aging	F1	S0	D12	13

Table B-1. Representative Hazards of Analyzed Accidents. (4 sheets)

Bin	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	Rep Acc
ACCIDENT NUMBER 14 - Subsurface Leak Resulting in Pool: WRSS Specific Analysis								
C-2-b	W320-B-TRANS22	Tank 241-AY-102 inventory	Release of radioactive liquid from transfer line due to local flooding during transfer which results in line being uncovered and breached.	1. Raw water leak 2. Natural flow	F3	S2	D19	14
ACCIDENT NUMBER 15 - Surface Leak Resulting in Pool: WRSS Specific Analysis								
C-2-b	W320-B-FLUSH06	Flushing water in Tank 241-AY-102 Pit	Release of radioactive liquid from transfer line due to a pipe break in Tank 241-AY-102 pit with the high capacity drain cover on resulting in overflow of pit onto the ground.	1. Equipment failure 2. Maintenance or assembly error	F2	S2	D12	15A
C-2-b	W320-BCD-TRANS10	Tank 241-AY-102 inventory	Release of radioactive liquid release from sluice transfer line due to the blank flange being left off flushing connection in Tank 241-AY-102 pit and drain cover left on resulting in overflow of pit onto the ground during sluicing.	1. Maintenance error 2. Communications error between different groups using the pit	F2	S2	E06	15B
ACCIDENT NUMBER 16 - Spray Leak in Structure or from Overground Waste Transfer: WRSS Specific Analysis								
A-1-a	W320-BCD-TRANS11	Transfer Line Inventory	Release of energetic radioactive aerosol from transfer line due to blank flange left off flushing connection in Tank 241-C-106 pit after flushing. Cover plug is lifted out of cover block on initiation of sluicing process.	1. Maintenance error 2. Communications error between different groups using the pit	F3	S3	E06	16A
A-1-a	W320-BCD-TRANS12	Transfer Line Inventory	Release of energetic radioactive aerosol from transfer line due to blank flange left off flushing connection in Tank 241-AY-102 pit after flushing. Cover plug is lifted out of cover block on initiation of sluicing process.	1. Maintenance error 2. Communications error between different groups using the pit	F3	S3	E06	16B
ACCIDENT NUMBER 17 - Spray Leak from Underground Waste Transfer Line: WRSS Specific Analysis								
B-1-a	W320-D-TRANS11	Transfer Line Inventory	Release of large high energy aerosolized radioactive waste to the atmosphere from a spray leak from transfer line due to seismic event.	1. Natural Phenomena	F1	S3	D18	17

CPS = criticality prevention specifications.
DST = double-shell tank.
HEPA = high-efficiency particulate air.
SST = single-shell tank.

Table B-2. Representative Hazards of Analyzed Accidents and the Represented Hazardous Conditions. (24 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	Rep Acc
HAZARDOUS CONDITION OF ANALYZED ACCIDENT: 1 - Nuclear Criticality								
RP	W320-BCD-TRANS 01	Tank 241-C-106 Plutonium Inventory	Release of ionizing radiation and radioactive gas from Tank 241-C-106 due to a criticality event in the tank pump vortices	1. Natural occurrence if conditions are met	F1	S2	A04	01
HAZARDOUS CONDITIONS								
RP	W320-BCD-TRANS 04	Tank 241-C-106 Plutonium Inventory	Release of ionizing radiation and radioactive gas from Tank 241-C-106 due to a criticality event in the tank during sluicing	1. Natural occurrence if conditions are met	F1	S2	A04	01X
RP	W320-D-TERM01	Tank 241-C-106 and Tank 241-AY-102 Plutonium Inventory	Release of ionizing radiation and radioactive gas from Tank 241-AY-102 due to a criticality event in the tank	1. Natural occurrence if conditions are met	F1	S2	A04	01X
RP	W320-BCD-TRANS 02	Tank 241-C-106 Plutonium Inventory	Release of ionizing radiation and radioactive gas from Tank 241-C-106 due to a criticality event in the tank	1. Flushing valve misposition 2. Pump controller fault 3. Excessive solids in slurry flow	F0	S2	A04	01X
RP	W320-BCD-TRANS 03	Tank 241-C-106 Plutonium Inventory	Release of ionizing radiation and radioactive gas from Tank 241-C-106 due to a criticality event in the tank	1. Primary failure of distributor 2. Severe water hammer 3. Severe thermal shock 4. Corrosion 5. Metal fatigue from vibration	F0	S2	A04	01X
HAZARDOUS CONDITION OF ANALYZED ACCIDENT: 2 - HEPA Filter Failure								
B-1-a	W320-D-ALL01	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol through failed filters from Tank 241-AY-102 due to a steam bump	1. Human error 2. Communications error with other workers using the tank 3. IOSRs require activation of ALCs in event temperature above limit	F3	S2	D14	02
HAZARDOUS CONDITIONS								
C-1-a	W320-ALL-TRANS 01	Duct and Filter Burden	Release of low energy radioactive aerosol through failed filters from Tank 241-AY-102 due to moisture buildup on ventilation system HEPA filters	1. Natural occurrence under proper conditions	F2	S2	D14	02X
C-1-a	W320-D-TRANS02	Tank Dome Space Inventory	Release of low energy radioactive aerosol from largely intact Tank 241-C-106 due to excessive sluicer flow which results in radioactive air release through HEPAs.	1. Natural outcome if conditions are met	F2	S2	D04	02X
C-1-a	W320-D-VENT04	Tank Dome Space Inventory	Release of small low energy radioactive aerosol through failed filters from Tank 241-AY-102 due to cold water spray into tank, tank vacuum and resulting tank bump	1. Possible result of slurry distribution	F1	S2	D11	02X

Table B-2. Representative Hazards of Analyzed Accidents and the Represented Hazardous Conditions. (24 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	Rep Acc
A-1-a	W320-B-FLUSH01	Tank Inventory	Release of energetic radioactive aerosol from damaged Tank 241-C-106 single shell tank due to ignition of flammable gas plume and resulting filter breach induced by large water intrusion into tank.	1. Maintenance error 2. Communications error between different groups using the pit	F0	S2	D07	02X
B-1-a	W320-B-FLUSH02	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol through failed filters due to a large steam bump in Tank 241-C-106 as a result of high tank vacuum resulting from flushing water spray condensing dome vapors.	1. Planned	F0	S2	D07	02X
C-1-a	W320-B-FLUSH03	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol through failed filters of Tank 241-AY-102 due to a large steam bump as a result of high tank vacuum due to high condensation rate in tank from flushing water spray through antisiphon holes.	1. Planned	F0	S2	D07	02X
B-1-a	W320-B-TRANS01	Tank 241-AY-102 inventory	Release of small low energy aerosolized waste from the annulus of Tank 241-AY-102 due to steam pulses from boiling waste in annulus region which results in the failure of annulus filters. Waste leaks into annulus due to corrosion of primary tank from new waste composition.	1. Inadequate prediction of waste behavior	F0	S2	D16	02X
HAZARDOUS CONDITION OF ANALYZED ACCIDENT: 3 - Unfiltered Release								
C-1-a	W320-D-VENT07	Tank Dome Space Inventory	Release of low energy radioactive aerosol from Tank 241-C-105/Tank 241-C-106 ventilation system due to failure to determine ventilation leak during sluicing.	1. Ducting corrosion 2. Seal deterioration	F3	S2	D14	03
HAZARDOUS CONDITIONS								
C-1-a	W320-D-VENT08	Tank Dome Space Inventory	Release of low energy radioactive aerosol from largely intact tank due to excessive vacuum in Tank 241-C-106 from new ventilation system which results in loop seal failure and unfiltered release.	1. Operator error 2. Communications error	F3	S2	D11	03X
C-1-a	W320-D-VENT11	Tank Dome Space Inventory	Release of low energy radioactive aerosol from largely intact tank due to excessive vacuum in Tank 241-C-106 from current ventilation system which results in loop seal failure and unfiltered release.	1. Operator error 2. Communications error	F3	S2	D11	03X

Table B-2. Representative Hazards of Analyzed Accidents and the Represented Hazardous Conditions. (24 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	Rep Acc
C-1-a	W320-ABCD-CHIL LO1	Tank Dome Space Inventory	Release of low energy radioactive aerosol from largely intact tank due to excessive cooling from process chiller and vacuum in Tank 241-C-106 from ventilation system which results in exceedance of loop seal vacuum and unfiltered release.	1. Chiller control fault 2. High humidity	F2	S2	D11	03X
C-1-a	W320-B-TRANS06	Tank Dome Space Inventory	Release of low energy radioactive aerosol from largely intact Tank 241-AY-102 due to excessive slurry flow resulting in increased aerosol generation and errant flow release.	1. 3-way ball valve in flushing system not fully open 2. Pump controller fault	F2	S2	D15	03X
C-1-a	W320-B-TRANS07	Tank Dome Space Inventory	Release of low energy radioactive aerosol from largely intact Tank 241-AY-102 due to startup of slurry flow to distributor resulting in air being bubbled through waste and release of vapor.	1. Normal procedure	F2	S2	D04	03X
C-1-a	W320-B-TRANS11	Tank Dome Space Inventory	Release of low energy radioactive aerosol from largely intact Tank 241-AY-102 due to excessive corrosion and heat loading from new waste.	1. Inadequate prediction of waste behavior	F2	S2	D16	03X
C-1-a	W320-B-TRANS12	Tank Dome Space Inventory	Release of low energy radioactive aerosol from interconnected tanks due to increased heat loading of Tank 241-AY-102 and loss of vacuum.	1. Inadequate prediction of waste behavior 2. Existing system cannot control flow rates from different tanks. Depends on inleakage 3. W030 system has lower exhaust capabilities	F2	S2	D01	03X
C-1-a	W320-D-TRANS04	Tank Dome Space Inventory	Release of low energy radioactive aerosol from largely intact Tank 241-C-106 due to high temperature sluice water which increases head space pressure with increased errant flow.	1. High temperature in Tank 241-AY-102	F2	S2	D04	03X
C-1-a	W320-B-TRANS08	Tank Dome Space Inventory	Release of low energy radioactive aerosol from largely intact Tank 241-AY-102 due to distributor breaking off which results in excessive aerosol generated in head space and release through HEPAs.	1. Primary failure of distributor 2. Severe Water hammer 3. Severe thermal shock 4. Corrosion 5. Metal fatigue from vibration	F1	S2	D15	03X
C-1-a	W320-B-TRANS10	Tank Dome Space Inventory	Release of low energy radioactive aerosol from largely intact Tank 241-AY-102 due to distributor breaking off which results in excessive aerosol generated in head space and release through HEPAs.	1. Primary failure of sluicer 2. Severe Water hammer 3. Severe thermal shock 4. Corrosion 5. Metal fatigue from vibration	F1	S2	D04	03X

Table B-2. Representative Hazards of Analyzed Accidents and the Represented Hazardous Conditions. (24 sheets)

A-1-a	W320-E-TERM01	Tank Inventory	Release of large high energy radioactive aerosol from Tank 241-AY-102 due to excessive fluffing of waste which results in tank structural damage and unfiltered release.	1. Inadequate prediction of waste behavior	F1	S2	D01	03X
C-1-a	W320-D-PURGE01	Tank Dome Space Inventory	Release of low energy aerosolized waste from largely intact Tank 241-C-106 due to nitrogen line break and loss of vacuum.	1. Tube failure 2. Improper Assembly 3. Regulator fault	F0	S2	D12	03X
HAZARDOUS CONDITION OF ANALYZED ACCIDENT: 4 - Fire in Contaminated Area								
A-1-a	W320-ABCD-TRANS11	Tank Inventory	Release of energetic radioactive aerosol release from line break due to flammable gas ignition in pit with cover block falling onto piping.	1. Chimney through deep drop legs 2. 6 in. high capacity drain to dome space 3. Pit sealed to minimize inleakage	F2	S3	B08	04
HAZARDOUS CONDITIONS								
A-1-a	W320-ABCD-CHILL02	Pit radionuclide inventory	Release of energetic radioactive aerosol from covered pit or dead end pipe due to propylene glycol spray leak into ventilation system of Tank 241-C-106 with ignition propagating into tank dome.	1. Piping or tubing leak	F1	S2	B12	04X
A-1-a	W320-BCD-ALL01	Pit radionuclide inventory	Release of energetic radioactive aerosol from covered pit on Tank 241-C-106 due to propylene glycol leak into pit with ignition.	1. Piping or tubing leak	F1	S2	B12	04X
HAZARDOUS CONDITION OF ANALYZED ACCIDENT: 5 - Caustic Spray Leak								
COVERED BY THE ANALYSIS IN SECTION 3.4.2.5 WHICH WILL BE INCORPORATED INTO THE MAIN TEXT OF THE TWRS BIO IN A FUTURE REVISION								
HAZARDOUS CONDITION OF ANALYZED ACCIDENT: 6 - Tank Failure - Due to Excessive Loads								
A-1-a	W320-ABCD-ALL01	Tank Inventory	Release of energetic radioactive aerosol from damaged tank due to flooding on top of Tank 241-C-106 dome	1. Raw water line rupture 2. Heavy rainfall	F1	S3	C19	06A
A-1-a	W320-ABCD-ALL02	Tank Inventory	Release of energetic radioactive aerosol from damaged tank due to flooding on top of Tank 241-AY-102 dome	1. Raw water line rupture 2. Heavy rainfall	F1	S3	C19	06B
HAZARDOUS CONDITIONS								
A-1-a	W320-ABCD-ALL03	Tank Inventory	Release of energetic radioactive aerosol from tank dome collapse due to flooding on top of tank dome	1. Raw water line rupture 2. Heavy rainfall	F0	S3	C19	06X
A-1-a	W320-B-ALL01	Tank Inventory	Release of a large amount of high energy aerosolized waste from Tank 241-C-106 dome collapse due to volcanic ashfall.	1. Natural phenomena	F0	S3	C18	06X

Table B-2. Representative Hazards of Analyzed Accidents and the Represented Hazardous Conditions. (24 sheets)

HAZARDOUS CONDITION OF ANALYZED ACCIDENT: 8 - Flammable Gas Deflagrations - DST/SST								
A-1-a	W320-D-ALL07	Tank Inventory	Release of energetic radioactive aerosol from damaged double shell Tank 241-AY-102 due to seismic event which releases flammable gas from the waste and after shocks cause mechanical sparks which ignites the flammable gas mixture.	1. Natural Phenomena	F2	S3	B18	08A
A-1-a	W320-BCD-PUMP04	Tank 241-AY-102 Inventory	Release of energetic radioactive aerosol to atmosphere due to submersible pump being raised too high in Tank 241-AY-102, winch lifting strap breaking, pump falling into waste resulting in a flammable gas release which is ignited by broken electrical cables.	1. Operator error in positioning direction 2. Inadvertent or accidental actuation 3. Winch controller fault	F0	S3	B08	08B
A-1-a	W320-A-TRANS05	Tank 241-C-106 inventory	Release of energetic radioactive aerosol to atmosphere due to temperature out of specification resulting in steam bump when Tank 241-C-106 level is lowered which induces a release of a flammable gas plume and then is ignited.	1. Operator mistake 2. Temperature measurement fault	F0	S3	B08	08C
HAZARDOUS CONDITIONS								
A-1-a	W320-ABCDF-ALL01*	Tank Inventory	Release of energetic radioactive aerosol to atmosphere due to buildup of flammable gas in Tank 241-AY-102 pit drain pipe which is then ignited.	1. Flammable gas generation from tank waste	F1	S3	B08	08X
A-1-a	W320-D-ALL08	Tank Inventory	Release of energetic radioactive aerosol to atmosphere due to start of air lift circulators in Tank 241-AY-102 resulting in a release of flammable gas plume which is then ignited.	1. Human error 2. Communications error with other workers using the tank 3. IOSRs require activation of ALCs in event temperature above limit	F1	S3	B08	08X
A-1-a	W320-D-TRANS05	Tank Inventory	Release of energetic radioactive aerosol to atmosphere due to head space gas concentration above LFL in Tank 241-AY-102 with the start of pumping which ignites the flammable gas.	1. Spontaneous GRE 2. Induced GRE	F1	S3	B08	08X

Table B-2. Representative Hazards of Analyzed Accidents and the Represented Hazardous Conditions. (24 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	Rep Acc
A-1-a	W320-D-TRANS07	Tank 241-AY-102 inventory	Release of high energetic aerosolized waste to the atmosphere due to sluice water transfer rate being excessive resulting in the Tank 241-AY-102 waste level being lowered quickly with the waste temperature too high. This results in a large steam bump and flammable gas release with ignition.	1. Operator mistake 2. Level indication fault 3. Pump controller fault	F1	S3	B08	08X
A-1-a	W320-D-VENT17	Tank 241-AY-102 Inventory	Release of high energy aerosolized release to the atmosphere due to an ice storm which prevents air inflow into Tank 241-AY-102 resulting in an excessive tank vacuum. This results in a flammable gas release with ignition.	1. Natural phenomena	F1	S3	B08	08X
A-1-a	W320-B-ALL08	Tank Inventory	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 due to a large water intrusion which induces a flammable gas release event. It is then ignited resulting in a dome space fire.	1. Raw water leak 2. Surface water flood	F0	S3	B08	08X
A-1-a	W320-B-TRANS14	Tank Inventory	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 to the atmosphere due to low slurry flow to distributor which results in solids piling up. Pile generates significant amount of flammable gas and LFL is reached in dome space. It is then ignited resulting in a dome space fire.	1. 3-way ball valve in flushing system not fully open 2. Pump controller fault	F0	S3	B08	08X
A-1-a	W320-B-TRANS15	Tank Inventory	Large high energy aerosolized waste release from Tank 241-AY-102 to the atmosphere due to air injected into the waste from the startup of slurry flow from the distributor. Gas is scrubbed from the waste and LFL is reached in dome space. It is then ignited resulting in a dome space fire.	1. Normal procedure	F0	S3	B08	08X
A-1-a	W320-B-TRANS16	Tank Inventory	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 to the atmosphere due to distributor nozzle breaking off which results in solids piling up. Pile generates significant amount of flammable gas and LFL is reached in dome space. It is then ignited resulting in a dome space fire.	1. Primary failure of distributor 2. Severe water hammer 3. Severe thermal shock 4. Corrosion 5. Metal fatigue from vibration	F0	S3	B08	08X
A-1-a	W320-D-VENT13	Tank Inventory	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 to the atmosphere due to influx of cold water spray into tank which results in an excessive vacuum. A large flammable gas release is induced. It is then ignited resulting in a dome space fire.	1. Possible result of slurry distribution	F0	S3	B08	08X

Table B-2. Representative Hazards of Analyzed Accidents and the Represented Hazardous Conditions. (24 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	Rep Acc
A-1-a	W320-D-VENT16	Tank 241-AY-102 Inventory	Large high energy aerosolized waste release from Tank 241-AY-102 to the atmosphere due to the loss of primary or annulus ventilation for an extended period which results in a gradual rise in waste temperature. Flammable gas builds up in the dome space to the LFL. It is then ignited resulting in a dome space fire.	1. Extended loss of power 2. Severe ventilation casualty	F0	S3	B08	08X
A-1-a	W320-D-VENT18	Tank 241-AY-102 Inventory	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 to the atmosphere due to volcanic ashfall which prevents air inflow to tank. Excessive vacuum results and flammable gas is released to the dome space. It is then ignited resulting in a dome space fire.	1. Natural phenomena	F0	S3	B18	08X
A-1-a	W320-E-TERM03	Tank Inventory	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 to the atmosphere due to lack of controls on operation of tank after it has been turned into a FG group 1 tank. It is ignited from a lightning strike or other event resulting in a dome space fire.	1. Inadequate prediction of waste behavior	F0	S3	D01	08X
C-1-a	W320-B-TERM01	Tank Toxic Gas Inventory	Release of toxic ammonia gas from tank due to burp which exposes facility personnel to toxic gases.	1. Inadequate prediction of waste behavior	F2	S2	D01	08X
C-1-a	W320-B-TRANS13	Tank Dome Space Inventory	Small low energy aerosolized waste release from largely intact tank due to flammable gas collecting in a Tank 241-AY-102 pit where it is ignited resulting in the cover blocks being displaced and falling into pit. Cover block strikes riser-liner joint resulting in an unfiltered release from dome space.	1. Chimney through deep drop legs 2. 6 in. high capacity drain to dome space 3. Pit sealed to minimize inleakage	F2	S2	B08	08X
A-1-a	W320-D-VENT15	Pit radionuclide inventory	Small low energy radioactive aerosolized waste release from standpipes in Tank 241-AY-102 due to flammable gas buildup where it is ignited resulting in the pipe being breached resulting in an unfiltered release.	1. Natural occurrence under proper conditions	F2	S2	B08	08X
A-1-a	W320-BCD-ALL10	Transfer Line Inventory	Small high energy aerosolized waste release to the atmosphere due to plugging and buildup of flammable gas in transfer line . Gas is then ignited resulting in a breach of transfer line. Pumping is started without knowledge of breach.	1. Low flow 2. Inadequate flushing	F1	S2	B08	08X

Table B-2. Representative Hazards of Analyzed Accidents and the Represented Hazardous Conditions. (24 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	Rep Acc
A-1-a	W320-BCD-PUMP03	Tank 241-AY-102 inventory	Release of small high energy aerosol to atmosphere due to immersible pump being raised too high in Tank 241-AY-102, winch lifting strap breaking, pump falling into waste results in a flammable gas release which is ignited by broken electrical cables, plume burn.	1. Operator error in positioning direction 2. Inadvertent or accidental actuation 3. Winch controller fault	F0	S2	B08	08X
A-1-a	W320-D-VENT14	Pit radionuclide inventory	Small high energy aerosolized waste release from Tank 241-AY-102 to the atmosphere due to the loss of primary or annulus ventilation for an extended period which results in a gradual rise in waste temperature. Flammable gas leaks into annulus. It is then ignited resulting in the annulus being breached.	1. Extended loss of power 2. Severe ventilation casualty	F0	S2	B08	08X
A-1-a	W320-D-PUMP04	Tank Inventory	Release of energetic radioactive aerosol from damaged Tank 241-AY-102 due to pumping of more solids than anticipated. Annulus cooling mod not completed resulting in overheating of waste and a tank bump. Bump induces large flammable gas release. It is then ignited resulting in a dome space fire.	1. Mass flowmeter fault or out of calibration 2. Operator error in positioning slurry pump 3. Inadvertent or accidental repositioning 4. Level indication fault 5. Waste level indicator on pump Tank 241-C-106 fault 6. Pump controller fault	F0	S3	B08	08X
C-1-a	W320-B-ALL07	Tank Dome Space Inventory	Small low energy aerosolized waste release from largely intact tank due to flammable gas collecting in a Tank 241-C-106 pit where it is ignited resulting in the cover blocks being displaced and falling into pit. Cover block strikes riser-liner joint resulting in an unfiltered release from dome space.	1. Chimney through deep drop legs 2. 6 in. high capacity drain to dome space 3. Pit sealed to minimize inleakage	F3	S2	B08	08X
A-1-a	W320-BCD-ALL05	Transfer Line Inventory	Small high energy aerosolized waste release to the atmosphere due to buildup of solids and flammable gas in transfer line . Gas is then ignited resulting in a breach of transfer line. Pumping is started without knowledge of breach.	1. Low flow 2. Inadequate flushing	F1	S2	B08	08X
A-1-a	W320-BCD-ALL06	Transfer Line Inventory	Small high energy aerosolized waste release to the atmosphere due to buildup of solids and flammable gas in transfer line . Gas is then ignited and detonates resulting in a breach of transfer line. Pumping is started without knowledge of breach.	1. Low flow 2. Inadequate flushing	F1	S2	B08	08X

Table B-2. Representative Hazards of Analyzed Accidents and the Represented Hazardous Conditions. (24 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	Rep Acc
A-1-a	W320-BCD-PUMP05	Tank Inventory	Release of small high energy aerosol to atmosphere due to immersible pump being raised too high in Tank 241-C-106, motor breaks gear assembly, pump freespools into waste resulting in a flammable gas release which is ignited by broken electrical cables, plume burn.	1. Operator error in positioning direction 2. Inadvertent or accidental actuation 3. Winch controller fault	F1	S2	B08	08X
A-1-a	W320-A-TRANS04	Tank Inventory	Release of large high energy aerosolized waste from Tank 241-C-106 due to high waste temperature during slurry transfer which results in a steam bump. Bump induces flammable gas release which is ignited resulting in a dome burn.	1. Flowmeters fault or out of calibration 2. Operator error in positioning Tank 241-C-106 pump 3. Inadvertent or accidental actuation of Tank 241-C-106 pump but not Tank 241-AY-102 pump 4. ENRAF level indication fault 5. Pump controller fault 6. Tank 241-C-106 T/C fault	F0	S2	B08	08X
A-1-a	W320-B-TRANS17	Tank Inventory	Release of high energy aerosolized waste from damaged Tank 241-C-106 due to the sluicer hose breaking which then impinges into the solids releasing a region of retained flammable gas. The gas is then ignited and a plume fire results.	1. Primary failure of Hose 2. Severe Water hammer 3. Severe thermal shock 4. Corrosion 5. Fatigue from vibration	F0	S2	B08	08X
A-1-a	W320-B-TRANS18	Tank Inventory	Release of large high energy aerosolized waste to the atmosphere due to sluice water transfer rate being excessive resulting in the Tank 241-C-106 waste level being lowered quickly with the waste temperature too high. This results in a large steam bump and flammable gas release with a plume burn.	1. Flowmeters fault or out of calibration 2. Operator error in positioning Tank 241-C-106 pump 3. Inadvertent or accidental actuation of Tank 241-C-106 pump but not Tank 241-AY-102 pump 4. ENRAF level indication fault 5. Pump controller fault 6. Tank 241-C-106 T/C fault	F0	S2	B08	08X
A-1-a	W320-BCD-PUMP09	Tank Inventory	Release of large high energy aerosolized waste to atmosphere due to immersible pump being raised too high in Tank 241-C-106, winch lifting strap breaking, pump falling into waste results in a flammable gas release which is ignited by broken electrical cables, plume burn.	1. Operator error in positioning direction 2. Inadvertent or accidental actuation 3. Winch controller fault	F0	S2	B08	08X
A-1-a	W320-D-TRANS06	Tank Inventory	Release of large high energy aerosolized waste to the atmosphere due to slurry transfer rate being excessive resulting in a rapid reduction in the hydrostatic pressure in Tank 241-C-106. This results in a flammable gas release. Gas is ignited and a dome space fire results.	1. Sluice flow control fault	F0	S2	B04	08X

Table B-2. Representative Hazards of Analyzed Accidents and the Represented Hazardous Conditions. (24 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	Rep Acc
HAZARDOUS CONDITION OF ANALYZED ACCIDENT: 9 - Organic Solvent Fire								
A-1-a	W320-B-ALL09	Tank Inventory and Filter Burden	Release of energetic radioactive aerosol from damaged tank due to formation of organic layer in Tank 241-AY-102 during slurry distribution and subsequent ignition of organics.	1. Sluicing causes organic separation	F1	S3	B04	09A
A-1-a	W320-B-ALL10	Tank Inventory and Filter Burden	Release of energetic radioactive aerosol from damaged tank due to formation of organic layer in Tank 241-C-106 during sluicing and subsequent ignition of organics.	1. Sluicing causes organic separation	F1	S3	B04	09B
HAZARDOUS CONDITIONS								
A-1-a	W320-A-TRANS06	Tank Inventory and Filter Burden	Release of energetic radioactive aerosol from damaged tank due to waste temperature being out of specification during start of slurry transfer in Tank 241-C-106 and subsequent ignition of organics.	1. Operator mistake 2. Temperature measurement fault	F0	S3	B08	09X
A-1-a	W320-B-VENT08	Tank Inventory and Filter Burden	Release of energetic radioactive aerosol from damaged tank due to loss of Tank 241-C-106 ventilation for many months, dry out of waste and subsequent ignition of organics.	1. Loss of power 2. Equipment casualty	F0	S3	B07	09X
A-1-a	W320-B-VENT09*	Tank Inventory and Filter Burden	Release of energetic radioactive aerosol from damaged tank due to loss of Tank 241-AY-102 ventilation for many months, dry out of waste and subsequent ignition of organics.	1. Loss of power 2. Equipment casualty	F0	S3	B07	09X
HAZARDOUS CONDITION OF ANALYZED ACCIDENT: 10 - In-Tank Fuel Fire/Deflagration								
A-1-a	W320-D-CHILL01	Tank Inventory and Filter Burden	Release of energetic radioactive aerosol from damaged tank due to a leak and ignition of propylene glycol from pit chiller into Tank 241-C-106.	1. Piping or tubing leak	F0	S3	B12	10
HAZARDOUS CONDITIONS								
A-1-a	W320-D-CHILL02	Tank Inventory and Filter Burden	Release of energetic radioactive aerosol from damaged tank due to a leak and ignition of propylene glycol from ventilation chiller into Tank 241-C-106.	1. Piping or tubing leak	F0	S3	B12	10X
A-1a	W320-ALL-VENTO 1	Duct and Filter Burden	Release of energetic radioactive aerosol from breached ventilation duct for Tank 241-AY-102 due to a buildup of ammonium nitrate in ventilation ducting and ignition via hot work, range fire etc.	1. Natural occurrence under proper conditions	F1	S2	B08	10X

Table B-2. Representative Hazards of Analyzed Accidents and the Represented Hazardous Conditions. (24 sheets)

A-1a	W320-D-VENT01	Tank Dome Space Inventory and Filter Burden	Release of energetic radioactive aerosol from filter breach due to a buildup of ammonium nitrate in ventilation ducting of Tank 241-AY-102 and ignition via hot work, range fire etc.	1. Natural occurrence under proper conditions	F1	S2	B08	10X
HAZARDOUS CONDITION OF ANALYZED ACCIDENT: 11 - Steam Bump								
C-1-a	W320-D-TRANS08	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol through failed filters due to excessive fluffing of waste in Tank 241-AY-102 resulting in large steam bump and unfiltered release.	1. Inadequate prediction of waste behavior	F1	S2	D01	11
HAZARDOUS CONDITIONS								
B-1-a	W320-A-TRANS03	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol through failed filters from Tank 241-AY-102 due to high waste temperature during slurry transfer and resulting steam bump.	1. Inadvertent or accidental actuation of Tank 241-C-106 pump but not Tank 241-AY-102 pump	F3	S2	D14	11X
B-1-a	W320-A-TRANS01	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol through failed filters from Tank 241-C-106 due to a large steam bump	1. Flowmeters fault or out of calibration 2. Operator error in positioning Tank 241-C-106 pump 3. Inadvertent or accidental actuation of Tank 241-C-106 pump but not Tank 241-AY-102 pump 4. ENRAF level indication fault 5. Pump controller fault 6. Tank 241-C-106 T/C fault	F2	S2	D14	11X
B-1-a	W320-D-ALL05	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol through failed filters from Tank 241-AY-102 due to long term loss of ventilation system resulting in tank bump and blowout of filters.	1. Loss of power 2. Equipment casualty	F2	S2	D14	11X
C-1-a	W320-D-VENT03	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol through failed filters in the 702A ventilation system of Tank 241-AY-102 due to severe ice storm, excessive tank vacuum and resulting tank bump.	1. Natural phenomena	F2	S2	D11	11X
C-1-a	W320-D-VENT05	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol through failed filters in the W030 ventilation system due to severe ice storm, excessive tank vacuum and resulting tank bump.	1. Natural phenomena	F2	S2	D11	11X
C-1-a	W320-B-TRANS02	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol through failed filters from Tank 241-AY-102 due to low slurry flow, piling of waste at base of distributor and resulting tank bump.	1. 3-way ball valve in flushing system not fully open 2. Pump controller fault 3. Excessive solids in sluicing flow	F1	S2	D07	11X

Table B-2. Representative Hazards of Analyzed Accidents and the Represented Hazardous Conditions. (24 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	Rep Acc
C-1-a	W320-B-TRANS04	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol through failed filters from Tank 241-C-106 due to high slurry transfer rate, high waste temperature and resulting tank bump.	1. Flowmeters fault or out of calibration 2. Operator error in positioning Tank 241-C-106 pump 3. Inadvertent or accidental actuation of Tank 241-C-106 pump but not Tank 241-AY-102 pump 4. ENRAF level indication fault 5. Pump controller fault 6. Tank 241-C-106 T/C fault	F1	S2	D14	11X
C-1-a	W320-B-TRANS05	Tank Dome Space Inventory	Release of low energy radioactive aerosol from largely intact Tank 241-AY-102 due to buildup of solids pile under distributor as a result of low slurry flow which results in steam bump and increased head space vapor pressure.	1. 3-way ball valve in flushing system not fully open 2. Pump controller fault 3. Excessive solids in sluicing flow	F1	S2	D14	11X
C-1-a	W320-B-TRANS09	Tank Dome Space Inventory	Release of low energy radioactive aerosol from largely intact Tank 241-AY-102 due to buildup of solids pile under distributor as a result of the distributor nozzle breaking off which results in steam bump and increased head space vapor pressure.	1. Primary failure of distributor 2. Severe water hammer 3. Severe thermal shock 4. Corrosion 5. Metal fatigue from vibration	F1	S2	D16	11X
C-1-a	W320-BCD-TRANS 08	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol through failed filters from Tank 241-C-106 due to undetected high waste temperature and resulting tank bump	1. Expected outcome of high pressure sluice. Many objects are in the waste.	F1	S2	D04	11X
A-1-a	W320-D-ALL02	Tank Inventory	Release of low energy radioactive aerosol through failed filters from Tank 241-AY-102 due to barometric pressure change, high waste temperature and resulting tank bump	1. Ventilation balance upset 2. Sudden barometric pressure change 3. Low intensity seismic event	F1	S2	D07	11X
C-1-a	W320-D-TRANS01	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol through failed filters from Tank 241-AY-102 due to rapid waste level change, high waste temperature and resulting tank bump	1. Flowmeters fault or out of calibration 2. Operator error in positioning Tank 241-AY-102 pump 3. Inadvertent or accidental actuation of Tank 241-AY-102 pump but not Tank 241-C-106 pump 4. ENRAF level indication fault 5. Pump controller fault	F1	S2	D14	11X
C-1-a	W320-D-VENT09	Tank Dome Space Inventory	Release of low energy radioactive aerosol from largely intact Tank 241-AY-102 due to loss of primary or annulus ventilation which results in steam release.	1. Extended loss of power 2. Severe ventilation casualty	F1	S2	D07	11X

Table B-2. Representative Hazards of Analyzed Accidents and the Represented Hazardous Conditions. (24 sheets)

B-1-a	W320-A-TRANS02	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol through failed filters from Tank 241-AY-102 due to lowering of tank level with temperature out of spec resulting in tank bump	1. Flowmeters fault or out of calibration 2. Operator error in positioning Tank 241-C-106 pump 3. ENRAF level indication fault 4. Pump controller fault 5. Tank 241-C-106 T/C fault	F0	S2	D14	11X
C-1-a	W320-B-PUMP01	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol from Tank 241-AY-102 through failed filters due to overheating of waste and subsequent steam bump	1. Mass flowmeter fault or out of calibration 2. Operator error in positioning 3. Inadvertent or accidental repositioning 4. Level indication fault 5. Waste level indicator on pump fault 6. Pump controller fault	F0	S2	D14	11X
C-1-a	W320-B-TRANS03	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol through failed filters due to condensation of vapor in head space of Tank 241-C-106 which resulted from the breaking off of sluicer head.	1. Primary failure of sluicer 2. Severe Water hammer 3. Severe thermal shock 4. Corrosion 5. Metal fatigue from vibration	F0	S2	D07	11X
C-1-a	W320-BCD-TRANS 05	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol through failed filters due to tank bump in Tank 241-AY-102 resulting from the vacuum developed in the head space from the condensation of vapor which resulted from the breaking off of distributor head.	1. Primary failure of distributor 2. Severe Water hammer 3. Severe thermal shock 4. Corrosion 5. Metal fatigue from vibration	F0	S2	D16	11X
C-1-a	W320-BCD-TRANS 06	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol through failed filters of Tank 241-AY-102 due to tank bump resulting from the which resulted from the breaking off of distributor head.	1. Primary failure of distributor 2. Severe water hammer 3. Severe thermal shock 4. Corrosion 5. Metal fatigue from vibration	F0	S2	D16	11X
C-1-a	W320-BCD-TRANS 07	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol through failed filters of Tank 241-C-106 due to failure of T/C Tree, sluicing outside of temperature specs, atmospheric change, and large steam bump resulting in filter breach.	1. Sluice flow control fault 2. Operator error	F0	S2	D04	11X
A-1-a	W320-D-ALL03	Tank Inventory	Release of low energy radioactive aerosol from Tank 241-AY-102 through failed filters due to bump in interconnected tank resulting in a tank bump and filter breach.	1. Ventilation balance upset 2. Sudden barometric pressure change 3. Low intensity seismic event	F0	S2	D07	11X

Table B-2. Representative Hazards of Analyzed Accidents and the Represented Hazardous Conditions. (24 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	Rep Acc
A-1-a	W320-D-ALL04	Tank Inventory	Release of low energy radioactive aerosol from Tank 241-AY-102 through failed filters due to bump in interconnected tank resulting in a tank bump and filter breach.	1. Ventilation balance upset 2. Sudden barometric pressure change 3. Low intensity seismic event	F0	S2	D07	11X
B-1-a	W320-D-VENT02	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol from Tank 241-AY-102 through failed filters due to inadequate ventilation from W030 resulting in increased waste temperature, steam bump and filter breach.	1. Error in calculations 2. Design error 3. Construction fault	F0	S2	D14	11X
C-1-a	W320-D-VENT06	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol from Tank 241-AY-102 through failed filters due to volcanic ashfall , excessive vacuum resulting in large steam bump and filter blowout.	1. Natural phenomena	F0	S2	D18	11X
B-1-a	W320-D-VENT19	Tank Dome Space Inventory and Filter Burden	Release of low energy radioactive aerosol through failed filters due to loss of primary or annulus ventilation for extended period of time resulting in rise in waste temperature and large bump in Tank 241-AY-102.	1. Extended loss of power 2. Severe ventilation casualty	F0	S2	D14	11X
HAZARDOUS CONDITION OF ANALYZED ACCIDENT: 12 - Steam Explosion between Steel Liner and Concrete Shell								
B-1-a	W320-ABCD-TRANS01	Tank Inventory	Release of liquid waste due to sluicer nozzle jet being directed at and breaching Tank 241-C-106 wall resulting in water leaking into liner gap where steam vapor forms and breaches tank bottom.	1. Unavoidable operator action	F3	S2	D04	12
HAZARDOUS CONDITIONS								
B-3-b	W320-ABCD-ALL04	Tank Inventory	Release of liquid waste below grade and aerosol release to atmosphere due to water intrusion into Tank 241-C-106 with water level exceeding maximum operating level resulting in leakage into liner gap, steam formation, breaching of tank bottom and steam bump.	1. Raw water leak 2. Surface water flood 3. Vent system water inleakage 4. Excessive transfer from Tank 241-AY-102 5. Water intrusion in Tank 241-C-105 that cascades over to Tank 241-C-106	F3	S2	D12	12X
B-3-b	W320-ABCD-ALL05	Tank Inventory	Release of liquid waste below grade and aerosol release to atmosphere due to water intrusion into Tank 241-C-106 with water level exceeding maximum operating level resulting in leakage into liner gap, steam formation, breaching of tank bottom and steam bump.	1. Raw water leak 2. Surface water flood 3. Vent system water inleakage 4. Excessive transfer from Tank 241-AY-102 5. Water intrusion in Tank 241-C-105 that cascades over to Tank 241-C-106	F2	S2	D12	12X

Table B-2. Representative Hazards of Analyzed Accidents and the Represented Hazardous Conditions. (24 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	Rep Acc
A-1-a	W320-ABCD-TRANS02	Tank Inventory	Release of liquid waste below grade and aerosol release to atmosphere due to loss of sluicer arm control in Tank 241-C-106 resulting in jet striking tank liner with liner being breached, water leakage into liner gap, steam formation, breaching of tank bottom and steam bump.	1. Unavoidable operator action	F2	S2	D04	12X
B-1-a	W320-ABCD-TRANS05	Tank Inventory	Release of liquid waste below grade and aerosol release to atmosphere due to sluicer hose break in Tank 241-C-106 resulting in jet striking tank liner with liner being breached, water leakage into liner gap, steam formation, and breaching of tank bottom.	1. Primary failure of Hose 2. Severe Water hammer 3. Fatigue from vibration	F2	S2	D04	12X
B-1-a	W320-ABCD-TRANS07	Tank Inventory	Release of liquid waste below grade and aerosol release to atmosphere due to sluicer flow being excessive in Tank 241-C-106 resulting in jet striking tank liner with liner being breached, water leakage under tank bottom, steam formation, breaching of tank bottom and large steam bump.	1. Sluice flow control fault 2. Operator error	F2	S2	D04	12X
B-1-a	W320-ABCD-TRANS08	Tank Inventory	Release of liquid waste below grade and aerosol release to atmosphere due to sluicer flow excessive into Tank 241-C-106 with water level exceeding maximum operating level resulting in leakage into liner gap, steam formation, breaching of tank bottom and large steam bump.	1. Sluice flow control fault 2. Operator error	F2	S2	D04	12X
B-1-a	W320-BCD-ALL08	Tank Inventory	Release of liquid waste below grade and aerosol release to atmosphere due to excessive corrosion because of waste disturbance in Tank 241-C-106 resulting in leakage into liner gap, steam formation, breaching of tank bottom and steam bump.	1. Inadequate prediction of waste behavior	F2	S2	D16	12X
B-3-b	W320-BCD-TRANS09	Tank Inventory	Release of liquid waste below grade and aerosol release to atmosphere due to loss of pumping from Tank 241-C-106 and continued pumping of Tank 241-AY-102 water exceeds maximum operating level resulting in water leakage into liner gap, steam formation, breaching of tank bottom and large steam bump.	1. Loss of power 2. Equipment casualty	F2	S2	D12	12X
C-3-b	W320-D-ALL09	Tank Inventory	Release of liquid waste below grade and aerosol release to atmosphere due to seismic event Tank 241-C-106 liner is breached resulting in water leakage into liner gap, steam formation, breaching of tank bottom and large steam bump.	1. Natural Phenomena	F2	S2	D18	12X

Table B-2. Representative Hazards of Analyzed Accidents and the Represented Hazardous Conditions. (24 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	Rep Acc
B-1-a	W320-D-TRANS09	Tank Inventory	Release of liquid waste below grade and aerosol release to atmosphere due to movement of debris during sluicing which impacts and breaches the Tank 241-C-106 liner, resulting in water leakage into liner gap, steam formation, breaching of tank bottom and steam bump.	1. Expected outcome of high pressure sluice. Many objects are in the waste.	F2	S2	D04	12X
A-1-a	W320-ABCD-TRAN S03	Tank 241-C-106 inventory	Release of liquid waste below grade and aerosol release to atmosphere due to siphoning of waste from Tank 241-AY-102 after the stoppage of pumping water exceeds maximum operating level in Tank 241-C-106 resulting in water leakage into liner gap, steam formation, breaching of tank bottom and large steam bump.	1. Buildup of solids in openings 2. Equipment casualty	F1	S2	D04	12X
B-1-a	W320-ABCD-TRAN S09	Tank Inventory	Release of liquid waste below grade and aerosol release to atmosphere due to excessive waste temperature change rate Tank 241-C-106 liner breaches, resulting in water leakage under tank bottom, steam formation, breaching of tank bottom and large steam bump.	1. High temperature in Tank 241-AY-102	F1	S2	D04	12X
A-1-a	W320-BCD-ALL07	Tank 241-C-106 Overflow Volume	Release of liquid waste below grade and aerosol release to atmosphere due to water intrusion into Tank 241-C-105 which travels through cascade line into Tank 241-C-106 with water level exceeding maximum operating level resulting in leakage into liner gap, steam formation, bulging of tank bottom, ripping of liner and steam bump.	1. Raw water leak 2. Surface water flood	F1	S2	D06	12X
B-1-a	W320-F-TERM05	Tank Inventory	Release of liquid waste below grade and aerosol release to atmosphere due to high heat load after completion of sluicing process resulting in the need for water addition to Tank 241-C-106 with a deteriorated tank liner, water leakage into liner gap, steam formation, liner breach and steam bump.	1. Error in calculations	F1	S2	D12	12X
B-1-a	W320-ABCD-TRAN S06	Tank Inventory	Release of liquid waste below grade and aerosol release to atmosphere due to sluicing arm breaking off and penetrating Tank 241-C-106 liner resulting in water leakage into liner gap, steam formation, liner breach and steam bump.	1. Primary failure of sluicer 2. Severe Water hammer 3. Severe thermal shock 4. Corrosion 5. Metal fatigue from vibration	F0	S2	D04	12X

Table B-2. Representative Hazards of Analyzed Accidents and the Represented Hazardous Conditions. (24 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	Rep Acc
B-1-a	W320-BCD-PUMP08	Tank Inventory	Release of liquid waste below grade and aerosol release to atmosphere due to submersible pump being raised too high, winch lifting strap breaking, pump falling and penetrating Tank 241-C-106 liner resulting in water leakage into liner gap, steam formation, liner bulges/rips and steam bump occurs.	1. Operator error in positioning direction 2. Inadvertent or accidental actuation 3. Winch controller fault	F0	S2	D14	12X
HAZARDOUS CONDITION OF ANALYZED ACCIDENT: 13 - Subsurface Leak Remaining Subsurface								
C-3-b	W320-B-TRANS19	Transfer Line Inventory	Release of radioactive liquid from breached transfer line due to a leak from primary transfer line and a defective secondary line resulting in an underground spill.	1. Line corrosion 2. ground movement 3. Aging	F1	S0	D12	13
HAZARDOUS CONDITIONS								
C-3-b	W320-B-ALL11	Tank Inventory	Release of liquid waste due to large water intrusion into Tank 241-C-106 resulting in high hydrostatic pressure and tank breach.	1. Raw water leak 2. Surface water flood 3. Vent system water inleakage 4. Excessive transfer from Tank 241-AY-102 5. Water intrusion in Tank 241-C-105 that cascades over to Tank 241-C-106	F2	S2	D19	13X
HAZARDOUS CONDITION OF ANALYZED ACCIDENT: 14 - Subsurface Leak Resulting in Pool								
C-2-b	W320-B-TRANS22	Tank 241-AY-102 inventory	Release of radioactive liquid from transfer line due to local flooding during transfer which results in line being uncovered and breached.	1. Raw water leak 2. Natural flow	F3	S2	D19	14
HAZARDOUS CONDITION OF ANALYZED ACCIDENT: 15 - Surface Leak Resulting in Pool								
C-2-b	W320-B-FLUSH06	Flushing water in Tank 241-AY-102 Pit	Release of radioactive liquid from transfer line due to a pipe break in Tank 241-AY-102 pit with the high capacity drain cover on resulting in overflow of pit onto the ground.	1. Equipment failure 2. Maintenance or assembly error	F2	S2	D12	15A
C-2-b	W320-BCD-TRANS10	Tank 241-AY-102 inventory	Release of radioactive liquid release from sluice transfer line due to the blank flange being left off flushing connection in Tank 241-AY-102 pit and drain cover left on resulting in overflow of pit onto the ground during sluicing.	1. Maintenance error 2. Communications error between different groups using the pit	F2	S2	E06	15B

Table B-2. Representative Hazards of Analyzed Accidents and the Represented Hazardous Conditions. (24 sheets)

A-1-a	W320-BCD-FLUSH 02*	Transfer Line Inventory	Release of energetic radioactive aerosol from flush tank of transfer truck due to start of submersible pump in Tank 241-C-106 during the flush of slurry transfer line. Flush tank is filled and pressurized resulting in rupture of tank or transfer line.	1. Human error 2. Communications error between different groups	F3	S3	E06	16X
A-1-a	W320-ABCD-TRAN S11	Tank Inventory	Release of energetic radioactive aerosol from transfer line in pit due to flammable gas collecting in pit and being ignited. Cover block lifted and falls onto piping in pit resulting in spray release.	1. Chimney through deep drop legs 2. 6 in. high capacity drain to dome space 3. Pit sealed to minimize inleakage	F2	S3	B08	16X
B-1-a	W320-ABCD-TRAN S12	Transfer Line Inventory	Release of energetic radioactive aerosol from line break due to pipe or jumper breach in distributor pit of Tank 241-AY-102 with cover block off during slurry transfer.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	F2	S3	D12	16X
A-1-a	W320-B-TRANS23	Transfer Line Inventory	Release of energetic radioactive aerosol from line break due to pipe or jumper breach in pump pit of Tank 241-AY-102 with cover block off during sluicing.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	F2	S3	D12	16X
A-1-a	W320-B-TRANS24	Transfer Line Inventory	Release of energetic radioactive aerosol from line break due to pipe or jumper breach in pump pit of Tank 241-C-106 with cover block off.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	F2	S3	D12	16X
A-1-a	W320-B-TRANS25	Transfer Line Inventory	Release of energetic radioactive aerosol from line break due to pipe or jumper breach in sluice pit of Tank 241-C-106 with cover block off.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	F2	S3	D12	16X
A-1-a	W320-B-TRANS26	Transfer Line Inventory	Release of energetic radioactive aerosol from transfer line in Tank 241-C-106 pit due to flammable gas collecting in pit and being ignited. Cover block lifted and falls onto piping in pit resulting in spray release.	1. Chimney through deep drop legs 2. 6 in. high capacity drain to dome space 3. Pit sealed to minimize inleakage	F2	S3	B08	16X
B-1-a	W320-D-TRANS10	Transfer Line Inventory	Release of energetic radioactive aerosol from jumper in pit due to seismic event. Cover block breached by ground motion resulting in spray release.	1. Natural Phenomena	F2	S3	D18	16X

Table B-2. Representative Hazards of Analyzed Accidents and the Represented Hazardous Conditions. (24 sheets)

A-1-a	W320-B-TRANS27	Transfer Line Inventory	Release of energetic radioactive aerosol from transfer line in pit due to flammable gas collecting in pit and being ignited. Cover block lifted and falls onto piping in pit resulting in spray release.	1. Chimney through deep drop legs 2. 6 in. high capacity drain to dome space 3. Pit sealed to minimize inleakage	F1	S3	B08	16X
B-1-a	W320-D-PUMP01	Tank 241-AY-102 Inventory	Release of energetic radioactive aerosol from line break in Tank 241-AY-102 transfer pit due to immersible pump being positioned too high resulting in air entrainment in transfer line. Booster pump torques in reaction to air in transfer line and jumper connectors break. Cover block is off.	1. Operator error in positioning 2. Inadvertent or accidental repositioning 3. Level indication fault 4. Waste level indicator on pump fault	F1	S3	D12	16X
B-1-a	W320-D-PUMP03	Transfer Line Inventory	Release of energetic radioactive aerosol from line break in Tank 241-C-106 transfer pit due to immersible pump being positioned too high resulting in air entrainment in transfer line. Booster pump torques in reaction to air in transfer line and jumper connectors break. Cover block is off.	1. Operator error in positioning 2. Inadvertent or accidental repositioning 3. Level indication fault 4. Waste level indicator on pump fault	F1	S3	D12	16X
B-1-a	W320-B-TRANS28	Tank 241-C-106 inventory	Release of radioactive aerosol from covered pit due to jumper or pipe breach in Tank 241-AY-102 distributor pit resulting in spray release from pit.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	F3	S2	D12	16X
B-1-a	W320-B-TRANS29	Tank 241-AY-102 inventory	Release of radioactive aerosol from covered pit due to jumper or pipe breach in Tank 241-AY-102 pump pit resulting in spray release from pit.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	F3	S2	D12	16X
B-1-a	W320-B-TRANS30	Tank 241-C-106 inventory	Release of radioactive aerosol from covered pit due to jumper or pipe breach in Tank 241-C-106 pump pit resulting in spray release from pit.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	F3	S2	D12	16X
B-1-a	W320-B-TRANS31	Tank 241-AY-102 inventory	Release of radioactive aerosol from covered pit due to jumper or pipe breach in Tank 241-C-106 sluice pit resulting in spray release from pit.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	F3	S2	D12	16X

Table B-2. Representative Hazards of Analyzed Accidents and the Represented Hazardous Conditions. (24 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	Rep Acc
A-1-a	W320-BCD-TRANS 13	Tank 241-C-106 inventory	Release of energetic radioactive aerosol from transfer line due to blank flange left off flushing connection and 3 way valve left in flush position after flushing. Cover plug remains in place on initiation of sluicing process. High capacity drain cover left on and pit overflows.	1. Maintenance error 2. Communications error between different groups using the pit	F3	S2	E06	16X
HAZARDOUS CONDITION OF ANALYZED ACCIDENT: 17 - Spray Leak from Underground Waste Transfer Line								
B-1-a	W320-D-TRANS11	Transfer Line Inventory	Release of large high energy aerosolized radioactive waste to the atmosphere from a spray leak from transfer line due to seismic event.	1. Natural Phenomena	F1	S3	D18	17
HAZARDOUS CONDITIONS								
A-1-a	W320-B-TRANS32	Transfer Line Inventory	Release of large high energy aerosolized radioactive waste from a spray leak from transfer line break due to aircraft strike on underground transfer line berm.	1. Light aircraft crash	F1	S3	D23	17X
HAZARDOUS CONDITIONS: 18a - Natural Phenomena - Seismic Events								
C-1-a	W320-D-ALL06	Tank Dome Space Inventory and Filter Burden	Release of a small amount of low energy aerosolized waste through failed filters due to seismic event which induces a steam bump in Tank 241-AY-102, and failure of filters or ducting.	1. Natural Phenomena	F1	S2	D18	18F
HAZARDOUS CONDITIONS: 18e - Natural Phenomena - Volcanic Activity								
A-1-a	W320-B-ALL01-dup	Tank Inventory	Release of a large amount of high energy aerosolized waste from Tank 241-C-106 dome collapse due to volcanic ashfall.	1. Natural phenomena	F0	S3	C18	06X
A-1-a	W320-D-VENT18-dup	Tank 241-AY-102 Inventory	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 to the atmosphere due to volcanic ashfall which prevents air inflow to tank. Excessive vacuum results and flammable gas is released to the dome space. It is then ignited resulting in a dome space fire.	1. Natural phenomena	F0	S3	B18	08X
HAZARDOUS CONDITIONS: 18f - Natural Phenomena - High Winds/Dust Devils								
C-1-a	W320-ALL-TRANS 02	Duct and Filter Burden	Release of small high energy aerosolized waste due to high winds or tornado resulting in failed ventilation ducting and unfiltered release.	1. Natural occurrence under proper conditions	F2	S2	D20	18A

Table B-2. Representative Hazards of Analyzed Accidents and the Represented Hazardous Conditions. (24 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	Rep Acc
C-1-a	W320-B-ALL14	Tank Dome Space Inventory	Release of small low energy aerosolized waste to the atmosphere from intact pit due to high winds/dust devils during plug removal from pit cover.	1. High winds	F1	S2	D20	18A
Radiation Protection								
RP	W320-BCD-FLUSH 03*	Transfer Line Inventory	Personnel exposure to ionizing radiation from flush tank of transfer truck due to start of submersible pump in Tank 241-C-106 during the flush of slurry transfer line. Flush tank is filled with radioactive material.	1. Operator Error 2. Failure in submersible pump circuitry	F3	S2	F06	21X

Table C-1. Hazardous Conditions With Potential Significant Offsite Consequences (S3). (6 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-BCD-FLUSH01	Release of energetic radioactive aerosol from transfer line due to 3-way valve left in flush position after flushing. Cover plug is lifted out of cover block on initiation of sluicing process.	1. Maintenance error 2. Communications error between different groups using the pit	F3	E2
W320-BCD-FLUSH02*	Release of energetic radioactive aerosol from flush tank of transfer truck due to start of submersible pump in Tank 241-C-106 during the flush of slurry transfer line. Flush tank is filled and pressurized resulting in rupture of tank or transfer line.	1. Human error 2. Communications error between different groups	F3	E2
W320-BCD-TRANS11	Release of energetic radioactive aerosol from transfer line due to blank flange left off flushing connection in Tank 241-C-106 pit after flushing. Cover plug is lifted out of cover block on initiation of sluicing process.	1. Maintenance error 2. Communications error between different groups using the pit	F3	E2
W320-BCD-TRANS12	Release of energetic radioactive aerosol from transfer line due to blank flange left off flushing connection in Tank 241-AY-102 pit after flushing. Cover plug is lifted out of cover block on initiation of sluicing process.	1. Maintenance error 2. Communications error between different groups using the pit	F3	E2
W320-ABCD-TRANS11	Release of energetic radioactive aerosol from transfer line in pit due to flammable gas collecting in pit and being ignited. Cover block lifted and falls onto piping in pit resulting in spray release.	1. Chimney through deep drop legs 2. 6 in. high capacity drain to dome space 3. Pit sealed to minimize inleakage	F2	E2
W320-ABCD-TRANS11	Release of energetic radioactive aerosol release from line break due to flammable gas ignition in pit with cover block falling onto piping.	1. Chimney through deep drop legs 2. 6 in. high capacity drain to dome space 3. Pit sealed to minimize inleakage	F2	E2
W320-ABCD-TRANS12	Release of energetic radioactive aerosol from line break due to pipe or jumper breach in distributor pit of Tank 241-AY-102 with cover block off during slurry transfer.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	F2	E2
W320-B-TRANS23	Release of energetic radioactive aerosol from line break due to pipe or jumper breach in pump pit of Tank 241-AY-102 with cover block off during sluicing.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	F2	E2
W320-B-TRANS24	Release of energetic radioactive aerosol from line break due to pipe or jumper breach in pump pit of Tank 241-C-106 with cover block off.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	F2	E2
W320-B-TRANS25	Release of energetic radioactive aerosol from line break due to pipe or jumper breach in sluice pit of Tank 241-C-106 with cover block off.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	F2	E2

Table C-1. Hazardous Conditions With Potential Significant Offsite Consequences (S3). (6 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-B-TRANS26	Release of energetic radioactive aerosol from transfer line in Tank 241-C-106 pit due to flammable gas collecting in pit and being ignited. Cover block lifted and falls onto piping in pit resulting in spray release.	1. Chimney through deep drop legs 2. 6 in. high capacity drain to dome space 3. Pit sealed to minimize inleakage	F2	E2
W320-D-ALL07	Release of energetic radioactive aerosol from damaged double shell Tank 241-AY-102 due to seismic event which releases flammable gas from the waste and after shocks cause mechanical sparks which ignites the flammable gas mixture.	1. Natural Phenomena	F2	E2
W320-D-TRANS10	Release of energetic radioactive aerosol from jumper in pit due to seismic event. Cover block breached by ground motion resulting in spray release.	1. Natural Phenomena	F2	E2
W320-B-ALL09	Release of energetic radioactive aerosol from damaged tank due to formation of organic layer in Tank 241-AY-102 during slurry distribution and subsequent ignition of organics.	1. Sluicing causes organic separation	F1	E3
W320-B-ALL10	Release of energetic radioactive aerosol from damaged tank due to formation of organic layer in Tank 241-C-106 during sluicing and subsequent ignition of organics.	1. Sluicing causes organic separation	F1	E3
W320-ABCD-ALL01	Release of energetic radioactive aerosol from damaged tank due to flooding on top of Tank 241-C-106 dome	1. Raw water line rupture 2. Heavy rainfall	F1	E2
W320-ABCD-ALL02	Release of energetic radioactive aerosol from damaged tank due to flooding on top of Tank 241-AY-102 dome	1. Raw water line rupture 2. Heavy rainfall	F1	E2
W320-ABCD-ALL07	Release of radioactive liquid from Tank 241-C-106 onto the ground due to large water intrusion into tank.	1. Raw water leak 2. Surface water flood 3. Vent system water inleakage 4. Excessive transfer from Tank 241-AY-102 5. Water intrusion in Tank 241-C-105 that cascades over to Tank 241-C-106	F1	E2
W320-ABCD-ALL08*	Release of radioactive liquid from Tank 241-C-106 due to siphoning of waste from Tank 241-AY-102 into Tank 241-C-106	1. Plugging of antisiphon holes 2. Loss of electrical power to the pumps 3. Shutdown from operations	F1	E2
W320-ABCD-CHILL03	Release of energetic radioactive aerosol from collapsed Tank 241-C-106 due to excessive cooling from process chiller which restricts inflow and loop seal fails to operate.	1. Chiller control fault 2. High humidity	F1	E2
W320-ABCDF-ALL01*	Release of energetic radioactive aerosol to atmosphere due to buildup of flammable gas in Tank 241-AY-102 pit drain pipe which is then ignited.	1. Flammable gas generation from tank waste	F1	E2

Table C-1. Hazardous Conditions With Potential Significant Offsite Consequences (S3). (6 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-B-FLUSH04	Release of low energy radioactive aerosol from breached Tank 241-C-106 due to flushing water spray through sluice nozzle resulting in excessive tank vacuum.	1. Planned	F1	E2
W320-B-TRANS27	Release of energetic radioactive aerosol from transfer line in pit due to flammable gas collecting in pit and being ignited. Cover block lifted and falls onto piping in pit resulting in spray release.	1. Chimney through deep drop legs 2. 6 in. high capacity drain to dome space 3. Pit sealed to minimize inleakage	F1	E2
W320-B-TRANS32	Release of large high energy aerosolized radioactive waste from a spray leak from transfer line break due to aircraft strike on underground transfer line berm.	1. Light aircraft crash	F1	E2
W320-BCD-ALL03	Release of energetic radioactive aerosol from damaged Tank 241-C-106 due to excessive vacuum resulting from ventilation system fan overspeed and failure of tank loop seal failure.	1. Rotameter valve to controller fault 2. Operator error in adjusting rotameter or inadvertent adjustment	F1	E2
W320-D-ALL08	Release of energetic radioactive aerosol to atmosphere due to start of air lift circulators in Tank 241-AY-102 resulting in a release of flammable gas plume which is then ignited.	1. Human error 2. Communications error with other workers using the tank 3. IOSRs require activation of ALCs in event temperature above limit	F1	E2
W320-D-PUMP01	Release of energetic radioactive aerosol from line break in Tank 241-AY-102 transfer pit due to immersible pump being positioned to high resulting in air entrainment in transfer line. Booster pump torques in reaction to air in transfer line and jumper connectors break. Cover block is off.	1. Operator error in positioning 2. Inadvertent or accidental repositioning 3. Level indication fault 4. Waste level indicator on pump fault	F1	E2
W320-D-PUMP03	Release of energetic radioactive aerosol from line break in Tank 241-C-106 transfer pit due to immersible pump being positioned to high resulting in air entrainment in transfer line. Booster pump torques in reaction to air in transfer line and jumper connectors break. Cover block is off.	1. Operator error in positioning 2. Inadvertent or accidental repositioning 3. Level indication fault 4. Waste level indicator on pump fault	F1	E2
W320-D-TRANS05	Release of energetic radioactive aerosol to atmosphere due to head space gas concentration above LFL in Tank 241-AY-102 with the start of pumping which ignites the flammable gas.	1. Spontaneous GRE 2. Induced GRE	F1	E2
W320-D-TRANS07	Release of high energetic aerosolized waste to the atmosphere due to sluice water transfer rate being excessive resulting in the Tank 241-AY-102 waste level being lowered quickly with the waste temperature to high. This results in a large steam bump and flammable gas release with ignition.	1. Operator mistake 2. Level indication fault 3. Pump controller fault	F1	E2
W320-D-TRANS11	Release of large high energy aerosolized radioactive waste to the atmosphere from a spray leak from transfer line due to seismic event.	1. Natural Phenomena	F1	E2

Table C-1. Hazardous Conditions With Potential Significant Offsite Consequences (S3). (6 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-D-VENT12	Release of energetic radioactive aerosol from collapsed Tank 241-C-106 due to incorrect alignment of current ventilation system through sluice nozzle resulting in excessive tank vacuum with loop seal failure.	1. Operator error 2. Communications error	F1	E2
W320-D-VENT17	Release of high energy aerosolized release to the atmosphere due to an ice storm which prevents air inflow into Tank 241-AY-102 resulting in an excessive tank vacuum. This results in a flammable gas release with ignition.	1. Natural phenomena	F1	E2
W320-D-VENT20	Release of energetic radioactive aerosol from collapsed Tank 241-C-106 due to incorrect alignment of new ventilation system through sluice nozzle resulting in excessive tank vacuum with loop seal failure.	1. Operator error 2. Communications error	F1	E2
W320-A-TRANS06	Release of energetic radioactive aerosol from damaged tank due to waste temperature being out of specification during start of slurry transfer in Tank 241-C-106 and subsequent ignition of organics.	1. Operator mistake 2. Temperature measurement fault	F0	E3
W320-B-VENT08	Release of energetic radioactive aerosol from damaged tank due to loss of Tank 241-C-106 ventilation for many months, dry out of waste and subsequent ignition of organics.	1. Loss of power 2. Equipment casualty	F0	E3
W320-B-VENT09*	Release of energetic radioactive aerosol from damaged tank due to loss of Tank 241-AY-102 ventilation for many months, dry out of waste and subsequent ignition of organics.	1. Loss of power 2. Equipment casualty	F0	E3
W320-D-CHILL01	Release of energetic radioactive aerosol from damaged tank due to a leak and ignition of propylene glycol from pit chiller into Tank 241-C-106.	1. Piping or tubing leak	F0	E3
W320-D-CHILL02	Release of energetic radioactive aerosol from damaged tank due to a leak and ignition of propylene glycol from ventilation chiller into Tank 241-C-106.	1. Piping or tubing leak	F0	E3
W320-A-TRANS05	Release of energetic radioactive aerosol to atmosphere due to temperature out of specification resulting in steam bump when Tank 241-C-106 level is lowered which induces a release of a flammable gas plume and then is ignited.	1. Operator mistake 2. Temperature measurement fault	F0	E2
W320-ABCD-ALL03	Release of energetic radioactive aerosol from tank dome collapse due to flooding on top of tank dome	1. Raw water line rupture 2. Heavy rainfall	F0	E2
W320-B-ALL01	Release of a large amount of high energy aerosolized waste from Tank 241-C-106 dome collapse due to volcanic ashfall.	1. Natural phenomena	F0	E2
W320-B-ALL02	Release of a large amount of high energy aerosolized waste from 241-AY-102 Tank dome collapse due to volcanic ashfall.	1. Natural phenomena	F0	E2

Table C-1. Hazardous Conditions With Potential Significant Offsite Consequences (S3). (6 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-B-ALL03	Release of high energy aerosolized waste to the atmosphere from Tank 241-C-106 dome collapse due to extreme snow fall.	1. Natural phenomena	F0	E2
W320-B-ALL04	Release of large amount of high energy aerosolized waste from 241-AY-102 Tank dome collapse due to extreme snow fall.	1. Natural phenomena	F0	E2
W320-B-ALL05	Release of energetic radioactive aerosol from Tank 241-C-106 dome collapse due to dome being overloaded.	1. Maintenance error 2. Procedure violation	F0	E2
W320-B-ALL06	Release of energetic radioactive aerosol from 241-AY-102 Tank dome collapse due to dome being overloaded.	1. Maintenance error 2. Procedure violation	F0	E2
W320-B-ALL08	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 due to a large water intrusion which induces a flammable gas release event. It is then ignited resulting in a dome space fire.	1. Raw water leak 2. Surface water flood	F0	E2
W320-B-TRANS14	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 to the atmosphere due to low slurry flow to distributor which results in solids piling up. Pile generates significant amount of flammable gas and LFL is reached in dome space. It is then ignited resulting in a dome space fire.	1. 3-way ball valve in flushing system not fully open 2. Pump controller fault	F0	E2
W320-B-TRANS15	Large high energy aerosolized waste release from Tank 241-AY-102 to the atmosphere due to air injected into the waste from the startup of slurry flow from the distributor. Gas is scrubbed from the waste and LFL is reached in dome space. It is then ignited resulting in a dome space fire.	1. Normal procedure	F0	E2
W320-B-TRANS16	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 to the atmosphere due to distributor nozzle breaking off which results in solids piling up. Pile generates significant amount of flammable gas and LFL is reached in dome space. It is then ignited resulting in a dome space fire.	1. Primary failure of distributor 2. Severe water hammer 3. Severe thermal shock 4. Corrosion 5. Metal fatigue from vibration	F0	E2
W320-BCD-ALL02	Release of energetic radioactive aerosol from collapsed Tank 241-AY-102 due to excessive vacuum resulting from W030 ventilation system inlet damper closing and failure of PCV fails to relieve vacuum.	1. Rotameter valve to controller fault 2. Operator error in adjusting rotameter or inadvertent adjustment	F0	E2
W320-BCD-PUMP04	Release of energetic radioactive aerosol to atmosphere due to submersible pump being raised to high in Tank 241-AY-102, winch lifting strap breaking, pump falling into waste resulting in a flammable gas release which is ignited by broken electrical cables.	1. Operator error in positioning direction 2. Inadvertent or accidental actuation 3. Winch controller fault	F0	E2

Table C-1. Hazardous Conditions With Potential Significant Offsite Consequences (S3). (6 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-D-PUMP04	Release of energetic radioactive aerosol from damaged Tank 241-AY-102 due to pumping of more solids than anticipated. Annulus cooling mod not completed resulting in overheating of waste and a tank bump. Bump induces large flammable gas release. It is then ignited resulting in a dome space fire.	1. Mass flowmeter fault or out of calibration 2. Operator error in positioning slurry pump 3. Inadvertent or accidental repositioning 4. Level indication fault 5. Waste level indicator on pump Tank 241-C-106 fault 6. Pump controller fault	F0	E2
W320-D-VENT13	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 to the atmosphere due to influx of cold water spray into tank which results in an excessive vacuum. A large flammable gas release is induced. It is then ignited resulting in a dome space fire.	1. Possible result of slurry distribution	F0	E2
W320-D-VENT16	Large high energy aerosolized waste release from Tank 241-AY-102 to the atmosphere due to the loss of primary or annulus ventilation for an extended period which results in a gradual rise in waste temperature. Flammable gas builds up in the dome space to the LFL. It is then ignited resulting in a dome space fire.	1. Extended loss of power 2. Severe ventilation casualty	F0	E2
W320-D-VENT18	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 to the atmosphere due to volcanic ashfall which prevents air inflow to tank. Excessive vacuum results and flammable gas is released to the dome space. It is then ignited resulting in a dome space fire.	1. Natural phenomena	F0	E2
W320-E-TERM03	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 to the atmosphere due to lack of controls on operation of tank after it has been turned into a FG group 1 tank. It is ignited from a lightning strike or other event resulting in a dome space fire.	1. Inadequate prediction of waste behavior	F0	E2

ALC = air lift circulator.
GRE = gas release event.
HEPA = high efficiency particulate air (filter).
IOSR = Interim Operational Safety Requirements.
LFL = lower flammability limit.

Table C-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2). (11 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-ABCD-ALL04	Release of liquid waste below grade and aerosol release to atmosphere due to water intrusion into Tank 241-C-106 with water level exceeding maximum operating level resulting in leakage into liner gap, steam formation, breaching of tank bottom and steam bump.	1. Raw water leak 2. Surface water flood 3. Vent system water inleakage 4. Excessive transfer from Tank 241-AY-102 5. Water intrusion in Tank 241-C-105 that cascades over to Tank 241-C-106	F3	E2
W320-ABCD-TRANS01	Release of liquid waste due to sluicer nozzle jet being directed at and breaching Tank 241-C-106 wall resulting in water leaking into liner gap where steam vapor forms and breaches tank bottom.	1. Unavoidable operator action	F3	E2
W320-A-TRANS03	Release of low energy radioactive aerosol through failed filters from Tank 241-AY-102 due to high waste temperature during slurry transfer and resulting steam bump.	1. Inadvertent or accidental actuation of Tank 241-C-106 pump but not Tank 241-AY-102 pump	F3	E1
W320-B-ALL07	Small low energy aerosolized waste release from largely intact tank due to flammable gas collecting in a Tank 241-C-106 pit where it is ignited resulting in the cover blocks being displaced and falling into pit. Cover block strikes riser-liner joint resulting in an unfiltered release from dome space.	1. Chimney through deep drop legs 2. 6 in. high capacity drain to dome space 3. Pit sealed to minimize inleakage	F3	E1
W320-B-TRANS22	Release of radioactive liquid from transfer line due to local flooding during transfer which results in line being uncovered and breached.	1. Raw water leak 2. Natural flow	F3	E1
W320-B-TRANS28	Release of radioactive aerosol from covered pit due to jumper or pipe breach in Tank 241-AY-102 distributor pit resulting in spray release from pit.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	F3	E1
W320-B-TRANS29	Release of radioactive aerosol from covered pit due to jumper or pipe breach in Tank 241-AY-102 pump pit resulting in spray release from pit.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	F3	E1
W320-B-TRANS30	Release of radioactive aerosol from covered pit due to jumper or pipe breach in Tank 241-C-106 pump pit resulting in spray release from pit.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	F3	E1
W320-B-TRANS31	Release of radioactive aerosol from covered pit due to jumper or pipe breach in Tank 241-C-106 sluice pit resulting in spray release from pit.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	F3	E1
W320-BCD-TRANS13	Release of energetic radioactive aerosol from transfer line due to blank flange left off flushing connection and 3 way valve left in flush position after flushing. Cover plug remains in place on initiation of sluicing process. High capacity drain cover left on and pit overflows.	1. Maintenance error 2. Communications error between different groups using the pit	F3	E1
W320-D-ALL01	Release of low energy radioactive aerosol through failed filters from Tank 241-AY-102 due to a steam bump	1. Human error 2. Communications error with other workers using the tank 3. IOSRs require activation of ALCs in event temperature above limit	F3	E1

Table C-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2). (11 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-D-VENT07	Release of low energy radioactive aerosol from Tank 241-C-105/Tank 241-C-106 ventilation system due to failure to determine ventilation leak during sluicing.	1. Ducting corrosion 2. Seal deterioration	F3	E1
W320-D-VENT08	Release of low energy radioactive aerosol from largely intact tank due to excessive vacuum in Tank 241-C-106 from new ventilation system which results in loop seal failure and unfiltered release.	1. Operator error 2. Communications error	F3	E1
W320-D-VENT11	Release of low energy radioactive aerosol from largely intact tank due to excessive vacuum in Tank 241-C-106 from current ventilation system which results in loop seal failure and unfiltered release.	1. Operator error 2. Communications error	F3	E1
W320-BCD-FLUSH03*	Personnel exposure to ionizing radiation from flush tank of transfer truck due to start of submersible pump in Tank 241-C-106 during the flush of slurry transfer line. Flush tank is filled with radioactive material.	1. Operator Error 2. Failure in submersible pump circuitry	F3	E0
W320-ABCD-ALL05	Release of liquid waste below grade and aerosol release to atmosphere due to water intrusion into Tank 241-C-106 with water level exceeding maximum operating level resulting in leakage into liner gap, steam formation, breaching of tank bottom and steam bump.	1. Raw water leak 2. Surface water flood 3. Vent system water inleakage 4. Excessive transfer from Tank 241-AY-102 5. Water intrusion in Tank 241-C-105 that cascades over to Tank 241-C-106	F2	E2
W320-ABCD-TRANS02	Release of liquid waste below grade and aerosol release to atmosphere due to loss of sluicer arm control in Tank 241-C-106 resulting in jet striking tank liner with liner being breached, water leakage into liner gap, steam formation, breaching of tank bottom and steam bump.	1. Unavoidable operator action	F2	E2
W320-ABCD-TRANS05	Release of liquid waste below grade and aerosol release to atmosphere due to sluicer hose break in Tank 241-C-106 resulting in jet striking tank liner with liner being breached, water leakage into liner gap, steam formation, and breaching of tank bottom.	1. Primary failure of Hose 2. Severe Water hammer 3. Fatigue from vibration	F2	E2
W320-ABCD-TRANS07	Release of liquid waste below grade and aerosol release to atmosphere due to sluicer flow being excessive in Tank 241-C-106 resulting in jet striking tank liner with liner being breached, water leakage under tank bottom, steam formation, breaching of tank bottom and large steam bump.	1. Sluice flow control fault 2. Operator error	F2	E2
W320-ABCD-TRANS08	Release of liquid waste below grade and aerosol release to atmosphere due to sluicer flow excessive into Tank 241-C-106 with water level exceeding maximum operating level resulting in leakage into liner gap, steam formation, breaching of tank bottom and large steam bump.	1. Sluice flow control fault 2. Operator error	F2	E2
W320-BCD-ALL08	Release of liquid waste below grade and aerosol release to atmosphere due to excessive corrosion because of waste disturbance in Tank 241-C-106 resulting in leakage into liner gap, steam formation, breaching of tank bottom and steam bump.	1. Inadequate prediction of waste behavior	F2	E2

Table C-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2). (11 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-BCD-TRANS09	Release of liquid waste below grade and aerosol release to atmosphere due to loss of pumping from Tank 241-C-106 and continued pumping of Tank 241-AY-102 water exceeds maximum operating level resulting in water leakage into liner gap, steam formation, breaching of tank bottom and large steam bump.	1. Loss of power 2. Equipment casualty	F2	E2
W320-D-ALL09	Release of liquid waste below grade and aerosol release to atmosphere due to seismic event Tank 241-C-106 liner is breached resulting in water leakage into liner gap, steam formation, breaching of tank bottom and large steam bump.	1. Natural Phenomena	F2	E2
W320-D-TRANS09	Release of liquid waste below grade and aerosol release to atmosphere due to movement of debris during sluicing which impacts and breaches the Tank 241-C-106 liner, resulting in water leakage into liner gap, steam formation, breaching of tank bottom and steam bump.	1. Expected outcome of high pressure sluice. Many objects are in the waste.	F2	E2
W320-A-TRANS01	Release of low energy radioactive aerosol through failed filters from Tank 241-C-106 due to a large steam bump	1. Flowmeters fault or out of calibration 2. Operator error in positioning Tank 241-C-106 pump 3. Inadvertent or accidental actuation of Tank 241-C-106 pump but not Tank 241-AY-102 pump 4. ENRAF level indication fault 5. Pump controller fault 6. Tank 241-C-106 T/C fault	F2	E1
W320-ABCD-CHILL01	Release of low energy radioactive aerosol from largely intact tank due to excessive cooling from process chiller and vacuum in Tank 241-C-106 from ventilation system which results in excedance of loop seal vacuum and unfiltered release.	1. Chiller control fault 2. High humidity	F2	E1
W320-ALL-TRANS01	Release of low energy radioactive aerosol through failed filters from Tank 241-AY-102 due to moisture buildup on ventilation system HEPA filters	1. Natural occurrence under proper conditions	F2	E1
W320-ALL-TRANS02	Release of small high energy aerosolized waste due to high winds or tornado resulting in failed ventilation ducting and unfiltered release.	1. Natural occurrence under proper conditions	F2	E1
W320-B-ALL11	Release of liquid waste due to large water intrusion into Tank 241-C-106 resulting in high hydrostatic pressure and tank breach.	1. Raw water leak 2. Surface water flood 3. Vent system water inleakage 4. Excessive transfer from Tank 241-AY-102 5. Water intrusion in Tank 241-C-105 that cascades over to Tank 241-C-106	F2	E1
W320-B-FLUSH06	Release of radioactive liquid from transfer line due to a pipe break in 241-AY-102 pit with the high capacity drain cover on resulting in overflow of pit onto the ground.	1. Equipment failure 2. Maintenance or assembly error	F2	E1
W320-B-FLUSH07	Release of radioactive liquid from transfer line due to pipe break in pit during flushing and drain plug cover on resulting in overflow of pit onto the ground.	1. Equipment failure 2. Maintenance or assembly error	F2	E1

Table C-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2). (11 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-B-TRANS06	Release of low energy radioactive aerosol from largely intact Tank 241-AY-102 due to excessive slurry flow resulting in increased aerosol generation and errant flow release.	1. 3-way ball valve in flushing system not fully open 2. Pump controller fault	F2	E1
W320-B-TRANS07	Release of low energy radioactive aerosol from largely intact Tank 241-AY-102 due to startup of slurry flow to distributor resulting in air being bubbled through waste and release of vapor.	1. Normal procedure	F2	E1
W320-B-TRANS11	Release of low energy radioactive aerosol from largely intact Tank 241-AY-102 due to excessive corrosion and heat loading from new waste.	1. Inadequate prediction of waste behavior	F2	E1
W320-B-TRANS12	Release of low energy radioactive aerosol from interconnected tanks due to increased heat loading of Tank 241-AY-102 and loss of vacuum.	1. Inadequate prediction of waste behavior 2. Existing system cannot control flow rates from different tanks. Depends on inleakage 3. W030 system has lower exhaust capabilities	F2	E1
W320-B-TRANS13	Small low energy aerosolized waste release from largely intact tank due to flammable gas collecting in a Tank 241-AY-102 pit where it is ignited resulting in the cover blocks being displaced and falling into pit. Cover block strikes riser-liner joint resulting in an unfiltered release from dome space.	1. Chimney through deep drop legs 2. 6 in. high capacity drain to dome space 3. Pit sealed to minimize inleakage	F2	E1
W320-B-VENT03	Release of low energy radioactive aerosol from breached Tank 241-AY-102 due to ice storm which prevents air inflow through W030 ventilation upgrade and results in excessive vacuum.	1. Natural phenomena	F2	E1
W320-B-VENT04	Release of low energy radioactive aerosol from breached Tank 241-AY-102 due to ice storm which prevents air inflow through existing exhaust system with W030 intake and results in excessive vacuum.	1. Natural phenomena	F2	E1
W320-B-VENT06	Release of low energy radioactive aerosol from breached Tank 241-AY-102 due to ice storm which prevents air inflow through existing ventilation system and results in excessive vacuum.	1. Natural phenomena	F2	E1
W320-BCD-TRANS10	Release of radioactive liquid release from sluice transfer line due to the blank flange being left off flushing connection in Tank 241-AY-102 pit and drain cover left on resulting in overflow of pit onto the ground during sluicing.	1. Maintenance error 2. Communications error between different groups using the pit	F2	E1
W320-D-ALL05	Release of low energy radioactive aerosol through failed filters from Tank 241-AY-102 due to long term loss of ventilation system resulting in tank bump and blowout of filters.	1. Loss of power 2. Equipment casualty	F2	E1
W320-D-TRANS02	Release of low energy radioactive aerosol from largely intact Tank 241-C-106 due to excessive sluicer flow which results in radioactive air release through HEPAs.	1. Natural outcome if conditions are met	F2	E1
W320-D-TRANS03	Release of low energy radioactive aerosol from largely intact Tank 241-C-106 due to sluicer moving debris impacting drop leg in tank which breaches dome.	1. Expected outcome of high velocity sluicing Many objects are in the waste	F2	E1

Table C-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2). (11 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-D-TRANS04	Release of low energy radioactive aerosol from largely intact Tank 241-C-106 due to high temperature sluice water which increases head space pressure with increased errant flow.	1. High temperature in Tank 241-AY-102	F2	E1
W320-D-VENT03	Release of low energy radioactive aerosol through failed filters in the 702A ventilation system of Tank 241-AY-102 due to severe ice storm, excessive tank vacuum and resulting tank bump	1. Natural phenomena	F2	E1
W320-D-VENT05	Release of low energy radioactive aerosol through failed filters in the W030 ventilation system due to severe ice storm, excessive tank vacuum and resulting tank bump.	1. Natural phenomena	F2	E1
W320-D-VENT15	Small low energy radioactive aerosolized waste release from standpipes in Tank 241-AY-102 due to flammable gas buildup where it is ignited resulting in the pipe being breached resulting in an unfiltered release.	1. Natural occurrence under proper conditions	F2	E1
W320-B-TERM01	Release of toxic ammonia gas from tank due to burp which exposes facility personnel to toxic gases.	1. Inadequate prediction of waste behavior	F2	E0
W320-ABCD-CHILL02	Release of energetic radioactive aerosol from covered pit or deadend pipe due to propylene glycol spray leak into ventilation system of Tank 241-C-106 with ignition propagating into tank dome.	1. Piping or tubing leak	F1	E2
W320-ABCD-TRANS03	Release of liquid waste below grade and aerosol release to atmosphere due to siphoning of waste from Tank 241-AY-102 after the stoppage of pumping water exceeds maximum operating level in Tank 241-C-106 resulting in water leakage into liner gap, steam formation, breaching of tank bottom and large steam bump.	1. Buildup of solids in openings 2. Equipment casualty	F1	E2
W320-ABCD-TRANS09	Release of liquid waste below grade and aerosol release to atmosphere due to excessive waste temperature change rate Tank 241-C-106 liner breaches, resulting in water leakage under tank bottom, steam formation, breaching of tank bottom and large steam bump.	1. High temperature in Tank 241-AY-102	F1	E2
W320-ALL-VENT01	Release of energetic radioactive aerosol from breached ventilation duct for Tank 241-AY-102 due to a buildup of ammonium nitrate in ventilation ducting and ignition via hot work, range fire etc.	1. Natural occurrence under proper conditions	F1	E2
W320-BCD-ALL07	Release of liquid waste below grade and aerosol release to atmosphere due to water intrusion into Tank 241-C-105 which travels through cascade line into Tank 241-C-106 with water level exceeding maximum operating level resulting in leakage into liner gap, steam formation, bulging of tank bottom, ripping of liner and steam bump.	1. Raw water leak 2. Surface water flood	F1	E2
W320-BCD-PUMP05	Release of small high energy aerosol to atmosphere due to immersible pump being raised to high in Tank 241-C-106, motor breaks gear assembly, pump freespools into waste resulting in a flammable gas release which is ignited by broken electrical cables, plume burn.	1. Operator error in positioning direction 2. Inadvertent or accidental actuation 3. Winch controller fault	F1	E2

Table C-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2). (11 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-D-ALL06	Release of a small amount of low energy aerosolized waste through failed filters due to seismic event which induces a steam bump in Tank 241-AY-102, and failure of filters or ducting.	1. Natural Phenomena	F1	E2
W320-F-TERM05	Release of liquid waste below grade and aerosol release to atmosphere due to high heat load after completion of sluicing process resulting in the need for water addition to Tank 241-C-106 with a deteriorated tank liner, water leakage into liner gap, steam formation, liner breach and steam bump.	1. Error in calculations	F1	E2
W320-B-ALL13	Release of radioactive liquid from Tank 241-AY-102 due to large water intrusion into tank	1. Raw water leak 2. Surface water flood 3. Vent system water inleakage	F1	E1
W320-B-ALL14	Release of small low energy aerosolized waste to the atmosphere from intact pit due to high winds/dust devils during plug removal from pit cover.	1. High winds	F1	E1
W320-B-TRANS02	Release of low energy radioactive aerosol through failed filters from Tank 241-AY-102 due to low slurry flow, piling of waste at base of distributor and resulting tank bump	1. 3-way ball valve in flushing system not fully open 2. Pump controller fault 3. Excessive solids in sluicing flow	F1	E1
W320-B-TRANS04	Release of low energy radioactive aerosol through failed filters from Tank 241-C-106 due to high slurry transfer rate, high waste temperature and resulting tank bump	1. Flowmeters fault or out of calibration 2. Operator error in positioning Tank 241-C-106 pump 3. Inadvertent or accidental actuation of Tank 241-C-106 pump but not Tank 241-AY-102 pump 4. ENRAF level indication fault 5. Pump controller fault 6. Tank 241-C-106 T/C fault	F1	E1
W320-B-TRANS05	Release of low energy radioactive aerosol from largely intact Tank 241-AY-102 due to buildup of solids pile under distributor as a result of low slurry flow which results in steam bump and increased head space vapor pressure.	1. 3-way ball valve in flushing system not fully open 2. Pump controller fault 3. Excessive solids in sluicing flow	F1	E1
W320-B-TRANS08	Release of low energy radioactive aerosol from largely intact Tank 241-AY-102 due to distributor breaking off which results in excessive aerosol generated in head space and release through HEPAs.	1. Primary failure of distributor 2. Severe Water hammer 3. Severe thermal shock 4. Corrosion 5. Metal fatigue from vibration	F1	E1
W320-B-TRANS09	Release of low energy radioactive aerosol from largely intact Tank 241-AY-102 due to buildup of solids pile under distributor as a result of the distributor nozzle breaking off which results in steam bump and increased head space vapor pressure.	1. Primary failure of distributor 2. Severe water hammer 3. Severe thermal shock 4. Corrosion 5. Metal fatigue from vibration	F1	E1
W320-B-TRANS10	Release of low energy radioactive aerosol from largely intact Tank 241-AY-102 due to distributor breaking off which results in excessive aerosol generated in head space and release through HEPAs.	1. Primary failure of sluicer 2. Severe Water hammer 3. Severe thermal shock 4. Corrosion 5. Metal fatigue from vibration	F1	E1

Table C-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2). (11 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-B-VENT07	Release of low energy radioactive aerosol from largely intact tank due to volcanic ashfall preventing air inflow into Tank 241-AY-102 through existing ventilation system resulting in tank breach.	1. Natural phenomena	F1	E1
W320-BCD-ALL01	Release of energetic radioactive aerosol from covered pit on Tank 241-C-106 due to propylene glycol leak into pit with ignition.	1. Piping or tubing leak	F1	E1
W320-BCD-ALL04	Release of low energy radioactive aerosol from largely intact Tank 241-C-106 due to fan controller failure resulting in excessive vacuum in tank and loop seal actuation.	1. Rotameter valve to controller fault 2. Operator error in adjusting rotameter or inadvertent adjustment	F1	E1
W320-BCD-ALL05	Small high energy aerosolized waste release to the atmosphere due to buildup of solids and flammable gas in transfer line . Gas is then ignited resulting in a breach of transfer line. Pumping is started without knowledge of breach.	1. Low flow 2. Inadequate flushing	F1	E1
W320-BCD-ALL06	Small high energy aerosolized waste release to the atmosphere due to buildup of solids and flammable gas in transfer line . Gas is then ignited and detonates resulting in a breach of transfer line. Pumping is started without knowledge of breach.	1. Low flow 2. Inadequate flushing	F1	E1
W320-BCD-ALL10	Small high energy aerosolized waste release to the atmosphere due to plugging and buildup of flammable gas in transfer line . Gas is then ignited resulting in a breach of transfer line. Pumping is started without knowledge of breach.	1. Low flow 2. Inadequate flushing	F1	E1
W320-BCD-TRANS01	Release of ionizing radiation and radioactive gas from Tank 241-C-106 due to a criticality event in the tank pump vortices	1. Natural occurrence if conditions are met	F1	E1
W320-BCD-TRANS04	Release of ionizing radiation and radioactive gas from Tank 241-C-106 due to a criticality event in the tank during sluicing	1. Natural occurrence if conditions are met	F1	E1
W320-BCD-TRANS08	Release of low energy radioactive aerosol through failed filters from Tank 241-C-106 due to undetected high waste temperature and resulting tank bump	1. Expected outcome of high pressure sluice. Many objects are in the waste.	F1	E1
W320-D-ALL02	Release of low energy radioactive aerosol through failed filters from Tank 241-AY-102 due to barometric pressure change, high waste temperature and resulting tank bump	1. Ventilation balance upset 2. Sudden barometric pressure change 3. Low intensity seismic event	F1	E1
W320-D-TERM01	Release of ionizing radiation and radioactive gas from Tank 241-AY-102 due to a criticality event in the tank	1. Natural occurrence if conditions are met	F1	E1
W320-D-TRANS01	Release of low energy radioactive aerosol through failed filters from Tank 241-AY-102 due to rapid waste level change, high waste temperature and resulting tank bump	1. Flowmeters fault or out of calibration 2. Operator error in positioning Tank 241-AY-102 pump 3. Inadvertent or accidental actuation of Tank 241-AY-102 pump but not Tank 241-C-106 pump 4. ENRAF level indication fault 5. Pump controller fault	F1	E1

Table C-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2). (11 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-D-TRANS08	Release of low energy radioactive aerosol through failed filters due to excessive fluffing of waste in Tank 241-AY-102 resulting in large steam bump and unfiltered release.	1. Inadequate prediction of waste behavior	F1	E1
W320-D-VENT01	Release of energetic radioactive aerosol from filter breach due to a buildup of ammonium nitrate in ventilation ducting of Tank 241-AY-102 and ignition via hot work, range fire etc.	1. Natural occurrence under proper conditions	F1	E1
W320-D-VENT04	Release of small low energy radioactive aerosol through failed filters from Tank 241-AY-102 due to cold water spray into tank, tank vacuum and resulting tank bump	1. Possible result of slurry distribution	F1	E1
W320-D-VENT09	Release of low energy radioactive aerosol from largely intact Tank 241-AY-102 due to loss of primary or annulus ventilation which results in steam release.	1. Extended loss of power 2. Severe ventilation casualty	F1	E1
W320-E-TERM01	Release of large high energy radioactive aerosol from Tank 241-AY-102 due to excessive fluffing of waste which results in tank structural damage and unfiltered release.	1. Inadequate prediction of waste behavior	F1	E1
W320-A-TRANS04	Release of large high energy aerosolized waste from Tank 241-C-106 due to high waste temperature during slurry transfer which results in a steam bump. Bump induces flammable gas release which is ignited resulting in a dome burn.	1. Flowmeters fault or out of calibration 2. Operator error in positioning Tank 241-C-106 pump 3. Inadvertent or accidental actuation of Tank 241-C-106 pump but not Tank 241-AY-102 pump 4. ENRAF level indication fault 5. Pump controller fault 6. Tank 241-C-106 T/C fault	F0	E2
W320-ABCD-TRANS06	Release of liquid waste below grade and aerosol release to atmosphere due to sluicing arm breaking off and penetrating Tank 241-C-106 liner resulting in water leakage into liner gap, steam formation, liner breach and steam bump.	1. Primary failure of sluicer 2. Severe Water hammer 3. Severe thermal shock 4. Corrosion 5. Metal fatigue from vibration	F0	E2
W320-B-FLUSH01	Release of energetic radioactive aerosol from damaged Tank 241-C-106 single shell tank due to ignition of flammable gas plume and resulting filter breach induced by large water intrusion into tank.	1. Maintenance error 2. Communications error between different groups using the pit	F0	E2
W320-B-TRANS17	Release of high energy aerosolized waste from damaged Tank 241-C-106 due to the sluicer hose breaking which then impinges into the solids releasing a region of retained flammable gas. The gas is then ignited and a plume fire results.	1. Primary failure of Hose 2. Severe Water hammer 3. Severe thermal shock 4. Corrosion 5. Fatigue from vibration	F0	E2
W320-B-TRANS18	Release of large high energy aerosolized waste to the atmosphere due to sluice water transfer rate being excessive resulting in the Tank 241-C-106 waste level being lowered quickly with the waste temperature to high. This results in a large steam bump and flammable gas release with a plume burn.	1. Flowmeters fault or out of calibration 2. Operator error in positioning Tank 241-C-106 pump 3. Inadvertent or accidental actuation of Tank 241-C-106 pump but not Tank 241-AY-102 pump 4. ENRAF level indication fault 5. Pump controller fault 6. Tank 241-C-106 T/C fault	F0	E2

Table C-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2). (11 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-BCD-PUMP03	Release of small high energy aerosol to atmosphere due to immersible pump being raised to high in Tank 241-AY-102, winch lifting strap breaking, pump falling into waste results in a flammable gas release which is ignited by broken electrical cables, plume burn.	1. Operator error in positioning direction 2. Inadvertent or accidental actuation 3. Winch controller fault	F0	E2
W320-BCD-PUMP08	Release of liquid waste below grade and aerosol release to atmosphere due to submersible pump being raised to high, winch lifting strap breaking, pump falling and penetrating Tank 241-C-106 liner resulting in water leakage into liner gap, steam formation, liner bulges/rips and steam bump occurs.	1. Operator error in positioning direction 2. Inadvertent or accidental actuation 3. Winch controller fault	F0	E2
W320-BCD-PUMP09	Release of large high energy aerosolized waste to atmosphere due to immersible pump being raised to high in Tank 241-C-106, winch lifting strap breaking, pump falling into waste results in a flammable gas release which is ignited by broken electrical cables, plume burn.	1. Operator error in positioning direction 2. Inadvertent or accidental actuation 3. Winch controller fault	F0	E2
W320-D-TRANS06	Release of large high energy aerosolized waste to the atmosphere due to slurry transfer rate being excessive resulting in a rapid reduction in the hydrostatic pressure in Tank 241-C-106. This results in a flammable gas release. Gas is ignited and a dome space fire results.	1. Sluice flow control fault	F0	E2
W320-A-TRANS02	Release of low energy radioactive aerosol through failed filters from Tank 241-AY-102 due to lowering of tank level with temperature out of spec resulting in tank bump	1. Flowmeters fault or out of calibration 2. Operator error in positioning Tank 241-C-106 pump 3. ENRAF level indication fault 4. Pump controller fault 5. Tank 241-C-106 T/C fault	F0	E1
W320-B-FLUSH02	Release of low energy radioactive aerosol through failed filters due to a large steam bump in Tank 241-C-106 as a result of high tank vacuum resulting from flushing water spray condensing dome vapors.	1. Planned	F0	E1
W320-B-FLUSH03	Release of low energy radioactive aerosol through failed filters of Tank 241-AY-102 due to a large steam bump as a result of high tank vacuum due to high condensation rate in tank from flushing water spray through antisiphon holes.	1. Planned	F0	E1
W320-B-FLUSH05	Release of low energy radioactive aerosol from largely intact Tank 241-AY-102 due to flushing water spray through antisiphon holes resulting in excessive vacuum in tank and tank breach.	1. Planned	F0	E1
W320-B-PUMP01	Release of low energy radioactive aerosol from Tank 241-AY-102 through failed filters due to overheating of waste and subsequent steam bump	1. Mass flowmeter fault or out of calibration 2. Operator error in positioning 3. Inadvertent or accidental repositioning 4. Level indication fault 5. Waste level indicator on pump fault 6. Pump controller fault	F0	E1

Table C-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2). (11 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-B-TRANS01	Release of small low energy aerosolized waste from the annulus of Tank 241-AY-102 due to steam pulses from boiling waste in annulus region which results in the failure of annulus filters. Waste leaks into annulus due to corrosion of primary tank from new waste composition.	1. Inadequate prediction of waste behavior	F0	E1
W320-B-TRANS03	Release of low energy radioactive aerosol through failed filters due to condensation of vapor in head space of Tank 241-C-106 which resulted from the breaking off of sluicer head.	1. Primary failure of sluicer 2. Severe Water hammer 3. Severe thermal shock 4. Corrosion 5. Metal fatigue from vibration	F0	E1
W320-B-VENT01	Release of low energy radioactive aerosol from largely intact Tank 241-AY-102 due to volcanic ashfall which prevents air intake through existing ventilation system with W030 intake resulting in excessive vacuum and tank breach.	1. Natural phenomena	F0	E1
W320-B-VENT02	Release of low energy radioactive aerosol from largely intact Tank 241-AY-102 due to volcanic ashfall which prevents air intake through W030 ventilation upgrade system resulting in excessive vacuum and tank breach.	1. Natural phenomena	F0	E1
W320-B-VENT05	Release of low energy radioactive aerosol from largely intact Tank 241-AY-102 due to cold water spray into tank which results in excessive vacuum and tank breach.	1. Possible result of slurry distribution	F0	E1
W320-BCD-TRANS02	Release of ionizing radiation and radioactive gas from Tank 241-C-106 due to a criticality event in the tank	1. Flushing valve misposition 2. Pump controller fault 3. Excessive solids in slurry flow	F0	E1
W320-BCD-TRANS03	Release of ionizing radiation and radioactive gas from Tank 241-C-106 due to a criticality event in the tank	1. Primary failure of distributor 2. Severe water hammer 3. Severe thermal shock 4. Corrosion 5. Metal fatigue from vibration	F0	E1
W320-BCD-TRANS05	Release of low energy radioactive aerosol through failed filters due to tank bump in Tank 241-AY-102 resulting from the vacuum developed in the head space from the condensation of vapor which resulted from the breaking off of distributor head.	1. Primary failure of distributor 2. Severe Water hammer 3. Severe thermal shock 4. Corrosion 5. Metal fatigue from vibration	F0	E1
W320-BCD-TRANS06	Release of low energy radioactive aerosol through failed filters of Tank 241-AY-102 due to tank bump resulting from the which resulted from the breaking off of distributor head.	1. Primary failure of distributor 2. Severe water hammer 3. Severe thermal shock 4. Corrosion 5. Metal fatigue from vibration	F0	E1
W320-BCD-TRANS07	Release of low energy radioactive aerosol through failed filters of Tank 241-C-106 due to failure of T/C Tree, sluicing outside of temperature specs, atmospheric change, and large steam bump resulting in filter breach.	1. Sluice flow control fault 2. Operator error	F0	E1
W320-D-ALL03	Release of low energy radioactive aerosol from Tank 241-AY-102 through failed filters due to bump in interconnected tank resulting in a tank bump and filter breach.	1. Ventilation balance upset 2. Sudden barometric pressure change 3. Low intensity seismic event	F0	E1

Table C-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2). (11 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-D-ALL04	Release of low energy radioactive aerosol from Tank 241-AY-102 through failed filters due to bump in interconnected tank resulting in a tank bump and filter breach.	1. Ventilation balance upset 2. Sudden barometric pressure change 3. Low intensity seismic event	F0	E1
W320-D-PURGE01	Release of low energy aerosolized waste from largely intact Tank 241-C-106 due to nitrogen line break and loss of vacuum.	1. Tube failure 2. Improper Assembly 3. Regulator fault	F0	E1
W320-D-VENT02	Release of low energy radioactive aerosol from 241-AY-102 through failed filters due to inadequate ventilation from W030 resulting in increased waste temperature, steam bump and filter breach.	1. Error in calculations 2. Design error 3. Construction fault	F0	E1
W320-D-VENT06	Release of low energy radioactive aerosol from Tank 241-AY-102 through failed filters due to volcanic ashfall , excessive vacuum resulting in large steam bump and filter blowout.	1. Natural phenomena	F0	E1
W320-D-VENT14	Small high energy aerosolized waste release from Tank 241-AY-102 to the atmosphere due to the loss of primary or annulus ventilation for an extended period which results in a gradual rise in waste temperature. Flammable gas leaks into annulus. It is then ignited resulting in the annulus being breached.	1. Extended loss of power 2. Severe ventilation casualty	F0	E1
W320-D-VENT19	Release of low energy radioactive aerosol through failed filters due to loss of primary or annulus ventilation for extended period of time resulting in rise in waste temperature and large bump in Tank 241-AY-102.	1. Extended loss of power 2. Severe ventilation casualty	F0	E1

ALC = air lift circulator
IOSR = Interim Operational Safety Requirements

Table C-3. Hazardous Conditions With Potential Significant Worker Consequences (S1).

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-ABCD-TRANS14	Personnel exposure to Ionizing radiation due to flooding which uncovers transfer lines.	1. Raw water line rupture 2. Natural flooding	F2	E0
W320-ABCD-TRANS16	Personnel exposure to Ionizing radiation due to excavation which uncovers transfer lines.	1. Mistake in excavation location 2. Failure to determine transfer line location	F1	E0
W320-ABCD-VENT01	Release of toxic gas from Tank 241-AY-102 due to failure of ventilation system and gradual rise in waste temperature resulting in toxic gas release from tank and to workers.	1. Loss of power 2. Equipment casualty	F1	E0
W320-D-VENT10	Release of toxic gas from Tank 241-AY-102 due to inadequate ventilation from W030 which results in high waste temperature , increased toxic gas release and facility worker inhalation of toxic gases.	1. Error in calculations 2. Design error 3. Construction fault	F1	E0
W320-E-TERM02	Release of toxic hydrogen cyanide gas from Tank 241-AY-102 due to burp	1. Inadequate prediction of waste behavior	F1	E0
W320-ABCD-TRANS15	Personnel exposure to Ionizing radiation due to high winds which uncovers transfer lines.	1. Natural phenomena	F0	E0

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (9 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-B-ALL09	Release of energetic radioactive aerosol from damaged tank due to formation of organic layer in Tank 241-AY-102 during slurry distribution and subsequent ignition of organics.	1. Sluicing causes organic separation	F1	E3
W320-B-ALL10	Release of energetic radioactive aerosol from damaged tank due to formation of organic layer in Tank 241-C-106 during sluicing and subsequent ignition of organics.	1. Sluicing causes organic separation	F1	E3
W320-A-TRANS06	Release of energetic radioactive aerosol from damaged tank due to waste temperature being out of specification during start of slurry transfer in Tank 241-C-106 and subsequent ignition of organics.	1. Operator mistake 2. Temperature measurement fault	F0	E3
W320-B-VENT08	Release of energetic radioactive aerosol from damaged tank due to loss of Tank 241-C-106 ventilation for many months, dry out of waste and subsequent ignition of organics.	1. Loss of power 2. Equipment casualty	F0	E3
W320-B-VENT09*	Release of energetic radioactive aerosol from damaged tank due to loss of Tank 241-AY-102 ventilation for many months, dry out of waste and subsequent ignition of organics.	1. Loss of power 2. Equipment casualty	F0	E3
W320-D-CHILL01	Release of energetic radioactive aerosol from damaged tank due to a leak and ignition of propylene glycol from pit chiller into Tank 241-C-106.	1. Piping or tubing leak	F0	E3
W320-D-CHILL02	Release of energetic radioactive aerosol from damaged tank due to a leak and ignition of propylene glycol from ventilation chiller into Tank 241-C-106.	1. Piping or tubing leak	F0	E3
W320-ABCD-ALL04	Release of liquid waste below grade and aerosol release to atmosphere due to water intrusion into Tank 241-C-106 with water level exceeding maximum operating level resulting in leakage into liner gap, steam formation, breaching of tank bottom and steam bump.	1. Raw water leak 2. Surface water flood 3. Vent system water inleakage 4. Excessive transfer from Tank 241-AY-102 5. Water intrusion in Tank 241-C-105 that cascades over to Tank 241-C-106	F3	E2
W320-ABCD-TRANS01	Release of liquid waste due to sluicer nozzle jet being directed at and breaching Tank 241-C-106 wall resulting in water leaking into liner gap where steam vapor forms and breaches tank bottom.	1. Unavoidable operator action	F3	E2
W320-BCD-FLUSH01	Release of energetic radioactive aerosol from transfer line due to 3 way valve left in flush position after flushing. Cover plug is lifted out of cover block on initiation of sluicing process.	1. Maintenance error 2. Communications error between different groups using the pit	F3	E2
W320-BCD-FLUSH02*	Release of energetic radioactive aerosol from flush tank of transfer truck due to start of submersible pump in Tank 241-C-106 during the flush of slurry transfer line. Flush tank is filled and pressurized resulting in rupture of tank or transfer line.	1. Human error 2. Communications error between different groups	F3	E2
W320-BCD-TRANS11	Release of energetic radioactive aerosol from transfer line due to blank flange left off flushing connection in Tank 241-C-106 pit after flushing. Cover plug is lifted out of cover block on initiation of sluicing process.	1. Maintenance error 2. Communications error between different groups using the pit	F3	E2

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (9 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-BCD-TRANS12	Release of energetic radioactive aerosol from transfer line due to blank flange left off flushing connection in Tank 241-AY-102 pit after flushing. Cover plug is lifted out of cover block on initiation of sluicing process.	1. Maintenance error 2. Communications error between different groups using the pit	F3	E2
W320-ABCD-ALL05	Release of liquid waste below grade and aerosol release to atmosphere due to water intrusion into Tank 241-C-106 with water level exceeding maximum operating level resulting in leakage into liner gap, steam formation, breaching of tank bottom and steam bump.	1. Raw water leak 2. Surface water flood 3. Vent system water inleakage 4. Excessive transfer from Tank 241-AY-102 5. Water intrusion in Tank 241-C-105 that cascades over to Tank 241-C-106	F2	E2
W320-ABCD-TRANS02	Release of liquid waste below grade and aerosol release to atmosphere due to loss of sluicer arm control in Tank 241-C-106 resulting in jet striking tank liner with liner being breached, water leakage into liner gap, steam formation, breaching of tank bottom and steam bump.	1. Unavoidable operator action	F2	E2
W320-ABCD-TRANS05	Release of liquid waste below grade and aerosol release to atmosphere due to sluicer hose break in Tank 241-C-106 resulting in jet striking tank liner with liner being breached, water leakage into liner gap, steam formation, and breaching of tank bottom.	1. Primary failure of Hose 2. Severe Water hammer 3. Fatigue from vibration	F2	E2
W320-ABCD-TRANS07	Release of liquid waste below grade and aerosol release to atmosphere due to sluicer flow being excessive in Tank 241-C-106 resulting in jet striking tank liner with liner being breached, water leakage under tank bottom, steam formation, breaching of tank bottom and large steam bump.	1. Sluice flow control fault 2. Operator error	F2	E2
W320-ABCD-TRANS08	Release of liquid waste below grade and aerosol release to atmosphere due to sluicer flow excessive into Tank 241-C-106 with water level exceeding maximum operating level resulting in leakage into liner gap, steam formation, breaching of tank bottom and large steam bump.	1. Sluice flow control fault 2. Operator error	F2	E2
W320-ABCD-TRANS11	Release of energetic radioactive aerosol from transfer line in pit due to flammable gas collecting in pit and being ignited. Cover block lifted and falls onto piping in pit resulting in spray release.	1. Chimney through deep drop legs 2. 6 in. high capacity drain to dome space 3. Pit sealed to minimize inleakage	F2	E2
W320-ABCD-TRANS11	Release of energetic radioactive aerosol release from line break due to flammable gas ignition in pit with cover block falling onto piping.	1. Chimney through deep drop legs 2. 6 in. high capacity drain to dome space 3. Pit sealed to minimize inleakage	F2	E2
W320-ABCD-TRANS12	Release of energetic radioactive aerosol from line break due to pipe or jumper breach in distributor pit of Tank 241-AY-102 with cover block off during slurry transfer.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	F2	E2
W320-B-TRANS23	Release of energetic radioactive aerosol from line break due to pipe or jumper breach in pump pit of Tank 241-AY-102 with cover block off during sluicing.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	F2	E2

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (9 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-B-TRANS24	Release of energetic radioactive aerosol from line break due to pipe or jumper breach in pump pit of Tank 241-C-106 with cover block off.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	F2	E2
W320-B-TRANS25	Release of energetic radioactive aerosol from line break due to pipe or jumper breach in sluice pit of Tank 241-C-106 with cover block off.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	F2	E2
W320-B-TRANS26	Release of energetic radioactive aerosol from transfer line in Tank 241-C-106 pit due to flammable gas collecting in pit and being ignited. Cover block lifted and falls onto piping in pit resulting in spray release.	1. Chimney through deep drop legs 2. 6 in. high capacity drain to dome space 3. Pit sealed to minimize inleakage	F2	E2
W320-BCD-ALL08	Release of liquid waste below grade and aerosol release to atmosphere due to excessive corrosion because of waste disturbance in Tank 241-C-106 resulting in leakage into liner gap, steam formation, breaching of tank bottom and steam bump.	1. Inadequate prediction of waste behavior	F2	E2
W320-BCD-TRANS09	Release of liquid waste below grade and aerosol release to atmosphere due to loss of pumping from Tank 241-C-106 and continued pumping of Tank 241-AY-102 water exceeds maximum operating level resulting in water leakage into liner gap, steam formation, breaching of tank bottom and large steam bump.	1. Loss of power 2. Equipment casualty	F2	E2
W320-D-ALL07	Release of energetic radioactive aerosol from damaged double shell Tank 241-AY-102 due to seismic event which releases flammable gas from the waste and after shocks cause mechanical sparks which ignites the flammable gas mixture.	1. Natural Phenomena	F2	E2
W320-D-ALL09	Release of liquid waste below grade and aerosol release to atmosphere due to seismic event Tank 241-C-106 liner is breached resulting in water leakage into liner gap, steam formation, breaching of tank bottom and large steam bump.	1. Natural Phenomena	F2	E2
W320-D-TRANS09	Release of liquid waste below grade and aerosol release to atmosphere due to movement of debris during sluicing which impacts and breaches the Tank 241-C-106 liner, resulting in water leakage into liner gap, steam formation, breaching of tank bottom and steam bump.	1. Expected outcome of high pressure sluice. Many objects are in the waste.	F2	E2
W320-D-TRANS10	Release of energetic radioactive aerosol from jumper in pit due to seismic event. Cover block breached by ground motion resulting in spray release.	1. Natural Phenomena	F2	E2
W320-ABCD-ALL01	Release of energetic radioactive aerosol from damaged tank due to flooding on top of Tank 241-C-106 dome.	1. Raw water line rupture 2. Heavy rainfall	F1	E2
W320-ABCD-ALL02	Release of energetic radioactive aerosol from damaged tank due to flooding on top of Tank 241-AY-102 dome.	1. Raw water line rupture 2. Heavy rainfall	F1	E2

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (9 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-ABCD-ALL07	Release of radioactive liquid from Tank 241-C-106 onto the ground due to large water intrusion into tank.	1. Raw water leak 2. Surface water flood 3. Vent system water inleakage 4. Excessive transfer from Tank 241-AY-102 5. Water intrusion in Tank 241-C-105 that cascades over to Tank 241-C-106	F1	E2
W320-ABCD-ALL08*	Release of radioactive liquid from Tank 241-C-106 due to siphoning of waste from Tank 241-AY-102 into Tank 241-C-106	1. Plugging of antisiphon holes 2. Loss of electrical power to the pumps 3. Shutdown from operations	F1	E2
W320-ABCD-CHILL02	Release of energetic radioactive aerosol from covered pit or deadend pipe due to propylene glycol spray leak into ventilation system of Tank 241-C-106 with ignition propagating into tank dome.	1. Piping or tubing leak	F1	E2
W320-ABCD-CHILL03	Release of energetic radioactive aerosol from collapsed Tank 241-C-106 due to excessive cooling from process chiller which restricts inflow and loop seal fails to operate.	1. Chiller control fault 2. High humidity	F1	E2
W320-ABCD-TRANS03	Release of liquid waste below grade and aerosol release to atmosphere due to siphoning of waste from Tank 241-AY-102 after the stoppage of pumping water exceeds maximum operating level in Tank 241-C-106 resulting in water leakage into liner gap, steam formation, breaching of tank bottom and large steam bump.	1. Buildup of solids in openings 2. Equipment casualty	F1	E2
W320-ABCD-TRANS09	Release of liquid waste below grade and aerosol release to atmosphere due to excessive waste temperature change rate Tank 241-C-106 liner breaches, resulting in water leakage under tank bottom, steam formation, breaching of tank bottom and large steam bump.	1. High temperature in Tank 241-AY-102	F1	E2
W320-ABCDF-ALL01*	Release of energetic radioactive aerosol to atmosphere due to buildup of flammable gas in Tank 241-AY-102 pit drain pipe which is then ignited.	1. Flammable gas generation from tank waste 2. 3.	F1	E2
W320-ALL-VENT01	Release of energetic radioactive aerosol from breached ventilation duct for Tank 241-AY-102 due to a buildup of ammonium nitrate in ventilation ducting and ignition via hot work, range fire etc.	1. Natural occurrence under proper conditions	F1	E2
W320-B-FLUSH04	Release of low energy radioactive aerosol from breached Tank 241-C-106 due to flushing water spray through sluice nozzle resulting in excessive tank vacuum.	1. Planned	F1	E2
W320-B-TRANS27	Release of energetic radioactive aerosol from transfer line in pit due to flammable gas collecting in pit and being ignited. Cover block lifted and falls onto piping in pit resulting in spray release.	1. Chimney through deep drop legs 2. 6 in. high capacity drain to dome space 3. Pit sealed to minimize inleakage	F1	E2
W320-B-TRANS32	Release of large high energy aerosolized radioactive waste from a spray leak from transfer line break due to aircraft strike on underground transfer line berm.	1. Light aircraft crash	F1	E2

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (9 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-BCD-ALL03	Release of energetic radioactive aerosol from damaged Tank 241-C-106 due to excessive vacuum resulting from ventilation system fan overspeed and failure of tank loop seal failure.	1. Rotameter valve to controller fault 2. Operator error in adjusting rotameter or inadvertent adjustment	F1	E2
W320-BCD-ALL07	Release of liquid waste below grade and aerosol release to atmosphere due to water intrusion into Tank 241-C-105 which travels through cascade line into Tank 241-C-106 with water level exceeding maximum operating level resulting in leakage into liner gap, steam formation, bulging of tank bottom, ripping of liner and steam bump.	1. Raw water leak 2. Surface water flood	F1	E2
W320-BCD-PUMP05	Release of small high energy aerosol to atmosphere due to immersible pump being raised to high in Tank 241-C-106, motor breaks gear assembly, pump freespools into waste resulting in a flammable gas release which is ignited by broken electrical cables, plume burn.	1. Operator error in positioning direction 2. Inadvertent or accidental actuation 3. Winch controller fault	F1	E2
W320-D-ALL06	Release of a small amount of low energy aerosolized waste through failed filters due to seismic event which induces a steam bump in Tank 241-AY-102, and failure of filters or ducting.	1. Natural Phenomena	F1	E2
W320-D-ALL08	Release of energetic radioactive aerosol to atmosphere due to start of air lift circulators in Tank 241-AY-102 resulting in a release of flammable gas plume which is then ignited.	1. Human error 2. Communications error with other workers using the tank 3. IOSRs require activation of ALCs in event temperature above limit	F1	E2
W320-D-PUMP01	Release of energetic radioactive aerosol from line break in Tank 241-AY-102 transfer pit due to immersible pump being positioned to high resulting in air entrainment in transfer line. Booster pump torques in reaction to air in transfer line and jumper connectors break. Cover block is off.	1. Operator error in positioning 2. Inadvertent or accidental repositioning 3. Level indication fault 4. Waste level indicator on pump fault	F1	E2
W320-D-PUMP03	Release of energetic radioactive aerosol from line break in Tank 241-C-106 transfer pit due to immersible pump being positioned to high resulting in air entrainment in transfer line. Booster pump torques in reaction to air in transfer line and jumper connectors break. Cover block is off.	1. Operator error in positioning 2. Inadvertent or accidental repositioning 3. Level indication fault 4. Waste level indicator on pump fault	F1	E2
W320-D-TRANS05	Release of energetic radioactive aerosol to atmosphere due to head space gas concentration above LFL in Tank 241-AY-102 with the start of pumping which ignites the flammable gas.	1. Spontaneous GRE 2. Induced GRE	F1	E2
W320-D-TRANS07	Release of high energetic aerosolized waste to the atmosphere due to sluice water transfer rate being excessive resulting in the Tank 241-AY-102 waste level being lowered quickly with the waste temperature to high. This results in a large steam bump and flammable gas release with ignition.	1. Operator mistake 2. Level indication fault 3. Pump controller fault	F1	E2
W320-D-TRANS11	Release of large high energy aerosolized radioactive waste to the atmosphere from a spray leak from transfer line due to seismic event.	1. Natural Phenomena	F1	E2

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (9 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-D-VENT12	Release of energetic radioactive aerosol from collapsed Tank 241-C-106 due to incorrect alignment of current ventilation system through sluice nozzle resulting in excessive tank vacuum with loop seal failure.	1. Operator error 2. Communications error	F1	E2
W320-D-VENT17	Release of high energy aerosolized release to the atmosphere due to an ice storm which prevents air inflow into Tank 241-AY-102 resulting in an excessive tank vacuum. This results in a flammable gas release with ignition.	1. Natural phenomena	F1	E2
W320-D-VENT20	Release of energetic radioactive aerosol from collapsed Tank 241-C-106 due to incorrect alignment of new ventilation system through sluice nozzle resulting in excessive tank vacuum with loop seal failure.	1. Operator error 2. Communications error	F1	E2
W320-F-TERM05	Release of liquid waste below grade and aerosol release to atmosphere due to high heat load after completion of sluicing process resulting in the need for water addition to Tank 241-C-106 with a deteriorated tank liner, water leakage into liner gap, steam formation, liner breach and steam bump.	1. Error in calculations	F1	E2
W320-A-TRANS04	Release of large high energy aerosolized waste from Tank 241-C-106 due to high waste temperature during slurry transfer which results in a steam bump. Bump induces flammable gas release which is ignited resulting in a dome burn.	1. Flowmeters fault or out of calibration 2. Operator error in positioning Tank 241-C-106 pump 3. Inadvertent or accidental actuation of Tank 241-C-106 pump but not Tank 241-AY-102 pump 4. ENRAF level indication fault 5. Pump controller fault 6. Tank 241-C-106 T/C fault	F0	E2
W320-A-TRANS05	Release of energetic radioactive aerosol to atmosphere due to temperature out of specification resulting in steam bump when Tank 241-C-106 level is lowered which induces a release of a flammable gas plume and then is ignited.	1. Operator mistake 2. Temperature measurement fault	F0	E2
W320-ABCD-ALL03	Release of energetic radioactive aerosol from tank dome collapse due to flooding on top of tank dome	1. Raw water line rupture 2. Heavy rainfall	F0	E2
W320-ABCD-TRANS06	Release of liquid waste below grade and aerosol release to atmosphere due to sluicing arm breaking off and penetrating Tank 241-C-106 liner resulting in water leakage into liner gap, steam formation, liner breach and steam bump.	1. Primary failure of sluicer 2. Severe Water hammer 3. Severe thermal shock 4. Corrosion 5. Metal fatigue from vibration	F0	E2
W320-B-ALL01	Release of a large amount of high energy aerosolized waste from Tank 241-C-106 dome collapse due to volcanic ashfall.	1. Natural phenomena	F0	E2
W320-B-ALL02	Release of a large amount of high energy aerosolized waste from Tank 241-AY-102 dome collapse due to volcanic ashfall.	1. Natural phenomena	F0	E2
W320-B-ALL03	Release of high energy aerosolized waste to the atmosphere from Tank 241-C-106 dome collapse due to extreme snow fall.	1. Natural phenomena	F0	E2
W320-B-ALL04	Release of large amount of high energy aerosolized waste from 241-AY-102 Tank dome collapse due to extreme snow fall.	1. Natural phenomena	F0	E2

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (9 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-B-ALL05	Release of energetic radioactive aerosol from Tank 241-C-106 dome collapse due to dome being overloaded.	1. Maintenance error 2. Procedure violation	F0	E2
W320-B-ALL06	Release of energetic radioactive aerosol from Tank 241-AY-102 dome collapse due to dome being overloaded.	1. Maintenance error 2. Procedure violation	F0	E2
W320-B-ALL08	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 due to a large water intrusion which induces a flammable gas release event. It is then ignited resulting in a dome space fire.	1. Raw water leak 2. Surface water flood	F0	E2
W320-B-FLUSH01	Release of energetic radioactive aerosol from damaged Tank 241-C-106 single shell tank due to ignition of flammable gas plume and resulting filter breach induced by large water intrusion into tank.	1. Maintenance error 2. Communications error between different groups using the pit	F0	E2
W320-B-TRANS14	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 to the atmosphere due to low slurry flow to distributor which results in solids piling up. Pile generates significant amount of flammable gas and LFL is reached in dome space. It is then ignited resulting in a dome space fire.	1. 3-way ball valve in flushing system not fully open 2. Pump controller fault	F0	E2
W320-B-TRANS15	Large high energy aerosolized waste release from Tank 241-AY-102 to the atmosphere due to air injected into the waste from the startup of slurry flow from the distributor. Gas is scrubbed from the waste and LFL is reached in dome space. It is then ignited resulting in a dome space fire.	1. Normal procedure	F0	E2
W320-B-TRANS16	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 to the atmosphere due to distributor nozzle breaking off which results in solids piling up. Pile generates significant amount of flammable gas and LFL is reached in dome space. It is then ignited resulting in a dome space fire.	1. Primary failure of distributor 2. Severe water hammer 3. Severe thermal shock 4. Corrosion 5. Metal fatigue from vibration	F0	E2
W320-B-TRANS17	Release of high energy aerosolized waste from damaged Tank 241-C-106 due to the sluicer hose breaking which then impinges into the solids releasing a region of retained flammable gas. The gas is then ignited and a plume fire results.	1. Primary failure of Hose 2. Severe Water hammer 3. Severe thermal shock 4. Corrosion 5. Fatigue from vibration	F0	E2
W320-B-TRANS18	Release of large high energy aerosolized waste to the atmosphere due to sluice water transfer rate being excessive resulting in the Tank 241-C-106 waste level being lowered quickly with the waste temperature to high. This results in a large steam bump and flammable gas release with a plume burn.	1. Flowmeters fault or out of calibration 2. Operator error in positioning Tank 241-C-106 pump 3. Inadvertent or accidental actuation of Tank 241-C-106 pump but not Tank 241-AY-102 pump 4. ENRAF level indication fault 5. Pump controller fault 6. Tank 241-C-106 T/C fault	F0	E2
W320-BCD-ALL02	Release of energetic radioactive aerosol from collapsed Tank 241-AY-102 due to excessive vacuum resulting from W030 ventilation system inlet damper closing and failure of PCV fails to relieve vacuum.	1. Rotameter valve to controller fault 2. Operator error in adjusting rotameter or inadvertent adjustment	F0	E2

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (9 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-BCD-PUMP03	Release of small high energy aerosol to atmosphere due to immersible pump being raised to high in Tank 241-AY-102, winch lifting strap breaking, pump falling into waste results in a flammable gas release which is ignited by broken electrical cables, plume burn.	1. Operator error in positioning direction 2. Inadvertent or accidental actuation 3. Winch controller fault	F0	E2
W320-BCD-PUMP04	Release of energetic radioactive aerosol to atmosphere due to submersible pump being raised to high in Tank 241-AY-102, winch lifting strap breaking, pump falling into waste resulting in a flammable gas release which is ignited by broken electrical cables.	1. Operator error in positioning direction 2. Inadvertent or accidental actuation 3. Winch controller fault	F0	E2
W320-BCD-PUMP08	Release of liquid waste below grade and aerosol release to atmosphere due to submersible pump being raised to high, winch lifting strap breaking, pump falling and penetrating Tank 241-C-106 liner resulting in water leakage into liner gap, steam formation, liner bulges/rips and steam bump occurs.	1. Operator error in positioning direction 2. Inadvertent or accidental actuation 3. Winch controller fault	F0	E2
W320-BCD-PUMP09	Release of large high energy aerosolized waste to atmosphere due to immersible pump being raised to high in Tank 241-C-106, winch lifting strap breaking, pump falling into waste results in a flammable gas release which is ignited by broken electrical cables, plume burn.	1. Operator error in positioning direction 2. Inadvertent or accidental actuation 3. Winch controller fault	F0	E2
W320-D-PUMP04	Release of energetic radioactive aerosol from damaged Tank 241-AY-102 due to pumping of more solids than anticipated. Annulus cooling mod not completed resulting in overheating of waste and a tank bump. Bump induces large flammable gas release. It is then ignited resulting in a dome space fire.	1. Mass flowmeter fault or out of calibration 2. Operator error in positioning slurry pump 3. Inadvertent or accidental repositioning 4. Level indication fault 5. Waste level indicator on pump Tank 241-C-106 fault 6. Pump controller fault	F0	E2
W320-D-TRANS06	Release of large high energy aerosolized waste to the atmosphere due to slurry transfer rate being excessive resulting in a rapid reduction in the hydrostatic pressure in Tank 241-C-106. This results in a flammable gas release. Gas is ignited and a dome space fire results.	1. Sluice flow control fault	F0	E2
W320-D-VENT13	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 to the atmosphere due to influx of cold water spray into tank which results in an excessive vacuum. A large flammable gas release is induced. It is then ignited resulting in a dome space fire.	1. Possible result of slurry distribution	F0	E2
W320-D-VENT16	Large high energy aerosolized waste release from Tank 241-AY-102 to the atmosphere due to the loss of primary or annulus ventilation for an extended period which results in a gradual rise in waste temperature. Flammable gas builds up in the dome space to the LFL. It is then ignited resulting in a dome space fire.	1. Extended loss of power 2. Severe ventilation casualty	F0	E2

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (9 sheets)

ID	Hazardous Condition	Cause	Initial Freq NC	Env Cons
W320-D-VENT18	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 to the atmosphere due to volcanic ashfall which prevents air inflow to tank. Excessive vacuum results and flammable gas is released to the dome space. It is then ignited resulting in a dome space fire.	1. Natural phenomena	F0	E2
W320-E-TERM03	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 to the atmosphere due to lack of controls on operation of tank after it has been turned into a FG group 1 tank. It is ignited from a lightning strike or other event resulting in a dome space fire.	1. Inadequate prediction of waste behavior	F0	E2

Table C-5. Hazardous Conditions With Potential Radiation Exposure Consequences (RP).

ID	Hazardous Condition	Cause
W320-ABCD-TRANS14	Personnel exposure to Ionizing radiation due to flooding which uncovers transfer lines.	1. Raw water line rupture 2. Natural flooding
W320-ABCD-TRANS15	Personnel exposure to Ionizing radiation due to high winds which uncovers transfer lines.	1. Natural phenomena
W320-ABCD-TRANS16	Personnel exposure to Ionizing radiation due to excavation which uncovers transfer lines.	1. Mistake in excavation location 2. Failure to determine transfer line location
W320-BCD-FLUSH03	Personnel exposure to ionizing radiation from flush tank of transfer truck due to start of submersible pump in Tank 241-C-106 during the flush of slurry transfer line. Flush tank is filled with radioactive material.	1. Operator Error 2. Failure in submersible pump circuitry

Table C-6. Hazardous Conditions With Potential Occupational Safety Consequences (OCC).

ID	Hazardous Condition	Cause
W320-ABCD-VENT01	Release of toxic gas from Tank 241-AY-102 due to failure of ventilation system and gradual rise in waste temperature resulting in toxic gas release from tank and to workers.	1. Loss of power 2. Equipment casualty
W320-D-VENT10	Release of toxic gas from Tank 241-AY-102 due to inadequate ventilation from W030 which results in high waste temperature , increased toxic gas release and facility worker inhalation of toxic gases.	1. Error in calculations 2. Design error 3. Construction fault
W320-E-TERM02	Release of toxic hydrogen cyanide gas from Tank 241-AY-102 due to burp	1. Inadequate prediction of waste behavior

W320-B-FLUSH04	Release of low energy radioactive aerosol from breached Tank 241-C-106 due to flushing water spray through sluice nozzle resulting in excessive tank vacuum.	1. Planned	None	None
W320-B-TRANS14	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 to the atmosphere due to low slurry flow to distributor which results in solids piling up. Pile generates significant amount of flammable gas and LFL is reached in dome space. It is then ignited resulting in a dome space fire.	1. 3-way ball valve in flushing system not fully open 2. Pump controller fault	Mon dome pressure in Tank 241-AY-102 Video mon of waste in Tank 241-AY-102 Meas background concentrations for 3-4 weeks prior to sluicing Mon vent flow rate in tanks	None
W320-B-TRANS15	Large high energy aerosolized waste release from Tank 241-AY-102 to the atmosphere due to air injected into the waste from the startup of slurry flow from the distributor. Gas is scrubbed from the waste and LFL is reached in dome space. It is then ignited resulting in a dome space fire.	1. Normal procedure	Mon dome pressure in Tank 241-AY-102 Video mon of waste in Tank 241-AY-102 Meas background concentrations for 3-4 weeks prior to sluicing Mon vent flow rate in tanks	None
W320-B-TRANS16	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 to the atmosphere due to distributor nozzle breaking off which results in solids piling up. Pile generates significant amount of flammable gas and LFL is reached in dome space. It is then ignited resulting in a dome space fire.	1. Primary failure of distributor 2. Severe water hammer 3. Severe thermal shock 4. Corrosion 5. Metal fatigue from vibration	Mon dome pressure in Tank 241-AY-102 Video mon of waste in Tank 241-AY-102 Meas background concentrations for 3-4 weeks prior to sluicing Mon vent flow rate in tanks Mon level growth	None
W320-B-TRANS17	Release of high energy aerosolized waste from damaged Tank 241-C-106 due to the sluicer hose breaking which then impinges into the solids releasing a region of retained flammable gas. The gas is then ignited and a plume fire results.	1. Primary failure of Hose 2. Severe Water hammer 3. Severe thermal shock 4. Corrosion 5. Fatigue from vibration	Mon dome pressure in Tank 241-C-106 Mon vent flow rate in tanks	None

Table D-4. Defense-in-Depth Controls for Potentially Severe (E3 and E2) Environmental Consequences. (16 sheets)

ID	Hazardous Conditions	Candidate Causes	DID-Preventive	DID-Mitigative
W320-B-TRANS18	Release of large high energy aerosolized waste to the atmosphere due to sluice water transfer rate being excessive resulting in the Tank 241-C-106 waste level being lowered quickly with the waste temperature too high. This results in a large steam bump and flammable gas release with a plume burn.	1. Flowmeters fault or out of calibration 2. Operator error in positioning Tank 241-C-106 pump 3. Inadvertant or accidental actuation of Tank 241-C-106 pump but not Tank 241-AY-102 pump 4. ENRAF level indication fault 5. Pump controller fault 6. Tank 241-C-106 T/C fault	Mon dome pressure in Tank 241-C-106 Meas background concentrations for 3-4 weeks prior to sluicing Mon vent flow rate in tanks	None
W320-B-TRANS23	Release of energetic radioactive aerosol from line break due to pipe or jumper breach in pump pit of Tank 241-AY-102 with cover block off during sluicing.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	Repositioned jumpers service tested Cameras used to verify initial jumper integrity	Process pit and vault pit leak detectors Material balance every 24 hrs
W320-B-TRANS24	Release of energetic radioactive aerosol from line break due to pipe or jumper breach in pump pit of Tank 241-C-106 with cover block off.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	Repositioned jumpers service tested Cameras used to verify initial jumper integrity	Process pit and vault pit leak detectors Material balance every 24 hrs
W320-B-TRANS25	Release of energetic radioactive aerosol from line break due to pipe or jumper breach in sluice pit of Tank 241-C-106 with cover block off.	1. Pipe failure 2. Improper Assembly 3. Other operators change jumper hookup 4. Connector faults	Repositioned jumpers service tested Cameras used to verify initial jumper integrity	Process pit and vault pit leak detectors Material balance every 24 hrs
W320-B-TRANS26	Release of energetic radioactive aerosol from transfer line in Tank 241-C-106 pit due to flammable gas collecting in pit and being ignited. Cover block lifted and falls onto piping in pit resulting in spray release.	1. Chimney through deep drop legs 2. 6 in. high capacity drain to dome space 3. Pit sealed to minimize inleakage	Repositioned jumpers service tested Cameras used to verify initial jumper integrity	Process pit and vault pit leak detectors Material balance every 24 hrs
W320-B-TRANS27	Release of energetic radioactive aerosol from transfer line in pit due to flammable gas collecting in pit and being ignited. Cover block lifted and falls onto piping in pit resulting in spray release.	1. Chimney through deep drop legs 2. 6 in. high capacity drain to dome space 3. Pit sealed to minimize inleakage	None	Process pit and vault pit leak detectors Material balance every 24 hrs

Table D-4. Defense-in-Depth Controls for Potentially Severe (E3 and E2) Environmental Consequences. (16 sheets)

ID	Hazardous Conditions	Candidate Causes	DID-Preventive	DID-Mitigative
W320-B-TRANS32	Release of large high energy aerosolized radioactive waste from a spray leak from transfer line break due to aircraft strike on underground transfer line berm.	1. Light aircraft crash	None	Access cntrl Material balance every 24 hrs
W320-B-VENT08	Release of energetic radioactive aerosol from damaged tank due to loss of Tank 241-C-106 ventilation for many months, dry out of waste and subsequent ignition of organics.	1. Loss of power 2. Equipment casualty	Vehicle position spotters Tank farm fences	HEPA filter replacement
W320-B-VENT09*	Release of energetic radioactive aerosol from damaged tank due to loss of Tank 241-AY-102 ventilation for many months, dry out of waste and subsequent ignition of organics.	1. Loss of power 2. Equipment casualty	Vehicle position spotters Tank farm fences	HEPA filter replacement
W320-BCD-ALL02	Release of energetic radioactive aerosol from collapsed Tank 241-AY-102 due to excessive vacuum resulting from W030 ventilation system inlet damper closing and failure of PCV fails to relieve vacuum.	1. Rotameter valve to controller fault 2. Operator error in adjusting rotameter or inadvertant adjustment	None	None
W320-BCD-ALL03	Release of energetic radioactive aerosol from damaged Tank 241-C-106 due to excessive vacuum resulting from ventilation system fan overspeed and failure of tank loop seal failure.	1. Rotameter valve to controller fault 2. Operator error in adjusting rotameter or inadvertant adjustment	None	None
W320-BCD-ALL07	Release of liquid waste below grade and aerosol release to atmosphere due to water intrusion into Tank 241-C-105 which travels through cascade line into Tank 241-C-106 with water level exceeding maximum operating level resulting in leakage into liner gap, steam formation, bulging of tank bottom, ripping of liner and steam bump.	1. Raw water leak 2. Surface water flood	Active vent for heat removal Material balance performed every 24 hrs Level mon of Tank 241-C-106 Comm maintained between control trailers	Cover blocks in place Emer Resp Plan/Procedures

Table D-4. Defense-in-Depth Controls for Potentially Severe (E3 and E2) Environmental Consequences. (16 sheets)

ID	Hazardous Conditions	Candidate Causes	DID-Preventive	DID-Mitigative
W320-BCD-ALL08	Release of liquid waste below grade and aerosol release to atmosphere due to excessive corrosion because of waste disturbance in Tank 241-C-106 resulting in leakage into liner gap, steam formation, breaching of tank bottom and steam bump.	1. Inadequate prediction of waste behavior	Active vent for heat removal Material balance performed every 24 hrs Level mon of Tank 241-C-106 Comm maintained between control trailers	Cover blocks in place Emer Resp Plan/Procedures
W320-BCD-FLUSH01	Release of energetic radioactive aerosol from transfer line due to 3-way valve left in flush position after flushing. Cover plug is lifted out of cover block on initiation of sluicing process.	1. Maintenance error 2. Communications error between different groups using the pit	Repositioned jumpers service tested Cameras used to verify initial jumper integrity Isolation valves (manual) for flush system Backflow preventers	Process pit and vault pit leak detectors Material balance every 24 hrs
W320-BCD-FLUSH02*	Release of energetic radioactive aerosol from flush tank of transfer truck due to start of submersible pump in Tank 241-C-106 during the flush of slurry transfer line. Flush tank is filled and pressurized resulting in rupture of tank or transfer line.	1. Human error 2. Communications error between different groups	Isolation valves (manual) for flush system	Backflow preventers
W320-BCD-PUMP03	Release of small high energy aerosol to atmosphere due to immersible pump being raised too high in Tank 241-AY-102, winch lifting strap breaking, pump falling into waste results in a flammable gas release which is ignited by broken electrical cables, plume burn.	1. Operator error in positioning direction 2. Inadvertant or accidental actuation 3. Winch controller fault	Mon dome pressure in Tank 241-AY-102 Video mon of waste in Tank 241-AY-102 Mon vent flow rate in tanks	None
W320-BCD-PUMP04	Release of energetic radioactive aerosol to atmosphere due to submersible pump being raised too high in Tank 241-AY-102, winch lifting strap breaking, pump falling into waste resulting in a flammable gas release which is ignited by broken electrical cables.	1. Operator error in positioning direction 2. Inadvertant or accidental actuation 3. Winch controller fault	Mon dome pressure in Tank 241-AY-102 Mon vent flow rate in tanks	None

Table D-4. Defense-in-Depth Controls for Potentially Severe (E3 and E2) Environmental Consequences. (16 sheets)

ID	Hazardous Conditions	Candidate Causes	DID-Preventive	DID-Mitigative
W320-BCD-PUMP05	Release of small high energy aerosol to atmosphere due to immersible pump being raised too high in Tank 241-C-106, motor breaks gear assembly, pump freespools into waste resulting in a flammable gas release which is ignited by broken electrical cables, plume burn.	1. Operator error in positioning direction 2. Inadvertant or accidental actuation 3. Winch controller fault	Mon dome pressure in Tank 241-C-106 Mon vent flow rate in tanks	None
W320-BCD-PUMP08	Release of liquid waste below grade and aerosol release to atmosphere due to submersible pump being raised too high, winch lifting strap breaking, pump falling and penetrating Tank 241-C-106 liner resulting in water leakage into liner gap, steam formation, liner bulges/rips and steam bump occurs.	1. Operator error in positioning direction 2. Inadvertant or accidental actuation 3. Winch controller fault	Active vent for heat removal Material balance performed every 24 hrs Level mon of Tank 241-C-106 Comm maintained between control trailers	Cover blocks in place Emer Resp Plan/Procedures
W320-BCD-PUMP09	Release of large high energy aerosolized waste to atmosphere due to immersible pump being raised too high in Tank 241-C-106, winch lifting strap breaking, pump falling into waste results in a flammable gas release which is ignited by broken electrical cables, plume burn.	1. Operator error in positioning direction 2. Inadvertant or accidental actuation 3. Winch controller fault	Mon dome pressure in Tank 241-C-106 Mon vent flow rate in tanks	None
W320-BCD-TRANS09	Release of liquid waste below grade and aerosol release to atmosphere due to loss of pumping from Tank 241-C-106 and continued pumping of Tank 241-AY-102 water exceeds maximum operating level resulting in water leakage into liner gap, steam formation, breaching of tank bottom and large steam bump.	1. Loss of power 2. Equipment casualty	Active vent for heat removal Material balance performed every 24 hrs Syphon protection Level mon of Tank 241-C-106 Comm maintained between control trailers	Cover blocks in place Emer Resp Plan/Procedures

W320-D-ALL09	Release of liquid waste below grade and aerosol release to atmosphere due to seismic event Tank 241-C-106 liner is breached resulting in water leakage into liner gap, steam formation, breaching of tank bottom and large steam bump.	1. Natural Phenomena	Active vent for heat removal Material balance performed every 24 hrs Level mon of Tank 241-C-106 Comm maintained between control trailers	Cover blocks in place Emer Resp Plan/Procedures
W320-D-CHILL01	Release of energetic radioactive aerosol from damaged tank due to a leak and ignition of propylene glycol from pit chiller into Tank 241-C-106.	1. Piping or tubing leak	Vehicle position spotters Tank farm fences	HEPA filter replacement
W320-D-CHILL02	Release of energetic radioactive aerosol from damaged tank due to a leak and ignition of propylene glycol from ventilation chiller into Tank 241-C-106.	1. Piping or tubing leak	Vehicle position spotters Tank farm fences	HEPA filter replacement
W320-D-PUMP01	Release of energetic radioactive aerosol from line break in Tank 241-AY-102 transfer pit due to immersible pump being positioned too high resulting in air entrainment in transfer line. Booster pump torques in reaction to air in transfer line and jumper connectors break. Cover block is off.	1. Operator error in positioning 2. Inadvertant or accidental repositioning 3. Level indication fault 4. Waste level indicator on pump fault	None	Process pit and vault pit leak detectors Material balance every 24 hrs
W320-D-PUMP03	Release of energetic radioactive aerosol from line break in Tank 241-C-106 transfer pit due to immersible pump being positioned too high resulting in air entrainment in transfer line. Booster pump torques in reaction to air in transfer line and jumper connectors break. Cover block is off.	1. Operator error in positioning 2. Inadvertant or accidental repositioning 3. Level indication fault 4. Waste level indicator on pump fault	None	Process pit and vault pit leak detectors Material balance every 24 hrs

Table D-4. Defense-in-Depth Controls for Potentially Severe (E3 and E2) Environmental Consequences. (16 sheets)

ID	Hazardous Conditions	Candidate Causes	DID-Preventive	DID-Mitigative
W320-D-PUMP04	Release of energetic radioactive aerosol from damaged Tank 241-AY-102 due to pumping of more solids than anticipated. Annulus cooling mod not completed resulting in overheating of waste and a tank bump. Bump induces large flammable gas release. It is then ignited resulting in a dome space fire.	1. Mass flowmeter fault or out of calibration 2. Operator error in positioning slurry pump 3. Inadvertant or accidental repositioning 4. Level indication fault 5. Waste level indicator on pump Tank 241-C-106 fault 6. Pump controller fault	Mon dome pressure in Tank 241-AY-102 Video mon of waste in Tank 241-AY-102 Mon vent flow rate in tanks	None
W320-D-TRANS05	Release of energetic radioactive aerosol to atmosphere due to head space gas concentration above LFL in Tank 241-AY-102 with the start of pumping which ignites the flammable gas.	1. Spontaneous GRE 2. Induced GRE	Mon dome pressure in Tank 241-AY-102 Video mon of waste in Tank 241-AY-102 Meas background concentrations for 3-4 weeks prior to sluicing Mon vent flow rate in tanks	None
W320-D-TRANS06	Release of large high energy aerosolized waste to the atmosphere due to slurry transfer rate being excessive resulting in a rapid reduction in the hydrostatic pressure in Tank 241-C-106. This results in a flammable gas release. Gas is ignited and a dome space fire results.	1. Sluice flow control fault	Mon dome pressure in Tank 241-C-106 Mon vent flow rate in tanks	None
W320-D-TRANS07	Release of high energetic aerosolized waste to the atmosphere due to sluice water transfer rate being excessive resulting in the Tank 241-AY-102 waste level being lowered quickly with the waste temperature too high. This results in a large steam bump and flammable gas release with ignition.	1. Operator mistake 2. Level indication fault 3. Pump controller fault	Mon dome pressure in Tank 241-AY-102 Video mon of waste in Tank 241-AY-102 Meas background concentrations for 3-4 weeks prior to sluicing Mon vent flow rate in tanks	None
W320-D-TRANS09	Release of liquid waste below grade and aerosol release to atmosphere due to movement of debris during sluicing which impacts and breaches the Tank 241-C-106 liner, resulting in water leakage into liner gap, steam formation, breaching of tank bottom and steam bump.	1. Expected outcome of high pressure sluice. Many objects are in the waste.	Active vent for heat removal Material balance performed every 24 hrs Level mon of Tank 241-C-106 Comm maintained between control trailers	Cover blocks in place Emer Resp Plan/Procedures

Table D-4. Defense-in-Depth Controls for Potentially Severe (E3 and E2) Environmental Consequences. (16 sheets)

ID	Hazardous Conditions	Candidate Causes	DID-Preventive	DID-Mitigative
W320-D-TRANS10	Release of energetic radioactive aerosol from jumper in pit due to seismic event. Cover block breached by ground motion resulting in spray release.	1. Natural Phenomena	Repositioned jumpers service tested Cameras used to verify initial jumper integrity	Process pit and vault pit leak detectors Material balance every 24 hrs
W320-D-TRANS11	Release of large high energy aerosolized radioactive waste to the atmosphere from a spray leak from transfer line due to seismic event.	1. Natural Phenomena	None	Access cntrl Material balance every 24 hrs
W320-D-VENT12	Release of energetic radioactive aerosol from collapsed Tank 241-C-106 due to incorrect alignment of current ventilation system through sluice nozzle resulting in excessive tank vacuum with loop seal failure.	1. Operator error 2. Communications error	None	None
W320-D-VENT13	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 to the atmosphere due to influx of cold water spray into tank which results in an excessive vacuum. A large flammable gas release is induced. It is then ignited resulting in a dome space fire.	1. Possible result of slurry distribution	Mon dome pressure in Tank 241-C-106 and Tank 241-AY-102 Video mon of waste in Tank 241-AY-102 Meas background concentrations for 3-4 weeks prior to sluicing Mon vent flow rate in tanks	None
W320-D-VENT16	Large high energy aerosolized waste release from Tank 241-AY-102 to the atmosphere due to the loss of primary or annulus ventilation for an extended period which results in a gradual rise in waste temperature. Flammable gas builds up in the dome space to the LFL. It is then ignited resulting in a dome space fire.	1. Extended loss of power 2. Severe ventilation casualty	Mon dome pressure in Tank 241-AY-102 Video mon of waste in Tank 241-AY-102 Meas background concentrations for 3-4 weeks prior to sluicing Mon vent flow rate in tanks	None
W320-D-VENT17	Release of high energy aerosolized release to the atmosphere due to an ice storm which prevents air inflow into Tank 241-AY-102 resulting in an excessive tank vacuum. This results in a flammable gas release with ignition.	1. Natural phenomena	Mon dome pressure in Tank 241-AY-102 Mon vent flow rate in tanks	None

Table D-4. Defense-in-Depth Controls for Potentially Severe (E3 and E2) Environmental Consequences. (16 sheets)

ID	Hazardous Conditions	Candidate Causes	DID-Preventive	DID-Mitigative
W320-D-VENT18	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 to the atmosphere due to volcanic ashfall which prevents air inflow to tank. Excessive vacuum results and flammable gas is released to the dome space. It is then ignited resulting in a dome space fire.	1. Natural phenomena	Mon dome pressure in Tank 241-AY-102 Mon vent flow rate in tanks	None
W320-D-VENT20	Release of energetic radioactive aerosol from collapsed Tank 241-C-106 due to incorrect alignment of new ventilation system through sluice nozzle resulting in excessive tank vacuum with loop seal failure.	1. Operator error 2. Communications error	None	None
W320-E-TERM03	Large high energy radioactive aerosolized waste release from Tank 241-AY-102 to the atmosphere due to lack of controls on operation of tank after it has been turned into a FG group 1 tank. It is ignited from a lightning strike or other event resulting in a dome space fire.	1. Inadequate prediction of waste behavior	Mon dome pressure in Tank 241-AY-102 Video mon of waste in Tank 241-AY-102 Mon vent flow rate in tanks	None
W320-F-TERM05	Release of liquid waste below grade and aerosol release to atmosphere due to high heat load after completion of sluicing process resulting in the need for water addition to Tank 241-C-106 with a deteriorated tank liner, water leakage into liner gap, steam formation, liner breach and steam bump.	1. Error in calculations	Active vent for heat removal Material balance performed every 24 hrs Level mon of Tank 241-C-106 Comm maintained between control trailers	Cover blocks in place Emer Resp Plan/Procedures

BIO = Basis for Interim Operation
GRE = gas release event

SAFETY ANALYSIS FOR THE REPLACEMENT CROSS-SITE TRANSFER SYSTEM

This page intentionally left blank.

EXECUTIVE SUMMARY

The purpose of this Addendum to the *Tank Waste Remediation System Basis for Interim Operation* (BIO), HNF-SD-WM-BIO-001, is to incorporate the safety analysis for Project W-058 (Replacement of the Cross-Site Transfer System) into the BIO. The replacement cross-site transfer system was an ongoing project when the BIO was being developed and thus was not included as part of its original scope.

Scope and Structure

The scope of this Addendum is the safety analysis for the replacement cross-site transfer system. The overall approach applied to the analysis for the replacement cross-site transfer system is the same as that described in the BIO. Therefore, many of the detailed discussions in the BIO are equally applicable to the analysis for the replacement cross-site transfer system and will not be repeated. Where there are differences, because of unique features of the replacement cross-site transfer system, these differences will be cited and discussed in detail. When the topics of discussion are the same (such as detailed descriptions of analysis methodologies), the Addendum will briefly discuss the topic and reference the BIO. It is important to note, however, that sufficient detail on the replacement cross-site transfer system will be provided in this Addendum for evaluating the acceptability of future proposed activities and the associated Unreviewed Safety Question determinations.

This Addendum is organized according to the format of DOE-STD-3009-94, *Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports*, with the exception of the Executive Summary, which follows the format established in the BIO. This facilitates comparisons of the summary conclusions drawn in each document. In those chapters where information is provided about Site-wide programmatic controls, the chapters are abbreviated to discuss only those programs or controls affected by the replacement cross-site transfer system. Descriptions of general Site wide programs are provided by reference only.

Safety Management

The discussion of the Safety Management System in the Executive Summary of the BIO is also applicable to the replacement cross-site transfer system.

Hazard Analysis

The discussion of hazard analysis in the Executive Summary of the BIO is also applicable to the replacement cross-site transfer system. Of the 29 representative accidents selected for quantitative analysis in the BIO, six were determined by hazard analysis to require further analysis to account for the replacement cross-site transfer system.

Hazard Classification

According to the BIO, the hazard classification of all double-shell and single-shell waste tanks, and the associated waste transfer systems, is Hazard

Category 2. The replacement cross-site transfer system is also used to transfer tank waste and is therefore classified as Hazard Category 2. (It should be noted that, per U.S. Department of Energy, Richland Operations Office (RL) direction, the Hazard Classification of the Tank Waste Remediation System facility was reevaluated during preparation of the Final Safety Analysis Report. This reevaluation concluded that Hazard Category 2 is the correct designation.)

Accident Analysis

The analysis results for existing transfer systems in the BIO are unaffected by the introduction of the replacement cross-site transfer system. Expansion of the Tank Waste Remediation System Authorization Basis to address the replacement cross-site transfer system, however, has required re-examination of six BIO accidents for specific applicability to the replacement cross-site transfer system. Summaries of these six accidents are presented below, along with a discussion of how the results differ from (or agree with) those originally determined in the BIO. The accidents are categorized in accordance with the definitions used in the Executive Summary of the BIO.

Accidents Below Risk Guidelines with Selected Controls

Analysis determined that five of the six accidents reanalyzed for the replacement cross-site transfer system do not pose significant risks with the application of controls (i.e., the risks are below the evaluation guidelines). For these accidents, application of controls ensures operations can be conducted safely. Additional Defense-in-Depth controls, that serve to further reduce the risks from these accidents, are also identified. The accidents are as follows:

- Nuclear Criticality
- Subsurface leak remaining subsurface
- Surface leak resulting in pool
- Subsurface leak resulting in pool
- Spray leak in structures or from overground waste transfer lines.

The designation of the first 4 accidents listed above, as accidents that are below risk guidelines with selected controls, is consistent with the conclusion drawn in the BIO (where the replacement cross-site transfer system was not considered). However, the conclusions for the spray leak accident are different. (The BIO showed this accident to be slightly above risk guidelines with controls.) The difference is that the two new structures (diversion box 6241-A and vent station 6241-V), evaluated for the replacement cross-site transfer system, both have high-efficiency particulate air filters (unlike other waste transfer structures), which serve to reduce the airborne dose.

Accidents Prevented with Selected Controls

The spray leak from underground waste transfer lines accident (as evaluated for the replacement cross-site transfer line) is prevented by the implemented controls on excavation activities. This conclusion is consistent with that drawn in the BIO.

General Accident Analysis Considerations

The BIO identifies a number of areas where conservatisms could be removed if additional work were performed. This discussion is also applicable to accident analysis for the replacement cross-site transfer system.

Controls

An overall discussion on the selection of controls is provided in the Executive Summary of the BIO. This discussion is also applicable to accident analysis for the replacement cross-site transfer system. The controls identified for the replacement cross-site transfer system have been integrated into the overall set of operational controls established for the Tank Waste Remediation System facility. The control descriptions in Chapter 6.0 of the BIO and in the Technical Safety Requirements document that identify safety functions, operability requirements, and surveillance requirements for the Tank Waste Remediation System facility, have been modified to include the replacement cross-site transfer system.

Defense-in-Depth

The discussion of Defense-in-Depth controls in the Executive Summary of the BIO is also applicable to the analysis for the replacement cross-site transfer system.

Summary Conclusions

In summary, this Addendum to the BIO reaches the following conclusions:

- The selected safety structures, systems, and components and the accompanying controls (Technical Safety Requirements, Health and Safety Plans, and implementing procedures) provide prevention and mitigation measures to address these vulnerabilities.

- The analyses show that these measures provide reasonable assurance that operation of the replacement cross-site transfer system can be conducted safely.

It is important to note that operation of the replacement cross-site transfer system will be integrated into the Tank Waste Remediation System facility operations. The new controls for the replacement cross-site transfer system, stipulated in this Addendum, have been added to Chapter 6.0, "Operational Controls," of the BIO.

Collectively, these conclusions find that the replacement cross-site transfer system can be operated safely following the requirements of this Addendum and the BIO until these documents are replaced by a fully compliant Final Safety Analysis Report.

1.0 SITE CHARACTERISTICS

The replacement cross-site transfer system (RCSTS) is located within the Tank Waste Remediation System (TWRS) facility, and therefore has the same site characteristics as the balance of the TWRS facility. A description of site characteristics necessary for understanding the TWRS and Hanford Site environment is being developed as Chapter 1.0 of the TWRS Final Safety Analysis Report (FSAR) and is included in its entirety in Appendix C, "Site Characteristics," of the Basis for Interim Operation (BIO).

1.1 INTRODUCTION

The objective of this chapter is to describe the site characteristics of the Hanford Site, as applicable to the safety analysis for the RCSTS.

1.2 REQUIREMENTS

Appendix C of the BIO lists the applicable requirements. No changes to these requirements result from the installation or operation of the RCSTS.

1.3 SITE CHARACTERISTICS

The site characteristics for the TWRS facility, which includes the RCSTS, are described in Appendix C of the BIO.

This page intentionally left blank.

2.0 FACILITY DESCRIPTION

A description of the Tank Waste Remediation System (TWRS) facility is provided in Section B2.0, "Facility Description" of Appendix B, "Facility and Process Description," of the Basis for Interim Operation (BIO).

2.1 INTRODUCTION

In this chapter, the replacement cross-site transfer system (RCSTS) facilities and operations are described to support assumptions used in Chapter 3.0, "Safety Analysis."

2.2 REQUIREMENTS

The design codes, standards, regulations, and U.S. Department of Energy orders required for establishing the Authorization Basis of the TWRS facilities are listed in Appendix B, Section B2.2, "Requirements," of the BIO. Because the RCSTS is a part of the TWRS facility, the listed documents also apply to the RCSTS. In addition to these documents, the RCSTS also was designed to comply with the following requirements:

- DOE 6430.1A, *General Design Criteria*, Change 0 (1989)
- SDC-4.1, *Standard Architectural-Civil Design Criteria: Design Loads for Facilities* (1993)
- WHC-SD-W058-FDC-001, *Functional Design Criteria for Project W-058, Replacement of the Cross-Site Transfer System* (1996)
- ACI 349-90, *Code Requirements for Nuclear Safety Related Concrete Structures* (1990)
- 40 CFR 264, "Standards for Owners and Operators of Hazardous Waste Treatment, Storage, and Disposal Facilities" (1995)
- 40 CFR 265, "Interim Status Standards for Owners and Operators of Hazardous Waste Treatment, Storage, and Disposal Facilities" (1995)
- WAC 173-303, "Dangerous Waste Regulations" (1995)
- DOE 5480.11, *Radiation Protection for Occupational Workers, Change 3* (1992)
- ANSI/ASME B31.3, *Chemical Plant and Petroleum Refinery Piping* (1993)
- ASME AG-1, *Code on Nuclear Air and Gas Treatment* (1991).

2.3 FACILITY OVERVIEW

An overview of the tank farm facilities configuration, including a brief history of TWRS operations, is provided in Section B2.3, "Facility Overview," of Appendix B of the BIO.

The RCSTS provides a means of transferring single-shell tank (SST) waste, double-shell tank (DST) waste, and other liquid slurry wastes resulting from normal 200 West Area operations to the treatment, storage, and disposal facilities in the 200 East Area. East to west transfers can also be made. The transfer route is shown in Figure 2-1.

2.4 FACILITY STRUCTURES

Detailed descriptions of the TWRS facilities are provided in Section 2.4, "Facility Structures," of Appendix B of the BIO. Many of these descriptions are relevant to the RCSTS, since it interfaces with these existing tank farm systems. Presented below is a description of the RCSTS transfer piping and associated systems and structures.

2.4.1 Transfer Pipe System Description

The RCSTS is a buried pipe-in-pipe system approximately 10.5 km (6.5 mi) long. The primary piping is 7.6-cm (3-in.), 304 L stainless steel, Schedule 40. The encasement piping is 15.2-cm (6-in.), ASTM A53 Grade B carbon steel, standard weight and 30.5-cm (12-in.) ASTM A53 Grade B carbon steel, standard weight at the expansion loops, with epoxy coating to minimize external corrosion. The primary piping is designed in accordance with the requirements of ANSI/ASME B31.3, while the overall pipe-in-pipe design complies with the secondary containment requirements stipulated in the standards listed in Section 2.2 of this addendum. A material of construction position paper (Parsons 1994, *Project W-058/W-028, Material of Construction Position Paper*) provides the justification for selecting the piping based on the reliability of the selected materials. The RCSTS pipe design is depicted in Figure 2-2.

The 241-SY-A and 241-SY-B valve pits in the 200 West Area are connected with the 244-A lift station in the 200 East Area by the RCSTS. Liquid waste can be transferred in either direction between the 200 East and 200 West Areas through one of the two RCSTS lines, using existing transfer pumps. The other RCSTS line is designed to transfer wastes with as much as 30 vol% solids from the 200 West Area to the 200 East Area, using existing tank farm transfer pumps and the RCSTS booster pumps. (It should be noted that this 30 vol% solids is based on a displacement measurement in a sight glass and that normal loading for slurry transfers is expected to be 10 vol% solids or less.)

The RCSTS provides one line each to the 241-SY-A and 241-SY-B valve pits in the 200 West Area. These buried lines follow a single construction trench to a new diversion box, also located in the 200 West Area (diversion box 6241-A). Two booster pumps are connected to one of the lines in this diversion box.

From diversion box 6241-A, the lines travel to another new structure at the high point in the route, vent station 6241-V, located in the 600 Area, between the 200 East and 200 West Areas. Each transfer line has a vent at the high point that allows air to be introduced into the line so that the line can drain after waste transfers are completed.

The transfer lines continue on to the 244-A lift station in the 200 East Area. The lines are connected to new nozzles that are installed in the lift station wall.

The primary and encasement pipe are all-welded construction. No remotely installed jumpers are used except at the interfaces with existing diversion boxes. In addition, the piping is buried below the frost line on the 200 Area plateau.

The system is designed to minimize the possibility of plugging in the pipes, pipe fittings, and other piping components. To promote gravity drainage, the system is designed so that the vent station is the high point and the end points in East and West Area are the low points with the pipe having a continuous slope of at least 0.25%. Valves will fail in the "as-is" position, allowing waste to drain to the source and destination tanks. The encasement piping is insulated with polyurethane foam and a fiberglass reinforced-plastic jacket to minimize the temperature drop of an uninterrupted waste transfer to a maximum of 20 °F.

The encasement piping is terminated inside each of the various structures encountered along the RCSTS route. Each segment of the encasement is provided with a drain valve at each end and with a rupture disk at the diversion box and vent station. The rupture disk limits any potential pressure buildup within the encasement. Regular leak testing of the encasement segments can be performed from inside the diversion box and vent station, and from the encasement connections located in the 244-A lift station and the 241-SY-A and 241-SY-B valve pits.

The buried piping is marked by a 15.2-cm- (6-in.-) wide continuous plastic sheet marker placed in the soil directly above each pipe, one foot below the ground surface for identification of hazardous waste lines. Additionally, magenta and yellow route markers that extend 1.5 m (5 ft) aboveground are located at road and rail crossings, are spaced at maximum intervals of 45.7 m (150 ft), are located at changes in direction, and are staggered every 22.9 m (75 ft) with electrical conduit markers.

In order to meet the RCSTS design requirements (WHC-SD-W058-FDC-001, *Functional Design Criteria for Project W-058, Replacement of the Cross-Site Transfer System*), the boosted system will have a maximum operating pressure of 8,446.1 kPa (1,225 lbs/in^2). The maximum pressure produced by a combination of the transfer and booster pumps during a no-flow condition is 9,859.5 kPa (1,430 lbs/in^2), which is within the limits of the piping code. Even though the maximum pressure produced in the line that does not use the booster pump is 1,585.8 kPa (230 lbs/in^2), both lines are designed to the higher pressures noted above. Because most wastes will not have the combination of all

possible worst-case design parameters, listed in Table 2-1, operating pressure will normally be significantly less than the design pressure. Pressure interfaces for the RCSTS are shown in Figure 2-3.

As indicated in Figure 2-3, the RCSTS is designed for a higher pressure than the piping beyond the lift station to which it is connected. This existing piping is protected from overpressurization by two redundant relief valves in the boosted line, which are installed in the 244-A lift station. A rupture disk is located immediately upstream of and in line with each relief valve to keep the valve from becoming contaminated under normal conditions and thereby facilitates valve calibration and maintenance. At a pressure of 230 psig (1586 kPa), the rupture disk will rupture, an alarm will activate at the operator control station (OCS), and the relief valve will discharge into the 244-A catch tank. It should be noted that the 230 psig (1586 kPa) relief valve setting is based on the lowest maximum operating pressure of the East Tank Farm piping that can receive flow from the RCSTS.

Each of the two rupture disk/relief valve systems is connected to the 244-A catch tank by a 3-inch line. The 244-A catch tank is a carbon steel tank located in a steel-lined vault within the 244-A lift station. The tank has a capacity of 61,627 L (16,280 gal). (The maximum amount of flow to the tank through the RCSTS pressure relief valve is 15,900 L [4,200 gal] based on an operator response of 30 minutes.)

2.4.1.1 Flush Water System. Flush water is provided at the 241-SY Tank Farm for boosted transfers. The flush system will be available before a transfer is started. The flush system is an aboveground installation designed to flush the boosted line at 1.8 m/s (6 ft/s). The water for this system comes from a 178,000-L (47,000-gal) tank that is filled by a raw water supply line from the 241-SY raw water service pit. The raw water used in making up flush solutions is low in chlorides and fluorides (historically less than 1 ppm of either). The insulated tank will store heated flush water and is vented to the atmosphere. The raw water supply line to the water flush tank allows chemical addition and mixing in order to adjust the pH. Flush water in the tank will be conditioned to a pH that is approximately 11.0.

The flush system is isolated from the waste transfer system by a check valve followed by two valves with a pressure transmitter (with an associated alarm) between them, in the 241-SY-A valve pit. During waste transfer operations the valves are closed to isolate the flush system from the transfer system. If waste leaks by the first valve, the pressure transmitter will actuate an alarm and shut down the transfer pumps. (The pressure transmitter is hardwired from its location in the 241-SY-A valve pit to the 241-SY-271 instrument building. On a high pressure indication it provides a signal into the existing 200 West master shutdown circuit.) The valves prevent the backflow of waste into the flush lines and water flush tank.

2.4.1.2 Leak Detection. Any leak detected in the RCSTS structures will automatically stop the transfer in progress by stopping all operating pumps and preventing additional waste from being transferred until the alarm is cleared. Leak detection systems are located at a low-point sump in the diversion box and vent station to provide an indication of a leak. These leak detection systems include dual probe electrodes, induction-type relays, fail-safe relays, transmitters, and reset switches.

In the RCSTS transfer line, a continuous coaxial cable is run in the annular region between the primary and secondary pipe (Figure 2-2). Before initial startup, this annular region is filled with an inert gas to minimize corrosion and spurious leak detection alarms. After the annular region is filled, valves on each end of each encasement section are then closed to isolate the purge gas. This system alarms in the OCS and provides the location of the detected leak.

2.4.1.3 Diversion Box 6241-A. Diversion Box 6241-A is located in the 200 West Area and contains two booster pumps connected in parallel to one of the transfer lines. An interlock prevents the two pumps from being operated simultaneously.

The two booster pumps are multistage, horizontal, split-case, centrifugal pumps with an all-stainless steel volute and impeller. Each booster pump has a variable speed drive that varies the speed of the pump to maintain waste velocity at the rate required to prevent line plugging (up to 1.8 m/s [6 ft/s]) over a wide range of waste characteristics. The pumps were fabricated and assembled in accordance with NFPA 70, *National Electrical Code*.

The diversion box pit is entered only for certain maintenance tasks and only after the transfer line has been flushed and appropriate entrance requirements are met. The pits are accessed for maintenance through an airtight entry door shielded by a labyrinth wall on the inside of the pit. Penetrations for an air sample line, an air exhauster hookup, a liner washdown system, and an emergency pumpout line are also provided. Air passes to and from the diversion box (due to temperature and pressure changes) through a HEPA filter connected to a 15 cm (6-in) pipe that penetrates the wall at grade level near the roof. A portable exhauster can be connected to the air exhauster hookup line to provide ventilation, when required.

2.4.1.4 Vent Station 6241-V. Vent station 6241-V is located approximately midway between the 200 West and 200 East Areas at the high point in the system. After a waste transfer and flush, a negative pressure will develop at the system high point as fluid attempts to drain by gravity to the sending and receiving tanks. Each transfer line has a vent at the high point that will allow air to be introduced into the transfer lines to break this vacuum.

Each vent line has two pneumatic valves in series that are normally closed to isolate the line from the waste transfer piping. A pressure transmitter is located between the two valves and is interlocked to shut down the transfer and booster pump upon detection of pressure when the two valves are closed. In addition, the two valves are interlocked such that they cannot be opened unless a pressure sensor in the vent station transfer piping registers a negative pressure, which will develop only when the line is

draining. When a break of the suction in the line is desired, the two pneumatic valves will be opened (along with a third isolation valve near the filter) and air will be drawn into the transfer line through a HEPA filter. The HEPA filter provides protection against the remote possibility of contaminated air exiting the transfer pipe into the vent station.

The vent station pit is entered only for certain maintenance tasks and only after the transfer line has been flushed and appropriate entrance requirements are met. The pits are accessed for maintenance through an airtight entry door shielded by a labyrinth wall on the inside of the pit. Penetrations for an air sample line, an air exhauster hookup, liner washdown system, and an emergency pumpout line are also provided. Air passes to and from the vent station (due to temperature and pressure changes) through a HEPA filter connected to a 15-cm (6-in) pipe that penetrates the wall at grade level near the roof. A portable exhauster can be connected to the air exhauster hookup line to provide ventilation, when required.

2.4.1.5 Instrumentation and Control System. Instrumentation and control of the RCSTS is centered around a computer-based monitor and control system that controls the entire process from the existing 242-S Evaporator building in the 200 West Area. The OCS consists of a personal computer running graphical, object-oriented, database software with a graphical cathode-ray tube/operator interface. The OCS is interconnected to a series of local process control units (PCUs) installed at each pit. Each PCU is used to collect process input, control process outputs, communicate with the OCS, and execute programmable control schemes. Local control may be accomplished from the PCU. The entire control system may be operated from any of the PCUs with the use of a portable terminal.

2.5 PROCESS DESCRIPTION

2.5.1 Waste Composition

The RCSTS will transfer wastes between the tanks in the 200 East and 200 West Area tank farms. The chemical composition of the waste for any given transfer through the RCSTS will depend on the originating tank.

2.5.2 Process Description

The most common type of transfer will be from the 200 West Area to the 200 East Area via Tank 241-SY-102. A transfer pump in the sending tank will retrieve the waste and send it to the 241-SY-A or 241-SY-B valve pit. Depending on the type of waste, the capabilities of the transfer pump and the destination of the waste, it will go either into the boosted or unboosted line. If the waste goes through 241-SY-B, it will enter the slurry line where booster pumps are available at RCSTS diversion box 6241-A (or they may be bypassed) to ensure that the required minimum velocity is maintained to prevent the settling of solids. The booster pumps have a variable speed drive that uses a flow-indicating controller to maintain the desired flow rate. A master pump shutdown circuit automatically shuts down a transfer in the

event that a leak occurs during a transfer. A single signal from a pit leak detector is sufficient to initiate the shutdown. (Depending on the nature and duration of the shutdown, the transfer will either be restarted or the line will be flushed.)

Once the route is established and a transfer is started, several parameters will be monitored at the interfacing facilities to ensure the transfer proceeds properly. The booster pump in use is monitored for start/stop, motor speed, pump bearing vibration, motor-winding temperature, pump-bearing temperature, and pump-seal failure. The pumped line is also monitored for pressure, temperature, flow rate, valve status, misrouting detection, and leak detection. The temperature is monitored at both the sending and the receiving tanks. A pressure transmitter on the boosted line provides high-pressure indication with a software interlock to shut down the pump on high pressure. Other indications that the transfer is not proceeding properly may result in an automatic or manual shutdown of the transfer.

Valves located within the RCSTS may be positioned by the operator at the OCS or can be operated locally. Position indication is provided locally and at the OCS by providing valves with limit switches for the fully open and the fully closed positions. A display graph shows the status of valves. Once a route has been selected, the valves are interlocked to prevent a misrouting.

Once a transfer is complete, the transfer piping is flushed with water as required. This flush reduces the radioactivity, removes any residual solids in the transfer lines, and also helps to minimize corrosion.

Transfer lines may be preheated, if required, by using flushing water heated in the water flush tank. This feature will be used if the waste is prone to plugging because of a decrease in temperature.

2.6 CONFINEMENT SYSTEMS

The confinement systems of the RCSTS include the transfer equipment (i.e., piping) and the associated structures (diversion box 6241-A and vent station 6241-V). The inner piping provides the primary confinement of the transferred waste while the encasement piping provides a secondary confinement. The RCSTS structures (diversion box 6241-A and vent station 6241-V) will provide confinement of any leaks that develop in equipment located within the structures (such as valves, or the booster pumps). Each of these structures is constructed of cast-in-place reinforced concrete, designed to comply with the structural requirements listed in Section 2.2 of this addendum. In addition, both structures have a HEPA filter (connected to a 15 cm (6-in) pipe that penetrates the wall at grade level near the roof), which serves as an additional confinement feature. These HEPA filters meet the requirements of ASME AG-1, *Code on Nuclear Air and Gas Treatment*. During transfer operations, the entry door is closed and the pipe penetrations are capped or flanged so that air forced from the structure (due to pressure or temperature changes) passes through the filter. (Prior to initial operation, a leak test of the diversion box and vent station was performed.)

2.7 SAFETY SUPPORT SYSTEMS

2.7.1 Fire Protection

It was concluded in WHC-SD-W058-FHA-001, *Fire Hazards Analysis for the Replacement Cross-Site Transfer System, Project W-058* that a fire protection system for the RCSTS is not required. Normal fire safety practices will be followed. Combustible material and fire loadings will be held to a minimum. The support buildings, diversion box 6241-A, and vent station 6241-V are constructed of concrete and the risk of fire loss within them is very small.

2.7.2 Radiation Protection Systems

There are no permanent radiation monitoring systems installed within the RCSTS structures. Portable radiation monitoring systems are used during inspection and maintenance activities.

2.8 UTILITY DISTRIBUTION SYSTEMS

2.8.1 Raw Water System

The RCSTS uses existing raw water systems for the normal flushing operation. The flush tank is connected to the 241-SY Tank Farm raw water system, and will be filled, as necessary, prior to commencing waste transfers.

2.8.2 Instrument Air System

At diversion box 6241-A and at vent station 6241-V, a small packaged air compressor and dryer are used to provide dry, oil-free, instrument-quality air for operation of the pneumatic valves and seal air for the booster pump shaft seals.

2.8.3 Electrical Power Distribution System

At diversion box 6241-A, new 13.8-kV lines extend from nearby existing 13.8-kV lines, C8-L3 and C8-L4. Each line supplies a pad-mounted 13.8 kV-480Y/277 V ac, 3-phase, 4-wire, 60 Hz transformer rated at 500 kVA. Each transformer is sized to meet all electrical requirements at this diversion box. The transformers supply a 480 V panel that distributes power to each component.

The electrical power for vent station 6241-V is provided from an existing 13.8 kV-480Y/277 V ac, 3-phase, 4-wire, 60 Hz transformer rated at 225 kVA, supplied by the existing overhead 13.8-kV line C8-L7. The transformer supplies a 480 V panel that distributes power to each component.

The electrical power for the flush system is provided from an existing 480V switchgear located in the 252-S substation building. Two new 480 V ac, 800 A, 3-phase, 60 Hz circuit breakers have been added to spare compartments of the switchgear. Each circuit breaker will provide power for one 498 KW flush water heater and smaller loads including the flush water pump.

2.9 AUXILIARY SYSTEMS AND SUPPORT FACILITIES

The TWRS auxiliary system and support facilities include administrative areas, control facilities, communications systems, lighting, and sewage treatment. These facilities will also be used to support RCSTS operation and are described in Section 2.9, "Auxiliary Systems and Support Facilities," in Appendix B of the BIO.

2.9.1 Control Facility

The 242-S Evaporator control room monitors the 200 West Area tank farm system parameters (e.g., ventilation and tank level) or valve positioning, pump operation, and tank-level data during waste transfers. In addition, the 242-S Evaporator control room will be used to monitor and control the transfers between the 200 Areas through the RCSTS.

3.0 SAFETY ANALYSIS

3.1 INTRODUCTION

The safety analysis of the replacement cross-site transfer system (RCSTS) facilities and operations are described in this chapter. The discussions in Section 5.0, "Safety Analysis," of the Basis for Interim Operation (BIO), on safety analysis, hazard classification, and the controls derived from hazard and accident analysis, are also applicable to the safety analysis for the RCSTS.

3.2 REQUIREMENTS

DOE orders and standards that provide requirements and guidance for hazard and accident analyses for nonreactor nuclear facilities are as follows:

- DOE 5480.23, *Nuclear Safety Analysis Reports*, Change 1 (1994)
- DOE-STD-1027-92, *Hazard Categorization and Accident Analysis Techniques for Compliance with DOE Order 5480.23, Nuclear Safety Analysis Reports* (1992)
- DOE-STD-3009-94, *Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports* (1994).

Additional requirements for hazard and accident analyses are identified in Section 5.0 of the BIO. The DOE requirements on the definition of the Hanford Site boundary and on risk guidelines, that were followed in the BIO, are also applied to the analyses presented in this Addendum.

3.3 HAZARD ANALYSIS

Presented in this section are the methodology and results of the hazard analysis conducted for the RCSTS facilities and operations. The types of events considered in the RCSTS hazard analysis are internal events, external events, and natural phenomena that can cause the uncontrolled release of radioactive or hazardous materials and affect the public, workers, or the environment. Sabotage and terrorism are not considered.

3.3.1 Methodology

The methodology used to perform the RCSTS hazard analysis is the same as that described in Section 5.2.1, "Methodology," and Appendix D, "Hazard Analysis Results Report," (Section D2.0, "Hazard Analysis Methodology") of the BIO. Details of the hazard analysis, as related to the RCSTS, are presented below.

3.3.1.1 Hazard Identification. The hazards analysis includes identification of the hazards associated with the RCSTS design, processes, and operations. The same methodology described in Section 5.2.1.1, "Hazard Identification," and D2.1, "Hazard Identification," (Appendix D) of the BIO was used for the RCSTS. The hazard identification form and related checklist used for the RCSTS evaluation are the same as those shown in Tables D2.1-1, "Hazards Identification Form," and D2.1-2, "Hazard Identification Checklist and Energy Designation," (Appendix D) of the BIO.

It should be noted that the RCSTS material at risk assumptions are based on the following:

- **Chemical Inventory** — The source for the RCSTS maximum hazardous chemical inventory is WHC-SD-WM-SARR-011, *Toxic Chemical Considerations for Tank Farm Releases*. This document contains the bounding limits for chemical concentrations for the waste to be transported through the RCSTS.

- **Radiological Inventory** — The RCSTS worst-dose radiological inventory is based on WHC-SD-WM-SARR-016, *Tank Waste Compositions and Atmospheric Dispersion Coefficients for Use in Safety Analysis Consequence Assessments*, and WHC-SD-WM-SARR-037, *Development of Radiological Concentrations and Unit Liter Doses for TWRS FSAR Radiological Consequence Calculations*. These documents contain bounding unit-liter doses for the tanks within the TWRS facility. Aging waste is the bounding unit-liter dose used in the RCSTS analysis. To be consistent with the BIO, a unit-liter dose of 33 vol% solids and 67 vol% liquids was conservatively used in the analyses to bound the RCSTS transfer capabilities (i.e., 30 vol% solids maximum).

3.3.1.2 Hazard Topography. The TWRS hazard topography is described in Section D2.2, "Hazard Topography," (Appendix D) of the BIO. The hazardous conditions identified for the components and activities of the RCSTS were mapped into this topography.

3.3.1.3 Hazard Evaluation. Detailed discussions of hazard evaluation techniques are presented in Sections 5.2.1.2, "Hazard Evaluation," and Section D2.3, "Hazard Evaluation," (Appendix D) of the BIO. The methodology described in these sections was applied to the hazard evaluation of the RCSTS. A hazards and operability (HazOp) study was performed by a team of cognizant TWRS Operations and Engineering personnel, safety analysts familiar with the RCSTS, and technical experts in specialty areas for the RCSTS. This study is documented in WHC-SD-W058-PHA-001, *Hazards and Operability Study for the Replacement Cross-Site Transfer System*. A revision to this document has been made to account for changes to the original RCSTS design.

After the list of hazards were identified through the HazOp process, these hazards were compared with those associated with the existing cross-site transfer line in the BIO hazards database. Each existing cross-site transfer line hazard was found to be accounted for in the RCSTS hazards list. The BIO hazard identifier was incorporated into the related RCSTS hazard identifier to facilitate future reference.

3.3.1.4 Candidate Accident Selection. The methodology for candidate accident selection is described in Section 5.2.1.3, "Accident Selection," and Section D2.4, "Candidate Accident Selection," (Appendix D) of the BIO. This methodology was applied to accident selection for the RCSTS. The initial list of bins was based on the list of candidate accidents developed for the BIO. Evaluation of the individual RCSTS hazards identified no unique hazards that would result in the establishment of another accident bin, beyond those used in the BIO.

3.3.1.5 Controls Identification. The methodology for controls identification is described in Section 5.2.1.4, "Controls Identification," and Section D2.5, "Controls Identification," (Appendix D) of the BIO. This BIO methodology was also applied to controls identification for the RCSTS.

3.3.2 Hazards Analysis Results

3.3.2.1 Hazard Identification. Results of the hazard identification activities for the RCSTS are presented in the following sections. Details of the hazard analysis are presented in the following appendices of this Addendum:

- Appendix A, "Hazard Basis"
- Appendix B, "Analyzed Accidents and Represented Hazardous Conditions"
- Appendix C, "Hazard Evaluation Result"
- Appendix D, "Control Allocation Tables."

3.3.2.1.1 Material at Risk. The material at risk for each component of the RCSTS is identified in Table A-2 and was developed from information obtained during hazard analysis activities. The RCSTS will transfer tank wastes which contain radioactive material and chemical compounds (e.g., sodium hydroxide and sodium nitrate) typically found in waste tanks. Radiological and chemical composition of the transferred waste will depend on the constituents of the originating tank. The RCSTS may also contain flush solutions, consisting of water with enough sodium hydroxide added to bring the pH to approximately 11. Other chemicals may be added (e.g., sodium nitrate) to the flush solution.

The radiological material at risk is assumed to be from the worst-case tank in the Aging Waste Facility. The composition of this waste is documented in WHC-SD-WM-SARR-037. The toxicological composition of the waste is defined in WHC-SD-WM-SARR-011.

Hazardous Materials External to RCSTS. The RCSTS does not store or provide chemicals for process activities other than small quantities of sodium hydroxide used in the flush water system.

3.3.2.1.2 Energy Sources. The next step in the hazard identification process entails the identification of the energy sources that could contribute to the uncontrolled release of the material at risk. The energy sources for the RCSTS were identified using an energy source checklist.

The checklist that was applied to the RCSTS was developed from the management oversight and risk tree list (DOE-76-45/4 SSDC-4, *MORT User's Manual*) with other energy sources, specific to TWRS facilities, included.

The energy sources identified for the RCSTS are recorded in Table 3-1 (and the definitions are shown in Table 3-2). These results reflect the energy sources present during routine operational activities.

3.3.2.2 Hazard Classification. DOE 5480.23 requires the hazard classification of nuclear facilities and operations. Section 5.1, "Hazard Classification," of the BIO documents the hazard classification of TWRS facilities performed in accordance with DOE-STD-1027-92. Single-shell tanks, double-shell tanks, aging waste facility tanks, and associated waste transfer systems are designated as Hazard Category 2 facilities. The RCSTS is part of the waste transfer system within the TWRS facility. It is interconnected to existing TWRS facility equipment and is not an independent segment. In addition, the RCSTS brings no new material at risk to the TWRS facility. Therefore, the RCSTS is also classified as Hazard Category 2. (It should be noted that, per RL direction, the Hazard Classification of the TWRS facility was reevaluated during preparation of the Final Safety Analysis Report. This reevaluation concluded that Hazard Category 2 is the correct designation.)

3.3.2.3 Hazard Evaluation. The hazard evaluation activity for the RCSTS identified hazardous conditions with the potential for significant health, environmental, occupational, and radiation exposure consequences. All consequence and frequency assessments developed during hazard analysis activities are based on an assumed RCSTS configuration with no controls.

3.3.2.3.1 Accident Selection. As noted in Section 3.3.1.4 of this addendum, the initial list of bins was based on the list of candidate accidents developed for the BIO. Evaluation of the individual RCSTS hazards identified no unique hazards that would result in the establishment of any additional accident bins. This initial set of candidate accidents represents all the S3 (offsite) and S2 (onsite) hazardous conditions that were selected for the TWRS facility in the BIO. These accidents are shown in Table 3-3.

Out of a total of 29 candidate accidents identified in the BIO, 13 accidents and one natural phenomena bin were used in the binning process for the RCSTS hazardous conditions. A list of the hazardous conditions represented for each of the 13 accidents is shown in Table B-1, while the list of binned RCSTS hazardous conditions is provided in Table B-2, which also includes the natural phenomena bin. Of the 13 accidents, six accidents were reanalyzed to account for the differences in the event scenario unique to the RCSTS. This final set of accidents, representing all S3 (offsite) and S2 (onsite) hazardous conditions that needed to be reanalyzed for the RCSTS, is shown in Table 3-4. A description of the reanalyzed accident scenarios and how the scenario differs from the original BIO scenario is provided in Section 3.4.

3.3.2.3.2 Defense-in-Depth. The hazardous conditions identified for the RCSTS are shown in Appendix C of this addendum and are arranged according to consequence category (i.e., S3, S2, S1, etc.). Where applicable, Defense-in-Depth controls have been allocated to hazardous conditions with potential S3, S2, E3, and E2 consequences. In addition, Defense-in-Depth controls have been allocated to the hazardous conditions with significant facility worker consequences (F3/S1). The control allocation tables are shown in Appendix D of this addendum.

Protection Against Offsite Consequences. The controls identified for the reanalyzed accidents with potential offsite consequences are described in Section 3.4 of this addendum. These descriptions also include a discussion of accident consequences and frequency.

Protection Against Onsite Consequences. The controls identified for the reanalyzed accidents with potential onsite consequences are described in Section 3.4. These descriptions also include a discussion of accident consequences and frequency.

3.3.2.3.3 Facility Worker Protection. In the course of the RCSTS hazard analysis process, a number of potential hazardous conditions only affecting the facility worker were identified. These hazardous conditions were divided into three categories: uncontrolled releases of radioactive or hazardous material, operational radiation and hazardous material protection concerns, and occupational safety concerns.

Protection Against Uncontrolled Releases. From the hazard analysis database a list of anticipated hazardous conditions resulting in only facility worker effects from releases was developed (i.e., F3, S1 hazardous conditions with no controls). The hazardous conditions were reviewed to determine if they represented the potential for serious injury or death to the facility worker. For those hazardous conditions, Safety-Significant SSCs and TSRs were developed. Appendix D lists the anticipated hazardous conditions affecting the facility worker along with the applicable SSCs and TSRs.

Operational Radiation and Hazardous Material Protection. The hazard evaluation for the RCSTS identified a number of potential facility worker radiation exposure concerns. Although identification of potential facility worker radiation exposure and hazardous material concerns was not the specific focus of the hazards evaluation, the exposure concerns are recorded in Appendix C, Table C-5 of this addendum.

Occupational Safety. The hazard evaluation for the RCSTS identified a number of potential facility worker occupational safety concerns. Potential facility worker occupational safety hazardous conditions are recorded in Appendix C, Table C-6 of this addendum. These occupational hazards associated with the RCSTS are typical of those associated with other waste transfer systems in the TWRS facility. Industrial safety is implemented through HNF-SD-WM-HSP-002, *Tank Farms Health and Safety Plan*, which establishes procedures and provides general guidelines to minimize health and safety risks to facility workers.

3.3.2.3.4 Environmental Protection. The hazard analysis identified hazardous conditions with significant environmental (E3 or E2) consequences. These hazardous conditions are recorded in Appendix C, Table C-4 of this addendum. For most of these hazardous conditions, the controls to protect the public, onsite worker, and facility worker also provide for protection of the environment. A listing of the hazardous conditions with significant environmental consequences (E3 and E2) and applicable SSCs and TSRs is provided in Appendix D of this addendum.

Table 3-1. RCSTS Hazards Identification.[a]

Energy Classification[b]	RCSTS	
	PF	PE
Corrosive	2	N/A
Explosive/pyrophoric	6,7,8,10	N/A
Nuclear criticality	N/A	N/A
Flammable materials	11,13,14	3,7

3.4 ACCIDENT ANALYSIS

3.4.1 Methodology

Six accidents previously analyzed in the BIO (nuclear criticality, subsurface leak remaining subsurface, surface leak resulting in pool, subsurface leak resulting in pool, spray leak in structure or from overground waste transfer lines, and spray leak from underground waste transfer lines) were reanalyzed for the RCSTS to determine whether the BIO analysis is bounding. These accidents were reanalyzed because parameters such as temperatures, pressures, flows, and component dimensions are different for the RCSTS and may therefore affect the BIO analysis results. The accident analysis methodology for reevaluation of these accidents is the same as that described in Section 5.3, "Accident Analysis," of the BIO. It should be noted that, because of the differences in design, some assumptions used in the analysis of the RCSTS are different from those used in the analysis of transfer systems in the BIO. However, these assumptions did not involve the overall analysis methodology (i.e., radiological and toxicological consequence calculation methodology and the basis for estimating frequency), which remained consistent with the BIO methodology. Analysis results are reported in the following sections and the supporting calculations are documented in HNF-2542, *Revised Spray Leak Calculations for Project W-058*.

3.4.2 Accident Analysis Scenarios

This section provides the analysis for the six accidents (nuclear criticality, subsurface leak remaining subsurface, surface leak resulting in pool, subsurface leak resulting in pool, spray leak in structure or from overground waste transfer lines, and spray leak from underground waste transfer lines) that need to be revisited for the RCSTS. To provide a complete picture of how the RCSTS relates to the other accident scenarios, all other BIO accident scenarios are discussed with a focus on any interfaces with the RCSTS.

The six reanalyzed accidents are presented in the same format that was used in the BIO. However, only the new controls are shown in this Addendum. The existing controls that remain applicable are provided by reference to the BIO.

It is important to note that the analysis addressing State Highway 240 transient populations and the control strategy for potential misrouting of waste transfers, that is outlined at the beginning of BIO Section 5.3.2, "Accident Analysis Scenarios," is also applicable to the RCSTS analysis. To support the BIO, an analysis of potential consequences to transient populations on State Highway 240 was performed for four bounding accidents

(including the spray leak) and is documented in HNF-SD-TWR-TI-002, *Analysis of Consequences at State Route 240 from Postulated Accidents at Tank Waste Remediation System Facilities to Support Development of Emergency Response Plans*. Both the radiological and toxicological doses for the spray leak accident (the worst-case transfer accident) were below the evaluation guidelines. (It should be noted that the organic salt-nitrate reaction produced results that were above the risk guidelines, but this is a waste tank accident and is not applicable to waste transfer systems.)

It is also important to note that plugging of the transfer lines (deemed to be highly improbable based on the system design) is an availability and operational concern, but not a safety concern (i.e., it will not cause a waste release nor would it worsen the consequences of the leak and spray accidents already evaluated).

3.4.2.1 Nuclear Criticality. Nuclear criticality is reevaluated for the RCSTS, not because of any criticality concern within the transfer line itself, but because of the potential transfer of solids (containing plutonium) between waste tanks. The background of the nuclear criticality analysis is described below.

The BIO evaluated the potential for nuclear criticality and concluded that no credible scenario has been identified that leads to a criticality in a double-contained receiver tank (DCRT), DST, or SST, according to the existing inventory of plutonium that is in the tank farms. For information purposes, an analysis was done in the BIO to quantify the consequences of a criticality event initiated by the hypothetical transfer of a large volume of new waste containing a high plutonium concentration. The described scenario assumes 500 L (130 gal) of solution with a concentration of 10 g Pu/L is transferred to the tank farm. The waste is assumed to form a compact sphere in the tank which expands until a criticality occurs. The criticality is modeled as a single burst and produces a pressure increase in the headspace leading to a release of material.

The RCSTS does not affect this scenario since the criticality is assumed to occur in the tank. In addition, a criticality in a 76-mm (3-in.) line is a practical impossibility since concentrations approaching that of pure Pu metal are needed to produce a criticality in an infinite 3-in. cylinder. This is a safe geometry, i.e., a criticality cannot occur in the solutions that are pumped.

However, a waste leak to the soil from the RCSTS is a potential criticality concern, since the leak could result in an accumulation of fissile material in a non-criticality safe geometry. Evaluations of the criticality safety implications of supernate leaking into the ground are documented in WHC-SD-SQA-CSA-20356, *CSER 92-009: An Analytical Model for Evaluating Subcritical Limits for Waste In Hanford Site Storage Tanks*, WHC-SD-SQA-CSA-20363, *CSER 94-001: Criticality Safety of Single-Shell Waste Storage Tanks*, and WHC-SD-SQA-CSA-20368, *CSER 94-004: Criticality Safety of Double-Shell Waste Storage Tanks*. A leak to the soil could result in the filtering and trapping of plutonium in the soil. A model of plutonium in the soil was created (the soil was modelled as SiO_2). The analysis concluded a

criticality would not occur because the solids contain a sufficient ratio of neutron absorbers to prevent criticality. Even if the absorbers were removed, a criticality would not occur because of the large quantity of plutonium required.

The final item to be evaluated for the RCSTS is the interface between the sending and receiving tanks. The RCSTS has the capability to transfer solutions with up to a 30 vol% solids content (while the BIO only considered supernate transfers for criticality). It is possible that the plutonium concentration in the solids transferred through the RCSTS may exceed the discharge limits in the receiver DST if the solids content is actually 30 vol%. Therefore, an additional control is necessary to ensure that transfers involving waste solids are evaluated, prior to commencing the transfer.

3.4.2.1.1 Controls. An additional control is added to the Administrative Control on nuclear criticality safety. Prior to any slurry transfers with waste tank solids through the RCSTS, a Criticality Safety Evaluation Report will be issued which addresses the suspension of solids in the sending tank and particle segregation after settling in the sending and receiving tanks.

The other criticality controls listed in the BIO are still applicable.

3.4.2.2 HEPA Filter Failure - Exposure to High Temperature or Pressure. Potential releases from HEPA filter failure are evaluated in the BIO. Fire is determined to be the bounding initiator. The heat from a fire in close proximity to a ventilation system degrades the HEPA filter and causes a release of a portion of the waste that has accumulated on the filter. In addition, the failed filter is assumed to provide an unfiltered release pathway that continues to operate for up to one year. Waste tanks with active ventilation systems produce the bounding consequences. The RCSTS diversion box 6241-A and vent station 6241-V are passively ventilated structures (whose atmospheres should be essentially uncontaminated except under spray or pool leak accident conditions) and thus are bounded by the BIO results.

A pressure differential of 2.5 kPa (0.4 psig) can fail HEPA filters. The only events identified in the BIO, that are capable of generating pressures in excess of 2.5 kPa (0.4 psig), occur in waste tanks and thus are bounding for the RCSTS.

The controls identified in the BIO for HEPA filters (i.e., periodic radiation monitoring of HEPA filter loading and HEPA filter change-out criteria) are applicable to the RCSTS. (However, for the RCSTS, these controls are based on the surface leak resulting in pool accident analyzed in Section 3.4.2.18 and the spray leak accident analyzed in Section 3.4.2.20.) No additional controls are required.

3.4.2.3 Fire In Contaminated Area. There are numerous contaminated areas associated with waste transfer systems that are routinely accessed, such as valve pits, pump pits, and diversion boxes. In the scenario analyzed in the BIO, fuel from a crane gas tank is spilled into a contaminated (and open) valve pit, where it catches fire. The analysis without controls showed that

controls are required to protect the onsite worker. To protect the onsite worker, an ignition control program has been established in the BIO Technical Safety Requirements (TSRs). These ignition controls are applicable to the RCSTS.

3.4.2.4 Evaporator Dump. This accident involves a loss of electrical power to the evaporator, which results in a discharge of the contents of the evaporator to a double-shell tank. This scenario is not applicable to the RCSTS. Therefore, no additional controls, beyond those listed in the BIO, are required.

3.4.2.5 Steam Intrusion from Interfacing Systems. This accident involves steam jets that are used to transfer waste into the tank farms. As a result of operator error, steam is routed to the headspace of a waste tank, which results in a pressure increase and HEPA filter failure. This scenario does not involve the RCSTS. Therefore, no additional controls, beyond those listed in the BIO, are required.

3.4.2.6 Leak from Railcar/Tank Trailer. This scenario evaluates the effects of a railcar breach, as the railcar is about to enter the 204-AR Waste Unloading Facility. This scenario is not applicable to the RCSTS. Therefore, no additional controls, beyond those listed in the BIO, are required.

3.4.2.7 Subsurface Leak Remaining Subsurface for the RCSTS.

Purpose of Analysis: The purpose of this analysis is to evaluate the risks associated with a potential leak of waste to the soil that remains subsurface.

Analysis Strategy: Subsurface leaks that remain subsurface are analyzed in the BIO for the TWRS waste transfer systems, but this analysis did not include the RCSTS, which was an ongoing project outside the original BIO scope. The BIO analysis considered both single-wall and encased line leaks. A leak from a single-walled direct-buried pipe was selected as the bounding accident. This scenario was considered bounding because the leak flows directly to the soil (i.e., there is no encasement) and the direct-buried pipe provides minimal soil shielding. Both these factors serve to maximize the radiological dose consequence. As also noted in the BIO, leaks from pipe encasements will tend to flow to process pits where the pit leak detectors will provide indication of a leak. The RCSTS is a pipe encased within a pipe system, which is continuously sloped (with vent station 6241-V representing the high point) to facilitate drainage of any primary pipe leak to a process pit. Therefore, the BIO analysis of subsurface leak that remains subsurface is bounding for the RCSTS.

3.4.2.7.1 Accident Scenario Assuming No Controls.

Sequence of Events. The bounding scenario for the subsurface leak remaining subsurface is described in Section 5.3.2.7.1, "Accident Analysis Assuming No Controls," of the BIO.

Results Summary. BIO Table 5.3.2.7-1, "Consequences of a Subsurface Leak Remaining Subsurface," presents the bounding onsite radiological consequences for the subsurface leak remaining subsurface accident assuming no controls. There are no offsite radiological nor any toxicological consequences for this accident, based on the distance to the site boundary and the fact the release remains below the soil surface.

Implication of Results. For the bounding accident, the onsite radiological consequences are below the risk guidelines. Therefore, no structures, systems, and components have been designated as Safety-Class or Safety-Significant for protection of the onsite and offsite receptor. However, controls have been established for protection of the facility worker.

3.4.2.7.2 Accident Scenario Assuming Controls. No accident scenarios assuming controls are postulated, because the radiological and toxicological consequences for the scenario without controls are below the risk guidelines.

3.4.2.7.3 Key Assumptions. Key assumptions are presented below.

Important to Accident Frequency. The accident assuming controls was not analyzed because the consequences with no controls were below the risk guidelines.

Important to Accident Consequences. The assumptions that are important to the calculation of accident consequences are described in Section 5.3.2.7.3, "Key Accident Scenario Assumptions," of the BIO.

3.4.2.7.4 Controls. The existing controls listed in the BIO are applicable to pipe-in-pipe encased lines and waste transfer-associated structures and thus are also applicable to the RCSTS.

Safety Structures, Systems, and Components. There are no additional Safety-Class or Safety-Significant structures, systems, and components selected for the RCSTS. Table 5.3.2.7-2, "Items Determined to be Safety-Significant by Extrapolating the Subsurface Leak Remaining Subsurface Accident Scenario to Other Applicable Tank Farm Transfer Equipment and Locations," in the BIO lists the Safety-Significant structures, systems, and components selected to prevent or mitigate the risk of subsurface leaks that remain subsurface. The Safety-Significant designation of the waste transfer pipe-in-pipe encasement, transfer leak detection systems, and tank level detection systems, identified in the BIO, are provided to protect the facility worker and are applicable to the RCSTS.

Technical Safety Requirements. There are no additional TSRs selected for the RCSTS. Table 5.3.2.7-3, "Technical Safety Requirement Controls for Subsurface Leaks Remaining Subsurface," in the BIO lists the TSRs selected to prevent or mitigate the risk of subsurface leaks that remain subsurface. These TSRs (regarding the transfer control program, transfer leak detection systems, and transfer pump administrative lock controls) identified in the BIO are applicable to the RCSTS.

Defense-in-Depth. There are no additional Defense-in-Depth controls identified for the RCSTS. The existing Defense-in-Depth controls identified in BIO Table 5.3.2.7-4 are applicable to the RCSTS.

3.4.2.8 Unplanned Excavation/Drilling in "Cribs, Ditches, and Ponds." This accident considers inadvertent excavation in a crib, ditch, or pond that contains a large quantity of contaminated soil. This accident does not involve the RCSTS. Therefore, no additional controls, beyond those listed in the BIO, are required.

Excavations that result in breaches of waste transfer lines (including the RCSTS) are addressed in Section 3.4.2.21.

3.4.2.9 Caustic Spray Leak. This accident involves a spray release of sodium hydroxide from a 1-inch Schedule 10 commercial steel pipe while the solution is being transferred to a waste tank. The RCSTS itself will not be used as a means for caustic addition to tanks. However, sodium hydroxide may be added to the flush tank that is interconnected to the RCSTS. Since the bounding accident (i.e., worst-case concentration and lightest piping used for transferring sodium hydroxide) has already been considered in the BIO, no additional analysis is required for the RCSTS and no additional controls, beyond those listed in the BIO, are required.

3.4.2.10 Sodium Fire. The 2727-W Sodium Storage Facility contains five tanks that are filled with solid sodium. The evaluated accident is initiated by high winds, that damage the building, and are followed by heavy rain that causes a sodium-water reaction followed by a fire. This accident is specific to the 2727-W Building and does not involve the RCSTS. Therefore, no additional controls, beyond those listed in the BIO, are required.

3.4.2.11 Mixing of Incompatible Material - Toxic Vapor Generation. The bounding scenario assumes a rapid uncontrolled addition of caustic to a double-contained receiver tank which increases the pH level and ultimately results in the release of ammonia. The analysis applies to DCRTs, DSTs, and SSTs. The BIO analysis does not include waste transfer systems, because caustic additions are typically done locally and not through waste transfer systems. Therefore, the existing BIO analysis is adequate for the RCSTS and no additional controls, beyond those listed in the BIO, are required.

3.4.2.12 Mixing of Incompatible Material - Tank Pressurization. This scenario assumes that an uncontrolled mixture of incompatible materials in a waste tank results in a tank pressurization and an airborne release. The bounding accident is a mistransfer of 416 L (110 gal) of 57% nitric acid from B-Plant to DCRT. The presence of the RCSTS has no impact on this bounding source term or accident scenario. Thus, the existing BIO analysis is adequate for the RCSTS. Transfer controls to ensure waste compatibility are established in the BIO. These controls are applicable to the RCSTS and no additional controls are required.

3.4.2.13 Tank Failure Due to Excessive Loads. This scenario involves tank failure caused by a load drop event. This accident is specific to waste tanks and is not applicable to the RCSTS. Therefore, no additional controls, beyond those listed in the BIO, are required.

3.4.2.14 Flammable Gas Deflagrations. The flammable gas hazard poses an Unreviewed Safety Question (USQ) originally identified in 1990. This USQ was expanded to include steady state accumulation as well as gas release event phenomena (Wagoner 1996, Contract Number DE-AC06-96RL13200; *The U.S. Department of Energy [DOE], Richland Operations Office [RL], Definition and Declaration of Flammable Gas Unreviewed Safety Question [USQ]*). The scope of the flammable gas USQ was also expanded to include miscellaneous transfer system components (e.g., transfer lines, valve pits, diversion boxes, process pits, and transfer line clean out boxes). The flammable gas USQ remains open for the miscellaneous transfer system components (TF-96-0433, *Consolidation of Flammable Gas/Slurry Growth Unreviewed Safety Question Issues*). This USQ is also applicable to the RCSTS. (It should also be noted that the BIO evaluates flammable gas deflagrations in waste tanks and these results are bounding for waste transfer systems such as the RCSTS.)

On November 1, 1996, RL issued authorization for continued operation of the Hanford Tank Farms (Wagoner 1996) for an interim period. This interim period ended with the approval of the operating contractor's Justification for Continued Operation, which now allows for continued operation. The JCO is incorporated into the BIO as Appendix E, "Flammable Gas/Slurry Growth Unreviewed Safety Question: Justification for Continued Operation for the Tank Farms at the Hanford Site."

Detailed quantitative analysis of the frequencies and consequences of flammable gas events in the RCSTS has not been performed. This is consistent with the open USQ (TF-96-0433) and the overall TWRS approach to the flammable gas issue. As noted in Section E5.4 of Appendix E of the BIO, the flammable gas control strategy for waste transfer systems is based on a qualitative evaluation that concludes that historical evidence exists that the risk posed by this hazard is low. Risk is reduced by flushing transfer lines after use. In addition, gas concentrations are monitored during entry to all vapor spaces, such as process pits, that might be connected to transfer lines. Gas monitoring verifies the risk is low. Flushing practices are required to be continued to maintain a low risk of flammable gas generation and accumulation. Lastly, RCSTS equipment is evaluated for compliance with Ignition Source Controls specific to the use and location of the equipment. It is judged that additional controls are not warranted at this time.

3.4.2.15 Organic Solvent Fire. Some waste tanks contain separable organic solvent phases. If ignited, the burning organic can liberate sufficient energy to release hazardous material from the tank. The oxygen in the tank is the limiting parameter for this scenario. It is important to note that there are no ignition sources in the pipes or structures unique to the RCSTS that are capable of igniting the solvent. In addition, there is not enough oxygen in the transfer pipes to support sustained combustion. The BIO analysis is therefore bounding.

3.4.2.15.1 Controls. A control is established in the BIO that requires all waste transfers to be evaluated to ensure the waste transfer does not create an organic solvent hazard in the receiving or delivering tank which is

outside the BIO safety envelope, i.e., the control prevents the creation of a new tank with an organic solvent hazard unless the required organic controls are extended to that tank. This control is applicable to the operation of the RCSTS.

3.4.2.16 In-Tank Fuel Fire/Deflagration. This scenario postulates that an errant motor vehicle shears off one or more tank risers and ruptures the vehicle fuel tank. This accident is specific to waste tanks and is not applicable to the RCSTS. Therefore, no additional controls, beyond those listed in the BIO, are required.

3.4.2.17 Organic Salt-Nitrate Reaction. Organic complexants were used during past Hanford operations and were discharged to the tank where they were mixed with sodium hydroxide, sodium nitrate, and other inorganic diluent already present in the tank. Organic complexants will react with these types of oxidizing materials. The reaction can be accelerated to a rapid combustion by heating to high temperatures by an initiator of sufficient energy. A combustion front would be generated by such a condition and would spread through the combustible waste releasing significant energy and gases.

This accident scenario is specific to waste tanks. Even with the highest solids content (30 vol%), the RCSTS poses no hazard of propagating combustion reactions (since the moisture content is much greater than the 20 wt% water needed to preclude combustion). The only potential concern would be if solids were allowed to accumulate and dry in the transfer lines. Solids accumulation is precluded by flushing the RCSTS after transfers are completed.

The scenario is also relevant to waste transfer systems insofar as they may be used for tank moisture removal or addition. (Moisture is a moderator for this type of reaction.) The BIO analysis states that the accident analysis and the specified controls are applicable to waste transfer lines. Therefore, the BIO control strategy is applicable to the RCSTS, and no additional controls, beyond those listed in the BIO, are required.

3.4.2.18 Surface Leak Resulting In Pool for the RCSTS.

Purpose of Analysis: A surface leak that occurs during a transfer through the RCSTS could form a pool. These waste pools are a safety concern because they can cause significant onsite and offsite inhalation doses and produce significant shine and skyshine doses to the onsite receptor.

Analysis Strategy: Surface leaks that result in pools have been analyzed in the BIO for existing transfer routes, but not the RCSTS which was an ongoing project outside the BIO scope. A misrouting of waste to a valve pit was analyzed as the bounding case in the BIO. The RCSTS adds two new structures, diversion box 6241-A and vent station 6241-V, that were not considered in the BIO analysis and are larger than existing waste transfer structures. (Note that the end points of the RCSTS, valve pits 241-SY-A and 241-SY-B in the 200 West Area and the 244-A lift station in the 200 East Area, are existing facilities for which the BIO analysis is bounding.) Thus, leaks were evaluated in the two RCSTS structures, with diversion box 6241-A providing the bounding case.

The scenario where an RCSTS subsurface leak washes away the soil and results in a surface pool is analyzed in Section 3.4.2.19 of this addendum.

3.4.2.18.1 Accident Scenario Assuming No Controls.

Sequence of Events. The RCSTS scenario postulates that the spill occurs in diversion box 6241-A. The spill is postulated to occur with the diversion box entry door and pipe penetrations open, so that no credit is taken for the HEPA filter. The event duration (12 hours) and receptor exposure times are the same as in the BIO (12 hours for the onsite receptor and 12 hours aerosol exposure for the offsite receptor). The event frequency is also the same (i.e., "anticipated").

The RCSTS scenario differs from the BIO scenario as follows. The leak rate is assumed to be the maximum RCSTS flow rate of 530 Lpm (140 gpm) versus the 1,130 Lpm (300 gpm) used in the BIO. Thus, maximum pool size is 381,600 L (100,800 gal) or 380 m^3, compared to 817,600 L (216,000 gal) in the BIO. Because the volume of the diversion box is 622 m^3 (21,960 ft^3), there will be no overflow. Splashing, however, is assumed to continue for the entire 12 hour period, unlike the valve pit scenario analyzed in the BIO, where splashing is assumed to stop after the pit is half full. Also, because only the supernate line, WT-SNL-3150 is authorized for operation, the spill is assumed to be aging waste supernate (5 vol% solids and 95 vol% liquids).

Results Summary. The onsite and offsite radiological and toxicological consequences for the RCSTS pool leak accident assuming no controls and the comparison to risk guidelines are shown in Table 3.4.2.18-1. Supporting calculations are documented in HNF-2542. It should be noted that the onsite dose is higher for the RCSTS accident than for the accident as analyzed in the BIO, because of the splashing that is assumed to occur for 12 hours (because of the large volume of the diversion box). The offsite dose is lower than the BIO analyzed accident, because (unlike the accident scenario analyzed in the BIO) there is no overflow.

Implication of Results. For the RCSTS pool leak accident, the onsite and offsite radiological and the onsite toxicological consequences exceed the risk guidelines. Therefore, controls are required.

3.4.2.18.2 Accident Scenario Assuming Controls. A suite of controls was selected for this accident in the BIO. Several additional controls were selected for the accident scenario as analyzed for the RCSTS. To maintain the validity of the analysis in the BIO for the piping downstream of the RCSTS, the pressure relief valve and rupture disk in lift station 244-A were elevated to Safety-Class status. (Note that the RCSTS is designed to withstand higher pressures than the existing piping to which it is connected.) This will preclude overpressurizing the downstream piping. A TSR control was selected to ensure that the doors and pipe penetrations (air sample line, exhauster hookup, liner washdown system, and emergency pumpout line) in diversion box 6241-A and vent station 6241-V are sealed during waste transfers to limit the release of unfiltered aerosols. A TSR control was also selected for the HEPA filter in diversion box 6241-A and vent station 6241-V to limit doses to the onsite receptor and facility worker.

Sequence of Events. The sequence of events for a pool leak in the RCSTS with controls is similar to that described in the BIO, except that the leak is assumed to occur in diversion box 6241-A, instead of a valve pit. As in the BIO, the maximum leak rate is assumed to be 1.3 L/s (20 gpm) and the leak detector in the diversion box is assumed to alarm after 51 mm (2 in.) of waste have accumulated. Flow is also assumed to occur for 30 minutes after the leak detector alarms to allow for operator response. The BIO assumptions on aerosols being generated from splatter and splashing while the pump is running and convection currents keeping some aerosols in suspension after the transfer pump is shut off are also retained in the RCSTS analysis. The entry door and pipe penetrations are assumed to be sealed and therefore the majority (90%) of the airborne release passes through a HEPA filter, which is credited with reducing the source term. The presence of the HEPA filter represents the major difference from the BIO (where the analyzed valve pit has no HEPA filter). Another BIO assumption that remains the same for the RCSTS is that the frequency of the event with controls is also assumed to be "anticipated."

The changes to the BIO sequence of events made for the RCSTS are as follows:

- The material spilled is aging waste supernate (5 vol% solids, 95 vol% liquids).
- The equipment leak occurs inside diversion box 6241-A with the entry door and pipe penetrations (air sample line, exhauster hookup, liner washdown system, and emergency pumpout line) assumed to be sealed.
- The amount of waste that is assumed to drain back through the leakage path after the pump is shut down is larger for the RCSTS. This maximum drain volume is 27.4 m^3 (968 ft^3) based on 5,730 m (18,800 ft) of 76-mm (3-in.) pipe.
- The majority (90%) of the airborne release is assumed to pass through a HEPA filter with a removal efficiency of 0.99. The remaining 10% of the airborne release is assumed to be unfiltered.

Results Summary. The radiological and toxicological consequences of the RCSTS accident assuming controls are presented in Table 3.4.2.18-2 and the associated calculations are documented in HNF-2542.

Implication of Results. The offsite and onsite radiological and toxicological consequences for the RCSTS surface leak resulting in pool accident, assuming controls, are below the risk guidelines.

3.4.2.18.3 Key Assumptions. Key assumptions are presented below.

Important to Accident Frequency. There are no key assumptions associated with the frequency of the RCSTS surface leak resulting in a pool accident.

Important to Accident Consequences. The BIO assumption that the operator shuts down the transfer pump 30 minutes after alarm actuation is also used in the RCSTS analysis. The important assumptions with an impact on consequences for the RCSTS, which differ from those used in the BIO, are as follows:

- The material spilled is aging waste supernate (5 vol% solids, 95 vol% liquids).
- The leak is assumed to occur in diversion box 6241-A, because this provides the bounding results for the two new waste transfer pits added by the RCSTS.
- The entry door is shut and the pipe penetrations (air sampling line, exhauster hookup, liner washdown system, and emergency pumpout line) are sealed.
- The majority (90%) of the airborne release passes through a HEPA filter with an assumed efficiency of 0.99. In addition, the HEPA filter is assumed to be radiologically clean, since it should only be exposed to radionuclides during accident conditions. The remaining 10% of the release is assumed to be unfiltered.
- The amount of waste that is assumed to drain back through the leakage path after the pump is shut down is larger for the RCSTS. This maximum drain volume is 27.4 m^3 (968 ft^3) based on 5,730 m (18,800 ft) of 76-mm (3-in) pipe.
- The pressure relief valve installed in the 244-A lift station precludes the RCSTS from overpressurizing the downstream piping. The pressure relief valve will lift at a preset pressure 1590 kPa (230 psig) that is equal to the maximum operating pressure of the existing downstream piping. This protects the analysis in the BIO, for surface leaks resulting in pool accidents, in equipment downstream of the RCSTS. It should also be noted that a rupture disk is located upstream of the relief valve (for As Low as Reasonably Achievable [ALARA] purposes, to allow testing and maintenance of the valve) and will rupture at a preset pressure to allow the relief valve to perform its safety function.

3.4.2.18.4 Controls. The following new controls are applicable to the RCSTS. It is important to note that these controls are an addition to the controls already listed in the BIO. These RCSTS controls have been added to the consolidated list of controls presented in Table 6-1, "Hazard and Accident Analyses; Safety Structures, Systems, Components and Technical Safety Requirement Cross Reference," of the BIO.

Safety Structures, Systems, and Components. Table 3.4.2.18-3 lists the new Safety-Class and Safety-Significant structures, systems, and components selected to prevent or mitigate the risk of RCSTS surface leaks resulting in a pool. These controls are unique to the RCSTS. The RCSTS pressure relief valve and rupture disk are only applicable to transfers through line WT-SLL-3160. Other Safety-Class and Safety-Significant structures, systems, and components are identified in BIO Table 5.3.2.18-3, "Safety

Structures, Systems, and Components for Surface Leak Resulting in Pool." The Safety-Class or Safety-Significant designations of the transfer leak detector and interlock to transfer pump(s) or alarm, the tank level detection systems, and the pressure switch with interlock to waste transfer pump or alarm (to prevent waste backflow to the flush system) are applicable to the RCSTS.

Technical Safety Requirements. Table 3.4.2.18-4 lists the new TSRs selected to prevent or mitigate the risk of RCSTS surface leaks resulting in a pool. These controls are unique to the RCSTS. The controls for the RCSTS pressure relief valve and rupture disk will be added to the TSR document after RL approval for transfers through WT-SLL-3160 is granted. Other TSRs are identified in BIO Table 5.3.2.18-4, "Technical Safety Requirement Controls for Surface Leak Resulting in Pool." The TSRs regarding the transfer pump administrative lock controls, the transfer leak detector and interlock to transfer pump(s) or alarm, the transfer control program, the pressure switch with interlock to waste transfer pump or alarm (to prevent waste backflow to the flush system), and the HEPA filter control program are applicable to the RCSTS.

Defense-in-Depth. There are no new Defense-in-Depth controls identified for the RCSTS. The existing Defense-in-Depth controls identified in BIO Table 5.3.2.18-5, "Defense-in-Depth Controls for Surface Leak Resulting in Pool," are applicable to the RCSTS.

Table 3.4.2.18-1. Consequences of RCSTS Surface Leak Resulting in Pool without Controls.

Receptor/Hazard	Calculated Dose	Evaluation guidelines "anticipated" frequency
Onsite radiological	2,400 mSv (240 rem)	5 mSv (0.5 rem)
Offsite radiological	3.1 mSv (0.31 rem)	1 mSv (0.1 rem)
Onsite Toxicological sum-of-fractions	3.7	1 (≤ERPG-1)
Offsite Toxicological sum-of-fractions	0.00061	1 (≤PEL-TWA)

Table 3.4.2.18-2. Consequences of RCSTS Surface Leak Resulting in Pool with Controls.

Receptor/Hazard	Calculated Dose	Evaluation guidelines "anticipated" frequency
Onsite radiological	1.9 mSv (0.19 rem)	5 mSv (0.5 rem)
Offsite radiological	3.6E-03 mSv (3.6E-04 rem)	1 mSv (0.1 rem)
Onsite Toxicological sum-of-fractions	7.3E-03	1 (≤ERPG-1)
Offsite Toxicological sum-of-fractions	1.2E-05	1 (≤PEL-TWA)

Table 3.4.2.18-3. New Safety Structures, Systems, and Components for RCSTS Surface Leaks Resulting in Pool.

Structure, Systems, or Components	SC	SS	Safety Function	Comments
Entry doors and penetrations for diversion box 6241-A and vent station 6241-V		X	Limit release of aerosols generated by splatter inside the structure	
HEPA filter in diversion box 6241-A and vent station 6241-V		X	Limit release of respirable aerosols by filtering	
RCSTS pressure relief valve and rupture disk	X		Precludes overpressurizing existing piping downstream of RCSTS	Protects BIO assumptions and analysis for existing piping

Note that these are the new safety SSCs that are unique to the RCSTS. All SSCs identified in BIO Table 5.3.2.18-3, "Safety Structures, Systems, and Components for Surface Leak Resulting in Pool," are still applicable.

Table 3.4.2.18-4. New Technical Safety Requirements Controls for RCSTS Surface Leaks Resulting in Pool. (2 sheets)

Control	Safety Function	Comments
Door and penetrations in diversion box 6241-A and vent station 6241-V	Ensure entry door is shut and air sampling line, exhauster hookup, liner washdown system, and emergency pumpout line are sealed during waste transfers	
RCSTS pressure relief valve and rupture disk	Ensure pressure relief valve and rupture disk are operable during transfers	Protects BIO assumptions and analysis for existing piping downstream of the RCSTS
HEPA Filter Control Program with the following key elements: • Periodic radiation survey to monitor HEPA filter loading • HEPA filter replacement per change-out criteria, i.e., ≤2 mSv/h (≤200 mrem/h) • Aerosol test upon installation • Periodic aerosol test	HEPA filter monitoring and replacement reduce consequences from a possible HEPA filter failure by limiting the inventory available for release Aerosol testing ensures filtering efficiency of HEPA filter	Applies to the inlet air HEPA filter system in diversion box 6241-A and vent station 6241-V

Note that these are the new TSRs that are unique to the RCSTS. All Technical Safety Requirement Controls listed in BIO Table 5.3.2.18-4, "Technical Safety Requirement Controls for Surface Leak Resulting in Pool," are still applicable. Also note that the HEPA filters listed in the preceding table are covered under the existing Administrative Control that requires periodic radiation surveillance and filter changeout with accumulations ≤200 mrem/h and verification of the nominal particulate removal efficiency (≥99.95%).

3.4.2.19 Subsurface Leak Resulting In Pool for the RCSTS.

Purpose of Analysis: Transfer line leaks at high flow rates that are in excess of the natural infiltration rate of the soil can result in surface pools of waste. These waste pools are a safety concern because they can cause significant onsite and offsite inhalation doses and produce significant shine and skyshine doses to the onsite receptor.

Analysis Strategy: Subsurface leaks that result in pools are analyzed in the BIO for the TWRS waste transfer systems, but this analysis did not include the RCSTS, which was an ongoing project outside the BIO scope. The three basic types of transfer lines considered in the BIO were unencased direct buried or bermed lines, buried concrete encased lines, and buried pipe-in-pipe lines. A subsurface leak from an unencased, bermed line was selected as the bounding accident in the BIO. The rationale for this is fourfold. First, unencased lines are older, in direct contact with the soil, and more prone to failure than the encased lines. Second, leaks into pipe encasements will tend to flow to process pits where the pit leak detectors will provide indication of a leak. Third, leaks from pipe encasements will be under low pressure and downward oriented, so that surface pools will be far less likely to form than in bermed unencased piping. Finally, the surface pools that can develop from washing out a berm are larger than pools than can develop as a result of leaks from buried lines. The RCSTS is a modern pipe encased within a pipe system, which is continuously sloped (with vent station 6241-V representing the high point) to facilitate drainage of any primary pipe leak to a process pit. (In addition, although it is not credited in the safety analysis, the RCSTS primary piping was designed to meet the criteria for a Safety-Class designation.) Therefore, the BIO analysis of subsurface leak resulting in a pool is bounding for the RCSTS.

The bounding scenario addresses transfer line leaks that are caused by internal initiators. Potential RCSTS leaks caused by excavation activities are addressed in Section 3.4.2.21, and potential RCSTS leaks caused by seismic events are addressed in Section 3.4.2.23.

3.4.2.19.1 Accident Scenario Assuming No Controls.

Sequence of Events. The bounding scenario for the subsurface leak resulting in a pool accident (without controls) is described in Section 5.3.2.19.1 of the BIO.

Results Summary. BIO Table 5.3.2.19-1, "Consequences of a Subsurface Leak Results in Pool Assuming No Controls," presents the bounding onsite and offsite radiological and toxicological consequences for the subsurface leak resulting in a pool accident assuming no controls.

Implication of Results. For the bounding accident, the onsite and offsite radiological consequences and the onsite toxicological consequences exceed the risk guidelines. Therefore, controls are required.

3.4.2.19.2 Accident Scenario Assuming Controls.

Sequence of Events. The leak from an unencased bermed line provides the bounding accident scenario with controls. This is based on the same arguments presented in the accident scenario without controls. These arguments are further buttressed by the Safety-Class designation applied to waste transfer pipe encasements and the fact that the RCSTS primary pipe is designed (although it is not credited in the analysis) to a Safety-Class designation.

The bounding scenario for the subsurface leak resulting in a pool accident (with controls) is described in Section 5.3.2.19.2, "Accident Scenario Assuming Controls," of the BIO.

Results Summary. The bounding onsite and offsite radiological and toxicological consequences for the subsurface leak resulting in a pool accident assuming controls are shown in BIO Table 5.3.2.19-2, "Consequences of a Subsurface Leak Resulting in Pool Assuming Controls."

Implication of Results. For the bounding accident, the onsite and offsite radiological and toxicological consequences satisfy the risk guidelines.

3.4.2.19.3 Key Assumptions. Key assumptions for the bounding accident are described in Section 5.3.2.19.3, "Key Assumptions," of the BIO. An additional assumption is made for the RCSTS, because of the potential pressure that may be achieved in the boosted line. The pressure relief valve installed in the 244-A lift station precludes the RCSTS from overpressurizing the downstream piping. The pressure relief valve will lift at a preset pressure (230 psig) that is equal to the maximum operating pressure of the existing downstream piping. This protects the analysis in the BIO, for subsurface leaks resulting in pool accidents, in equipment downstream of the RCSTS. It should also be noted that a rupture disk is located upstream of the relief valve (for ALARA purposes, to allow testing and maintenance of the valve) and will rupture at a preset pressure (1,590 kPa [230 psig]) to allow the relief valve to perform its safety function.

3.4.2.19.4 Controls. The following new controls are applicable to the RCSTS. It is important to note that these controls are an addition to the controls already listed in the BIO. These controls have been added to the consolidated list of controls presented in Table 6-1 of the BIO.

Safety Structures, Systems, and Components. Table 3.4.2.19-1 lists the new Safety-Class and Safety-Significant structures, systems, and components selected to prevent or mitigate the risk of RCSTS subsurface leaks resulting in pools. The listed SSCs are unique to the RCSTS. The RCSTS pressure relief valve and rupture disk are only applicable to transfers through line WT-SLL-3160. Other Safety-Class and Safety-Significant structures, systems, and components are identified in BIO Table 5.3.2.19-3, "Safety Structures, Systems, and Components for Subsurface Leak Resulting in Pool."

The Safety-Class designation of the waste transfer pipe-in-pipe encasement and Safety-Significant designation of the tank level detection systems are applicable to the RCSTS. (The RCSTS pit leak detectors have also been added to BIO Table 6-1 as a Safety-Class item, because the detectors work in tandem with the pipe encasement to detect leaks in the primary pipe and thereby limit the volume of the subsurface leak.)

Technical Safety Requirements. Table 3.4.2.19-2 lists the new TSRs selected to prevent or mitigate the risk of RCSTS subsurface leaks that result in pools. These controls are unique to the RCSTS. The controls for the RCSTS pressure relief valve and rupture disk will be added to the TSR document after RL approval for transfers through WT-SLL-3160 is granted. The TSRs identified in BIO Table 5.3.2.19-4, "Technical Safety Requirement Controls for Subsurface Leak Resulting in Pool," regarding the waste transfer control program and emergency response procedures are also applicable to the RCSTS. (The TSR control on the transfer leak detection system has also been added to BIO Table 6-1, because the detectors work in tandem with the pipe encasement to detect leaks in the primary pipe and thereby limit the volume of the subsurface leak.)

Defense-in-Depth. There are no new Defense-in-Depth controls identified for the RCSTS. The Defense-in-Depth control identified in BIO Table 5.3.2.19-5, "Defense-in-Depth Controls for Subsurface Leak Resulting in Pool," regarding encasement leak detectors is also applicable to the RCSTS.

Table 3.4.2.19-1. New Safety Structures, Systems, and Components for RCSTS Subsurface Leak Resulting in Pool.

Structure, Systems, or Components	SC	SS	Safety Function	Comments
RCSTS pressure relief valve and rupture disk	X		Precludes overpressurizing existing piping downstream of RCSTS	Protects BIO assumptions/ analysis for existing piping
Transfer leak detector and interlock to transfer pump(s) or alarm	X		Detect the presence of leaks in diversion box 6241-A or vent station 6241-V and to either provide an alarm to alert operators to take mitigative action, or provide an interlock to shut down transfer pump operation to limit the volume of the waste spilled to 6241-A or 6241-V	

Note that this is the new safety SSC that is unique to the RCSTS. All SSCs identified in BIO Table 5.3.2.19-3 are still applicable.

Table 3.4.2.19-2. New Technical Safety Requirements Controls for RCSTS Subsurface Leak Resulting in Pool.

Control	Safety Function	Comments
RCSTS pressure relief valve and rupture disk	Ensure pressure relief valve and rupture disk are operable during transfers	Protects BIO assumptions and analysis for existing piping downstream of the RCSTS
Transfer leak detection systems and interlock to transfer pump(s) or alarm	Ensure leak detectors and their interlocks or alarms are operable during transfers	

Note that this is the new TSR that is unique to the RCSTS. All Technical Safety Requirement Controls listed in BIO Table 5.3.2.19-4 are still applicable.

3.4.2.20 Spray Leak In the RCSTS.

Purpose of Analysis: A breach of containment during a transfer through the RCSTS could result in a pressurized spray release. These spray releases are a safety concern because, depending on the waste pressure and leak dimensions, they can be relatively efficient generators of respirable-sized aerosols.

Analysis Strategy: Spray leaks have been analyzed in the BIO for existing transfer routes, but not for the RCSTS, which was an ongoing project outside the BIO scope. A spray leak in a valve pit was analyzed as the bounding case in the BIO. The RCSTS adds two new structures, diversion box 6241-A and vent station 6241-V, that were not considered in the BIO analysis. (Note that the end points of the RCSTS, valve pits 241-SY-A and 241-SY-B in the 200 West Area and the 244-A lift station in the 200 East Area, are existing facilities for which the BIO analysis is bounding.) Thus, for the RCSTS, spray leaks were evaluated in the two RCSTS structures, with diversion box 6241-A providing the bounding case.

As noted in the BIO, spray leaks from underground transfer lines are mitigated by the soil cover. The scenario where a subsurface leak in the RCSTS washes away the soil and results in a surface pool is analyzed in Section 3.4.2.19 of this addendum. RCSTS spray leaks caused by excavation activities are addressed in Section 3.4.2.21, and RCSTS spray leaks caused by a seismic event are addressed in Section 3.4.2.23.

3.4.2.20.1 Accident Scenario Assuming No Controls.

Sequence of Events. The RCSTS spray leak accident scenario assumes that the spray leak develops in diversion box 6241-A as a result of a leak in the piping or a valve. The spray leak is postulated to occur with the diversion box entry door and pipe penetrations open, so that no credit is taken for the HEPA filter or the diversion box structure. The event duration (24 hours) and receptor exposure times are the same as in the BIO (24 hours for the offsite receptor and 12 hours for the onsite receptor.) The event frequency is also the same (i.e., "anticipated"). Because only the supernate line, WT-SNL-3150, is authorized for operation, the spill is assumed to be aging waste supernate (5 vol% solids and 95 vol% liquids).

Results Summary. The onsite and offsite radiological and toxicological consequences for the RCSTS spray leak accident assuming no controls and the comparison to risk guidelines are shown in Table 3.4.2.20-1. Supporting calculations are documented in HNF-2542.

Implication of Results. For the RCSTS spray leak, the onsite and offsite radiological and the onsite toxicological consequences exceed the risk guidelines. Therefore, controls are required.

3.4.2.20.2 Accident Scenario Assuming Controls

Sequence of Events. The sequence of events for a spray leak in the RCSTS with controls is similar to that described in the BIO, except that the leak is assumed to occur in diversion box 6241-A, instead of a valve pit. The entry doors and pipe penetrations (air sample line, exhauster hookup, liner washdown system, and emergency pumpout line) are credited with being sealed and therefore the majority (90%) of the airborne release passes through a HEPA filter, which is credited with reducing the source term. The presence of the HEPA filter represents a major difference from the BIO (where the analyzed valve pit has no HEPA filter). The other major difference is that the material spilled is aging waste supernate (5 vol% solids, 95 vol% liquids). There are two other BIO assumptions that remain the same for the RCSTS. The concentration of respirable-sized particles is assumed to be 100 mg/m^3 and the frequency of the event with controls is also assumed to be "anticipated."

Results Summary. The radiological and toxicological consequences of a spray leak in the RCSTS are presented in Table 3.4.2.20-2 and the associated calculations are documented in HNF-2542.

Implication of Results. The offsite and onsite radiological and toxicological consequences of the spray leak in the RCSTS assuming controls are below the risk guidelines. This represents a major difference from the spray leak analyzed for the valve pit in the BIO, where the onsite radiological consequences exceeded the risk guidelines. This difference can be attributed to the presence of the HEPA filter in diversion box 6241-A.

3.4.2.20.3 Key Assumptions. Key assumptions are presented below.

Important to Accident Frequency. There are no key assumptions associated with the frequency of the RCSTS spray leak.

Important to Accident Consequences. The important assumptions with an impact on consequences for the RCSTS, which differ from those used in the BIO, are as follows:

- The material spilled is aging waste supernate (5 vol% solids, 95 vol% liquids).
- For the scenario without controls, the RCSTS spray leak is assumed to occur at the maximum RCSTS pressure of 8,960 kPa (1,300 psig).
- The entry door and pipe penetrations (air sampling line, exhauster hookup, liner washdown system, and emergency pumpout line) in diversion box 6241-A are sealed.
- The majority (90%) of the airborne release passes through a HEPA filter with an assumed efficiency of 0.99. In addition, the HEPA filter is assumed to be radiologically clean, since it should only be exposed to radionuclides during accident conditions. The remaining 10% of the release is assumed to be unfiltered.

- The pressure relief valve installed in the 244-A lift station precludes the RCSTS from overpressurizing the downstream piping. The pressure relief valve will lift at a preset pressure (1590 kPa [230 psig]) that is equal to the maximum operating pressure of the existing downstream piping. This protects the analysis in the BIO, for spray leaks, in equipment downstream of the RCSTS. It should also be noted that a rupture disk is located upstream of the relief valve (for ALARA purposes, to allow testing and maintenance of the valve) and will rupture at a preset pressure to allow the relief valve to perform its safety function.

3.4.2.20.4 Controls. The following new controls are applicable to the RCSTS. It is important to note that these controls are an addition to the controls already listed in the BIO. These RCSTS controls have been added to the consolidated list of controls presented in Table 6-1 of the BIO.

Safety Structures, Systems, and Components. Table 3.4.2.20-3 lists the Safety-Class and Safety-Significant structures, systems, and components selected to prevent or mitigate the risk of RCSTS spray leaks. These SSCs are unique to the RCSTS. The RCSTS pressure relief valve and rupture disk are only applicable to transfers through line WT-SLL-3160. Other Safety-Class and Safety-Significant structures, systems, and components are identified in BIO Table 5.3.2.20-3, "Safety Structures, Systems, and Components for Spray Leaks." The Safety-Class designations for the pressure switch with interlock to waste transfer pump or alarm (to prevent waste backflow to the flush system) is applicable to the RCSTS.

Technical Safety Requirements. Table 3.4.2.20-4 lists the new TSRs selected to prevent or mitigate the risk of RCSTS spray leaks. These controls are unique to the RCSTS. The controls for the RCSTS pressure relief valve and rupture disk will be added to the TSR document after RL approval for transfers through WT-SLL-3160 is granted. Other TSRs are identified in BIO Table 5.3.2.20-4, "Technical Safety Requirement Controls for Spray Leaks." The TSRs regarding the transfer pump administrative lock controls, the transfer control program, the pressure switch with interlock to waste transfer pump or alarm (to prevent waste backflow to the flush system), and the HEPA filter control program are applicable to the RCSTS.

Defense-in-Depth. There are no new Defense-in-Depth controls identified for the RCSTS. The existing Defense-in-Depth controls identified for spray leaks in BIO Table 5.3.2.20-5, "Defense-in-Depth Controls for Transfer System Spray Leaks," are applicable to the RCSTS.

Table 3.4.2.20-1. Consequences of RCSTS Spray Leak without Controls.

Receptor/Hazard	Calculated dose	Evaluation guidelines "anticipated" frequency
Onsite radiological (RCSTS)	1.93E+02 Sv (1.93E+04 rem)	5 mSv (0.5 rem)
Offsite radiological (RCSTS)	0.27 Sv (27 rem)	1 mSv (0.1 rem)
Onsite Toxicological (RCSTS) sum-of-fractions	291	1 (≤ERPG-1)
Offsite Toxicological (RCSTS) sum-of-fractions	0.49	1 (≤PEL-TWA)

Table 3.4.2.20-2. Consequences of RCSTS Spray Leak with Controls.

Receptor/Hazard	Calculated dose	Evaluation guidelines "anticipated" frequency
Onsite radiological (RCSTS)	2.1 mSv (0.21 rem)	5 mSv (0.5 rem)
Offsite radiological (RCSTS)	1.84E-03 mSv (1.84E-04 rem)	1 mSv (0.1 rem)
Onsite toxicological (RCSTS) sum-of-fractions	2.4E-02	1 (≤ERPG-1)
Offsite toxicological (RCSTS) sum-of-fractions	4E-05	1 (≤PEL-TWA)

Table 3.4.2.20-3. New Safety Structures, Systems, and Components for RCSTS Spray Leaks.

Structure, Systems, or Components	SC	SS	Safety Function	Comments
Entry doors and pipe penetrations for diversion box 6241-A and vent station 6241-V	X		Limit release of aerosols generated by spray inside the structure	
HEPA filter in diversion box 6241-A and vent station 6241-V		X	Limit release of respirable aerosols by filtering	
RCSTS pressure relief valve and rupture disk	X		Precludes overpressurizing existing piping downstream of RCSTS	Protects BIO assumptions/ analysis for existing piping

Note that these are the new safety SSCs that are unique to the RCSTS. All SSCs identified in BIO Table 5.3.2.20-3 are still applicable.

Table 3.4.2.20-4. New Technical Safety Requirements Controls for RCSTS Spray Leaks.

Control	Safety Function	Comments
Door and penetrations in diversion box 6241-A and vent station 6241-V	Ensure entry door is shut and air sampling line, exhauster hookup, liner washdown system, and emergency pumpout line are sealed during waste transfers	
RCSTS pressure relief valve and rupture disk	Ensure pressure relief valve and rupture disk are operable during transfers	Protects BIO assumptions and analysis for existing piping downstream of the RCSTS
HEPA Filter Control Program with the following key elements: • Periodic radiation survey to monitor HEPA filter loading • HEPA filter replacement per change-out criteria, i.e., ≤2 mSv/h (≤200 mrem/h) • Aerosol test upon installation • Periodic aerosol test	HEPA filter monitoring and replacement reduce consequences from a possible HEPA filter failure by limiting the inventory available for release Aerosol testing ensures filtering efficiency of HEPA filter	Applies to the inlet air HEPA filter system in diversion box 6241-A and vent station 6241-V

Note that these are the new TSRs that are unique to the RCSTS. All Technical Safety Requirement Controls listed in BIO Table 5.3.2.20-4 are still applicable. Also note that the HEPA filters listed in the preceding table are covered under the existing Administrative Control that requires periodic radiation surveillance and filter changeout with accumulations ≤200 mrem/h and verification of the nominal particulate removal efficiency (≥99.95%).

3.4.2.21 Spray Leak From Underground Waste Transfer Lines (RCSTS).

Purpose of Analysis: A construction excavation accident could conceivably breach the RCSTS piping and cause a spray leak or a surface leak that results in a pool.

Analysis Strategy: Although this accident has a different initiator (i.e., excavation activities), the result will be either a surface leak or spray leak, which have been previously analyzed. The BIO analysis concludes that the calculations performed for spray leaks (assuming no controls) provide the bounding results for both spray leaks and surface leaks. This conclusion is also true for the RCSTS (i.e. the results reported in Section 3.4.2.20 are bounding).

3.4.2.21.1 Accident Scenario Assuming No Controls.

Sequence of Events. The BIO develops a scenario for various types of waste transfer piping including double-encased piping (similar to that used in the RCSTS). The sequence of events for the RCSTS is the same as that reported for other waste transfer systems in the BIO.

Results Summary. Because no credit was taken for the confinement of the spray within the RCSTS structure, the onsite and offsite radiological and toxicological consequences for the RCSTS excavation accident are bounded by the consequences calculated for the spray leak accident in Section 3.4.2.20.1.

Implication of Results. For the RCSTS spray leak, the onsite and offsite radiological and toxicological consequences exceed the risk guidelines. Therefore, controls are required.

3.4.2.21.2 Accident Scenario Assuming Controls.

Sequence of Events. Controls were selected to prevent the excavation accident by restricting and monitoring excavation activities in the vicinity of waste transfer lines. These controls, imposed in the BIO, are also applicable to the RCSTS. No additional controls are required.

3.4.2.21.3 Key Assumptions. The key assumptions documented in the BIO are applicable to the RCSTS. No additional assumptions are required.

3.4.2.21.4 Controls. The existing excavation controls listed in the BIO are applicable to the RCSTS. One additional Defense-in-Depth control is identified for the RCSTS.

Safety Structures, Systems, and Components. There are no Safety-Class and Safety-Significant structures, systems, and components required for this accident scenario in the BIO nor are any required for the RCSTS.

Technical Safety Requirements. Table 5.3.2.21-1, "Technical Safety Requirement Controls for Spray Leak and Surface Pools from Underground Waste Transfer Lines," in the BIO lists the TSRs selected to prevent leaks initiated by excavation activities. These TSRs identified in the BIO are applicable to the RCSTS.

Defense-in-Depth. The Defense-in-Depth controls identified in BIO Table 5.3.2.21-2, "Defense-in-Depth Controls for Spray Leak and Surface Pools from Underground Waste Transfer Lines," are applicable to the RCSTS. In addition, the magnetic warning tape that lies above the transfer lines (to warn of the underground piping and conduit) is also a Defense-in-Depth control for the RCSTS.

3.4.2.22 Tank Bump. Tank bumps occur when steam trapped in the waste causes a waste rollover and a rapid pressurization of the tank headspace. This accident is specific to waste tanks and is not applicable to the RCSTS. Therefore, no additional controls, beyond those listed in the BIO, are required.

3.4.2.23 Natural Phenomena. Natural phenomena analyzed in the BIO include high winds, lightning, and earthquakes. The BIO indicates that seismically induced spray leaks present the bounding natural phenomena accident for waste transfer systems. The BIO further indicates that no Safety-Class or Safety-Significant structures, systems, and components are associated with seismic protection. This statement also applies to the structures, systems, and components of the RCSTS (i.e., none are designated as Safety-Class or Safety-Significant for seismic protection). It should be noted, however, that diversion box 6241-A and vent station 6241-V were designed and constructed as Safety-Class (i.e., to withstand a 0.2 g earthquake), although this feature is not credited in the analysis. Administrative Emergency Preparedness controls mitigate the consequences of the seismic event by terminating waste transfers. These controls are listed in BIO Table 5.3.2.23.3-1, "Technical Safety Requirement Controls for Seismic Event," and are applicable to the RCSTS.

3.4.3 Beyond Design Basis Events

An analysis of Beyond Design Basis events, that includes all TWRS facility accidents and accident contributors, will be documented in the Final Safety Analysis Report.

This page intentionally left blank.

4.0 SAFETY STRUCTURES, SYSTEMS, AND COMPONENTS

The safety classifications for RCSTS structures, systems, and components (SSCs) are presented in the following sections. Safety classifications for TWRS facility SSCs are described in Section 2.1, "Structures, Systems, and Components Important to Safety," of the BIO.

4.1 INTRODUCTION

The controls selected for each accident are described in Chapter 3.0, "Safety Analysis." The selection process follows the SSC classification methodology described in WHC-CM-4-46*, *Nonreactor Facility Safety Analysis Manual*, and Dunford 1996, *Tank Waste Remediation System Final Safety Analysis Report Project Plan Comment Response; Risk-Based Approach*. In addition, the control decision criteria described in Chapter 5.4.1, "Control Decision Criteria," of the BIO are also followed.

The SSCs included in this report are divided into two categories, Safety-Class SSCs and Safety-Significant SSCs. Safety-Class SSCs prevent or mitigate releases to the public that would otherwise exceed the offsite radiological risk guidelines, or prevent a nuclear criticality. Those SSCs that support the safety function of a Safety-Class SSC are also Safety-Class SSCs.

Safety-Significant SSCs prevent or mitigate releases of radiological materials to onsite workers and toxic chemicals to the offsite public and onsite workers. Safety-Significant SSCs also include those safety SSCs that protect the facility worker from serious injury (or fatality) due to hazards not controlled by institutional safety programs. Those SSCs which support the safety function of a Safety-Significant SSC are also Safety-Significant SSCs.

It should be noted that some SSCs of the RCSTS are designated as Safety-Class for one accident and designated as Safety-Significant for a different accident. In conformance with Section 2.1 of the BIO, SSCs that serve more than one safety function are classified for the higher function.

4.2 REQUIREMENTS

DOE orders and standards that provide requirements and guidance for safety classification of SSCs are as follows:

- DOE 5480.23, *Nuclear Safety Analysis Reports*, Change 1 (1994)

---

*Refer to Appendix F, "Sitewide Controlled Manual Cross-Reference Table," of the BIO for cross-walk between Site-wide controlled manuals (e.g., WHC-CM-X-XXX) superseded by Fluor Daniel Hanford, Inc., procedures (e.g., HNF-PRO-XXX).

- DOE-STD-3009-94, *Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports* (1994).

The design codes, standards, and regulations for the safety SSCs are defined in WHC-CM-4-46.

4.3 SAFETY-CLASS STRUCTURES, SYSTEMS, AND COMPONENTS

This section provides information about the Safety-Class SSCs identified in Chapter 3.0. Table 4-1 provides a summary list of those SSCs.

It is important to note that the 241-SY-A and 241-SY-B valve pits and the 244-A lift station, which are connected to the RCSTS, were evaluated within the scope of the BIO and therefore Safety-Class and Safety-Significant SSCs that are applicable only to these structures (and not diversion box 6241-A and vent station 6241-V) will not be discussed here, since they are already documented in the BIO.

4.3.1 Safety-Class SSCs

The following is a summary of SSCs that perform a Safety-Class function for the RCSTS. Safety-Class items that are unique to the RCSTS are described, as well as Safety-Class items that were previously identified in the BIO but are also applicable to the RCSTS.

The new Safety-Class SSCs identified for the RCSTS are the pressure relief valve and rupture disk, and the diversion box 6241-A and vent station 6241-V entry doors and pipe penetrations (air sampling line, exhauster hookup, liner washdown system, and emergency pumpout line). Safety-Class SSCs, previously identified in the BIO, that are also applicable to the RCSTS include waste transfer pipe encasements, pressure switch interlock(s) or alarm to waste transfer pumps (to prevent waste backflow into the flush line), and transfer leak detection systems.

4.3.1.1 Safety Function(s). The reanalyzed accidents in Sections 3.4.2.18, 3.4.2.19, and 3.4.2.20 identified new Safety-Class SSCs. The safety function of the SSCs are listed in Table 4-1.

4.3.1.2 System Descriptions. System descriptions of the Safety-Class SSCs are provided below. Additional descriptions are provided in Section 2.4.1.

4.3.1.2.1 Entry Door and Penetrations on Diversion Box 6241-A and Vent Station 6241-V. Entry doors, shielded by a labyrinth wall on the inside of the pit, allow pit access. In addition, pipes (that penetrate the walls) are provided for an air sample line, an air exhauster hookup, liner washdown system, and an emergency pumpout line on both RCSTS structures. The door is verified to be closed and the pipe penetrations sealed prior to commencing waste transfers. The safety function of the entry door and pipe penetrations (air sampling line, exhauster hookup, liner washdown system, and emergency pumpout line), credited in the spray leak in the RCSTS structures, is to provide a physical barrier in case of a spray release during a transfer.

4.3.1.2.2 RCSTS Pressure Relief Valve. Two pressure relief valves are located on the boosted line in the 244-A Lift Station. This provides protection from a single failure of a valve failing to lift. The valves are set to relieve at 1,590 kPa (230 psig). The safety function of the RCSTS pressure relief valve, credited in spray leak in structures or from overground lines, surface leak resulting in pool, and subsurface leak resulting in pool accident analyses, is to lift at a preset pressure that is equal to the maximum operating pressure of the existing downstream piping. This precludes overpressurizing the downstream piping connected to the RCSTS and thereby protects the existing accident analysis in the BIO. The rupture disk is located upstream of the relief valve and must rupture at a preset pressure to allow the relief valve to perform its safety function.

4.3.1.2.3 Rupture Disk. A rupture disk is installed upstream from (and in line with) each of the pressure relief valves noted above. Because the rupture disk isolates the pressure relief valve (for maintenance and testing purposes) it is also a Safety-Class item. The rupture disks must fail at the designated pressure of 1,590 kPa (230 psig) to preserve the Safety-Class function of the pressure relief valve.

4.3.1.2.4 Other RCSTS Safety-Class SSCs Identified in BIO. The following Safety-Class SSCs have been identified in the BIO (for other waste transfer systems) and are also applicable to the RCSTS.

- **Pressure Switch Interlock(s) or Alarm to Waste Transfer Pumps.** (Section 2.1.1.2, "Pressure Switch Interlock(s) or Alarm to Waste Transfer Pumps [Raw Water and Other Water Service Supply Lines] of the BIO.) The pressure switch, between the two valves in the 241-SY-A valve pit that serve to isolate the RCSTS from the interconnected flush system, is covered by this Safety-Class designation. During waste transfer operations the valves are closed to isolate the flush system from the transfer system. If waste leaks by the first valve during transfer operations, then the rise in pressure will be detected and an alarm will be actuated and the interlock will shut down the transfer pump. When the transfer system is being flushed, the pressure of the flush water is above the pressure switch setpoint thus ensuring that the transfer pump is in the shut down condition. The safety function of the pressure switch interlocks to waste transfer pumps, credited in the spray leak in structures and surface leak resulting in pool accident analyses, is to prevent backflow of waste into interconnecting systems.

- **Transfer Leak Detection Systems.** (Section 2.1.1.5, "Transfer Leak Detection System," of the BIO.) The RCSTS pit leak detectors are new SSCs for the subsurface leak resulting in pool accident. Leak detection conductivity probes are located at a low-point sump in the diversion box and vent station to provide an indication of a leak. The safety function of the transfer leak detection system, credited in the BIO for the surface leak resulting in pool accident and the RCSTS subsurface leak resulting in pool accident, is to detect waste accumulation in the pits (when 51 mm [2 in.] have accumulated) and provide a transfer pump auto stop or alarm function.

The RCSTS transfer leak detectors are described in Section 2.4.1.2 of this addendum.

- **Waste Transfer Pipe Encasements.** (Section 2.1.1.19, "Waste Transfer Pipe Encasement," of the BIO.) The safety function of the pipe encasements, credited in the subsurface leak resulting in pool accident, is to ensure that a leak in the primary waste transfer system piping is directed to a waste transfer-associated structure. This Safety-Class designation also applies to the RCSTS.

  The waste transfer pipe encasements are described in Section 2.4.1 of this addendum.

4.3.1.3 Functional Requirements. The functional requirements are listed in Table 4-1.

4.3.1.4 System Evaluation. The system evaluation for performance criteria for TSRs are listed in Table 4-1.

4.3.1.5 Controls (TSRs). The controls required to support the new Safety-Class SSCs for the RCSTS (i.e., entry doors and pipe penetrations on diversion box 6241-A and vent station 6241-V, pressure relief valves/rupture disks in the 244-A lift station, and transfer leak detection systems) have been added to Table 6-1 of the BIO, which shows the consolidated list of controls for the TWRS facility. Controls for the Safety-Class SSCs that are applicable to the RCSTS (but have already been identified for other waste transfer systems) are also shown in Table 6-1, "Hazard and Accident Analyses; Safety Structures, Systems, and Components; and Technical Safety Requirements Cross Reference," of the BIO.

4.4 SAFETY-SIGNIFICANT STRUCTURES, SYSTEMS, AND COMPONENTS

This section provides information about the Safety-Significant SSCs identified for the RCSTS in Chapter 3.0. Table 4-2 provide a summary list of those SSCs.

4.4.1 Safety-Significant SSCs

The following is a summary of SSCs that perform a Safety-Significant function for the RCSTS. Safety-Significant items that are unique to the RCSTS are described, as well as Safety-Significant items that were previously identified in the BIO but are also applicable to the RCSTS.

The new Safety-Significant SSCs identified for the RCSTS are the diversion box 6241-A and vent station 6241-V entry doors and pipe penetrations (air sampling line, exhauster hookup, liner washdown system, and emergency pumpout line) and the inlet HEPA filter unit on the diversion box and vent station. Safety-Significant SSCs, previously identified in the BIO, that are also applicable to the RCSTS include tank level monitors, waste transfer pipe encasements, and transfer leak detection.

4.4.1.1 Safety Function(s). The reanalyzed accidents in Sections 3.4.2.18, 3.4.2.19, and 3.4.2.20 identified new Safety-Significant SSCs. The safety functions of the SSCs are listed in Table 4-2.

4.4.1.2 System descriptions. System descriptions of the Safety-Significant SSCs are provided below. Additional descriptions are provided in Section 2.4.1.

4.4.1.2.1 Entry Door and Penetrations on Diversion Box 6241-A and Vent Station 6241-V. Entry doors, shielded by a labyrinth wall on the inside of the pit, allow pit access. In addition, pipes (that penetrate the walls) are provided for an air sample line, an air exhauster hookup, liner washdown system, and an emergency pumpout line on both RCSTS structures. The door is verified to be closed and the pipe penetrations sealed prior to commencing waste transfers. The safety function of the entry door and pipe penetrations (air sampling line, exhauster hookup, liner washdown system, and emergency pumpout line), credited in the surface leak resulting in pool accident analysis for the RCSTS, is to limit release of aerosols generated by splatter inside the structure.

4.4.1.2.2 High-Efficiency Air Filters on Diversion Box 6241-A and Vent Station 6241-V. The HEPA filter in the diversion box and vent station are credited with providing an efficiency of 0.99 in the analysis of pool leaks and spray leaks. The actual HEPA filter efficiency is 0.999, but because moisture can degrade filter performance, an efficiency of 0.99 is conservatively used in the analysis. The safety function of the HEPA filters, credited in spray leak in structures and surface leak resulting in pool accident analyses for the RCSTS, is to remove respirable airborne particulates from the airborne release and thereby reduce the inhalation dose to the onsite receptor and facility worker.

4.4.1.2.3 Other RCSTS Safety-Significant SSCs Identified in BIO. The following Safety-Significant SSCs have been identified in the BIO and are also applicable to the RCSTS.

- **Tank Level Monitors.** (Section 2.1.2.6, "Tank Level Monitors," of the BIO.) The safety function of the level monitors credited in the RCSTS subsurface leak remaining subsurface, subsurface leak resulting in pool, and surface leak resulting in pool accidents, is to indicate the waste level in the tank to support mass balance calculations during waste transfers.

  The waste tank level monitors are described in Section B2.4.11.2, "Liquid and Sludge-Level Monitoring Systems," of Appendix B of the BIO.

- **Waste Transfer Pipe Encasements.** (Section 2.1.2.10, "Waste Transfer Pipe Encasements," of the BIO.) The safety function of the pipe encasements credited in the subsurface leak remaining subsurface accident is to ensure that a leak in the primary waste transfer system piping is directed to a waste transfer-associated structure.

The waste transfer pipe encasements are described in Section 2.4.1. of this addendum.

- **Transfer Leak Detection Systems.** (Section 2.1.1.5, "Transfer Leak Detection System," of the BIO.) Leak detection conductivity probes are located at a low-point sump in the diversion box and vent station to provide an indication of a leak. The safety function of the transfer leak detection system, credited in the BIO for the subsurface leak remaining subsurface accident, is to detect waste accumulation in the pits (when 51 mm [2 in.] have accumulated) and provide a transfer pump auto stop or alarm function.

  The RCSTS transfer leak detectors are described in Section 2.4.1.2 of this addendum.

4.4.1.3 Functional Requirements. The functional requirements are listed in Table 4-2.

4.4.1.4 System Evaluation. The system evaluation for performance criteria for TSRs are listed in Table 4-2.

4.4.1.5 Controls (TSRs). The controls required to support the new Safety-Significant SSCs for the RCSTS (i.e., entry doors and penetrations on diversion box 6241-A and vent station 6241-V, and HEPA filters on the diversion box and vent station) have been added to Table 6-1 of the BIO which shows the consolidated list of controls for the TWRS facility. Controls for the Safety-Significant SSCs that are applicable to the RCSTS (but have already been identified for other waste transfer systems) are also shown in Table 6-1 of the BIO.

Table 4-1. New RCSTS Safety-Class Structures, Systems, and Components Summary. (3 sheets)

SSC	Accident(s)	Safety functions	Functional requirements	Performance criteria for TSRs
Diversion Box 6241-A and Vent Station 6241-V Entry Doors and Penetrations (4.3.1.2.1)	Spray Leak in Structure or from Overground Waste Transfer Lines (3.4.2.20)	The safety function of the diversion box and vent station entry doors and pipe penetrations is to provide a physical barrier in case of a spray leak during a transfer and thereby limit the release of aerosols and the subsequent dose to the offsite receptor.	The entry door and pipe penetrations must confine direct spray leaks to the inside of the structure. The entry door assemblies shall seal fit the structure, so that there are no paths for a direct spray leak or aerosol release to the atmosphere. The pipe penetrations must also be capable of being sealed during waste transfers.	The door assembly shall be visually inspected prior to a waste transfer to ensure that the door is closed and operable. The pipe penetrations for the air sampling line, exhauster hookup, liner washdown system, and emergency pumpout line are also verified to be flanged or capped prior to commencing waste transfers.
Pressure Relief Valve (4.3.1.2.2)	Surface Leak Resulting in Pool (3.4.2.18) Subsurface Leak Resulting in Pool (3.4.2.19) Spray Leak in Structure or from Overground Waste Transfer Lines (3.4.2.20)	The safety function of the pressure relief valve is to prevent overpressurization of the piping downstream from the RCSTS. This protects the assumptions used in the BIO accident analyses, which did not account for interfaces with the RCSTS.	The pressure relief valve shall relieve at a pressure of 1590 kPa (230 psig).	Prior to waste transfers (utilizing the booster pump), it shall be verified that the pressure relief valve has not relieved and is operable. It should be noted that this control is not required until transfers utilizing the booster pumps are initiated.

Table 4-1. New RCSTS Safety-Class Structures, Systems, and Components Summary. (3 sheets)

SSC	Accident(s)	Safety functions	Functional requirements	Performance criteria for TSRs
Rupture Disk (4.3.1.2.3)	Surface Leak Resulting in Pool (3.4.2.18) Subsurface Leak Resulting in Pool (3.4.2.19) Spray Leak in Structure or from Overground Waste Transfer Lines (3.4.2.20)	The safety function of the rupture disk is to fail and thereby allow the pressure relief valve to perform its Safety-Class function of preventing overpressurization of the piping downstream from the RCSTS.	The rupture disk shall fail at a pressure of 1590 kPa (230 psig).	Prior to waste transfers (utilizing the booster pump), it shall be verified that the rupture disk has not failed and is operable. It should be noted that this control is not required until transfers utilizing the booster pumps are initiated.

Table 4-1. New RCSTS Safety-Class Structures, Systems, and Components Summary. (3 sheets)

SSC	Accident(s)	Safety functions	Functional requirements	Performance criteria for TSRs
RCSTS transfer leak detection system (4.3.1.2.4)	Subsurface Leak Resulting in Pool (3.4.2.19)	The safety functions of the RCSTS transfer leak detection system are to detect the presence of leaks in diversion box 6241-A or vent station 6241-V and to either provide an alarm to alert operators to take mitigative action, or provide an interlock to shut down transfer pump operation, thus limiting the volume of the waste leak and decreasing the consequences of the Surface Leak Resulting in Pool and the Subsurface Leak Resulting in Pool accidents.	The RCSTS leak detectors shall detect a 51 mm (2-in) deep waste leak. The leak detection system shall activate an alarm or an interlock to prevent or stop operation of the transfer pump when a leak is detected.	The operability of the RCSTS leak detectors in diversion box 6241-V (and the associated alarm or control circuitry) that are physically connected to a waste transfer pump not under an administrative lock shall be verified quarterly by a functional test.

Note: The other Safety-Class SSCs that are applicable to the RCSTS (i.e., waste transfer line encasements) have been previously identified in the BIO. A consolidated list of all SSCs and TSRs (revised to include the RCSTS) is provided in Table 6-1 of the BIO.

Table 4-2. New Safety-Significant Structures, Systems, and Components Summary.

SSC	Accident(s)	Safety functions	Functional requirements	Performance criteria for TSRs
Diversion Box 6241-A and Vent Station 6241-V Entry Doors and Penetrations (4.4.1.2.1)	Surface Leak Resulting in a Pool (3.4.2.18)	The safety function of the diversion box and vent station entry doors and pipe penetrations is to provide a barrier to limit the release of aerosols generated by splatter during a pool leak accident and thereby limit the subsequent dose to the onsite receptor.	The entry door and pipe penetrations must confine aerosols to the inside of the structure. The entry door assemblies shall seal fit the structure, so that there are no paths for a direct aerosol leak to the atmosphere. The pipe penetrations must also be capable of being sealed during waste transfers.	The door assembly shall be visually inspected prior to a waste transfer to ensure that the door is closed and operable. The pipe penetrations for the air sampling line, exhauster hookup, liner washdown system, and emergency pumpout line are also verified to be flanged or capped prior to commencing waste transfers.
Inlet Air HEPA Unit (4.4.1.2.2)	Spray Leak in Structure or from Overground Waste Transfer Lines (3.4.2.20) Surface Leak Resulting in Pool (3.4.2.18)	The safety function of the diversion box and vent station ventilation system HEPA filter unit is to provide filtration of aerosols generated by splatter or by direct spray releases within the pits.	The HEPA filter radiation level is less than or equal to 200 mrem/hr on contact. The HEPA filter nominal particulate removal efficiency is at least 99.95%.	Operability of the HEPA filter units is verified at the time of installation and annually thereafter using a challenge aerosol.

Note: The other Safety-Significant SSCs that are applicable to the RCSTS (i.e., tank level monitors, waste transfer line encasements, and transfer leak detection systems) have been previously identified in the BIO. A consolidated list of all SSCs and TSRs (revised to include the RCSTS) is provided in Table 6-1 of the BIO.

5.0 DERIVATION OF TECHNICAL SAFETY REQUIREMENTS

5.1 INTRODUCTION

The existing operating envelope for the Tank Waste Remediation System (TWRS) is defined by the Technical Safety Requirements (TSRs) listed in Chapter 6.0 of the Basis for Interim Operation (BIO). These controls are implemented through HNF-SD-WM-TSR-006, *Tank Waste Remediation System Technical Safety Requirements*, which was prepared using the guidance of DOE 5480.22, *Technical Safety Requirements*. The purpose of this chapter is to identify the additional TSRs that bring the RCSTS within the TWRS safety envelope. The new TSRs have been added to HNF-SD-WM-TSR-006.

5.2 REQUIREMENTS

The DOE Orders required for establishing the safety basis of the RCSTS are listed below.

- DOE 5480.22, *Technical Safety Requirements*, Change 2, (1996)
- DOE 5480.23, *Nuclear Safety Analysis Reports*, Change 1 (1994).

The documents used to implement the DOE Order requirements include:

- DOE-STD-3009-94, *Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports* (1994)
- WHC-CM-4-46, *Nonreactor Facility Safety Analysis Manual* (1989)
- HNF-SD-WM-HSP-002, *Tank Farms Health and Safety Plan* (1998).

5.3 TECHNICAL SAFETY REQUIREMENT COVERAGE, AND DERIVATIONS

The accident analysis in Chapter 3.0, along with the designation of safety SSCs and the associated TSRs in Chapter 4.0, indicated that operation of the RCSTS adds several new TSRs to the TWRS facility. These new controls are added to BIO Table 6-1, "Hazard and Accident Analyses; Safety Structures, Systems, and Components; and Technical Safety Requirement Cross Reference," to account for the reanalyzed accident scenarios and allow the BIO to envelope operation of the RCSTS. BIO Table 6-1 correlates the reanalyzed accident scenarios with the necessary controls and includes the Safety-Class and Safety-Significant SSCs, the type of TSR control (i.e., LCO [Limiting Condition for Operation] or AC [Administrative Control]) and the specific location of the control within the TSR (e.g., LCO 3.1.1 or AC 5.12), and a summary of the key elements of the TSR derivation basis.

The new or modified controls are discussed below. Other Safety-Class and Safety-Significant SSCs identified for the RCSTS are not unique and are covered by TSRs previously identified in the BIO.

5.3.1 AC 5.7 Nuclear Criticality Safety

The RCSTS has the capability to transfer wastes with up to a 30 vol% solids content. The intentional redistribution of solids in waste tanks (which would result from the transfer of a slurry with a high solids content) is not considered a routine activity and must be evaluated on a case by case basis. Therefore, a new control is added to AC 5.7 to require that a Criticality Safety Evaluation Report be completed prior to initiating transfers of waste slurries with high solids content through the RCSTS.

5.3.2 AC 5.18 HEPA Filter Controls

Each of the two RCSTS structures (diversion box 6241-A and vent station 6241-V) is passively ventilated with a HEPA filter. The accident analysis for the Surface Leak Resulting in Pool and Spray Leak in Structure accidents assumes that 90% of the airborne release passes through a HEPA filter with an assumed efficiency of 0.99. Because this filtering reduces the onsite consequences to below the risk evaluation guidelines, the HEPA filters are designated as Safety-Significant. Therefore, to protect the assumptions in the accident analysis, the applicability of AC 5.18 is extended to include the HEPA filters in diversion box 6241-A and vent station 6241-V. AC 5.18 requires that the filters be monitored periodically to verify that the radiation level is less than or equal to 200 mrem/h on contact and be tested annually to verify an efficiency of greater than or equal to 99.95%.

5.3.3 LCO 3.1.1 Transfer System Covers and Entry Doors

The two new RCSTS structures (diversion box 6241-A and vent station 6241-V) are designed differently than the existing waste transfer structures and will use an entry door for routine access instead of concrete covers. Therefore, LCO 3.1.1 is modified to include the entry doors for diversion box 6241-A and vent station 6241-V. The entry door will be verified to be closed prior to commencing waste transfers. In addition, both structures have several pipes (i.e. air sampling line, exhauster hookup, liner washdown system, and emergency pumpout line) that penetrate the concrete walls. These are also added to LCO 3.1.1 to ensure that the lines are either flanged or capped prior to commencing waste transfers. The purpose of these controls is to provide a barrier for aerosols that could potentially be generated from spray leaks or from splatter during pool leak events.

5.3.4 LCO 3.1.3 RCSTS Transfer Leak Detection System

The accident analysis for the RCSTS Subsurface Leak Resulting in Pool accident assumes that the subsurface leaks will drain through the encasement to a waste transfer structure where the RCSTS transfer leak detection system will detect the leak and either provide an alarm to alert operators to take mitigative action, or provide an interlock to shut down transfer pump operation, thus limiting the volume of the waste leaked. Because the accident without controls results in unacceptable offsite consequences, the RCSTS

transfer leak detection system is designated as Safety-Class. LCO 3.1.3, which applies to all process pits and diversion boxes, will ensure operability of the RCSTS transfer leak detection system.

5.3.5 LCO 3.1.5 Replacement Cross-Site Transfer System PRV and Rupture Disk

The RCSTS piping is designed for a higher pressure than the piping to which it is interconnected at the 244-A lift station. Therefore, pressure relief valves are installed in the 244-A lift station and are designed to lift at 1590 kPa (230 psig). This is equivalent to the maximum operating pressure of the existing downstream piping. The Safety-Class designation and accompanying Limiting Condition for Operation (LCO) are required to preclude introducing new potential accident initiators (from overpressurization) for the piping systems previously analyzed in the BIO. A rupture disk is located immediately upstream of and in line with each relief valve to keep the valves from becoming contaminated under normal conditions and thereby facilitates valve calibration and maintenance. At a pressure of 1590 kPa (230 psig), the rupture disks will rupture, an alarm will activate at the operator control station, and the relief valves will discharge into the 244-A catch tank. LCO 3.1.5 will verify operability of these relief devices.

Note: Transfers through replacement cross-site transfer line WT-SLL-3160 are not authorized (Wagoner 1997, Contract Number DE-AC06-96RL13200; *Approval of Authorization Basis [AB] Amendment Package for Project W-058, Replacement Cross-Site Transfer System*). LCO 3.1.5 will be added to HNF-SD-WM-TSR-006 after DOE-RL approval for transfers through line WT-SLL-3160 is granted.

5.4 DERIVATION OF FACILITY MODES

The operational modes for the TWRS facility are defined in the Technical Safety Requirements document. Operation of the RCSTS does not change any of these definitions of facility operating modes.

5.5 INTERFACE WITH TSRs FROM OTHER FACILITIES

The TSRs for the RCSTS are contained within the TSRs for TWRS.

This page intentionally left blank.

6.0 PREVENTION OF INADVERTENT CRITICALITY

This chapter contains information on prevention of inadvertent criticality as a result of the installation and/or operation of the replacement cross-site transfer system (RCSTS). Further information on the criticality safety and protection program for the Tank Waste Remediation System (TWRS) facility is provided in Section 4.3, "Criticality Protection," of the BIO. The program ensures that sufficient controls are in place to prevent inadvertent nuclear criticality excursions in the TWRS facilities.

6.1 REQUIREMENTS

See Section 4.3 of the BIO for requirements.

6.2 FACILITY IMPLEMENTATION

Prior to any slurry transfers through the RCSTS with waste tank solids, a Criticality Safety Evaluation Report will be issued which addresses the suspension of solids in the sending tank and the particle segregation after settling in the sending and receiving tanks. See Section 4.3 of the TWRS BIO for facility implementation.

6.3 PROJECT IMPLEMENTATION

Project implementation is achieved by requiring the Criticality Safety Evaluation Reports discussed in Section 6.2 above. See Chapter 3.0, Section 3.4.2.1 for further discussion on criticality.

This page intentionally left blank.

7.0 RADIATION PROTECTION

This chapter identifies the requirements for radiation protection as a result of the installation and operation of the replacement cross-site transfer system (RCSTS).

7.1 REQUIREMENTS

See Section 4.4, "Radiological Protection," of the BIO for the requirements.

7.2 FACILITY IMPLEMENTATION

See Section 4.4 of the BIO for facility implementation.

7.3 PROJECT IMPLEMENTATION

Because of the anticipated dose rates, the diversion box and vent station pits will be considered high radiation zones during all waste transfers and the entry doors will be locked. Procedural controls on physical access to high radiation zones require the person-in-charge to account for all personnel who have entered the high radiation area and to verify that all personnel have exited prior to placing the locks.

Entry will not normally be allowed to diversion box 6241-A or vent station 6241-V when waste is in the transfer line (i.e., during waste transfers or before the line has been flushed, after a transfer is complete). Entry, when waste is in the line, will only be allowed after management review and concurrence or in case of emergency. No other project-specific requirements related to radiation protection were identified for the RCSTS.

This page intentionally left blank.

8.0 HAZARDOUS MATERIAL PROTECTION

This chapter identifies the requirements for hazardous material protection other than radiological hazards for the replacement cross-site transfer system (RCSTS).

8.1 REQUIREMENTS

See Section 4.5, "Hazardous Material Protection," of the BIO for the requirements.

8.2 FACILITY IMPLEMENTATION

See Section 4.5 of the BIO for facility implementation.

8.3 PROJECT IMPLEMENTATION

No project-specific requirements related to hazardous material protection were identified for the RCSTS.

This page intentionally left blank.

9.0 RADIOACTIVE AND HAZARDOUS WASTE MANAGEMENT

This chapter lists the requirement documents for the radiological and hazardous waste management for the replacement cross-site transfer system (RCSTS).

9.1 REQUIREMENTS

See Section 4.6, "Radioactive and Hazardous Material Waste Management," of the BIO for the requirements.

9.2 FACILITY IMPLEMENTATION

See Section 4.6 of the BIO for facility implementation.

9.3 PROJECT IMPLEMENTATION

Slightly contaminated flush water is the only additional waste that is expected to be generated through operation of the RCSTS. No additional requirements relating to radioactive and hazardous waste management were identified for the RCSTS.

This page intentionally left blank.

10.0 INITIAL TESTING, IN-SERVICE SURVEILLANCE, AND MAINTENANCE

This chapter identifies the requirements for testing, surveillance, and maintenance for the replacement cross-site transfer system (RCSTS) and the implementing program documents.

10.1 REQUIREMENTS

See Section 4.7, "Testing, Surveillance, and Maintenance," of the BIO for the requirements.

10.2 FACILITY IMPLEMENTATION

See Section 4.7 of the BIO for facility implementation.

10.3 PROJECT IMPLEMENTATION

10.3.1 Initial Testing

The RCSTS is a new system and must be tested prior to becoming fully operational. A detailed test plan, HNF-SD-W058-SUP-002, *Project W058 Startup Test Plan*, describes the overall testing activities. These are summarized below.

10.3.1.1 Factory Acceptance Testing. Factory acceptance tests are performed by the vendor on the booster pumps and the monitor and control system.

10.3.1.2 Construction Acceptance Testing. Acceptance tests are conducted by the equipment vendors and the construction contractor to demonstrate compliance with fabrication, assembly, installation, and construction requirements as identified in the procurement and construction specifications.

10.3.1.3 Preoperational Testing. Preoperational testing includes testing of components, subsystems, and system operation to verify setpoints for alarms, control functions, and normal operating values for system parameters.

10.3.1.4 Operational Testing. Operational testing will be performed by operations personnel coincident with initial process operations. Testing will verify the design function of the systems in the actual operating environment.

10.3.2 In-Service Surveillance

Procedures for in-service surveillance testing will be developed in accordance with DOE 5480.19, *Conduct of Operations Requirements for DOE Facilities*.

10.3.3 Maintenance

Procedures for maintenance will be developed in accordance with DOE 5480.19.

11.0 OPERATIONAL SAFETY

This chapter identifies requirements for conduct of operations, fire protection, and the implementing program documents resulting from the operation of the replacement cross-site transfer system (RCSTS).

11.1 REQUIREMENTS

See Sections 4.8, "Conduct of Operation," 4.9, "Work Control," and 4.10, "Fire Protection Program," of the BIO for the requirements.

11.2 FACILITY IMPLEMENTATION

See Sections 4.8, 4.9, and 4.10 of the BIO for facility implementation.

11.3 PROJECT IMPLEMENTATION

No project-specific requirements related to fire protection were identified for the RCSTS. It was concluded in WHC-SD-W058-PHA-001 that a fire protection system for the RCSTS is not required. Normal fire safety practices will be followed.

One operational safety concern, related to the pit entry doors, has been identified for the diversion box and the vent station. This concern is actually twofold and involves ensuring free and unobstructed egress when the structure is occupied and preventing inadvertent entrapment when the doors are closed and locked prior to initiating waste transfers.

The situation where the structures are occupied is considered first. Because of the mass of the doors and the attendant forces required for opening, industrial safety requirements (as described in 29 CFR 1910, "Occupational Safety and Health Standards", DOE 5480.7A[1], *Fire Protection*, and NFPA 101, *Life Safety Code*) mandate that the doors be locked or blocked in the open position when the pits are occupied. Signs indicating this requirement are posted in both the diversion box and vent station. Adherence to posted personnel protection requirements is mandated through operating procedures.

The entrapment concern arises when the entry doors are closed and locked prior to waste transfers. This concern derives from the structure design which includes a corridor that runs between the entry door and the pit and precludes visual contact with the pit for an operator standing at the door. Prevention of inadvertent entrapment is achieved through maintaining personnel accountability and verifying that the area is unoccupied prior to placing the locks as will be described below.

---

[1]Although DOE 5480.7A has been rescinded, the contractor is obligated by the existing contract to meet the requirements stated in this order.

As noted in Chapter 7.0 of this addendum, the diversion box and vent station pits will be considered high radiation zones during waste transfers and the entry doors will be locked. This posting and locking of the doors will occur before initiating any waste transfer. Radiological protection procedures also require that the area be verified to be unoccupied prior to placing the locks.

Additional programmatic controls also protect against the entrapment scenario. The diversion box and vent station will be procedurally defined as hazardous facilities and thus be subject to hazardous facility access controls. Per procedure, access control to hazardous facilities is maintained by the shift manager. These procedures require that the shift manager be notified prior to entry of the facility and upon final exit and securing of the facility.

As discussed above, personnel accountability in the diversion box and vent station pits is maintained through two different sets of controls: radiological protection controls and hazardous facility access controls. These controls provide dual and independent levels of protection against inadvertent entrapment.

12.0 PROCEDURES AND TRAINING

This chapter lists the requirements for the procedures and training programs for the replacement cross-site transfer system (RCSTS).

12.1 REQUIREMENTS

See Section 4.11, "Training and Procedures," of the BIO for the requirements.

12.2 FACILITY IMPLEMENTATION

See Section 4.11 of the BIO for facility implementation.

12.3 PROJECT IMPLEMENTATION

No project-specific requirements related to training were identified for the RCSTS.

This page intentionally left blank.

13.0 HUMAN FACTORS

This chapter lists the requirements for a human factors program to demonstrate that human factors are considered in facility design for the replacement cross-site transfer system (RCSTS) where human actions are relied on for preventive or mitigative actions.

13.1 REQUIREMENTS

See Section 4.18, "Human Factors," of the BIO for the requirements.

13.2 FACILITY IMPLEMENTATION

See Section 4.18 of the BIO for facility implementation.

13.3 PROJECT IMPLEMENTATION

The application of human factors is graded on project risk, complexity, and level of involvement of the operator at the facility. The TWRS design authority and safety organization are responsible for ensuring human factors are included as an explicit consideration in the modification of TWRS facilities, systems, or equipment that may affect safety. The risk, complexity, and level of operator involvement for the RCSTS are similar to normal DST operations. However, in March of 1995 a human factors programming session was conducted. Consequently, no additional human factors analysis is required.

This page intentionally left blank.

14.0 QUALITY ASSURANCE

This chapter lists the requirements for a quality assurance program to ensure the safety of personnel and the public, for environmental protection, and for the implementing program documents for the replacement cross-site transfer system (RCSTS).

14.1 REQUIREMENTS

See Section 4.12, "Quality Assurance," of the BIO for the requirements.

14.2 FACILITY IMPLEMENTATION

See Section 4.12 of the BIO for facility implementation.

14.3 PROJECT IMPLEMENTATION

Implementation of specific quality assurance requirements for the RCSTS is controlled by HNF-SD-W058-QAPP-001, *Project Specific Quality Assurance Plan Project W-058, Replacement of the Cross-Site Transfer System.*

The quality assurance program consists of the following:

- Personnel performing work on this project have been trained and qualified in accordance with the above quality assurance programs and DOE 5480.20A, *Personnel Selection, Qualification, and Training Requirements for DOE Nuclear Facilities.*
- Quality improvement processes described in the quality assurance programs provide for the detection and correction of quality problems throughout the design and construction of this project.
- Documents associated with this project have been independently reviewed for completeness and accuracy. A record index is available to classify all quality assurance records to aid in retrieval.
- Work processes associated with this project have been and will be strictly adhered to in accordance with this quality assurance program. Appropriate administrative procedures have been developed and approved to control key aspects in the design and construction of this project.
- Designs associated with this project have been independently reviewed and approved. Completed construction is accurately depicted by as-built drawings.

- Procurement of Safety-Class and Safety-Significant items for this project are in compliance with this quality assurance program in that such items have been purchased from qualified suppliers where applicable and all stated requirements have been met as verified through independent inspections, tests, and assessments. All required Certified Vendor Information has been received and appropriately indexed and filed to support continuity of service for this project.

- Inspection and testing of items associated with this project will meet required standards as verified by properly trained and qualified personnel. Records supplied on project turnover will attest to the accuracy and completeness of the inspection and testing.

- Periodic management assessment of this project has been established to ensure this project is compliant with this quality assurance plan and the objectives stated therein.

- Independent assessments will be planned, scheduled, and conducted to confirm that project deliverables and service quality are adequate to meet operational objectives.

15.0 EMERGENCY PREPAREDNESS PROGRAM

This chapter identifies the requirements for the emergency preparedness functions and response at the site of the replacement cross-site transfer system (RCSTS).

15.1 REQUIREMENTS

See Section 4.13, "Emergency Preparedness," of the BIO for the requirements.

15.2 FACILITY IMPLEMENTATION

See Section 4.13 of the BIO for facility implementation.

15.3 PROJECT IMPLEMENTATION

No project-specific requirements related to emergency preparedness were identified for the RCSTS.

This page intentionally left blank.

16.0 PROVISIONS FOR DECONTAMINATION AND DECOMMISSIONING

This chapter describes provisions that facilitate future decontamination and decommissioning (D&D) of the replacement cross-site transfer system (RCSTS).

16.1 REQUIREMENTS

See Section 4.14, "Decontamination and Decommissioning," of the BIO for the requirements.

16.2 IMPLEMENTATION

See Section 4.14 of the BIO for implementation.

16.3 PROJECT IMPLEMENTATION

There is no requirement for a specific implementing document for D&D of the RCSTS.

This page intentionally left blank.

17.0 MANAGEMENT, ORGANIZATION, AND INSTITUTIONAL SAFETY PROVISIONS

This section provides the requirements for organization and institutional safety provisions that are pertinent to the safety analysis and the implementing program documents for the replacement cross-site transfer system (RCSTS).

17.1 REQUIREMENTS

See Section 4.1, "Organizational Structure and Management Responsibilities," of the BIO for the requirements.

17.2 FACILITY IMPLEMENTATION

See Section 4.1 of the BIO for facility implementation.

17.3 PROJECT IMPLEMENTATION

No project-specific requirements related to management, organization, and institutional safety provisions were identified for the RCSTS.

This page intentionally left blank.

APPENDIX A

HAZARDS BASES

This page intentionally left blank.

LIST OF TABLES

A-1 RCSTS Hazards Identification A-5

A-2 RCSTS Material at Risk A-6

A-3 RCSTS Facility Configurations A-7

This page intentionally left blank.

Table A-1. RCSTS Hazards Identification.[a]

Energy classification[b]	RCSTS	
	PF	PE
Corrosive	2	NA
Explosive/pyrophoric	6,7,8,10	NA
Nuclear criticality	NA	NA
Flammable materials	11,13,14	3,7
Thermal radiation	NA	NA
Chemical reactions	1	NA
Friction	NA	NA
Electrical	3,4,5,9,10	NA
Kinetic-rotational	2,3	NA
Kinetic-linear	NA	1,4,5
Mass, gravity, height	2,3,11,13,14, 16	5
Pressure-volume	7,9,11	NA
Thermal (except radiant)	NA	NA

[a]The hazards identification represents the hazards that could potentially cause an uncontrolled release of radioactive or hazardous materials only. Hazards only resulting in personnel injury are not included.

[b]Table 3-2, "Hazard Identification Checklist and Energy Designators," in this addendum, has the specific energy classifications represented by the numeric designators.

NA = not applicable.
PE = potentially present elsewhere in/adjacent to facility.
PF = potentially present in the facility.

Table A-2. RCSTS Material at Risk (MAR).

Field Name	MAR-subject	MAR description	MAR classification	Capacity	Material type	Physical form	Volume or activity	Transient	Quantity	Comments
RCSTS	Contents of Pipeline or Source tank during transfer	Transfer Piping	NA	NA	NA	Liquid Slurry	NA	NA	NA	Two RCSTS Transfer Lines
Diversion Box 6241-A	Contamination in Sump	RCSTS Diversion Box	Residual	NA	NA	Residue	Unknown	No	1 Pit	
Diversion Box 6241-A	Ventilation Filter Contents	Exhauster HEPA Filter	NA	NA	NA	Particulate	NA	NA	NA	Portable Exhauster
Diversion Box 6241-A	Ventilation Filter Contents	Air Inlet HEPA Filter	NA	NA	NA	Particulate	NA	NA	NA	
Vent Station 6241-V	Contamination in Sump	RCSTS Diversion Box	Residual	NA	NA	Residue	Unknown	No	1 Pit	
Vent Station 6241-V	Ventilation Filter Contents	Exhauster HEPA Filter	NA	NA	NA	Particulate	NA	NA	NA	Portable Exhauster
Vent Station 6241-V	Ventilation Filter Contents	Air Inlet HEPA Filter	NA	NA	NA	Particulate	NA	NA	NA	
RCSTS Water Flush System	Dilute Caustic	RCSTS Water Flush System	Caustic	47,000 gal	Dilute Caustic	Liquid	140 gpm	NA	NA	Flush of the RCSTS after usage with caustic solution
RCSTS Chemical Injection Package	25% NaOH	Chemical Injection Package	Caustic	55 gal	NaOH	Liquid	NA	NA	NA	

Table A-3. RCSTS Facility Configurations.

Facility Name	Type	Ventilation	Comment Ventilation	Flush	Comment Flush
RCSTS	Pipeline	NA	NA	Yes	Pipeline Flushed after usage
Diversion Box 6241-A	Pump Station	Passive	Exhauster connected up with ventilation system when needed	Yes	Pipeline in Diversion Box Flushed after usage
Vent Station 6241-V	Vent Station	Passive	Exhauster connected up with ventilation system when needed	Yes	Pipeline in Vent Station Flushed after usage

APPENDIX B

ANALYZED ACCIDENTS AND REPRESENTED HAZARDOUS CONDITIONS

This page intentionally left blank.

LIST OF TABLES

B-1 Analyzed Accidents B-1-1

B-2 Analyzed Accidents and the Represented Hazardous Conditions . . . B-2-1

This page intentionally left blank.

Table B-1. Analyzed Accidents. (3 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	BIO Acc
ANALYZED ACCIDENT: Nuclear Criticality								
A-1-a	I-PFP-1-AGT-A	Fission product gases and aerosols from receiver tank.	Release of fission product gases and aerosols from receiver tank due to: Potential for solids to collect in D-5. If mixed later, potential for composition of next batch to exceed Criticality Prevention Specifications (CPS). Potential "Criticality Issue."	Human Error or Agitator fails results in criticality	F3	S2	A05	01
ANALYZED ACCIDENT: HEPA Filter Failure - Exposure to High Temperature or Pressure								
A-1-a	106C-10J	Tank atmosphere and surface contamination on HEPA filters	Release of radioactive and/or hazardous material from Tank 241-C-106 tank due to tank structural damage, HEPA damage caused by high temperature	Fire in or around ventilation system	F2	S2	B09	02A
ANALYZED ACCIDENT: Unfiltered Release								
B-1-a	114SX-04.c.2.a	Radioactive aerosols contained in the tank headspace	Radioactive aerosols released from Tank SX-114 head space to atmosphere due to exhauster HEPA filter seal failure	HEPA filter seal failure	F3	S2	D07	02B
ANALYZED ACCIDENT: Fire in Contaminated Area								
A-1-a	CRN-05	Pits and risers inventory	Release of radioactive and/or toxic materials from pits and risers due to fuel tank fire in crane or support vehicle (see In-Tank Equipment Installation for tank fires)	Human error in positioning crane load	F3	S2	B26	03
ANALYZED ACCIDENT: Subsurface Leak Remaining Subsurface								
B-3-b	102S-01.b3	Radioactive/hazardous material contained in pumpable liquids from S-102.	Radioactive liquid released to the soil subsurface from leaks in transfer Lines SL-140, SN-242. (Plume)	Line leak during salt well pumping (corrosion)	F3	S2	D12	07
ANALYZED ACCIDENT: Caustic Spray Leak								
B-1-a	107AN-02-PRES	Contents of caustic truck	Release of caustic aerosol from caustic truck transfer piping due to spray leak	Piping/hose leak initiated by various causes	F3	S2	D12	09

Table B-1. Analyzed Accidents. (3 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	BIO Acc
ANALYZED ACCIDENT: Mixing of Incompatible Material - Toxic Vapor Generation								
C-1-a	XS-26-PRES XS-26-TEMP	DST vapor/aerosols	Release of toxic vapors from Tank 241-SY-102 due to chemical reaction	Mistransfer of incompatible waste causes chemical reaction	F3	S2	E06	11
ANALYZED ACCIDENT: Mixing of Incompatible Material - Tank Pressurization								
B-1-a	I-222S-1-RXN-A	Aerosols and/or toxic vapors from receiver tank	Release of aerosols and/or toxic vapors from receiver tank due adverse chemical reactions from incompatible waste.	Transfer of incompatible waste	F3	S2	D01	12
ANALYZED ACCIDENT: Flammable Gas Deflagrations								
A-1-a	ITK-10-b	DST tank inventory	Release of radioactive material from in-tank fire or explosion due to intrusive activity (Dome Collapse)	Spark from equipment or tools	F3	S3	B04	14A
A-1-a	XS-01-FLOW03	SST and DCRT tank contents	Release of liquids, solids, and/or vapors from single shell tank due to dome collapse and DCRT pressurization caused by flammable gas explosion/fire propagating from DCRT to single shell tank	Pipeline connecting single shell tank and DCRT fills with flammable gas; loss of ventilation flow in DCRT so that a flammable gas atmosphere is ignited by the ventilation outlet heater	F2	S3	B07	14B
ANALYZED ACCIDENT: Surface Leak Resulting in Pool								
C-2-b	W058-PRES01	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (Pool)	Water hammer plus mitigative features failure	F3	S2	D17	18
ANALYZED ACCIDENT: Subsurface Leak Resulting in Pool								
B-3-b	XS-07-FLOW02	Liquid radioactive waste transferred out of DCRT	Release of radioactive waste to soil from transfer piping out of 244-TX DCRT due to leak in primary pipe and encasement	Corrosion of inner and outer pipe	F3	S2	D16	19A
B-3-b	XS-07-FLOW06	Liquid radioactive waste transferred out of DCRT	Release of radioactive waste to soil from transfer pipe out of 244-TX-DCRT due to leak in primary pipe and encasement	Water hammer causes failure of primary pipe and encasement	F3	S2	D17	19B
ANALYZED ACCIDENT: Spray Leak in Structure or from Overground Waste Transfer Lines								
B-1-a	XS-06-FLOW02	DCRT waste being transferred to 102-SY	Release of liquid radioactive waste from DCRT transfer piping to Tank 241-SY-102 due to spray leak in DCRT pump pit	Pipe failure in DCRT pump pit causing spray leak	F2	S3	D12	20
ANALYZED ACCIDENT: Spray Leak from Underground Waste Transfer Lines								
B-1-a	EE-16	Material leaked from transfer line	Release of radioactive and hazardous material from transfer line spray leak due to excavation error	Excavation into waste transfer line during a transfer	F3	S3	D22	21

Table B-1. Analyzed Accidents. (3 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	BIO Acc
ANALYZED ACCIDENT: Natural Phenomena - Seismic								
B-1-a	NP-07	Multiple tanks and ventilation systems inventories, 204-AR tanker spill	Radioactive and hazardous material releases from tanks and ventilation systems due to seismic event	Earthquake collapses domes	F1	S3	D18	25

CPS = criticality prevention specifications.
DCRT = double-contained receiver tank.
DST = double-shell tank.
HEPA = high-efficiency particulate air (filter).
MISF = miscellaneous inactive storage facility.
NC = no controls.
SST = single-shell tank.

This page intentionally left blank.

Table B-2. Analyzed Accidents and the Represented Hazardous Conditions. (25 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	BIO Acc
ANALYZED ACCIDENT: Nuclear Criticality								
A-1-a	I-PFP-1-AGT-A	Fission product gases and aerosols from receiver tank.	Release of fission product gases and aerosols from receiver tank due to: Potential for solids to collect in D-5. If mixed later, potential for composition of next batch to exceed Criticality Prevention Specifications (CPS). Potential "Criticality Issue."	Human Error or Agitator fails results in criticality	F3	S2	A05	01
HAZARDOUS CONDITIONS								
A-1-a	RCSTS-01-FLOW02	Fissile material in waste Tank 241-SY-102	Release of radioactive aerosols and entrained solids to the atmosphere from Tank 241-SY-102 due to criticality.	Mistransfer of material containing organic extractant from east area via the supernate piping route	F1	S2	A01	01X
ANALYZED ACCIDENT: HEPA Filter Failure - Exposure to High Temperature or Pressure								
A-1-a	106C-10J	Tank atmosphere and surface contamination on HEPA filters	Release of radioactive and/or hazardous material from Tank 241-C-106 tank due to tank structural damage, HEPA damage caused by high temperature	Fire in or around ventilation system	F2	S2	B09	02A
HAZARDOUS CONDITIONS								
C-1-c	RCSTS-08-FILTER01*	Residual contamination in Diversion Box 6241-A	Release of residual contamination from Diversion Box 6241-A due to failure of inlet HEPA filter.	Tornado or high winds across inlet	F1	S2	D20	02X
C-1-c	RCSTS-09-FILTER01*	Residual contamination in Vent Station 6241-V	Release of residual contamination from Vent Station 6241-V due to failure of inlet HEPA filter.	Tornado or high winds across inlet	F1	S2	D20	02X
ANALYZED ACCIDENT: Unfiltered Release								
B-1-a	114SX-04,c.2.a	Radioactive aerosols contained in the tank headspace	Radioactive aerosols released from Tank 241-SX-114 head space to atmosphere due to exhauster HEPA filter seal failure	HEPA filter seal failure	F3	S2	D07	02B
HAZARDOUS CONDITIONS								
C-1-c	RCSTS-08-FILTER02*	Residual contamination in Diversion Box 6241-A	Release of residual contamination from Diversion Box 6241-A due to failure of inlet HEPA filter.	HEPA filter structural failure or seal failure	F3	S2	D12	02X

Table B-2. Analyzed Accidents and the Represented Hazardous Conditions. (25 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	BIO Acc
C-1-c	RCSTS-09-FILTER02*	Residual contamination in Vent Station 6241-V	Release of residual contamination from Vent Station 6241-V due to failure of inlet HEPA filter.	HEPA filter structural failure or seal failure	F3	S2	D12	02X
			ANALYZED ACCIDENT: Fire in Contaminated Area					
A-1-a	CRN-05	Pits and risers inventory	Release of radioactive and/or toxic materials from pits and risers due to fuel tank fire in crane or support vehicle (see In-Tank Equipment Installation for tank fires)	Human error in positioning crane load	F3	S2	B26	03
			HAZARDOUS CONDITIONS					
B-1-a	RCSTS-03-TEMP01*	Residual contamination in valve pit	Release of radioactive material to the atmosphere from the SY valve pit due to fire in pit.	Fire in the pit caused by maintenance or electrical problem	F2	S2	D09	03X
			ANALYZED ACCIDENT: Subsurface Leak Remaining Subsurface					
B-3-b	102S-01.b3	Radioactive/hazardous material contained in pumpable liquids from Tank 241-S-102.	Radioactive liquid released to the soil subsurface from leaks in transfer Lines SL-140, SN-242. (Plume)	Line leak during salt well pumping (corrosion)	F3	S2	D12	07
			HAZARDOUS CONDITIONS					
C-3-b	RCSTS-10/11-INTEG02b*	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to the soil subsurface from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to corrosion	F2	S2	D16	07X
C-3-b	RCSTS-10/11-INTEG05b*	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to the soil subsurface from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to unrecognized material flaw	F2	S2	D12	07X
C-3-b	RCSTS-10/11-PRES01b*	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to the soil subsurface from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to water hammer	F3	S2	D17	07X
C-3-b	RCSTS-12/13-INTEG02b*	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to the soil subsurface from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to corrosion	F2	S2	D16	07X

Table B-2. Analyzed Accidents and the Represented Hazardous Conditions. (25 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	BIO Acc
C-3-b	RCSTS-12/13-INTEG05b*	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to the soil subsurface from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to unrecognized material flaw	F2	S2	D12	07X
C-3-b	RCSTS-12/13-PRES01b*	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to the soil subsurface from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to steam hammer caused by loss of flushwater flow to steam mixing chamber in east area	F3	S2	D26	07X
ANALYZED ACCIDENT: Caustic Spray Leak								
B-1-a	107AN-02-PRES	Contents of caustic truck	Release of caustic aerosol from caustic truck transfer piping due to spray leak	Piping/hose leak initiated by various causes	F3	S2	D12	09
HAZARDOUS CONDITIONS								
B-1-a	RCSTS-2FS-FLOW01	Caustic water based solution	Release of caustic solution spray to the atmosphere from the water flush system due to a transfer line break.	Line break (upstream of flush pump) due to structural failure	F2	S2	D26	09X
B-1-a	RCSTS-2FS-FLOW02	Caustic water based solution	Release of caustic solution spray to the atmosphere from the water flush system due to a transfer line break.	Line break (downstream of flush pump) due to structural failure	F2	S2	D26	09X
B-1-a	RCSTS-2FS-FLOW03	Caustic water based solution	Release of caustic solution spray to the atmosphere from the water flush system due to a transfer line break.	Line plug - before heaters due to debris buildup causing a pressure buildup and failure of line	F2	S2	D26	09X
B-1-a	RCSTS-2FS-FLOW04	Caustic water based solution	Release of caustic solution spray to the atmosphere from the water flush system due to a transfer line break.	Line plug - after heaters due to debris buildup causing pressure buildup at the heater and resulting in heater pipe failure	F2	S2	D26	09X
B-1-a	RCSTS-2FS-FLOW05	Caustic water based solution	Release of caustic solution spray to the atmosphere from the water flush system due to a relief valve failure.	Caustic injection pressure relief valve failure	F3	S2	D12	09X
B-1-a	RCSTS-2FS-FLOW07	Caustic water based solution	Release of caustic solution spray to the atmosphere from the water flush system due to a transfer line break.	Flush line break due to structural failure	F2	S2	D26	09X
B-1-a	RCSTS-2FS-PRES01	Caustic water based solution	Release of caustic solution spray to the atmosphere from the water flush system due line plug.	Flush line plug - before heaters due to debris buildup causing a pressure buildup and failure of line	F2	S2	D26	09X

Table B-2. Analyzed Accidents and the Represented Hazardous Conditions. (25 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	BIO Acc
B-1-a	RCSTS-2FS-PRES02	Caustic water based solution	Release of caustic solution spray to the atmosphere from the water flush system due to a line plug.	Flush line plug - after heaters due to debris buildup causing pressure buildup at the heater and resulting in heater pipe failure	F2	S2	D26	09X
B-1-a	RCSTS-2FS-PRES03	Caustic water based solution	Release of caustic solution spray to the atmosphere from the water flush system due to a line break.	Flush line break due to structural failure	F2	S2	D26	09X
B-1-a	RCSTS-2FS-TEMP01	Caustic water based solution	Release of caustic solution spray to the atmosphere from the water flush system due to a line plug.	Flush line plug - before heaters due to debris buildup causing a pressure buildup and failure of line	F2	S2	D26	09X
B-1-a	RCSTS-2FS-TEMP02	Caustic water based solution	Release of caustic solution spray to the atmosphere from the water flush system due to freezing conditions.	Freezing weather with loss of heat trace function	F2	S2	D24	09X
B-1-a	RCSTS-4FS-FLOW03	Concentrated caustic	Release of caustic to the atmosphere from the caustic system due to pressure relief valve failing open.	Pressure relief valve fails open	F2	S2	D12	09X
B-1-a	RCSTS-4FS-FLOW04	Concentrated caustic	Release of caustic to the atmosphere from the caustic system due to over pressurization of line and failure of pressure relief valve to open.	Back pressure valve fails in closed position	F2	S2	D12	09X
B-1-a	RCSTS-4FS-FLOW05	Concentrated caustic	Release of caustic to the atmosphere from the caustic system due to line failure in chemical injection package.	Line failure/leak due to structural failure	F2	S2	D19	09X
B-1-a	RCSTS-4FS-FLOW06	Concentrated caustic	Release of caustic to the atmosphere from the caustic system due to a caustic system drain valve leak.	Caustic drain valve leak	F2	S2	D12	09X
B-1-a	RCSTS-4FS-PRES/TEMP01	Concentrated caustic	Release of caustic to the atmosphere from the caustic system due to pressure relief valve failing open.	Pressure relief valve fails open on caustic injection system.	F2	S2	D06	09X
B-1-a	RCSTS-4FS-PRES/TEMP02	Concentrated caustic	Release of caustic to the atmosphere from the caustic system due to pressure relief valve failing in closed position and rupture of line.	Back pressure relief valve fails in closed position.	F3	S2	D12	09X
B-1-a	RCSTS-5FS-FLOW01	Caustic water based solution	Release of caustic to the atmosphere from caustic line due to a line break.	Line break due to structural failure.	F2	S2	D19	09X

Table B-2. Analyzed Accidents and the Represented Hazardous Conditions. (25 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	BIO Acc
B-1-a	RCSTS-5FS-FLOW02	Caustic water based solution	Release of caustic to the atmosphere from caustic line due to a line break.	Line plug due to debris buildup causing pressure buildup resulting in pipe failure.	F2	S2	D19	09X
ANALYZED ACCIDENT: Mixing of Incompatible Material - Toxic Vapor Generation								
C-1-a	XS-26-PRES XS-26-TEMP	DST vapor/aerosols	Release of toxic vapors from Tank 241-SY-102 due to chemical reaction	Mistransfer of incompatible waste causes chemical reaction	F3	S2	E06	11
HAZARDOUS CONDITIONS								
A-1-a	RCSTS-01-FLOW05	Ammonia liberated from mixing waste with a limited number of drums of relatively dilute caustic	Release of ammonia to atmosphere from a fire or a gas release resulting in an explosion due to addition of inadequately diluted caustic.	Human error	F2	S3	D01	11X
ANALYZED ACCIDENT: Mixing of Incompatible Material - Tank Pressurization								
B-1-a	I-222S-1-RXN-A	Aerosols and/or toxic vapors from receiver tank	Release of aerosols and/or toxic vapors from receiver tank due adverse chemical reactions from incompatible waste.	Transfer of incompatible waste	F3	S2	D01	12
HAZARDOUS CONDITIONS								
A-1-a	RCSTS-01-FLOW04	Amount of reactive chemicals in waste transferred (20,00 to 1,000,000 gallons)	Release of radioactive aerosols/entrained solids and/or toxic gases to the atmosphere from Tank 241-SY-102 due to chemical reaction.	Mistransfer of incompatible material from east area via the supernate piping route.	F2	S3	D01	12X
ANALYZED ACCIDENT: Flammable Gas Deflagrations								
A-1-a	ITK-10-b	DST tank inventory	Release of radioactive material from in-tank fire or explosion due to intrusive activity (Dome Collapse)	Spark from equipment or tools	F3	S3	B04	14A
A-1-a	XS-01-FLOW03	SST and DCRT tank contents	Release of liquids, solids, and/or vapors from single shell tank due to dome collapse and DCRT pressurization caused by flammable gas explosion/fire propagating from DCRT to single shell tank	Pipeline connecting single shell tank and DCRT fills with flammable gas; loss of ventilation flow in DCRT so that a flammable gas atmosphere is ignited by the ventilation outlet heater	F2	S3	B07	14B
HAZARDOUS CONDITIONS								

Table B-2. Analyzed Accidents and the Represented Hazardous Conditions. (25 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	BIO Acc
B-1-a	RCSTS-03-INTEG01	Aerosol fraction of supernate or slurry spill created by fire or explosion	Release of radioactive aerosols to the atmosphere from the SY valve pit due to fire or explosion of flammable gas.	Fire or explosion in the valve pit caused by buildup of flammable gas because of spill of supernate or slurry	F2	S2	B08	14X
B-1-a	RCSTS-03-INTEG02	Aerosol fraction of slurry spill created by fire or explosion	Release of radioactive aerosols to the atmosphere from the SY valve pit due to fire or explosion of flammable gas.	Fire or explosion due to leakage of flammable gas due to pipe breach in slurry line caused by gas release from slurry	F2	S2	B08	14X
C-2-b	RCSTS-08-INTEG03	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Flammable gas explosion from release of trapped flammable gas within pipe combined with ignition source	F2	S2	B08	14X
A-1-a	RCSTS-08-INTEG12	Aerosol fraction of supernate spill	Release of radioactive aerosols to the atmosphere from the 6241-A diversion box due to fire or explosion of flammable gas.	Fire or explosion in the diversion box caused by buildup of flammable gas because of spill of supernate to diversion box sump	F2	S3	B08	14X
C-2-b	RCSTS-09-INTEG05	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	Flammable gas explosion from release of trapped flammable gas within pipe combined with ignition source	F2	S2	B08	14X
B-1-a	RCSTS-09-INTEG06	Aerosol fraction of supernate spill	Release of radioactive aerosols to the atmosphere from the vent station due to fire or explosion of flammable gas.	Fire or explosion in the vent station caused by buildup of flammable gas because of spill of supernate or slurry to vent station	F2	S2	B08	14X
B-1-a	RCSTS-09-INTEG14	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from vent station due to piping system leak.	Flammable gas explosion from release of trapped flammable gas within pipe combined with ignition source	F2	S3	B08	14X
C-3-b	RCSTS-18/19-INTEG05	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to flammable gas explosion in primary piping	F2	S2	B08	14X
B-1-a	RCSTS-24-INTEG03	Aerosol fraction of supernate or slurry spill created by fire or explosion	Release of radioactive aerosols to the atmosphere from the lift station due to fire or explosion of flammable gas.	Fire or explosion in the lift station caused by buildup of flammable gas because of spill of supernate or slurry	F2	S2	B08	14X
B-1-a	RCSTS-24-INTEG06	Aerosol fraction of slurry spill created by fire or explosion	Release of radioactive aerosols to the atmosphere from the lift station due to fire or explosion of flammable gas.	Fire or explosion due to leakage of flammable gas due to pipe breach in slurry line caused by gas release from slurry	F2	S2	B08	14X

Table B-2. Analyzed Accidents and the Represented Hazardous Conditions. (25 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	BIO Acc
ANALYZED ACCIDENT: Surface Leak Resulting in Pool								
C-2-b	W058-PRES01	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (Pool)	Water hammer plus mitigative features failure	F3	S2	D17	18
HAZARDOUS CONDITIONS								
C-2-b	RCSTS-01-FLOW03	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to the soil surface from overflow of Tank 241-SY-102 tank due to mistransfer.	Mistransfer of material from east area via the supernate piping route.	F3	S2	D06	18X
C-2-b	RCSTS-03-FLOW/INTEG01	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Failure of jumper due to misalignment (human error).	F3	S2	E06	18X
C-2-b	RCSTS-03-FLOW/INTEG02a	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Failure of jumper due to misalignment (human error)	F3	S2	E06	18X
C-2-b	RCSTS-03-FLOW/INTEG02b	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Failure of jumper due to gasket failure	F2	S2	D12	18X
C-2-b	RCSTS-03-FLOW/INTEG02c	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Failure of jumper due to corrosion	F2	S2	D12	18X
C-2-b	RCSTS-03-FLOW02	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Computer failure or human error causing misrouting of material when flow path is not completely connected	F3	S2	E06	18X
C-2-b	RCSTS-03-FLOW03	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	External leak of valve or valves to the valve pit	F2	S2	D12	18X
C-2-b	RCSTS-03-FLOW04	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Computer failure or human error causing misrouting of material when flow path is not completely connected	F3	S2	E06	18X
C-2-b	RCSTS-03-FLOW05	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	External leak of valve or valves to the valve pit	F2	S2	D12	18X

Table B-2. Analyzed Accidents and the Represented Hazardous Conditions. (25 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	BIO Acc
C-2-b	RCSTS-03-INTEG05	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak.	External event (airplane crash, etc)	F0	S2	D23	18X
C-2-b	RCSTS-03-INTEG07	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak.	External event (airplane crash, etc)	F0	S2	D23	18X
C-2-b	RCSTS-03-PRES02	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Water hammer	F3	S2	D17	18X
C-2-b	RCSTS-03-PRES03	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Water hammer	F3	S2	D17	18X
C-2-b	RCSTS-08-FLOW03	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to soil surface from overflow of diversion box due to piping system leak.	External leak of valve or valves to the diversion box	F3	S2	D12	18X
C-2-b	RCSTS-08-FLOW04	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	External leak of valve or valves to the diversion box	F3	S2	D12	18X
C-2-b	RCSTS-08-FLOW05	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to soil surface from overflow of diversion box due to piping system leak.	Backflow of supernate to sump pump line, through sump pump and onto diversion box floor	F3	S2	D06	18X
C-2-b	RCSTS-08-INTEG01	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Failure of piping due to corrosion	F2	S2	D16	18X
C-2-b	RCSTS-08-INTEG02	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	External event (airplane crash, etc)	F0	S2	D23	18X
C-2-b	RCSTS-08-INTEG04	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Failure of piping due to material defect	F2	S2	D12	18X
C-2-b	RCSTS-08-INTEG05	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Slurry pump overspeed causing catastrophic failure of pump with missiles damaging pipe	F1	S2	D26	18X

Failure of primary and encasement piping due to seismic event	F1	S2	D18	25X

Table B-2. Analyzed Accidents and the Represented Hazardous Conditions. (25 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	BIO Acc
C-2-b	RCSTS-08-INTEG06	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Seismic event	F1	S2	D18	25X
C-2-b	RCSTS-08-INTEG07	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to soil surface from overflow of diversion box due to piping system leak.	Seismic event	F1	S2	D18	25X
B-1-a	RCSTS-08-INTEG15	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	Seismic event	F1	S3	D18	25X
B-1-a	RCSTS-08-INTEG16	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from diversion box due to piping system leak.	Seismic event	F1	S3	D18	25X
C-2-b	RCSTS-09-INTEG09	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	Seismic event	F1	S2	D18	25X
C-2-b	RCSTS-09-INTEG10	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	Seismic event	F1	S2	D18	25X
B-1-a	RCSTS-09-INTEG16	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from vent station due to piping system leak.	Seismic event	F1	S3	D18	25X
B-1-a	RCSTS-09-INTEG17	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from vent station due to piping system leak.	Seismic event	F1	S3	D18	25X
C-3-b	RCSTS-10/11-INTEG06	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to seismic event	F1	S2	D18	25X
C-3-b	RCSTS-12/13-INTEG06	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to the soil from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to seismic event	F1	S2	D18	25X

Table B-2. Analyzed Accidents and the Represented Hazardous Conditions. (25 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Initial Freq NC	Initial Safety Cons NC	Cause Grp	BIO Acc
C-2-b	RCSTS-15/16-INTEG04	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and the diversion box due to piping system leak.	Failure of primary and encasement piping due to seismic event	F1	S2	D18	25X
C-3-b	RCSTS-18/19-INTEG07	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to seismic event	F1	S2	D18	25X
C-2-b	RCSTS-24-INTEG04	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to soil surface from overflow of lift station due to piping system leak.	Seismic event	F1	S2	D18	25X
C-2-b	RCSTS-24-INTEG05	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	Seismic event	F1	S2	D18	25X
B-1-a	RCSTS-24-INTEG09	Amount of slurry transferrable through a limited size orifice	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from lift station due to piping system leak.	Seismic event	F1	S3	D18	25X
B-1-a	RCSTS-24-INTEG10	Amount of supernate transferrable through a limited size orifice	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from lift station due to piping system leak.	Seismic event	F1	S3	D18	25X

CPS = criticality prevention specifications.
DCRT = double-contained receiver tank.
DST = double-shell tank.
HEPA = high-efficiency particulate air (filter).
MISF = miscellaneous inactive storage facility.
NC = no controls.
SST = single-shell tank.

Table C-1. Hazardous Conditions With Potential Significant Offsite Consequences (S3). (5 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-01-FLOW04	Release of radioactive aerosols/entrained solids and/or toxic gases to the atmosphere from Tank 241-SY-102 due to chemical reaction.	Mistransfer of incompatible material from east area via the supernate piping route.	F2	E3
RCSTS-01-FLOW05	Release of ammonia to atmosphere from a fire or a gas release resulting in an explosion due to addition of inadequately diluted caustic.	Human error	F2	E3
RCSTS-03-FLOW/INTEG03a	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak.	Failure of jumper due to misalignment (human error)	F2	E3
RCSTS-03-FLOW/INTEG03b	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak.	Failure of jumper due to gasket failure	F2	E3
RCSTS-03-FLOW/INTEG03c	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak.	Failure of jumper due to corrosion	F2	E3
RCSTS-03-FLOW/INTEG04a	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak.	Failure of jumper due to misalignment (human error)	F2	E3
RCSTS-03-FLOW/INTEG04b	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak.	Failure of jumper due to gasket failure	F2	E3
RCSTS-03-FLOW/INTEG04c	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak.	Failure of jumper due to corrosion	F2	E3
RCSTS-03-FLOW06	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak.	Computer failure or human error causing misrouting of material when flow path is not completely connected	F2	E3
RCSTS-03-FLOW07	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak.	External leak of valve or valves to the valve pit	F2	E3
RCSTS-03-FLOW08	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak.	Computer failure or human error causing misrouting of material when flow path is not completely connected	F2	E3
RCSTS-03-INTEG03	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak.	External leak of valve or valves to the valve pit	F2	E3

Table C-1. Hazardous Conditions With Potential Significant Offsite Consequences (S3). (5 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-03-INTEG04	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak.	Seismic event	F1	E3
RCSTS-03-INTEG09	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak.	External event (airplane crash, etc)	FO	E3
RCSTS-03-INTEG10	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak.	Seismic event	F1	E3
RCSTS-03-INTEG11	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak.	External event (airplane crash, etc)	FO	E3
RCSTS-08-FLOW08	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	External leak of valve or valves to the diversion box	F3	E3
RCSTS-08-INTEG08	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	Failure of piping due to corrosion	F2	E3
RCSTS-08-INTEG09	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	External event (airplane crash, etc)	FO	E3
RCSTS-08-INTEG10	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from diversion box due to piping system leak.	External event (airplane crash, etc)	FO	E3
RCSTS-08-INTEG11	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	Flammable gas explosion from release of trapped flammable gas within pipe combined with ignition source	F2	E3
RCSTS-08-INTEG12	Release of radioactive aerosols to the atmosphere from the 6241-A diversion box due to fire or explosion of flammable gas.	Fire or explosion in the diversion box caused by buildup of flammable gas because of spill of supernate to diversion box sump	F2	E3
RCSTS-08-INTEG13	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	Failure of piping due to material defect	F2	E3
RCSTS-08-INTEG14	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	Slurry pump overspeed causing catastrophic failure of pump with missiles damaging pipe and challenging diversion box confinement	F1	E3

Table C-1. Hazardous Conditions With Potential Significant Offsite Consequences (S3). (5 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-08-INTEG15	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	Seismic event	F1	E3
RCSTS-08-INTEG16	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from diversion box due to piping system leak.	Seismic event	F1	E3
RCSTS-08-PRES04	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	Water hammer	F3	E3
RCSTS-08-PRES05	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from diversion box due to piping system leak.	Water hammer	F3	E3
RCSTS-08-TEMP02	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	Freezing of piping within the diversion box due to cold temperatures caused by running the exhauster	F2	E3
RCSTS-08-TEMP03	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from diversion box due to piping system leak.	Freezing of piping within the diversion box due to cold temperatures caused by running the exhauster	F2	E3
RCSTS-09-FLOW10	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from vent station due to piping system leak.	External leak of valve or valves to the vent station	F3	E3
RCSTS-09-FLOW11	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	Backflow of supernate to sump pump line, through sump pump and onto vent station floor	F3	E3
RCSTS-09-INTEG11	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from vent station due to piping system leak.	Failure of piping due to corrosion	F2	E3
RCSTS-09-INTEG12	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from vent station due to piping system leak.	External event (airplane crash, etc)	F0	E3
RCSTS-09-INTEG13	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from vent station due to piping system leak.	External event (airplane crash, etc)	F0	E3
RCSTS-09-INTEG14	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from vent station due to piping system leak.	Flammable gas explosion from release of trapped flammable gas within pipe combined with ignition source	F2	E3
RCSTS-09-INTEG15	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from vent station due to piping system leak.	Failure of piping due to material defect	F2	E3

Table C-1. Hazardous Conditions With Potential Significant Offsite Consequences (S3). (5 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-09-INTEG16	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from vent station due to piping system leak.	Seismic event	F1	E3
RCSTS-09-INTEG17	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from vent station due to piping system leak.	Seismic event	F1	E3
RCSTS-09-PRES04	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from vent station due to piping system leak.	Water hammer	F3	E3
RCSTS-09-PRES05	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from vent station due to piping system leak.	Water hammer	F3	E3
RCSTS-09-TEMP03	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from vent station due to piping system leak.	Freezing of piping within the vent station due to cold temperatures caused by running the exhauster	F2	E3
RCSTS-09-TEMP04	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from vent station due to piping system leak.	Freezing of piping within the vent station due to cold temperatures caused by running the exhauster	F2	E3
RCSTS-22-PRESS01*	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from 244-A Lift Station due to piping system leak.	Dead heading of flow through the 244-A Lift Station with failure of PRV and development of crack in downstream piping	F3	E3
RCSTS-22-PRESS02*	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from 244-A Lift Station due to piping system leak.	Dead heading of flow through the 244-A Lift Station with failure of PRV and development of crack in downstream piping	F3	E3
RCSTS-24-FLOW/INTEG07	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from lift station due to piping system leak.	Failure of jumper due to corrosion	F2	E3
RCSTS-24-FLOW/INTEG08	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from lift station due to piping system leak.	Failure of jumper due to corrosion	F2	E3
RCSTS-24-FLOW/INTEG09	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from lift station due to piping system leak.	Failure of jumper due to gasket failure	F3	E3
RCSTS-24-FLOW/INTEG10	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from lift station due to piping system leak.	Failure of jumper due to gasket failure	F3	E3

Table C-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2). (11 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-01-FLOW02	Release of radioactive aerosols and entrained solids to the atmosphere from Tank 241-SY-102 due to criticality.	Mistransfer of material containing organic extractant from east area via the supernate piping route	F1	E3
RCSTS-01-FLOW03	Release of radioactive supernate to the soil surface from overflow of Tank 241-SY-102 due to mistransfer.	Mistransfer of material from east area via the supernate piping route.	F3	E2
RCSTS-03-FLOW/INTEG01	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Failure of jumper due to misalignment (human error).	F3	E2
RCSTS-03-FLOW/INTEG02a	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Failure of jumper due to misalignment (human error)	F3	E2
RCSTS-03-FLOW/INTEG02b	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Failure of jumper due to gasket failure	F2	E2
RCSTS-03-FLOW/INTEG02c	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Failure of jumper due to corrosion	F2	E2
RCSTS-03-FLOW02	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Computer failure or human error causing misrouting of material when flow path is not completely connected	F3	E2
RCSTS-03-FLOW03	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	External leak of valve or valves to the valve pit	F2	E2
RCSTS-03-FLOW04	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Computer failure or human error causing misrouting of material when flow path is not completely connected	F3	E2
RCSTS-03-FLOW05	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	External leak of valve or valves to the valve pit	F2	E2
RCSTS-03-INTEG01	Release of radioactive aerosols to the atmosphere from the SY valve pit due to fire or explosion of flammable gas.	Fire or explosion in the valve pit caused by buildup of flammable gas because of spill of supernate or slurry	F2	E2
RCSTS-03-INTEG02	Release of radioactive aerosols to the atmosphere from the SY valve pit due to fire or explosion of flammable gas.	Fire or explosion due to leakage of flammable gas due to pipe breach in slurry line caused by gas release from slurry	F2	E2
RCSTS-03-INTEG05	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak.	External event (airplane crash, etc)	F0	E2
RCSTS-03-INTEG06	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak.	Seismic event	F1	E2
RCSTS-03-INTEG07	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak.	External event (airplane crash, etc)	F0	E2
RCSTS-03-INTEG08	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Seismic event	F1	E2

Table C-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2). (11 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-03-PRES02	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Water hammer	F3	E2
RCSTS-03-PRES03	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Water hammer	F3	E2
RCSTS-03-TEMP01*	Release of radioactive material to the atmosphere from the SY valve pit due to fire in pit.	Fire in the pit caused by maintenance or electrical problem	F2	E1
RCSTS-04/05-INTEG01a	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to corrosion	F2	E2
RCSTS-04/05-INTEG01b	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to unrecognized material flaw	F2	E2
RCSTS-04/05-INTEG02	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to external event (airplane crash, volcanism, etc)	F0	E2
RCSTS-04/05-INTEG03	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and the diversion box due to piping system leak.	Failure of primary and encasement piping due to external event (excavation accident)	F3	E2
RCSTS-04/05-INTEG04	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to external event (undermining from broken fluid transfer lines in vicinity)	F2	E2
RCSTS-04/05-INTEG05	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to seismic event	F1	E2
RCSTS-04/05-TEMP01	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to freezing	F1	E2
RCSTS-08-FILTER01*	Release of residual contamination from Diversion Box 6241-A due to failure of inlet HEPA filter.	Tornado or high winds across inlet	F1	E1
RCSTS-08-FILTER02*	Release of residual contamination from Diversion Box 6241-A due to failure of inlet HEPA filter.	HEPA filter structural failure or seal failure	F3	E1
RCSTS-08-FLOW03	Release of radioactive supernate to soil surface from overflow of diversion box due to piping system leak.	External leak of valve or valves to the diversion box	F3	E2
RCSTS-08-FLOW04	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	External leak of valve or valves to the diversion box	F3	E2

Table C-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2). (11 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-08-FLOW05	Release of radioactive supernate to soil surface from overflow of diversion box due to piping system leak.	Backflow of supernate to sump pump line, through sump pump and onto diversion box floor	F3	E2
RCSTS-08-INTEG01	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Failure of piping due to corrosion	F2	E2
RCSTS-08-INTEG02	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	External event (airplane crash, etc)	F0	E2
RCSTS-08-INTEG03	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Flammable gas explosion from release of trapped flammable gas within pipe combined with ignition source	F2	E2
RCSTS-08-INTEG04	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Failure of piping due to material defect	F2	E2
RCSTS-08-INTEG05	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Slurry pump overspeed causing catastrophic failure of pump with missiles damaging pipe	F1	E2
RCSTS-08-INTEG06	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Seismic event	F1	E2
RCSTS-08-INTEG07	Release of radioactive supernate to soil surface from overflow of diversion box due to piping system leak.	Seismic event	F1	E2
RCSTS-08-INTEG17a	Release of radioactive supernate to the soil surface from overflow of diversion box due to piping system leak.	Failure of piping due to corrosion plus mitigative features failure	F2	E2
RCSTS-08-INTEG17b	Release of radioactive supernate to the soil surface from overflow of diversion box due to piping system leak.	Failure of piping due to unrecognized material flaw	F2	E2
RCSTS-08-INTEG18	Release of radioactive supernate to the soil surface from overflow of diversion box due to piping system leak.	Failure of piping due to external event (airplane crash, volcanism, etc)	F0	E2
RCSTS-08-PRES02	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Water hammer	F3	E2
RCSTS-08-PRES03	Release of radioactive supernate to soil surface from overflow of diversion box due to piping system leak.	Water hammer	F3	E2
RCSTS-08-TEMP01	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Freezing of piping within the diversion box due to cold temperatures caused by running the exhauster	F2	E2
RCSTS-08-TEMP04	Release of radioactive supernate to the soil surface from overflow of diversion box due to piping system leak.	Failure of piping due to freezing	F1	E2
RCSTS-09-FILTER01*	Release of residual contamination from Vent Station 6241-V due to failure of inlet HEPA filter.	Tornado or high winds across inlet	F1	E1

Table C-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2). (11 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-09-FILTER02*	Release of residual contamination from Vent Station 6241-V due to failure of inlet HEPA filter.	HEPA filter structural failure or seal failure	F3	E1
RCSTS-09-FLOW01	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	Flow of slurry to vent station due to incomplete closing of vent valves after venting	F3	E2
RCSTS-09-FLOW04	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	External leak of valve or valves to the vent station	F3	E2
RCSTS-09-FLOW05	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	External leak of valve or valves to the vent station	F3	E2
RCSTS-09-FLOW06	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	Flow of supernate to vent station due to incomplete closing of vent valves after venting	F3	E2
RCSTS-09-FLOW07	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	Backflow of supernate to sump pump line, through sump pump and onto vent station floor	F3	E2
RCSTS-09-INTEG01	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	Failure of piping due to corrosion	F2	E2
RCSTS-09-INTEG02	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	Failure of piping due to corrosion	F2	E2
RCSTS-09-INTEG03	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	External event (airplane crash, etc)	F0	E2
RCSTS-09-INTEG04	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	External event (airplane crash, etc)	F0	E2
RCSTS-09-INTEG05	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	Flammable gas explosion from release of trapped flammable gas within pipe combined with ignition source	F2	E2
RCSTS-09-INTEG06	Release of radioactive aerosols to the atmosphere from the vent station due to fire or explosion of flammable gas.	Fire or explosion in the vent station caused by buildup of flammable gas because of spill of supernate or slurry to vent station	F2	E2
RCSTS-09-INTEG07	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	Failure of piping due to material defect	F2	E2
RCSTS-09-INTEG08	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	Failure of piping due to material defect	F2	E2
RCSTS-09-INTEG09	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	Seismic event	F1	E2
RCSTS-09-INTEG10	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	Seismic event	F1	E2

Table C-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2). (11 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-09-PRES01	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	Water hammer	F3	E2
RCSTS-09-PRES02	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	Water hammer	F3	E2
RCSTS-09-TEMP01	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	Freezing of piping within the vent station due to cold temperatures caused by running the exhauster	F2	E2
RCSTS-09-TEMP02	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	Freezing of piping within the vent station due to cold temperatures caused by running the exhauster	F2	E2
RCSTS-10/11-INTEG01	Release of radioactive supernate to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to external event (undermining from broken fluid transfer lines in vicinity)	F3	E2
RCSTS-10/11-INTEG02a	Release of radioactive supernate to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to corrosion	F2	E2
RCSTS-10/11-INTEG02b*	Release of radioactive supernate to the soil subsurface from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to corrosion	F2	E2
RCSTS-10/11-INTEG03a	Release of radioactive supernate to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to external event (excavation accident)	F3	E2
RCSTS-10/11-INTEG03b*	Release of radioactive supernate to the atmosphere from the underground piping between the diversion box and the vent station due to excavation of piping system and subsequent leak.	Failure of primary and encasement piping due to external event (excavation accident)	F3	E2
RCSTS-10/11-INTEG04	Release of radioactive supernate to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to external event (airplane crash, volcanism etc)	F0	E2
RCSTS-10/11-INTEG05a	Release of radioactive supernate to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to unrecognized material flaw	F2	E2
RCSTS-10/11-INTEG05b*	Release of radioactive supernate to the soil subsurface from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to unrecognized material flaw	F2	E2
RCSTS-10/11-INTEG06	Release of radioactive supernate to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to seismic event	F1	E2

Table C-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2). (11 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-10/11-PRES01a	Release of radioactive supernate to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to water hammer	F3	E2
RCSTS-10/11-PRES01b*	Release of radioactive supernate to the soil subsurface from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to water hammer	F3	E2
RCSTS-10/11-TEMP01	Release of radioactive supernate to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary piping and encasement due to freezing	F1	E2
RCSTS-10/11-TEMP02	Release of radioactive supernate to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to thermal stress	F3	E2
RCSTS-12/13-INTEG01	Release of radioactive supernate to the soil from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to external event (undermining from broken fluid transfer lines in vicinity)	F3	E2
RCSTS-12/13-INTEG02a	Release of radioactive supernate to the soil from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to corrosion	F2	E2
RCSTS-12/13-INTEG02b*	Release of radioactive supernate to the soil subsurface from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to corrosion	F2	E2
RCSTS-12/13-INTEG03a	Release of radioactive supernate to the soil from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to external event (excavation accident)	F3	E2
RCSTS-12/13-INTEG03b*	Release of radioactive supernate to the atmosphere from the underground piping between the vent station and the 244-A Lift Station due to excavation of piping system and subsequent leak.	Failure of primary and encasement piping due to external event (excavation accident)	F3	E2
RCSTS-12/13-INTEG04	Release of radioactive supernate to the soil from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to external event (airplane crash, volcanism etc)	F0	E2
RCSTS-12/13-INTEG05a	Release of radioactive supernate to the soil from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to unrecognized material flaw	F2	E2
RCSTS-12/13-INTEG05b*	Release of radioactive supernate to the soil subsurface from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to unrecognized material flaw	F2	E2

Table C-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2). (11 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-12/13-INTEG06	Release of radioactive supernate to the soil from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to seismic event	F1	E2
RCSTS-12/13-PRES01a	Release of radioactive supernate to the soil from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to steam hammer caused by loss of flushwater flow to steam mixing chamber in east	F3	E2
RCSTS-12/13-PRES01b*	Release of radioactive supernate to the soil from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to steam hammer caused by loss of flushwater flow to steam mixing chamber in east area	F3	E2
RCSTS-12/13-PRES02	Release of radioactive supernate to the soil from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to water hammer	F3	E2
RCSTS-12/13-TEMP01	Release of radioactive supernate to the soil from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary piping and encasement due to freezing	F1	E2
RCSTS-12/13-TEMP02	Release of radioactive supernate to the soil from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to thermal stress	F3	E2
RCSTS-15/16-INTEG01a	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to corrosion	F2	E2
RCSTS-15/16-INTEG01b	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to unrecognized material flaw	F2	E2
RCSTS-15/16-INTEG02	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and the diversion box due to piping system leak.	Failure of primary and encasement piping due to external event (excavation accident)	F2	E2
RCSTS-15/16-INTEG03a	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to external event (undermining from broken fluid transfer lines in vicinity)	F3	E2
RCSTS-15/16-INTEG03b	Release of radioactive slurry to the soil surface from overflow of diversion box due to piping system leak.	Failure of piping due to external event (undermining from broken fluid transfer lines in vicinity)	F2	E2
RCSTS-15/16-INTEG04	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and the diversion box due to piping system leak.	Failure of primary and encasement piping due to seismic event	F1	E2

Table C-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2). (11 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-15/16-INTEG05	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to external event (airplane crash, volcanism, etc)	FO	E2
RCSTS-15/16-TEMP01	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to freezing	F1	E2
RCSTS-18/19-INTEG01	Release of radioactive slurry to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to external event (undermining from broken fluid transfer lines in vicinity)	F3	E2
RCSTS-18/19-INTEG02	Release of radioactive slurry to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to corrosion	F2	E2
RCSTS-18/19-INTEG03a	Release of radioactive slurry to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to external event (excavation accident)	F3	E2
RCSTS-18/19-INTEG03b*	Release of radioactive slurry to the atmosphere from the underground piping between the diversion box and the vent station due to excavation of piping system and subsequent leak.	Failure of primary and encasement piping due to external event (excavation accident)	F3	E2
RCSTS-18/19-INTEG04	Release of radioactive slurry to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to external event (airplane crash, volcanism etc)	FO	E2
RCSTS-18/19-INTEG05	Release of radioactive slurry to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to flammable gas explosion in primary piping	F2	E2
RCSTS-18/19-INTEG06	Release of radioactive slurry to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to unrecognized material flaw	F2	E2
RCSTS-18/19-INTEG07	Release of radioactive slurry to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to seismic event	F1	E2
RCSTS-18/19-PRES01	Release of radioactive slurry to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to water hammer	F3	E2
RCSTS-18/19-TEMP01	Release of radioactive slurry to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary piping and encasement due to freezing	F1	E2

Table C-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2). (11 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-18/19-TEMP02	Release of radioactive slurry to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to thermal stress	F3	E2
RCSTS-1FS-LEVEL03	Release of caustic solution and radionuclides to the sump pit from the water flush tank due to over filling of tank.	Overfilling of flush tank from flow of radioactive waste from transfer line. Block valves open, valve limit switch and pressure switch fail and administrative control of raw water block valves fail	F2	E2
RCSTS-22-PRESS03*	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping break.	Dead heading of flow through the 244-A Lift Station with failure of PRV and subsequent downstream pipe failure	F3	E3
RCSTS-22-PRESS04*	Release of radioactive slurry to soil surface from overflow of 244-A Lift Station due to piping break.	Dead heading of flow through the 244-A Lift Station with failure of PRV and subsequent downstream pipe failure	F3	E3
RCSTS-24-FLOW/INTEG01	Release of radioactive slurry to soil surface from overflow of lift station due to piping system leak.	Failure of jumper due to corrosion	F2	E2
RCSTS-24-FLOW/INTEG02	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	Failure of jumper due to corrosion	F2	E2
RCSTS-24-FLOW/INTEG03	Release of radioactive slurry to soil surface from overflow of lift station due to piping system leak.	Failure of jumper due to gasket failure	F3	E2
RCSTS-24-FLOW/INTEG04	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	Failure of jumper due to gasket failure	F3	E2
RCSTS-24-FLOW/INTEG05	Release of radioactive slurry to soil surface from overflow of lift station due to piping system leak.	Failure of jumper due to misalignment	F3	E2
RCSTS-24-FLOW/INTEG06	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	Failure of jumper due to misalignment	F3	E2
RCSTS-24-FLOW01	Release of radioactive slurry to soil surface from overflow of lift station due to piping system leak.	Computer failure or human error causing misrouting of material when flow path is not completely connected	F3	E2
RCSTS-24-FLOW02	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	Computer failure or human error causing misrouting of material when flow path is not completely connected	F3	E2
RCSTS-24-FLOW03	Release of radioactive slurry to soil surface from overflow of lift station due to piping system leak.	External leak of valve or valves to the lift station	F3	E2
RCSTS-24-FLOW04	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	External leak of valve or valves to the lift station	F3	E2
RCSTS-24-INTEG01	Release of radioactive slurry to soil surface from overflow of lift station due to piping system leak.	External event (airplane crash, etc)	F0	E2

Table C-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2). (11 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-24-INTEG02	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	External event (airplane crash, etc)	FO	E2
RCSTS-24-INTEG03	Release of radioactive aerosols to the atmosphere from the lift station due to fire or explosion of flammable gas.	Fire or explosion in the lift station caused by buildup of flammable gas because of spill of supernate or slurry	F2	E2
RCSTS-24-INTEG04	Release of radioactive slurry to soil surface from overflow of lift station due to piping system leak.	Seismic event	F1	E2
RCSTS-24-INTEG05	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	Seismic event	F1	E2
RCSTS-24-INTEG06	Release of radioactive aerosols to the atmosphere from the lift station due to fire or explosion of flammable gas.	Fire or explosion due to leakage of flammable gas due to pipe breach in slurry line caused by gas release from slurry	F2	E2
RCSTS-24-PRES01	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	Steam hammer or thermal stress caused by loss of flushwater flow to steam mixing chamber in east area	F3	E2
RCSTS-24-PRES02	Release of radioactive slurry to soil surface from overflow of lift station due to piping system leak.	Water hammer	F3	E2
RCSTS-24-PRES03	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	Water hammer	F3	E2
RCSTS-2FS-FLOW01	Release of caustic solution spray to the atmosphere from the water flush system due to a transfer line break.	Line break (upstream of flush pump) due to structural failure	F2	E2
RCSTS-2FS-FLOW02	Release of caustic solution spray to the atmosphere from the water flush system due to a transfer line break.	Line break (downstream of flush pump) due to structural failure	F2	E2
RCSTS-2FS-FLOW03	Release of caustic solution spray to the atmosphere from the water flush system due to a transfer line break.	Line plug - before heaters due to debris buildup causing a pressure buildup and failure of line	F2	E2
RCSTS-2FS-FLOW04	Release of caustic solution spray to the atmosphere from the water flush system due to a transfer line break.	Line plug - after heaters due to debris buildup causing pressure buildup at the heater and resulting in heater pipe failure	F2	E2
RCSTS-2FS-FLOW05	Release of caustic solution spray to the atmosphere from the water flush system due to a relief valve failure.	Caustic injection pressure relief valve failure	F3	E2
RCSTS-2FS-FLOW07	Release of caustic solution spray to the atmosphere from the water flush system due to a transfer line break.	Flush line break due to structural failure	F2	E2
RCSTS-2FS-PRES01	Release of caustic solution spray to the atmosphere from the water flush system due line plug.	Flush line plug - before heaters due to debris buildup causing a pressure buildup and failure of line	F2	E2
RCSTS-2FS-PRES02	Release of caustic solution spray to the atmosphere from the water flush system due to a line plug.	Flush line plug - after heaters due to debris buildup causing pressure buildup at the heater and resulting in heater pipe failure	F2	E2

Table C-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2). (11 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-2FS-PRES03	Release of caustic solution spray to the atmosphere from the water flush system due to a line break.	Flush line break due to structural failure	F2	E2
RCSTS-2FS-TEMP01	Release of caustic solution spray to the atmosphere from the water flush system due to a line plug.	Flush line plug - before heaters due to debris buildup causing a pressure buildup and failure of line	F2	E2
RCSTS-2FS-TEMP02	Release of caustic solution spray to the atmosphere from the water flush system due to freezing conditions.	Freezing weather with loss of heat trace function	F2	E2
RCSTS-4FS-FLOW03	Release of caustic to the atmosphere from the caustic system due to pressure relief valve failing open.	Pressure relief valve fails open	F2	E2
RCSTS-4FS-FLOW04	Release of caustic to the atmosphere from the caustic system due to over pressurization of line and failure of pressure relief valve to open.	Back pressure valve fails in closed position	F2	E2
RCSTS-4FS-FLOW05	Release of caustic to the atmosphere from the caustic system due to line failure in chemical injection package.	Line failure/leak due to structural failure	F2	E2
RCSTS-4FS-FLOW06	Release of caustic to the atmosphere from the caustic system due to a caustic system drain valve leak.	Caustic drain valve leak	F2	E2
RCSTS-4FS-PRES/TEMP01	Release of caustic to the atmosphere from the caustic system due to pressure relief valve failing open.	Pressure relief valve fails open on caustic injection system.	F2	E2
RCSTS-4FS-PRES/TEMP02	Release of caustic to the atmosphere from the caustic system due to pressure relief valve failing in closed position and rupture of line.	Back pressure relief valve fails in closed position.	F3	E2
RCSTS-5FS-FLOW01	Release of caustic to the atmosphere from caustic line due to a line break.	Line break due to structural failure.	F2	E2
RCSTS-5FS-FLOW02	Release of caustic to the atmosphere from caustic line due to a line break.	Line plug due to debris buildup causing pressure buildup resulting in pipe failure.	F2	E2

Table C-3. Hazardous Conditions With Potential Significant Worker Consequences (S1). (3 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-01-FLOW01	Release of radioactive slurry or supernate to the soil surface from overflow of the 244-S catch station due to reverse flow.	Reverse flow to 244-S catch station caused by improper valve lineup.	F3	E1
RCSTS-03-FLOW01	Release of radioactive slurry or supernate to the SY flush pit from transfer line due to backflow.	Reverse flow to flush pit caused by improper valving sequence	F3	E1
RCSTS-03-PRES01	Release of radioactive material to atmosphere from SY valve pit due to over-pressurization event in Tank 241-SY-102.	Pressure event in Tank 241-SY-102 with loss of valve pit seal loop water	F3	E1
RCSTS-08-AIR01	Release of radioactive vapors to the diversion box atmosphere from accumulated waste in diversion box due to pipe encasement draining.	Draining of the encasement	F3	E0
RCSTS-08-AIR02	Exposure to chemical vapors and liquids in diversion box due to the spill or leak of chemicals in confined space.	Chemicals brought in for decontamination and maintenance	F3	E0
RCSTS-08-AIR03	Release of radioactive vapors to the diversion box atmosphere due to waste being present in box.	Leak of waste solution	F3	E0
RCSTS-08-AIR04	Release of chemical waste into diversion box from leak of waste solution resulting in worker exposure.	Leak of waste solution	F3	E0
RCSTS-08-OCC01	Worker injury due to welding gas bottle becoming a missile in diversion box.	Damage from welding gas bottle during maintenance activity in diversion box	F3	E0
RCSTS-08-OCC02	Worker discomfort from cold temperatures in diversion box.	Running an exhauster during cold weather	F3	E0
RCSTS-08-RAD01	Release of radioactive material to the diversion box from transfer piping due to encasement draining.	Draining of the encasement	F3	E0
RCSTS-08-RAD02	Release of radioactive material to the diversion box from transfer line due to pipe leak.	Leak of waste solution	F2	E0
RCSTS-08-RAD03	High radiation dose to worker from the diversion box due to the presence of residual radioactive contamination.	Holdup of radionuclides due to trapped radioactive material in pumps or pipes	F3	E0
RCSTS-09-AIR02	Release of radioactive vapors to the vent station atmosphere due to waste being present in station.	Leak of waste solution	F3	E0
RCSTS-09-AIR03	Exposure to chemical vapors and liquids in vent station due to the spill or leak of chemicals.	Chemicals brought in for decontamination and maintenance	F3	E0
RCSTS-09-AIR04	Release of chemical waste into diversion box from leak of waste solution resulting in worker exposure.	Leak of waste solution	F3	E0

Table C-3. Hazardous Conditions With Potential Significant Worker Consequences (S1). (3 sheets)

RCSTS-09-OCC01	Worker injury due to welding gas bottle becoming a missile in vent station.	Damage from welding gas bottle during maintenance activity in vent station	F3	E0
RCSTS-09-OCC02	Worker discomfort from cold temperatures in vent station.	Running an exhauster during cold weather	F3	E0
RCSTS-09-RAD02	Release of radioactive material to the vent station from transfer line due to pipe leak.	Leak of waste solution	F2	E0
RCSTS-09-RAD03	High radiation dose to worker from the vent station due to the presence of residual radioactive contamination.	Holdup of radionuclides due to trapped radioactive material in pipes	F3	E0
RCSTS-1FS-LEVEL01	Release of caustic solution to the sump pit from the water flush tank due to over filling of tank.	Operator error - overfill of caustic material	F3	E0
RCSTS-1FS-LEVEL02	Release of caustic solution and radionuclides to the sump pit from the water flush tank due to over filling of tank.	Flush tank receives radioactive waste from transfer line during drainback process. Jumper block valves and raw water block valves opened during the drainback of waste from vent station of the cross site transfer line.	F3	E0
RCSTS-1FS-LEVEL04	Release of caustic solution to the sump pit from the water flush tank due to human error.	Human error - drain valve left open	F3	E0
RCSTS-1FS-LEVEL05	Release of caustic solution to the sump pit from the water flush tank due to drain valve failure.	Drain valve fails open	F1	E0
RCSTS-1FS-LEVEL06	Release of caustic solution to the sump pit from the water flush tank due to tank connection failure.	Structural failure of flush tank connections	F2	E0
RCSTS-1FS-LEVEL07	Release of caustic solution to the sump pit from the water flush tank due to tank structural failure.	Structural failure of flush tank	F1	E0
RCSTS-1FS-PRES01	Release of caustic solution to the sump pit from the water flush tank due to tank failure.	Tank vent and overflow line blockage with flush pump running in flush cycle	F2	E0
RCSTS-1FS-STRUCT01	Release of caustic solution to the sump pit from the water flush tank due to tank connection failure.	Structural failure of pipe connections/expansion joint	F2	E0
RCSTS-1FS-STRUCT02	Release of caustic solution to the sump pit from the water flush tank due to structural failure of tank.	Structural failure of water flush tank	F1	E0
RCSTS-1FS-STRUCT03	Release of caustic solution to the sump pit from the water flush tank due to tank corrosion failure.	External water flush tank corrosion	F1	E0
RCSTS-1FS-STRUCT04	Release of caustic solution to the sump pit from the water flush tank due to tank failure.	Natural phenomena - high winds, seismic event, ash fall	F1	E0
RCSTS-2FS-FLOW06	Release of caustic solution to the atmosphere from the water flush system due to a mistransfer.	Flush line block valve failure, or valve left open due to operator error	F2	E0
RCSTS-3FS-FLOW01	Release of caustic solution to the sump from the water flush system due to rupture of tank fittings.	Raw water line break/rupture, floats flush water tank, damages tank/equipment	F2	E1

Table C-3. Hazardous Conditions With Potential Significant Worker Consequences (S1). (3 sheets)

RCSTS-3FS-FLOW02	Release of caustic to the sump from the caustic system due to rupture of caustic drum.	Raw water line break/rupture, overfilling of chemical addition equipment sump breaching drum containment	F2	E1
RCSTS-4FS-FLOW01	Release of caustic to the sump from the caustic system due to rupture of drum.	Caustic drum failure due to corrosion	F2	E1
RCSTS-4FS-FLOW02	Release of caustic material to caustic storage area from caustic drum due to handling error.	Materials handling accident	F3	E0
RCSTS-4FS-FLOW07	Release of caustic to the sump from the caustic system due to failure of check valve and overfilling of caustic drum with raw water.	Check valve fails open and bypass valve left open, backflow of raw water into caustic addition line of flush system.	F2	E1
RCSTS-5FS-FLOW03	Release of radioactive material into water flush tank due to loss of flush system pump operation.	Loss of pump pressure during flush operation causing back flow of waste	F3	E0
RCSTS-GENERAL-PRES	Release of radioactive material to the soil surface from supernate or slurry piping due to encasement breach (pipe is considered empty except for residual contamination).	Pneumatic leak testing	F3	E1

This page intentionally left blank.

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (14 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-01-FLOW02	Release of radioactive aerosols and entrained solids to the atmosphere from Tank 241-SY-102 due to criticality.	Mistransfer of material containing organic extractant from east area via the supernate piping route	F1	E3
RCSTS-01-FLOW04	Release of radioactive aerosols/entrained solids and/or toxic gases to the atmosphere from Tank 241-SY-102 due to chemical reaction.	Mistransfer of incompatible material from east area via the supernate piping route.	F2	E3
RCSTS-01-FLOW05	Release of ammonia to atmosphere from a fire or a gas release resulting in an explosion due to addition of inadequately diluted caustic.	Human error	F2	E3
RCSTS-03-FLOW/INTEG03a	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak.	Failure of jumper due to misalignment (human error)	F2	E3
RCSTS-03-FLOW/INTEG03b	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak.	Failure of jumper due to gasket failure	F2	E3
RCSTS-03-FLOW/INTEG03c	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak.	Failure of jumper due to corrosion	F2	E3
RCSTS-03-FLOW/INTEG04a	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak.	Failure of jumper due to misalignment (human error)	F2	E3
RCSTS-03-FLOW/INTEG04b	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak.	Failure of jumper due to gasket failure	F2	E3
RCSTS-03-FLOW/INTEG04c	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak.	Failure of jumper due to corrosion	F2	E3
RCSTS-03-FLOW06	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak.	Computer failure or human error causing misrouting of material when flow path is not completely connected	F2	E3
RCSTS-03-FLOW07	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak.	External leak of valve or valves to the valve pit	F2	E3
RCSTS-03-FLOW08	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak.	Computer failure or human error causing misrouting of material when flow path is not completely connected	F2	E3
RCSTS-03-INTEG03	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak.	External leak of valve or valves to the valve pit	F2	E3
RCSTS-03-INTEG04	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak.	Seismic event	F1	E3
RCSTS-03-INTEG09	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak.	External event (airplane crash, etc)	F0	E3
RCSTS-03-INTEG10	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak.	Seismic event	F1	E3

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (14 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-03-INTEG11	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak.	External event (airplane crash, etc)	F0	E3
RCSTS-08-FLOW08	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	External leak of valve or valves to the diversion box	F3	E3
RCSTS-08-INTEG08	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	Failure of piping due to corrosion	F2	E3
RCSTS-08-INTEG09	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	External event (airplane crash, etc)	F0	E3
RCSTS-08-INTEG10	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from diversion box due to piping system leak.	External event (airplane crash, etc)	F0	E3
RCSTS-08-INTEG11	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	Flammable gas explosion from release of trapped flammable gas within pipe combined with ignition source	F2	E3
RCSTS-08-INTEG12	Release of radioactive aerosols to the atmosphere from the 6241-A diversion box due to fire or explosion of flammable gas.	Fire or explosion in the diversion box caused by buildup of flammable gas because of spill of supernate to diversion box sump	F2	E3
RCSTS-08-INTEG13	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	Failure of piping due to material defect	F2	E3
RCSTS-08-INTEG14	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	Slurry pump overspeed causing catastrophic failure of pump with missiles damaging pipe and challenging diversion box confinement	F1	E3
RCSTS-08-INTEG15	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	Seismic event	F1	E3
RCSTS-08-INTEG16	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from diversion box due to piping system leak.	Seismic event	F1	E3
RCSTS-08-PRES04	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	Water hammer	F3	E3
RCSTS-08-PRES05	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from diversion box due to piping system leak.	Water hammer	F3	E3
RCSTS-08-TEMP02	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	Freezing of piping within the diversion box due to cold temperatures caused by running the exhauster	F2	E3
RCSTS-08-TEMP03	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from diversion box due to piping system leak.	Freezing of piping within the diversion box due to cold temperatures caused by running the exhauster	F2	E3

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (14 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-09-FLOW10	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from vent station due to piping system leak.	External leak of valve or valves to the vent station	F3	E3
RCSTS-09-FLOW11	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	Backflow of supernate to sump pump line, through sump pump and onto vent station floor	F3	E3
RCSTS-09-INTEG11	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from vent station due to piping system leak.	Failure of piping due to corrosion	F2	E3
RCSTS-09-INTEG12	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from vent station due to piping system leak.	External event (airplane crash, etc)	F0	E3
RCSTS-09-INTEG13	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from vent station due to piping system leak.	External event (airplane crash, etc)	F0	E3
RCSTS-09-INTEG14	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from vent station due to piping system leak.	Flammable gas explosion from release of trapped flammable gas within pipe combined with ignition source	F2	E3
RCSTS-09-INTEG15	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from vent station due to piping system leak.	Failure of piping due to material defect	F2	E3
RCSTS-09-INTEG16	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from vent station due to piping system leak.	Seismic event	F1	E3
RCSTS-09-INTEG17	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from vent station due to piping system leak.	Seismic event	F1	E3
RCSTS-09-PRES04	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from vent station due to piping system leak.	Water hammer	F3	E3
RCSTS-09-PRES05	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from vent station due to piping system leak.	Water hammer	F3	E3
RCSTS-09-TEMP03	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from vent station due to piping system leak.	Freezing of piping within the vent station due to cold temperatures caused by running the exhauster	F2	E3
RCSTS-09-TEMP04	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from vent station due to piping system leak.	Freezing of piping within the vent station due to cold temperatures caused by running the exhauster	F2	E3
RCSTS-22-PRESS01*	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from 244-A Lift Station due to piping system leak.	Dead heading of flow through the 244-A Lift Station with failure of PRV and development of crack in downstream piping	F3	E3
RCSTS-22-PRESS02*	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from 244-A Lift Station due to piping system leak.	Dead heading of flow through the 244-A Lift Station with failure of PRV and development of crack in downstream piping	F3	E3

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (14 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-22-PRESS03*	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping break.	Dead heading of flow through the 244-A Lift Station with failure of PRV and subsequent downstream pipe failure	F3	E3
RCSTS-22-PRESS04*	Release of radioactive slurry to soil surface from overflow of 244-A Lift Station due to piping break.	Dead heading of flow through the 244-A Lift Station with failure of PRV and subsequent downstream pipe failure	F3	E3
RCSTS-24-FLOW/INTEG07	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from lift station due to piping system leak.	Failure of jumper due to corrosion	F2	E3
RCSTS-24-FLOW/INTEG08	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from lift station due to piping system leak.	Failure of jumper due to corrosion	F2	E3
RCSTS-24-FLOW/INTEG09	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from lift station due to piping system leak.	Failure of jumper due to gasket failure	F3	E3
RCSTS-24-FLOW/INTEG10	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from lift station due to piping system leak.	Failure of jumper due to gasket failure	F3	E3
RCSTS-24-FLOW/INTEG11	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from lift station due to piping system leak.	Failure of jumper due to misalignment	F3	E3
RCSTS-24-FLOW/INTEG12	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from lift station due to piping system leak.	Failure of jumper due to misalignment	F3	E3
RCSTS-24-FLOW05	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from lift station due to piping system leak.	Computer failure or human error causing misrouting of material when flow path is not completely connected	F3	E3
RCSTS-24-FLOW06	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from lift station due to piping system leak.	Computer failure or human error causing misrouting of material when flow path is not completely connected	F3	E3
RCSTS-24-FLOW07	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from lift station due to piping system leak.	External leak of valve or valves to the lift station	F3	E3
RCSTS-24-FLOW08	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from lift station due to piping system leak.	External leak of valve or valves to the lift station	F3	E3
RCSTS-24-INTEG07	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from lift station due to piping system leak.	External event (airplane crash, etc)	F0	E3
RCSTS-24-INTEG08	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from lift station due to piping system leak.	External event (airplane crash, etc)	F0	E3
RCSTS-24-INTEG09	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from lift station due to piping system leak.	Seismic event	F1	E3

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (14 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-24-INTEG10	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from lift station due to piping system leak.	Seismic event	F1	E3
RCSTS-01-FLOW03	Release of radioactive supernate to the soil surface from overflow of Tank 241-SY-102 due to mistransfer.	Mistransfer of material from east area via the supernate piping route.	F3	E2
RCSTS-03-FLOW/INTEG01	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Failure of jumper due to misalignment (human error).	F3	E2
RCSTS-03-FLOW/INTEG02a	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Failure of jumper due to misalignment (human error)	F3	E2
RCSTS-03-FLOW/INTEG02b	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Failure of jumper due to gasket failure	F2	E2
RCSTS-03-FLOW/INTEG02c	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Failure of jumper due to corrosion	F2	E2
RCSTS-03-FLOW02	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Computer failure or human error causing misrouting of material when flow path is not completely connected	F3	E2
RCSTS-03-FLOW03	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	External leak of valve or valves to the valve pit	F2	E2
RCSTS-03-FLOW04	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Computer failure or human error causing misrouting of material when flow path is not completely connected	F3	E2
RCSTS-03-FLOW05	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	External leak of valve or valves to the valve pit	F2	E2
RCSTS-03-INTEG01	Release of radioactive aerosols to the atmosphere from the SY valve pit due to fire or explosion of flammable gas.	Fire or explosion in the valve pit caused by buildup of flammable gas because of spill of supernate or slurry	F2	E2
RCSTS-03-INTEG02	Release of radioactive aerosols to the atmosphere from the SY valve pit due to fire or explosion of flammable gas.	Fire or explosion due to leakage of flammable gas due to pipe breach in slurry line caused by gas release from slurry	F2	E2
RCSTS-03-INTEG05	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak.	External event (airplane crash, etc)	F0	E2
RCSTS-03-INTEG06	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak.	Seismic event	F1	E2
RCSTS-03-INTEG07	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak.	External event (airplane crash, etc)	F0	E2

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (14 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-03-INTEG08	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Seismic event	F1	E2
RCSTS-03-PRES02	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Water hammer	F3	E2
RCSTS-03-PRES03	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Water hammer	F3	E2
RCSTS-04/05-INTEG01a	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to corrosion	F2	E2
RCSTS-04/05-INTEG01b	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to unrecognized material flaw	F2	E2
RCSTS-04/05-INTEG02	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to external event (airplane crash, volcanism, etc)	FO	E2
RCSTS-04/05-INTEG03	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and the diversion box due to piping system leak.	Failure of primary and encasement piping due to external event (excavation accident)	F3	E2
RCSTS-04/05-INTEG04	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to external event (undermining from broken fluid transfer lines in vicinity)	F2	E2
RCSTS-04/05-INTEG05	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to seismic event	F1	E2
RCSTS-04/05-TEMP01	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to freezing	F1	E2
RCSTS-08-FLOW03	Release of radioactive supernate to soil surface from overflow of diversion box due to piping system leak.	External leak of valve or valves to the diversion box	F3	E2
RCSTS-08-FLOW04	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	External leak of valve or valves to the diversion box	F3	E2
RCSTS-08-FLOW05	Release of radioactive supernate to soil surface from overflow of diversion box due to piping system leak.	Backflow of supernate to sump pump line, through sump pump and onto diversion box floor	F3	E2
RCSTS-08-INTEG01	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Failure of piping due to corrosion	F2	E2
RCSTS-08-INTEG02	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	External event (airplane crash, etc)	FO	E2

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (14 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-08-INTEG03	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Flammable gas explosion from release of trapped flammable gas within pipe combined with ignition source	F2	E2
RCSTS-08-INTEG04	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Failure of piping due to material defect	F2	E2
RCSTS-08-INTEG05	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Slurry pump overspeed causing catastrophic failure of pump with missiles damaging pipe	F1	E2
RCSTS-08-INTEG06	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Seismic event	F1	E2
RCSTS-08-INTEG07	Release of radioactive supernate to soil surface from overflow of diversion box due to piping system leak.	Seismic event	F1	E2
RCSTS-08-INTEG17a	Release of radioactive supernate to the soil surface from overflow of diversion box due to piping system leak.	Failure of piping due to corrosion plus mitigative features failure	F2	E2
RCSTS-08-INTEG17b	Release of radioactive supernate to the soil surface from overflow of diversion box due to piping system leak.	Failure of piping due to unrecognized material flaw	F2	E2
RCSTS-08-INTEG18	Release of radioactive supernate to the soil surface from overflow of diversion box due to piping system leak.	Failure of piping due to external event (airplane crash, volcanism, etc)	F0	E2
RCSTS-08-PRES02	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Water hammer	F3	E2
RCSTS-08-PRES03	Release of radioactive supernate to soil surface from overflow of diversion box due to piping system leak.	Water hammer	F3	E2
RCSTS-08-TEMP01	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Freezing of piping within the diversion box due to cold temperatures caused by running the exhauster	F2	E2
RCSTS-08-TEMP04	Release of radioactive supernate to the soil surface from overflow of diversion box due to piping system leak.	Failure of piping due to freezing	F1	E2
RCSTS-09-FLOW01	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	Flow of slurry to vent station due to incomplete closing of vent valves after venting	F3	E2
RCSTS-09-FLOW04	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	External leak of valve or valves to the vent station	F3	E2
RCSTS-09-FLOW05	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	External leak of valve or valves to the vent station	F3	E2
RCSTS-09-FLOW06	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	Flow of supernate to vent station due to incomplete closing of vent valves after venting	F3	E2

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (14 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-09-FLOW07	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	Backflow of supernate to sump pump line, through sump pump and onto vent station floor	F3	E2
RCSTS-09-INTEG01	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	Failure of piping due to corrosion	F2	E2
RCSTS-09-INTEG02	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	Failure of piping due to corrosion	F2	E2
RCSTS-09-INTEG03	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	External event (airplane crash, etc)	F0	E2
RCSTS-09-INTEG04	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	External event (airplane crash, etc)	F0	E2
RCSTS-09-INTEG05	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	Flammable gas explosion from release of trapped flammable gas within pipe combined with ignition source	F2	E2

RCSTS-09-INTEG07	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	Failure of piping due to material defect	F2	E2
RCSTS-09-INTEG08	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	Failure of piping due to material defect	F2	E2
RCSTS-09-INTEG09	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	Seismic event	F1	E2
RCSTS-09-INTEG10	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	Seismic event	F1	E2
RCSTS-09-PRES01	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	Water hammer	F3	E2
RCSTS-09-PRES02	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	Water hammer	F3	E2
RCSTS-09-TEMP01	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	Freezing of piping within the vent station due to cold temperatures caused by running the exhauster	F2	E2
RCSTS-09-TEMP02	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	Freezing of piping within the vent station due to cold temperatures caused by running the exhauster	F2	E2

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (14 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-10/11-INTEG01	Release of radioactive supernate to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to external event (undermining from broken fluid transfer lines in vicinity)	F3	E2
RCSTS-10/11-INTEG02a	Release of radioactive supernate to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to corrosion	F2	E2
RCSTS-10/11-INTEG02b*	Release of radioactive supernate to the soil subsurface from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to corrosion	F2	E2
RCSTS-10/11-INTEG03a	Release of radioactive supernate to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to external event (excavation accident)	F3	E2
RCSTS-10/11-INTEG03b*	Release of radioactive supernate to the atmosphere from the underground piping between the diversion box and the vent station due to excavation of piping system and subsequent leak.	Failure of primary and encasement piping due to external event (excavation accident)	F3	E2
RCSTS-10/11-INTEG04	Release of radioactive supernate to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to external event (airplane crash, volcanism etc)	F0	E2
RCSTS-10/11-INTEG05a	Release of radioactive supernate to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to unrecognized material flaw	F2	E2
RCSTS-10/11-INTEG05b*	Release of radioactive supernate to the soil subsurface from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to unrecognized material flaw	F2	E2
RCSTS-10/11-INTEG06	Release of radioactive supernate to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to seismic event	F1	E2
RCSTS-10/11-PRES01a	Release of radioactive supernate to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to water hammer	F3	E2
RCSTS-10/11-PRES01b*	Release of radioactive supernate to the soil subsurface from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to water hammer	F3	E2
RCSTS-10/11-TEMP01	Release of radioactive supernate to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary piping and encasement due to freezing	F1	E2
RCSTS-10/11-TEMP02	Release of radioactive supernate to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to thermal stress	F3	E2
RCSTS-12/13-INTEG01	Release of radioactive supernate to the soil from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to external event (undermining from broken fluid transfer lines in vicinity)	F3	E2
RCSTS-12/13-INTEG02a	Release of radioactive supernate to the soil from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to corrosion	F2	E2

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (14 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-12/13-INTEGO2b*	Release of radioactive supernate to the soil subsurface from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to corrosion	F2	E2
RCSTS-12/13-INTEGO3a	Release of radioactive supernate to the soil from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to external event (excavation accident)	F3	E2
RCSTS-12/13-INTEGO3b*	Release of radioactive supernate to the atmosphere from the underground piping between the vent station and the 244-A Lift Station due to excavation of piping system and subsequent leak.	Failure of primary and encasement piping due to external event (excavation accident)	F3	E2
RCSTS-12/13-INTEGO4	Release of radioactive supernate to the soil from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to external event (airplane crash, volcanism etc)	F0	E2
RCSTS-12/13-INTEGO5a	Release of radioactive supernate to the soil from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to unrecognized material flaw	F2	E2
RCSTS-12/13-INTEGO5b*	Release of radioactive supernate to the soil subsurface from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to unrecognized material flaw	F2	E2
RCSTS-12/13-INTEGO6	Release of radioactive supernate to the soil from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to seismic event	F1	E2
RCSTS-12/13-PRESO1a	Release of radioactive supernate to the soil from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to steam hammer caused by loss of flushwater flow to steam mixing chamber in east	F3	E2
RCSTS-12/13-PRESO1b*	Release of radioactive supernate to the soil subsurface from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to steam hammer caused by loss of flushwater flow to steam mixing chamber in east area	F3	E2
RCSTS-12/13-PRESO2	Release of radioactive supernate to the soil from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to water hammer	F3	E2
RCSTS-12/13-TEMPO1	Release of radioactive supernate to the soil from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary piping and encasement due to freezing	F1	E2
RCSTS-12/13-TEMPO2	Release of radioactive supernate to the soil from the underground piping between the vent station and the 244-A Lift Station due to piping system leak.	Failure of primary and encasement piping due to thermal stress	F3	E2
RCSTS-15/16-INTEGO1a	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to corrosion	F2	E2
RCSTS-15/16-INTEGO1b	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to unrecognized material flaw	F2	E2
RCSTS-15/16-INTEGO2	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and the diversion box due to piping system leak.	Failure of primary and encasement piping due to external event (excavation accident)	F2	E2

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (14 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-15/16-INTEG03a	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to external event (undermining from broken fluid transfer lines in vicinity)	F3	E2
RCSTS-15/16-INTEG03b	Release of radioactive slurry to the soil surface from overflow of diversion box due to piping system leak.	Failure of piping due to external event (undermining from broken fluid transfer lines in vicinity)	F2	E2
RCSTS-15/16-INTEG04	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and the diversion box due to piping system leak.	Failure of primary and encasement piping due to seismic event	F1	E2
RCSTS-15/16-INTEG05	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to external event (airplane crash, volcanism, etc)	F0	E2
RCSTS-15/16-TEMP01	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to freezing	F1	E2
RCSTS-18/19-INTEG01	Release of radioactive slurry to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to external event (undermining from broken fluid transfer lines in vicinity)	F3	E2
RCSTS-18/19-INTEG02	Release of radioactive slurry to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to corrosion	F2	E2
RCSTS-18/19-INTEG03a	Release of radioactive slurry to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to external event (excavation accident)	F3	E2
RCSTS-18/19-INTEG03b*	Release of radioactive slurry to the atmosphere from the underground piping between the diversion box and the vent station due to excavation of piping system and subsequent leak.	Failure of primary and encasement piping due to external event (excavation accident)	F3	E2
RCSTS-18/19-INTEG04	Release of radioactive slurry to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to external event (airplane crash, volcanism etc)	F0	E2
RCSTS-18/19-INTEG05	Release of radioactive slurry to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to flammable gas explosion in primary piping	F2	E2
RCSTS-18/19-INTEG06	Release of radioactive slurry to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to unrecognized material flaw	F2	E2
RCSTS-18/19-INTEG07	Release of radioactive slurry to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to seismic event	F1	E2
RCSTS-18/19-PRES01	Release of radioactive slurry to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to water hammer	F3	E2
RCSTS-18/19-TEMP01	Release of radioactive slurry to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary piping and encasement due to freezing	F1	E2

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (14 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-18/19-TEMP02	Release of radioactive slurry to the soil from the underground piping between the diversion box and the vent station due to piping system leak.	Failure of primary and encasement piping due to thermal stress	F3	E2
RCSTS-1FS-LEVEL03	Release of caustic solution and radionuclides to the sump pit from the water flush tank due to over filling of tank.	Overfilling of flush tank from flow of radioactive waste from transfer line. Block valves open, valve limit switch and pressure switch fail and administrative control of raw water block valves fail	F2	E2
RCSTS-24-FLOW/INTEG01	Release of radioactive slurry to soil surface from overflow of lift station due to piping system leak.	Failure of jumper due to corrosion	F2	E2
RCSTS-24-FLOW/INTEG02	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	Failure of jumper due to corrosion	F2	E2
RCSTS-24-FLOW/INTEG03	Release of radioactive slurry to soil surface from overflow of lift station due to piping system leak.	Failure of jumper due to gasket failure	F3	E2
RCSTS-24-FLOW/INTEG04	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	Failure of jumper due to gasket failure	F3	E2
RCSTS-24-FLOW/INTEG05	Release of radioactive slurry to soil surface from overflow of lift station due to piping system leak.	Failure of jumper due to misalignment	F3	E2
RCSTS-24-FLOW/INTEG06	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	Failure of jumper due to misalignment	F3	E2
RCSTS-24-FLOW01	Release of radioactive slurry to soil surface from overflow of lift station due to piping system leak.	Computer failure or human error causing misrouting of material when flow path is not completely connected	F3	E2
RCSTS-24-FLOW02	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	Computer failure or human error causing misrouting of material when flow path is not completely connected	F3	E2
RCSTS-24-FLOW03	Release of radioactive slurry to soil surface from overflow of lift station due to piping system leak.	External leak of valve or valves to the lift station	F3	E2
RCSTS-24-FLOW04	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	External leak of valve or valves to the lift station	F3	E2
RCSTS-24-INTEG01	Release of radioactive slurry to soil surface from overflow of lift station due to piping system leak.	External event (airplane crash, etc)	F0	E2
RCSTS-24-INTEG02	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	External event (airplane crash, etc)	F0	E2

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (14 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-24-INTEG03	Release of radioactive aerosols to the atmosphere from the lift station due to fire or explosion of flammable gas.	Fire or explosion in the lift station caused by buildup of flammable gas because of spill of supernate or slurry	F2	E2
RCSTS-24-INTEG04	Release of radioactive slurry to soil surface from overflow of lift station due to piping system leak.	Seismic event	F1	E2
RCSTS-24-INTEG05	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	Seismic event	F1	E2
RCSTS-24-INTEG06	Release of radioactive aerosols to the atmosphere from the lift station due to fire or explosion of flammable gas.	Fire or explosion due to leakage of flammable gas due to pipe breach in slurry line caused by gas release from slurry	F2	E2
RCSTS-24-PRES01	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	Steam hammer or thermal stress caused by loss of flushwater flow to steam mixing chamber in east area	F3	E2
RCSTS-24-PRES02	Release of radioactive slurry to soil surface from overflow of lift station due to piping system leak.	Water hammer	F3	E2
RCSTS-24-PRES03	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	Water hammer	F3	E2
RCSTS-2FS-FLOW01	Release of caustic solution spray to the atmosphere from the water flush system due to a transfer line break.	Line break (upstream of flush pump) due to structural failure	F2	E2
RCSTS-2FS-FLOW02	Release of caustic solution spray to the atmosphere from the water flush system due to a transfer line break.	Line break (downstream of flush pump) due to structural failure	F2	E2
RCSTS-2FS-FLOW03	Release of caustic solution spray to the atmosphere from the water flush system due to a transfer line break.	Line plug - before heaters due to debris buildup causing a pressure buildup and failure of line	F2	E2
RCSTS-2FS-FLOW04	Release of caustic solution spray to the atmosphere from the water flush system due to a transfer line break.	Line plug - after heaters due to debris buildup causing pressure buildup at the heater and resulting in heater pipe failure	F2	E2
RCSTS-2FS-FLOW05	Release of caustic solution spray to the atmosphere from the water flush system due to a relief valve failure.	Caustic injection pressure relief valve failure	F3	E2
RCSTS-2FS-FLOW07	Release of caustic solution spray to the atmosphere from the water flush system due to a transfer line break.	Flush line break due to structural failure	F2	E2
RCSTS-2FS-PRES01	Release of caustic solution spray to the atmosphere from the water flush system due line plug.	Flush line plug - before heaters due to debris buildup causing a pressure buildup and failure of line	F2	E2

Table C-4. Hazardous Conditions with Potential Severe Environmental Consequences (E2 and E3). (14 sheets)

ID	Hazardous Conditions	Cause	Freq NC	Env Cons
RCSTS-2FS-PRES02	Release of caustic solution spray to the atmosphere from the water flush system due to a line plug.	Flush line plug - after heaters due to debris buildup causing pressure buildup at the heater and resulting in heater pipe failure	F2	E2
RCSTS-2FS-PRES03	Release of caustic solution spray to the atmosphere from the water flush system due to a line break.	Flush line break due to structural failure	F2	E2
RCSTS-2FS-TEMP01	Release of caustic solution spray to the atmosphere from the water flush system due to a line plug.	Flush line plug - before heaters due to debris buildup causing a pressure buildup and failure of line	F2	E2
RCSTS-2FS-TEMP02	Release of caustic solution spray to the atmosphere from the water flush system due to freezing conditions.	Freezing weather with loss of heat trace function	F2	E2
RCSTS-4FS-FLOW03	Release of caustic to the atmosphere from the caustic system due to pressure relief valve failing open.	Pressure relief valve fails open	F2	E2
RCSTS-4FS-FLOW04	Release of caustic to the atmosphere from the caustic system due to over pressurization of line and failure of pressure relief valve to open.	Back pressure valve fails in closed position	F2	E2
RCSTS-4FS-FLOW05	Release of caustic to the atmosphere from the caustic system due to line failure in chemical injection package.	Line failure/leak due to structural failure	F2	E2
RCSTS-4FS-FLOW06	Release of caustic to the atmosphere from the caustic system due to a caustic system drain valve leak.	Caustic drain valve leak	F2	E2
RCSTS-4FS-PRES/TEMP01	Release of caustic to the atmosphere from the caustic system due to pressure relief valve failing open.	Pressure relief valve fails open on caustic injection system.	F2	E2
RCSTS-4FS-PRES/TEMP02	Release of caustic to the atmosphere from the caustic system due to pressure relief valve failing in closed position and rupture of line.	Back pressure relief valve fails in closed position.	F3	E2
RCSTS-5FS-FLOW01	Release of caustic to the atmosphere from caustic line due to a line break.	Line break due to structural failure.	F2	E2
RCSTS-5FS-FLOW02	Release of caustic to the atmosphere from caustic line due to a line break.	Line plug due to debris buildup causing pressure buildup resulting in pipe failure.	F2	E2

Table C-5. Hazardous Conditions With Potential Radiation Exposure Consequences (RP).

ID	Hazardous Conditions	Cause
RCSTS-03-FLOW01	Release of radioactive slurry or supernate to the SY flush pit from transfer line due to backflow.	Reverse flow to flush pit caused by improper valving sequence
RCSTS-08-AIR01	Release of radioactive vapors to the diversion box atmosphere from accumulated waste in diversion box due to pipe encasement draining.	Draining of the encasement
RCSTS-08-AIR03	Release of radioactive vapors to the diversion box atmosphere due to waste being present in box.	Leak of waste solution
RCSTS-08-RAD01	Release of radioactive material to the diversion box from transfer piping due to encasement draining.	Draining of the encasement
RCSTS-08-RAD02	Release of radioactive material to the diversion box from transfer line due to pipe leak.	Leak of waste solution
RCSTS-08-RAD03	High radiation dose to worker from the diversion box due to the presence of residual radioactive contamination.	Holdup of radionuclides due to trapped radioactive material in pumps or pipes
RCSTS-09-AIR02	Release of radioactive vapors to the vent station atmosphere due to waste being present in station.	Leak of waste solution
RCSTS-09-RAD02	Release of radioactive material to the vent station from transfer line due to pipe leak.	Leak of waste solution
RCSTS-09-RAD03	High radiation dose to worker from the vent station due to the presence of residual radioactive contamination.	Holdup of radionuclides due to trapped radioactive material in pipes
RCSTS-5FS-FLOW03	Release of radioactive material into water flush tank due to loss of flush system pump operation.	Loss of pump pressure during flush operation causing back flow of waste

This page intentionally left blank.

Table C-6. Hazardous Conditions With Potential Occupational Safety Consequences (OCC). (2 sheets)

ID	Hazardous Conditions	Cause
RCSTS-08-AIR02	Exposure to chemical vapors and liquids in diversion box due to the spill or leak of chemicals in confined space.	Chemicals brought in for decontamination and maintenance
RCSTS-08-AIR04	Release of chemical waste into diversion box from leak of waste solution resulting in worker exposure.	Leak of waste solution
RCSTS-08-OCC01	Worker injury due to welding gas bottle becoming a missile in diversion box.	Damage from welding gas bottle during maintenance activity in diversion box
RCSTS-08-OCC02	Worker discomfort from cold temperatures in diversion box.	Running an exhauster during cold weather
RCSTS-09-AIR03	Exposure to chemical vapors and liquids in vent station due to the spill or leak of chemicals.	Chemicals brought in for decontamination and maintenance
RCSTS-09-AIR04	Release of chemical waste into diversion box from leak of waste solution resulting in worker exposure.	Leak of waste solution
RCSTS-09-OCC01	Worker injury due to welding gas bottle becoming a missile in vent station.	Damage from welding gas bottle during maintenance activity in vent station
RCSTS-09-OCC02	Worker discomfort from cold temperatures in vent station.	Running an exhauster during cold weather
RCSTS-1FS-LEVEL01	Release of caustic solution to the sump pit from the water flush tank due to over filling of tank.	Operator error - overfill of caustic material
RCSTS-1FS-LEVEL04	Release of caustic solution to the sump pit from the water flush tank due to human error.	Human error - drain valve left open
RCSTS-1FS-LEVEL05	Release of caustic solution to the sump pit from the water flush tank due to drain valve failure.	Drain valve fails open
RCSTS-1FS-LEVEL06	Release of caustic solution to the sump pit from the water flush tank due to tank connection failure.	Structural failure of flush tank connections
RCSTS-1FS-LEVEL07	Release of caustic solution to the sump pit from the water flush tank due to tank structural failure.	Structural failure of flush tank
RCSTS-1FS-PRES01	Release of caustic solution to the sump pit from the water flush tank due to tank failure.	Tank vent and overflow line blockage with flush pump running in flush cycle
RCSTS-1FS-STRUCT01	Release of caustic solution to the sump pit from the water flush tank due to tank connection failure.	Structural failure of pipe connections/expansion joint
RCSTS-1FS-STRUCT02	Release of caustic solution to the sump pit from the water flush tank due to structural failure of tank.	Structural failure of water flush tank

Table C-6. Hazardous Conditions With Potential Occupational Safety Consequences (OCC). (2 sheets)

ID	Hazardous Conditions	Cause
RCSTS-1FS-STRUCT03	Release of caustic solution to the sump pit from the water flush tank due to tank corrosion failure.	External water flush tank corrosion
RCSTS-2FS-FLOW06	Release of caustic solution to the atmosphere from the water flush system due to a mistransfer.	Flush line block valve failure, or valve left open due to operator error
RCSTS-3FS-FLOW01	Release of caustic solution to the sump from the water flush system due to rupture of tank fittings.	Raw water line break/rupture, floats flush water tank, damages tank/equipment
RCSTS-3FS-FLOW02	Release of caustic to the sump from the caustic system due to rupture of caustic drum.	Raw water line break/rupture, overfilling of chemical addition equipment sump breaching drum containment
RCSTS-4FS-FLOW01	Release of caustic to the sump from the caustic system due to rupture of drum.	Caustic drum failure due to corrosion
RCSTS-4FS-FLOW02	Release of caustic material to caustic storage area from caustic drum due to handling error.	Materials handling accident
RCSTS-4FS-FLOW07	Release of caustic to the sump from the caustic system due to failure of check valve and overfilling of caustic drum with raw water.	Check valve fails open and bypass valve left open, backflow of raw water into caustic addition line of flush system.

BIO Acc	ID	Hazardous Conditions	Cause	DID-Preventive	DID-Mitigative
18X	RCSTS-09-INTEG02	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	Failure of piping due to corrosion	None	None
18X	RCSTS-09-INTEG03	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	External event (airplane crash, etc)	None	None
18X	RCSTS-09-INTEG04	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	External event (airplane crash, etc)	None	None
18X	RCSTS-09-INTEG07	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	Failure of piping due to material defect	None	None
18X	RCSTS-09-INTEG08	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	Failure of piping due to material defect	None	None
18X	RCSTS-09-PRES01	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	Water hammer	None	None
18X	RCSTS-09-PRES02	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	Water hammer	None	None
18X	RCSTS-09-TEMP01	Release of radioactive slurry to soil surface from overflow of vent station due to piping system leak.	Freezing of piping within the vent station due to cold temperatures caused by running the exhauster	None	None
18X	RCSTS-09-TEMP02	Release of radioactive supernate to soil surface from overflow of vent station due to piping system leak.	Freezing of piping within the vent station due to cold temperatures caused by running the exhauster	None	None
18X	RCSTS-15/16-INTEG03b	Release of radioactive slurry to the soil surface from overflow of diversion box due to piping system leak.	Failure of piping due to external event (undermining from broken fluid transfer lines in vicinity)	None	None
18X	RCSTS-1FS-LEVEL03	Release of caustic solution and radionuclides to the sump pit from the water flush tank due to over filling of tank.	Overfilling of flush tank from flow of radioactive waste from transfer line. Block valves open, valve limit switch and pressure switch fail and administrative control of raw water block valves fail	None	None

Table D-4. Defense In Depth Controls For Potential S3 and S2 Consequences. (23 sheets)

BIO Acc	ID	Hazardous Conditions	Cause	DID-Preventive	DID-Mitigative
18X	RCSTS-22-PRESS03*	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping break.	Dead heading of flow through the 244-A Lift Station with failure of PRV and subsequent downstream pipe failure	None	None
18X	RCSTS-22-PRESS04*	Release of radioactive slurry to soil surface from overflow of 244-A Lift Station due to piping break.	Dead heading of flow through the 244-A Lift Station with failure of PRV and subsequent downstream pipe failure	None	None
18X	RCSTS-24-FLOW/INTEG01	Release of radioactive slurry to soil surface from overflow of lift station due to piping system leak.	Failure of jumper due to corrosion	None	None
18X	RCSTS-24-FLOW/INTEG02	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	Failure of jumper due to corrosion	None	None
18X	RCSTS-24-FLOW/INTEG03	Release of radioactive slurry to soil surface from overflow of lift station due to piping system leak.	Failure of jumper due to gasket failure	None	None
18X	RCSTS-24-FLOW/INTEG04	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	Failure of jumper due to gasket failure	None	None
18X	RCSTS-24-FLOW/INTEG05	Release of radioactive slurry to soil surface from overflow of lift station due to piping system leak.	Failure of jumper due to misalignment	None	None
18X	RCSTS-24-FLOW/INTEG06	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	Failure of jumper due to misalignment	None	None
18X	RCSTS-24-FLOW01	Release of radioactive slurry to soil surface from overflow of lift station due to piping system leak.	Computer failure or human error causing misrouting of material when flow path is not completely connected	None	None
18X	RCSTS-24-FLOW02	Release of radioactive supernate to soil surface from overflow of 244-A Lift Station due to piping system leak.	Computer failure or human error causing misrouting of material when flow path is not completely connected	None	None
18X	RCSTS-24-FLOW03	Release of radioactive slurry to soil surface from overflow of lift station due to piping system leak.	External leak of valve or valves to the lift station	None	None

Table D-5. Defense In Depth For Potential S1 Consequences With F3 Frequency. (2 sheets)

ID	Hazardous Conditions	Cause	DID-Preventive	DID-Mitigative
RCSTS-01-FLOW01	Release of radioactive slurry or supernate to the soil surface from overflow of the 244-S catch station due to reverse flow.	Reverse flow to 244-S catch station caused by improper valve lineup.	None	None
RCSTS-03-FLOW01	Release of radioactive slurry or supernate to the SY flush pit from transfer line due to backflow.	Reverse flow to flush pit caused by improper valving sequence	None	None
RCSTS-03-PRES01	Release of radioactive material to atmosphere from SY valve pit due to over-pressurization event in Tank 241-SY-102.	Pressure event in Tank 241-SY-102 with loss of valve pit seal loop water	None	None
RCSTS-08-AIR01	Release of radioactive vapors to the diversion box atmosphere from accumulated waste in diversion box due to pipe encasement draining.	Draining of the encasement	None	None
RCSTS-08-AIR02	Exposure to chemical vapors and liquids in diversion box due to the spill or leak of chemicals in confined space.	Chemicals brought in for decontamination and maintenance	None	None
RCSTS-08-AIR03	Release of radioactive vapors to the diversion box atmosphere due to waste being present in box.	Leak of waste solution	None	None
RCSTS-08-AIR04	Release of chemical waste into diversion box from leak of waste solution resulting in worker exposure.	Leak of waste solution	None	None
RCSTS-08-OCC01	Worker injury due to welding gas bottle becoming a missile in diversion box.	Damage from welding gas bottle during maintenance activity in diversion box	None	None
RCSTS-08-OCC02	Worker discomfort from cold temperatures in diversion box.	Running an exhauster during cold weather	None	None
RCSTS-08-RAD01	Release of radioactive material to the diversion box from transfer piping due to encasement draining.	Draining of the encasement	None	None
RCSTS-08-RAD03	High radiation dose to worker from the diversion box due to the presence of residual radioactive contamination.	Holdup of radionuclides due to trapped radioactive material in pumps or pipes	Diversion Box Design Features	Diversion Box Design Features ALARA Program
RCSTS-09-AIR02	Release of radioactive vapors to the vent station atmosphere due to waste being present in station.	Leak of waste solution	None	None
RCSTS-09-AIR03	Exposure to chemical vapors and liquids in vent station due to the spill or leak of chemicals.	Chemicals brought in for decontamination and maintenance	None	None
RCSTS-09-AIR04	Release of chemical waste into diversion box from leak of waste solution resulting in worker exposure.	Leak of waste solution	None	None

Table D-5. Defense In Depth For Potential S1 Consequences With F3 Frequency. (2 sheets)

ID	Hazardous Conditions	Cause	DID-Preventive	DID-Mitigative
RCSTS-09-OCC01	Worker injury due to welding gas bottle becoming a missile in vent station.	Damage from welding gas bottle during maintenance activity in vent station	None	None
RCSTS-09-OCC02	Worker discomfort from cold temperatures in vent station.	Running an exhauster during cold weather	None	None
RCSTS-09-RAD03	High radiation dose to worker from the vent station due to the presence of residual radioactive contamination.	Holdup of radionuclides due to trapped radioactive material in pipes	None	None
RCSTS-1FS-LEVEL01	Release of caustic solution to the sump pit from the water flush tank due to over filling of tank.	Operator error - overfill of caustic material	Water Flush System Design	Flush Tank Sump
RCSTS-1FS-LEVEL02	Release of caustic solution and radionuclides to the sump pit from the water flush tank due to over filling of tank.	Flush tank receives radioactive waste from transfer line during drainback process. Jumper block valves and raw water block valves opened during the drain back of waste from vent station of the cross site transfer line.	None	None
RCSTS-1FS-LEVEL04	Release of caustic solution to the sump pit from the water flush tank due to human error.	Human error - drain valve left open	None	None
RCSTS-4FS-FLOW 02	Release of caustic material to caustic storage area from caustic drum due to handling error.	Materials handling accident	None	None
RCSTS-5FS-FLOW 03	Release of radioactive material into water flush tank due to loss of flush system pump operation.	Loss of pump pressure during flush operation causing back flow of waste	None	None
RCSTS-GENERAL-PRES	Release of radioactive material to the soil surface from supernate or slurry piping due to encasement breach (pipe is considered empty except for residual contamination).	Pneumatic leak testing	None	None

Table D-6. Defense In Depth Controls For Potentially Severe (E3 and E2) Environmental Consequences. (22 sheets)

ID	Hazardous Conditions	Cause	DID-Preventive	DID-Mitigative
RCSTS-01-FLOW02	Release of radioactive aerosols and entrained solids to the atmosphere from Tank 241-SY-102 due to criticality.	Mistransfer of material containing organic extractant from east area via the supernate piping route	None	None
RCSTS-01-FLOW03	Release of radioactive supernate to the soil surface from overflow of Tank 241-SY-102 due to mistransfer.	Mistransfer of material from east area via the supernate piping route.	None	None
RCSTS-01-FLOW04	Release of radioactive aerosols/entrained solids and/or toxic gases to the atmosphere from Tank 241-SY-102 due to chemical reaction.	Mistransfer of incompatible material from east area via the supernate piping route.	Tank Farm Waste Compat Prog Waste Trans Proc Cntrls	None
RCSTS-01-FLOW05	Release of ammonia to atmosphere from a fire or a gas release resulting in an explosion due to addition of inadequately diluted caustic.	Human error	Industrial Hygiene Program	None
RCSTS-03-FLOW/INTEG01	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Failure of jumper due to misalignment (human error).	None	None
RCSTS-03-FLOW/INTEG02a	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Failure of jumper due to misalignment (human error)	None	None
RCSTS-03-FLOW/INTEG02b	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Failure of jumper due to gasket failure	None	None
RCSTS-03-FLOW/INTEG02c	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Failure of jumper due to corrosion	None	None
RCSTS-03-FLOW/INTEG03a	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak.	Failure of jumper due to misalignment (human error)	None	Trans Leak Detection: Material Balance
RCSTS-03-FLOW/INTEG03b	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak.	Failure of jumper due to gasket failure	None	Trans Leak Detection: Material Balance

Table D-6. Defense In Depth Controls For Potentially Severe (E3 and E2) Environmental Consequences. (22 sheets)

ID	Hazardous Conditions	Cause	DID-Preventive	DID-Mitigative
RCSTS-03-FLOW/INTEG03c	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak.	Failure of jumper due to corrosion	None	Trans Leak Detection: Material Balance
RCSTS-03-FLOW/INTEG04a	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak.	Failure of jumper due to misalignment (human error)	None	Trans Leak Detection: Material Balance
RCSTS-03-FLOW/INTEG04b	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak.	Failure of jumper due to gasket failure	None	Trans Leak Detection: Material Balance
RCSTS-03-FLOW/INTEG04c	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak.	Failure of jumper due to corrosion	None	Trans Leak Detection: Material Balance
RCSTS-03-FLOW02	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Computer failure or human error causing misrouting of material when flow path is not completely connected	None	None
RCSTS-03-FLOW03	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	External leak of valve or valves to the valve pit	None	None
RCSTS-03-FLOW04	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Computer failure or human error causing misrouting of material when flow path is not completely connected	None	None
RCSTS-03-FLOW05	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	External leak of valve or valves to the valve pit	None	None
RCSTS-03-FLOW06	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak.	Computer failure or human error causing misrouting of material when flow path is not completely connected	None	Trans Leak Detection: Material Balance

Table D-6. Defense In Depth Controls For Potentially Severe (E3 and E2) Environmental Consequences. (22 sheets)

ID	Hazardous Conditions	Cause	DID-Preventive	DID-Mitigative
RCSTS-03-FLOW07	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak.	External leak of valve or valves to the valve pit	None	Trans Leak Detection: Material Balance
RCSTS-03-FLOW08	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak.	Computer failure or human error causing misrouting of material when flow path is not completely connected	None	Trans Leak Detection: Material Balance
RCSTS-03-INTEG01	Release of radioactive aerosols to the atmosphere from the SY valve pit due to fire or explosion of flammable gas.	Fire or explosion in the valve pit caused by buildup of flammable gas because of spill of supernate or slurry	None	None
RCSTS-03-INTEG02	Release of radioactive aerosols to the atmosphere from the SY valve pit due to fire or explosion of flammable gas.	Fire or explosion due to leakage of flammable gas due to pipe breach in slurry line caused by gas release from slurry	None	None
RCSTS-03-INTEG03	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak.	External leak of valve or valves to the valve pit	None	Trans Leak Detection: Material Balance
RCSTS-03-INTEG04	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak.	Seismic event	None	None
RCSTS-03-INTEG05	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak.	External event (airplane crash, etc)	None	None
RCSTS-03-INTEG06	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak.	Seismic event	None	None
RCSTS-03-INTEG07	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak.	External event (airplane crash, etc)	None	None
RCSTS-03-INTEG08	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Seismic event	None	None

Table D-6. Defense In Depth Controls For Potentially Severe (E3 and E2) Environmental Consequences. (22 sheets)

ID	Hazardous Conditions	Cause	DID-Preventive	DID-Mitigative
RCSTS-03-INTEG09	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak.	External event (airplane crash, etc)	None	Material Balance
RCSTS-03-INTEG10	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak.	Seismic event	None	None
RCSTS-03-INTEG11	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak.	External event (airplane crash, etc)	None	Mass Balance
RCSTS-03-PRES02	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Water hammer	None	None
RCSTS-03-PRES03	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool).	Water hammer	None	None
RCSTS-04/05-INTEG01a	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to corrosion	None	None
RCSTS-04/05-INTEG01b	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to unrecognized material flaw	None	None
RCSTS-04/05-INTEG02	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to external event (airplane crash, volcanism, etc)	None	None
RCSTS-04/05-INTEG03	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and the diversion box due to piping system leak.	Failure of primary and encasement piping due to external event (excavation accident)	None	None

Table D-6. Defense In Depth Controls For Potentially Severe (E3 and E2) Environmental Consequences. (22 sheets)

ID	Hazardous Conditions	Cause	DID-Preventive	DID-Mitigative
RCSTS-04/05-INTEG04	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to external event (undermining from broken fluid transfer lines in vicinity)	None	None
RCSTS-04/05-INTEG05	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to seismic event	None	None
RCSTS-04/05-TEMP01	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak.	Failure of primary and encasement piping due to freezing	None	None
RCSTS-08-FLOW03	Release of radioactive supernate to soil surface from overflow of diversion box due to piping system leak.	External leak of valve or valves to the diversion box	None	None
RCSTS-08-FLOW04	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	External leak of valve or valves to the diversion box	None	None
RCSTS-08-FLOW05	Release of radioactive supernate to soil surface from overflow of diversion box due to piping system leak.	Backflow of supernate to sump pump line, through sump pump and onto diversion box floor	None	None
RCSTS-08-FLOW08	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	External leak of valve or valves to the diversion box	None	Trans Leak Detection: Material Balance
RCSTS-08-INTEG01	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Failure of piping due to corrosion	None	None
RCSTS-08-INTEG02	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	External event (airplane crash, etc)	None	None
RCSTS-08-INTEG03	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Flammable gas explosion from release of trapped flammable gas within pipe combined with ignition source	None	None
RCSTS-08-INTEG04	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Failure of piping due to material defect	None	None

Table D-6. Defense In Depth Controls For Potentially Severe (E3 and E2) Environmental Consequences. (22 sheets)

ID	Hazardous Conditions	Cause	DID-Preventive	DID-Mitigative
RCSTS-08-INTEG05	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Slurry pump overspeed causing catastrophic failure of pump with missiles damaging pipe	None	None
RCSTS-08-INTEG06	Release of radioactive slurry to soil surface from overflow of diversion box due to piping system leak.	Seismic event	None	None
RCSTS-08-INTEG07	Release of radioactive supernate to soil surface from overflow of diversion box due to piping system leak.	Seismic event	None	None
RCSTS-08-INTEG08	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	Failure of piping due to corrosion	None	Trans Leak Detection: Material Balance
RCSTS-08-INTEG09	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	External event (airplane crash, etc)	None	Material Balance
RCSTS-08-INTEG10	Release of radioactive aerosols to the atmosphere caused by spray leak of supernate from diversion box due to piping system leak.	External event (airplane crash, etc)	None	Material Balance
RCSTS-08-INTEG11	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	Flammable gas explosion from release of trapped flammable gas within pipe combined with ignition source	None	Trans Leak Detection: Material Balance
RCSTS-08-INTEG12	Release of radioactive aerosols to the atmosphere from the 6241-A diversion box due to fire or explosion of flammable gas.	Fire or explosion in the diversion box caused by buildup of flammable gas because of spill of supernate to diversion box sump	None	None
RCSTS-08-INTEG13	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	Failure of piping due to material defect	None	Trans Leak Detection: Material Balance
RCSTS-08-INTEG14	Release of radioactive aerosols to the atmosphere caused by spray leak of slurry from diversion box due to piping system leak.	Slurry pump overspeed causing catastrophic failure of pump with missiles damaging pipe and challenging diversion box confinement	None	Trans Leak Detection: Material Balance

702-AZ VENTILATION SYSTEM
(241-AZ-702)
SAFETY ANALYSIS

ADDENDUM 3

September 1998

This page intentionally left blank.

EXECUTIVE SUMMARY

ES.1 FACILITY BACKGROUND AND MISSION

The Aging Waste Facility (AWF) provides underground tank storage of high-level radioactive waste at the Hanford Site. The four tanks in the AWF require ventilation for confinement, cooling, and flammable gas mitigation. This document is the basis for the interim operation of the 241-AZ-702 ventilation system. The 241-AZ-702 ventilation system (28.3 m^3/min [1,000 scfm] maximum) replaces the existing 241-A-702 ventilation system (113.3 m^3/min [4,000 scfm] maximum). This document provides the safety analysis for closure of the Unreviewed Safety Question Evaluation (USQ TF-93-0055, *Tank Farm Ventilation Upgrade, Project W-030*) for this change to the AWF.

ES.2 SCOPE

This Addendum to the HNF-SD-WM-BIO-001, *Tank Waste Remediation System Basis for Interim Operation*, (BIO), document provides safety analysis for the operation of the 241-AZ-702 ventilation system for normal operations of the AWF.

ES.3 FACILITY OVERVIEW

The AWF, 241-AY and 241-AZ Tank Farms, are located in the 200 East Area of the Hanford Site as shown in Figure 1-1. The AWF is described in the BIO, Appendix B, "Facility and Process Description." A detailed description of the 241-AZ-702 ventilation system is found in Section 2.0 "Facility Description."

The 241-AZ-702 ventilation system provides a maximum 28.3 m^3/min (1,000 scfm) flow from the four tanks (2.83 m^3/min [100 scfm] nominal from each tank) as described in Section 2.5.1.2 of this addendum.

ES.4 FACILITY HAZARD CATEGORY

The AWF Tank Farms are identified in the BIO as Hazard Category 2 facilities.

ES.5 SAFETY ANALYSIS OVERVIEW

The operation of the 241-AZ-702 ventilation system is compared with the 29 accident analyses in the BIO and is found to be bounded by all accidents. In addition, before initial release of the BIO as part of the Authorization Basis, hazards associated with operation of the 241-AZ-702 ventilation system were evaluated using preliminary hazard analysis (PHA) and hazards and operability (HazOp) evaluation techniques. From the results of the hazard analysis, five accidents were identified as representative of the significant hazards. These accidents are the high-efficiency particulate air (HEPA) filter failure due to high temperature, HEPA filter failure due to high

pressure, Flammable Gas Deflagration, Tank Bump, and tank dome collapse. The risk evaluation guidelines are identified in Revision 1, Section 7.0, "Risk" of WHC-CM-4-46[1], *Safety Analysis Manual*.

An expansion of an existing BIO control unique to the 241-AZ-702 ventilation system is required to protect the assumption on the filter source term used in the comparisons with the BIO. It is required that the high-efficiency mist eliminator (HEME), assumed to be equivalent to four HEPA filter volumes, be monitored and replaced at $\leq$ 800 mrem/h. The high efficiency gas adsorber (HEGA) must be replaced before the upstream HEPA filter in the associated filter train has been replaced 20 times and when the upstream HEPA filter in the associated filter train is determined to have a particulate removal efficiency of < 99.95% by performance of an aerosol test, or other indication of degraded HEPA filter performance.

ES.6 ORGANIZATIONS

The AWF is part of the Tank Waste Remediation System which is operated by Lockheed Martin Hanford Corporation (LMHC) under contract to the Fluor Daniel Hanford, Inc. (FDH). This document was developed by Duke Engineering and Services Hanford, Incorporated (DESH) for LMHC.

ES.7 SAFETY ANALYSIS CONCLUSIONS

The findings of this document conclude that the 241-AZ-702 ventilation system provides those controls and features necessary and sufficient to ensure the protection of workers, the environment, and the public during its operation.

ES.8 DOCUMENT ORGANIZATION

This document is organized in the format of DOE-STD-3009-94, *Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports*. For those sections where information would be provided about Site-wide programmatic controls, only the portions of those programs directly applicable to the 241-AZ-702 ventilation system are described. The remaining portions of the Addendum sections reference the BIO.

1.0 SITE CHARACTERISTICS

1.1 INTRODUCTION

This section describes the Hanford Site characteristics applicable to the Aging Waste Facility (AWF) ventilation upgrade project (Project W-030) at the Tank Waste Remediation System (TWRS) facilities. The ventilation upgrade is referred to as the 241-AZ-702 ventilation system. The AWF is located in the 200 East Area of the Hanford Site.

It is not the intent of this section to provide all of the information required by the guidance of DOE-STD-3009-94, but to provide the information necessary to describe the facility's location, and critical parameters used in Section 3.0, "Hazard and Accident Analyses."

1.2 REQUIREMENTS

The following standards, regulations, and U.S. Department of Energy (DOE) Orders establish the site characterization requirements for support of safety analysis and design unique to 241-AZ-702 ventilation system.

- DOE 4700.1, *Project Management System*, Change 1 (1992)
- HPS-SDC 4.1, Hanford Plant Standards, Revision 11, (for natural phenomena loading).

Additional requirements related to site characteristics can be found in HNF-SD-WM-BIO-001, Appendix C, "Site Characteristics," Section C1.2, "Requirements."

1.3 SITE DESCRIPTION

This section addresses the site boundary and site location with respect to the AWF. See the BIO, Appendix C, Section C1.3, "Site Description" for site geography, general site description and demography.

The TWRS AWF is located in the 200 East Area of the Hanford Site (Figure 1-1). For this analysis, the site boundary used for calculations is 8.7 km (5.44 mi) to the north (the near side of the Columbia River) (BIO, Section 5.3.1, "Methodology.")

1.4 ENVIRONMENTAL DESCRIPTION

The meteorological, hydrological and geological characteristics of the site, in conjunction with the 241-AZ-702 ventilation system, do not create any new, unique hazards for the 241-AZ-702 ventilation system (BIO, Appendix C, Section C1.4, "Environmental Description").

1.5 NATURAL PHENOMENA THREATS

No changes result from the installation or operation of the 241-AZ-702 ventilation system. See BIO, Appendix C, Section C1.5, "Natural Phenomena Threats," for the description of the natural phenomena threats.

1.6 EXTERNAL MAN-MADE THREATS

There are no unique external man-made threats for the 241-AZ-702 ventilation system (BIO, Appendix C, Section C1.6, "External Man-made Threats").

1.7 NEARBY FACILITIES

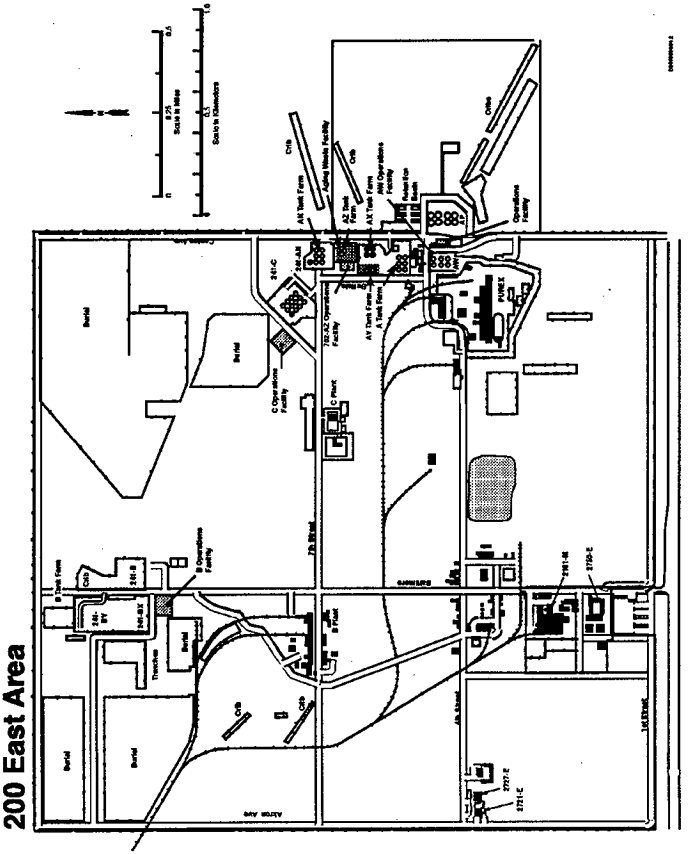
Accidents attributed to nearby facilities are discussed in BIO, Appendix C, Section C1.7, "Nearby Facilities." There are no unique accidents from nearby facilities identified for the 241-AZ-702 ventilation system.

The AWF accidents with the potential to affect the onsite individual at 100 m (which may include persons at some of the facilities discussed in the BIO, Appendix C, Section C1.7) are discussed in Section 3.0.

1.8 VALIDITY OF EXISTING ENVIRONMENTAL ANALYSES

The 241-AZ-702 ventilation system was evaluated in WHC-SD-W030-EE-001, *Environmental Evaluation*, and found to be within the scope of the existing Environmental Impact Statement, DOE/EIS-0113, *Final Environmental Impact Statement: Disposal of Hanford Defense High-Level, Transuranic, and Tank Waste, Hanford Site, Richland, Washington.* The consequences of all analyzed accidents for the project do not create any additional and unreviewed insults to the environment. In fact, WHC-SD-W030-EE-001 shows that normal operations of this system enhance environmental compliance by reducing liquid effluents. The system design requirements were based on analyses to meet environmental requirements and therefore provide compliance with 40 CFR 61, "National Emission Standards for Hazardous Air Pollutants (NESHAP)," *Code of Federal Regulations*, (NESHAPs) by reducing stack effluents.

Figure 1-1. The 200 East Area.



This page intentionally left blank.

2.0 FACILITY DESCRIPTION

2.1 INTRODUCTION

The purpose of this section is to provide a general description of the 241-AZ-702 ventilation system. Defense-in-Depth and Safety-Class or Safety-Significant structures, systems, and components (SSCs) are addressed in Sections 3.0, "Hazard and Accident Analyses," and 4.0, "Safety Structure, Systems, and Components," of this addendum.

The 241-AZ-702 ventilation system safety documentation does not include in its scope the operation of the Project W-151 mixer pump in Tank 241-AZ-101 nor the Project W-320 activities for the receipt of waste from Tank 241-C-106. Each of these projects is preparing separate safety documentation.

2.2 REQUIREMENTS

The design codes, standards, regulations, and U.S. Department of Energy (DOE) Orders relevant to the design and construction of the 241-AZ-702 ventilation system are listed in the functional design criteria, WHC-SD-600-FDC-001, *Functional Design Criteria for the Tank Farm Ventilation Upgrade, Project W-030*. The safety SSCs were designed to DOE 6430.1A, *General Design Criteria*, as SC-2. After the system was designed and built, the safety analysis required changing some of these to SC-1. See Section 4.0 of this addendum for details.

2.3 FACILITY OVERVIEW

The Aging Waste Facility (AWF), 241-AY and 241-AZ Tank Farms, is located in the 200 East Area of the Hanford Site in a complex of tank farms known as the Plutonium Uranium Extraction (Facility) (PUREX) 241-A Tank Farm Complex, situated to the northeast of the PUREX Plant. As shown in Figure 1-1, the 241-AZ Tank Farm is located in the northernmost fringe of the 241-A Tank Farm Complex. The 241-AY Tank Farm is located southwest of the 241-AZ tanks west of AX Tank Farm. The 241-AZ-702 ventilation system supports the currently defined mission of waste storage for the AWF.

2.4 FACILITY STRUCTURE

The 241-AZ-702 ventilation system includes three new buildings: a ventilation building, a generator/service building, and a control building. It also includes four recirculation/cooling cells. The location of the new buildings and cells are shown on Figure 2-1. The ventilation, generator/service, and control buildings were designed to DOE 6430.1A and Hanford Plant Standard SDC 4.1, *Architectural - Civil Design Criteria, Design Loads for Facilities*, as described in the functional design criteria for 241-AZ-702 (WHC-SD-600-FDC-001). Floor plans for these buildings and facility are shown in Figures 2-2 through 2-5.

The new ventilation building houses the primary tank ventilation equipment, including condensers, high-efficiency mist eliminator (HEME), heater coils, high-efficiency particulate air (HEPA) filters, high-efficiency gas adsorbers (HEGAs), fans, near isokinetic stack sampling, continuous air monitoring instruments, and ventilation facility local control units. The ventilation building has a floor area of approximately 1394 m^2 (15,000 ft^2) and is made of cast-in-place reinforced concrete. The building has four exterior doors. Two of these doors have a double door arrangement. Doors, frames, and hardware are designed to maintain a negative pressure inside the building.

The new generator/service building houses one diesel generator and standby power distribution equipment. Backflow preventers, strainers, and flow meters for the raw water supply are located in the service room. The generator/service building has a floor area of approximately 288 m^2 (3,100 ft^2) and is made of cast-in-place reinforced concrete. The building is constructed of non-combustible materials.

The control building is a prefabricated metal structure on a reinforced concrete slab. The control building houses the automated control and indication information such as tank head space pressure.

The recirculation/cooling cells house the process cooling equipment for recirculation cooling of the tank ventilation off gas. The process equipment included is a shell-and-tube heat exchanger, moisture separator, electric motor driven fan, flow control valve, miscellaneous remote/manual actuated valves, interconnecting piping and instrumentation. The cells were constructed of reinforced concrete with outside dimensions of 4.6 m (15 ft) by 4.9 m (16 ft) by 3.4 m (11 ft) high. A cover block is provided in the roof for future removal of the heat exchanger. A steel door is provided for personnel access into the cell for maintenance. The cell has capped connections for hookup of temporary ventilation when personnel access is required.

2.5 PROCESS DESCRIPTION

The activities and operations performed within the AWF include waste storage, transfer, characterization, concentration, and other miscellaneous activities. Other than tank ventilation, the 241-AZ-702 ventilation system does not impact the currently-defined storage mission or the basic processes in use in the facility. This section describes the new ventilation system process.

2.5.1 System Overview

2.5.1.1 System Functional Overview

2.5.1.1.1 Confinement and Heat Removal. The 241-AZ-702 ventilation system provides uninterrupted operations during normal operation, maintenance or testing. Selected components of the 241-AZ-702 tank ventilation system are redundant. Automatic transfer of ventilation system functions from the

primary system components to the redundant system components is provided. Transfer of functions is activated at the first indication of system failure to prevent the loss of system confinement.

The 241-AZ-702 ventilation system is sized such that a negative differential pressure with respect to atmospheric pressure can be maintained under normal operating conditions to contain radioactive and non-radioactive gases, vapors, suspended droplets, and airborne particulates within the system until appropriately treated and discharged. Sufficient controls are provided to maintain the tank at less than atmospheric pressure. The primary tank ventilation system is capable of removing heat and water vapor from the tank vapor space, and compensate for normal air infiltration and process air introduced into the tank through the airlift circulators. Pressure sensors in the head space of each tank provide pressure indication in the control room and on strip chart recorders in the instrumentation buildings, 241-AY-801 and 241-AZ-801.

Heat removal is provided primarily by recirculation ventilation cooling with some additional cooling provided by once through air flow. See Table 2-1 for system heat removal and operating temperatures.

The 241-AZ-702 ventilation system does not compromise the present tank operating capabilities and requirements. Features provided by the 241-AZ-702 ventilation system are listed below:

- Active and/or passive cold weather protection for all new heating, ventilation, and air conditioning (HVAC) instrumentation, duct work, fans, exhaust stacks, drains, and sealpots.
- Features to prevent moisture accumulation on HEPA filters (e.g., deentrainers, HEME filters).
- Provisions for measuring pressure differential across, and in-place testing of, individual filters in accordance with American Society of Mechanical Engineers (ASME) N510, *Testing of Nuclear Air Treatment Systems*; gauges and instruments are located and/or suitably protected to prevent moisture accumulation.
- Electrical equipment enclosures with temperature controls to provide a suitable environment for the installed equipment.
- Safe access provided to all areas of operation, including ladders, walkways, platforms, as applicable.
- Stack airflow and discharge volume measurement.
- Near isokinetic particulate sampling for the exhaust stack.
- Features (HEME, condenser, and recirculation system) to prevent ammonium nitrate or other soluble compound accumulation on the filters.

- Instrumentation to provide monitoring of the equipment operation for each stage of exhaust treatment and ports for future additional monitoring and control.

- A HEGA to remove organic carbon vapors and iodine gas.

2.5.1.1.2 Air Cleaning and Treatment. Exhaust air from the primary tank system is treated to minimize releases of radioactive and hazardous effluents to the atmosphere. The filtered airstream is continuously sampled for radioactive and known hazardous substances, and continuously monitored for gross beta and gamma. Instruments record radioactive releases and alarm before allowable radioactive release limits are exceeded.

The listing of radioactive and hazardous effluents to the atmosphere to be measured can be found in Bauer (1994a and 1994b). These documents are the Notices for Construction sent from the DOE to the Environmental Protection Agency and the Washington State Department of Ecology, respectively.

2.5.1.1.3 Condensate Collection and Disposal. Water vapor removed from the tanks is condensed, and the condensate is returned to AY and/or AZ high heat tanks. The design for condensate collection and disposal complies with WAC-173-460, "Controls for New Sources of Toxic Air Pollutants," as amended, and 40 CFR 61, "National Emission Standards for Hazardous Air Pollutants (NESHAP)," *Code of Federal Regulations*, as amended.

2.5.1.1.4 Monitoring and Control. A new instrument/control center is provided to house the new instrumentation for the tank ventilation. Environmental controls are provided for the new facility, commensurate with the requirements for equipment to be installed.

Instrumentation is installed to provide safe and reliable operation of the tank ventilation system and standby power systems. Continuous air monitors (CAM) and record air samplers are provided on the primary tank ventilation system to detect and measure hazardous and/or radioactive releases to the atmosphere, with alarms for low flow conditions and for loss of sample flow. The alarms are separate and distinct from that used for high radiation. Stack record air sampling is continuous and representative of the airflow in the duct work. The flow meters are Safety-Class instrumentation for the 241-AZ-702 ventilation system (HNF-SD-WM-SEL-040, *TWRS Facility Safety Equipment List*).

Temperature and leak detector alarms and signals are sent to the Tank Monitoring and Control System (TMACS) (Table 2-2). New instrument and electrical wire runs are enclosed in separate raceways where practicable and to facilitate future mission flexibility.

Instrumentation that has alarm features, are designed to alarm on loss of signal.

2.5.1.2 System Design Overview. The Primary Tank Ventilation System for the 241-AY-101, 241-AY-102, 241-AZ-101, and 241-AZ-102 tanks contains individually controlled air inlets, independent cooling systems, and a common ventilation off gas exhaust. A functional overview of the 241-AZ-702 ventilation system is found in Figure 2-6.

The tank ventilation off gas from each tank is exhausted through a flow control valve, processed through a condenser, mist eliminator, heater, and then filtered before being exhausted to the atmosphere through a stack. The filter/fan train is redundant to maintain tank pressures during anticipated maintenance shutdowns or component failure. Likewise, the flow control valve can be bypassed during anticipated maintenance shutdowns or valve failure.

The entire system is automatically controlled by the monitor and control system (MCS). Should the MCS fail, the ventilation system will remain in its current state but can then be run manually. The approach will be to shut down all ancillary equipment and to manually operate primary exhaust fans while monitoring the primary stack CAM and tank pressure instrumentation. The failure of the computer controlled equipment, from an individual component to an entire system failure, has appropriate alarm response procedures and guidance to the operators' actions to restore the system to a safe configuration and restore primary tank ventilation. Once stable operation is achieved, the remainder of the system would be restored.

The Primary Tank Ventilation System performs the following functions:

- Provides filtered inlet air for tank cooling and gas dilution for any flammable gases
- Maintains a negative pressure in the waste storage tanks of approximately 3 to 8 cm (1 to 3 in.) water gauge during normal operation
- Provides cooling-condensing of the off gas streams for tritium removal, in a recirculation loop for each tank.
- Removes particulates and condensable vapors from the radioactive off gas streams
- Exhausts the primary tank ventilation stream from the four tanks to the atmosphere through a primary exhaust stack
- Monitors exhaust emissions.

The system has three operating modes: 1) recirculation (Figure 2-7), 2) bypass (Figure 2-8), and 3) high heat (Figure 2-9). The alignment of the ventilation system on any one tank is independent of the alignment of the ventilation system on the other tanks:

1. Each tank's recirculation mode directs tank headspace gases through their respective Recirculation Ventilation Cooling System with, typically, 80% of the airstream returned back into the tank and 20% to the common exhaust system. The common exhaust system draws enough air to maintain a negative pressure in all of the tanks, relative to atmospheric pressure, with the majority of the flow back to the tank. The air flow through the recirculation loop is fixed by equipment design, however each tank's exhaust flow rate is actively-controlled and held constant.

2. The bypass mode directs tank headspace gases directly to the common exhaust system, bypassing the Recirculation Ventilation Cooling System.

3. The high heat mode directs tank headspace gases through the Recirculation Ventilation Cooling System then into the common exhaust system with no air returning to the tank. When any tank is in the high heat mode, the common exhaust fan flow is increased in order to increase evaporative cooling of the tank operating in high heat mode. Exhaust flow is routed through the Recirculation Ventilation Cooling System to help remove moisture.

Operation of the three modes is controlled with valving within the duct work. The selection of the operating mode is manually established. The operating mode is thus established by the configuration of the valves in the recirculation system. The lineups and flow paths of the different operating modes are illustrated in Figures 2-7, 2-8, and 2-9.

Normal operation, with all of the recirculation systems available, results in 14.2 m^3/min (500 scfm) being withdrawn from each tank. In this case, 80%, or 11.3 m^3/min (400 scfm), is returned to the tank while the remaining 20%, or 2.8 m^3/min (100 scfm), goes out the stack. This 2.8 m^3/min (100 scfm) is compensated by introducing atmospheric air through the inlet filter system into the tank. This results in 56.6 m^3/min (2,000 scfm) being withdrawn from the four AWF tanks and only 11.3 m^3/min (400 scfm) going into the main ventilation system. Each tank can be set at a different flow rate (e.g., one tank could be set to send 17.0 m^3/min [600 scfm] to the main ventilation system, and each of the others can be set at 2.8 m^3/min [100 scfm], for a total flow of 25.5 m^3/min [900 scfm] at the main ventilation system). The total ventilation flow is limited by the system capacity of 28.3 m^3/min (1,000 scfm). Each 241-AZ-702 fan is capable of 59.8 mmHg (32 in. WG) vacuum at peak. The recirculation fans add 33 mmHg (17.5 in. WG) vacuum at peak.

The airlift circulators (ALCs) are designed to operate at a minimum of 1.6 m^3/min (55 scfm) with normal operation of 2.3 m^3/min (80 scfm) for each tank. The maximum airflow for one tank is 12.5 m^3/min (440 scfm). The total ALC compressor capacity for all of the AWF tanks is limited to either 11.3 m^3/min (400 scfm) or 14.2 m^3/min (500 scfm) depending on whether the primary or backup compressor is being used. This additional ALC airflow remains within the operating capacity for the 241-AZ-702 ventilation system since the flow can be adjusted for each tank.

Instrumentation is provided at each tank to monitor and control pressure. The MCS is provided with its own uninterruptible power supply that ensures the MCS remains operational while the diesel generator comes on line. The diesel generator provides the backup electric power to the exhaust fans which are safety equipment (HNF-SD-WM-SEL-040).

Because flammable gas generation is a concern during the operation of any equipment with direct communication with the tank headspace, such equipment is required to meet National Fire Protection Association (NFPA) Class 1 Division 2 criteria or its equivalent (BIO, Appendix E, "Flammable Gas/Slurry Growth Unreviewed Safety Question: Justification for Continued Operation for

the Tank Farms at the Hanford Site [FG JCO])." The 241-AZ-702 equipment meets these requirements before the first mixing point as defined in the FG JCO through compliance with the Flammable Gas Equipment Advisory Board (FGEAB) direction. The board reviewed three aspects of the 241-AZ-702 ventilation system: 1) the equipment before the first mixing point (Inlet Filter Arrangement and Recirculation Module), 2) the equipment after the first mixing point, and 3) tie-ins related to construction. The board's directions are summarized below.

- Inlet Filter Arrangement
  - Equipment not listed below complies with the FG JCO.
  - Heater, control/electrical Box, HEPA filter differential pressure switch and heat trace require either modifications or de-energizing during waste disturbing activities (FGEAB 97-005a, "Operation of new ventilation system to support the AWF (INLET FILTER ARRANGEMENT)" [FGEAB 1997]). The heater has been modified per the directions and the others will be de-energized as directed.
- Recirculation Module
  - Equipment not listed below either complies with the FG JCO requirements or is beyond the first mixing point.
  - The fans require modification. The board directed a stop plate near the sheave to prevent axial movement of the shaft and this modification was performed (FGEAB 97-005b, "Operation of New Ventilation System to Support the Aging Waste Facility (RE-CIRCULATION MODULE)" [FGEAB 1997]).
- Equipment Beyond First Mixing Point
  - No requirements are on this equipment (FGEAB 97-031, "Project W-030, Activity and equipment located after the first mixing point" [FGEAB 1997]).

The 241-AZ-702 ventilation system equipment complies with the board's recommendations. Another report was issued dealing with the tie-in activities (FGEAB 97-005c, "Hot Tie-in of the New Ventilation System to Support the Aging Waste Facility" [FGEAB 1997]). Although performed before the issuance of the FG JCO and determination of the AWF tank Facility Group (all are Facility Group 2 tanks), a mixing study was performed for the 241-AZ-702 ventilation system that corroborates the board's findings (WHC-SD-WM-ER-592, *Assessment of the Project W-030 Ventilation System Following a Hypothetical Gas Release Event*).

2.5.2 Inlet Breather

The tank air inlet breather, installed on each of the AWF tanks, consists of a heater, prefilter, HEPA filter, flow control valve, flow meter, and a vacuum relief valve. The functions performed by these components are described below.

- The heaters protect the pre-filters from excessive humidity or frost.
- The prefilters protect the HEPA filters from excessive particulate loading that would shorten their lives.
- The HEPA filters protect the environment against potential backflow from the waste tank inlet.
- The flow control valves are automatically modulated to maintain a negative pressure range in the waste storage tanks.
- The flow meters monitor air flow into each of the waste storage tanks.
- The vacuum relief valves are provided to prevent excessive negative pressure in the waste storage tank. The vacuum relief valves have direct communication between the tank vapor space and the atmosphere. The valves are actuated before a pressure of 1.49 kPa (-6 in. WG) by a diaphragm that senses tank pressure.

2.5.3 Recirculation Ventilation Cooling

The four Recirculation Ventilation Cooling systems help to reduce moisture and remove the heat generated in the tanks. The cooling equipment for each tank is located in concrete vaults. This system consists of four basic parts: 1) ductwork, 2) the condenser, 3) the Recirculation Ventilation Cooling Module, and 4) the Evaporator Cooling Tower. The vaults are reinforced concrete structures with equipment access from the top and personnel access through a door. The Recirculation Ventilation Cooling Module does not have backup power. Backup power is not needed because if the Recirculation Ventilation Cooling Module fails, once-through cooling is sufficient to maintain tank temperature below limits (Table 2-1).

There is an independent recirculation cooling system for each tank in the AWF. Each system is similar in design but differs in cooling capacity. The cooling capacity for Tank 241-AZ-101 is higher than the other three tanks (i.e., the evaporative cooling tower has a higher capacity). A continuous cable leak detection system is located around the condenser, moisture separator, and recirculation fan to sense condensate leaks. An alarm is activated upon leak detection.

2.5.3.1 Duct Work. The duct work of the recirculation cooling sub-system provides gas and moisture confinement for the exhaust stream during the cooling process. The duct work is buried, double-encased piping with 35.6 cm (14-in.) carbon steel pipe around 25.4 cm (10-in.) stainless steel pipe. The

buried ducting is cathodically protected with an active system. A leak detector is located at the low spot of both the inlet and outlet encased piping to the waste tanks. The detector monitors for liquid condensate that has entered the encasement (presumably from a leaking liner pipe). When a leak is detected, an alarm is activated (e.g., alarm to the control room) and corrective action is taken according to the requirements of the radioactive and hazardous waste management program (HNF-SD-WM-BIO-001, Section 4.6, "Radioactive and Hazardous Material Waste Management"). This corrective action in the case of the 241-AZ-702 ventilation system is in the form of pumping out the encasement.

2.5.3.2 Recirculation Ventilation Cooling Module. The recirculation ventilation cooling module consists of the following:

- Condenser
- Recirculation Fan
- Moisture Separator.

2.5.3.2.1 Condenser. Each condenser is a shell-and-tube heat exchanger. The ventilation gas stream is cooled by circulating 1,900 L (500 gal) of 50% propylene glycol, 50% water solution through the tubes. This 50/50 mixture cannot be demonstrated to have a flashpoint. Condensate collected in the condenser is drained back to the tank by means of a drain line that is connected to the return ventilation duct. The drain line is isolated from the ventilation duct by a seal loop. Instrumentation monitors differential pressure across the condenser, inlet temperature, and outlet temperature.

2.5.3.2.2 Recirculation Fan. Each recirculation fan is single housing, single impeller, centrifugal type, non-overloading, and direct driven by an electric motor. Each fan operates at 14 m^3/min (500 scfm). The recirculation fan circulates the tank headspace gases through the Recirculation Ventilation Cooling Module.

Instrumentation is provided to monitor motor current and differential pressure across the fan. A low differential pressure across the condenser indicates that the fan is not operating properly and activates an alarm. Flow meters monitor air flow from each of the waste storage tanks.

2.5.3.2.3 Moisture Separator. Each vertical gas-liquid separator is designed to remove entrained liquid, which prevents erosion of the fan wheel. The separator removes liquids from the air stream by centrifugal force and gravity. Moisture removed from the exhaust stream drains by gravity back to the tank along the return ventilation duct. The drain line from the condenser to the ventilation duct is isolated by a seal loop.

2.5.3.3 Evaporator Cooling Tower. The Evaporator Cooling Tower consists of an evaporative cooling tower, two circulation pumps, an expansion tank, an air separator, and instruments for monitoring the closed loop cooling system. The cooling medium is a propylene glycol solution that is circulated between the evaporative cooling tower and the recirculation condenser. A propylene glycol solution is used for freeze protection and corrosion prevention. The

propylene glycol solution receives heat in the recirculation ventilation condenser and rejects heat to the atmosphere in the evaporative cooler. The evaporator is provided with a fan and a spray water system to remove heat from the fluid.

A circulation line transports the propylene glycol solution to and from the recirculation condenser and the evaporative cooling tower. A manually operated globe valve is provided for initial propylene glycol flow adjustment. Instrumentation is provided to monitor the line for flow, pressure, and temperature. The main piping is carbon steel with welded fittings.

2.5.3.3.1 Condenser Pumps. Each evaporator cooling tower has two pumps (one active and one standby) to circulate the propylene glycol solution through the condenser and the evaporator cooling tower. Both pumps are provided with isolation valves. The pumps also are provided with suction and discharge local pressure indicators.

The pumps are provided with current indication and alarms to show whether the pump is running or has failed. Status alarms are used to indicate a disagreement between the hand switch position and the pump operation. To facilitate equal pump wear, indication of total pump operation time is provided.

During a low-flow condition, the operating pump is shut down, a low-flow alarm is activated, and the standby pump becomes the operating pump. If the flow is not reestablished, then the standby pump also is shut down. Both pumps must be reset for the system to operate again. Low flow could be a warning sign of a leak, a clogged line, a low level in the propylene glycol tank, or a malfunctioning pump.

2.5.3.3.2 Expansion Tank. Each propylene glycol expansion tank will provide adequate system pressurization under all operating conditions. The tank provides for system expansion and contraction. A low-level alarm will notify the operator of a pending problem.

2.5.3.3.3 Evaporative Fluid Cooler. The evaporative fluid cooler removes heat from the propylene glycol solution returning from the recirculation condenser. The cooler is equipped with a heat exchanger, cooling fan, spray pump, and water collection pan. A closed-loop sump water recirculation system also is provided for water quality control.

The cooling fan has temperature-controlled dampers to modulate air flow for greater power savings over the operating season. The damper package consists of a single airfoil-type damper blade located in the fan discharge housing. The controls consist of a control transformer, damper motor actuator with linkage, and end switches to cycle fan motors. A proportional-acting temperature controller to control the damper actuators is installed on the outlet line of the evaporative fluid cooler.

The spray pump circulates sump water to spray nozzles, which spray onto a heat exchanger and the water drains back into the sump. The level control automatically provides raw water for sump water makeup. A low water level switch prevents operation of the spray pump. The sump water is provided with a heater controlled by a thermostat with the sensing bulb located in the sump water. The heater protects sump water from freezing.

Sump water quality is maintained by a closed-loop circulation system. Sump water is recirculated by means of a recirculation pump through a strainer and centrifugal separator for particulate removal. Particulates removed by the separator are captured in a bag filter as the separator drain discharges back to the pump suction. Particulate buildup on the filter will initiate an alarm.

Water conductivity is measured by a conductivity probe in the circulation system. A circulation flow is passed over the probe for indication of salts and dissolved solids buildup in the sump water. At a predetermined operator setpoint, high conductivity will actuate the sump water drain valve to drain the sump water to manhole No. 1. Raw water makeup is automatically provided by means of the sump water level controls. A flow switch is provided to prevent operation of the conductivity controls without water flow.

2.5.4 Common Exhaust System

The common exhaust system consists of five basic parts: 1) duct work, 2) a condenser subsystem, 3) a HEME, 4) two filtration trains, and 5) a primary tank ventilation exhaust stack. The common exhaust system provides flammable gas removal and confinement of radiological particulates by maintaining air flow out of the tank and a negative pressure relative to atmospheric pressure in the tank headspace.

The common exhaust flow is taken from the Recirculation Ventilation Cooling Module return line. The flow rate is determined by an automatic control valve that responds to the flow rate setpoint. The exhaust lines from each tank are combined and routed to the ventilation facility. The line then passes through the condenser, where it is cooled, and then through the HEME to eliminate any water droplet carryover into the filter system. The condensate from the condenser and HEME is drained into a seal pot and then passes to catch Tank 241-AZ-151. The condenser and/or the HEME can be valved out and bypassed for maintenance or replacement purposes.

Upon exiting the HEME, the gas stream is heated. Heating the exhaust air extends the service life of the HEPA filters downstream by providing air with reduced humidity relative to the filter unit inlet. The inlet motor-operated valves to both trains are normally open and are closed only during maintenance on the train or when high temperatures are present at the outlet to the filter bank. To smother any possible fires, both the inlet and outlet valves are closed automatically when high temperatures occur at the train outlet.

Upon heater startup, the associated outlet motor-operated valve (MOV) is automatically opened. Under normal operations, only one of the outlet MOVs may be closed at any one time. The outlet MOVs close upon de-energization of the heater, high radiation in the exhaust stack, high differential pressure across the filter train, or high temperature at the outlet to the filter bank. The system can be manually configured by individually setting each MOV.

In a high radiation condition, interlocks from the K1 exhaust duct radiation monitor will open the outlet valve to the standby filter train and close the outlet valve to the operating filter train in the K1 exhaust system. Manual over-ride of this interlock is possible only by changes to the MCS. The MCS uses a password-oriented security system so only authorized personnel can make changes involving over-rides.

Each heater system and associated filter bank are contained in a train. Normally, one train will be in operation while the second train is in standby. Each filter bank consists of two HEPA filters and a HEGA. Instrumentation provided for each filter bank monitors the pressure differential across each stage and the temperature downstream of each bank. The system will shut down and switch over to the standby train upon high differential pressure across any stage of the filter train, upon heater failure, or when the heater high temperature setpoint is tripped.

Once the ventilation gas stream has passed through one of the two filter banks, it is exhausted by the exhaust fan through the monitor system and then through the exhaust stack into the atmosphere. One fan will be in standby while the operating fan maintains a vacuum on the four storage tanks. The second filter bank is provided to allow operation of the ventilation system during routine maintenance activities (e.g., filter replacement). Manually-operated valves are located upstream and downstream of each primary fan. The purpose of these isolation valves is to facilitate maintenance activities. As an additional feature, each fan includes a back draft damper on its discharge. Either fan can exhaust through either ventilation train through the cross-over capability of the system. This provides isolation and maintenance capability for each ventilation train and for each main system fan.

2.5.4.1 Duct Work. The duct work provides gas and moisture confinement for the exhaust stream. It is double-encased piping with carbon steel around stainless steel. The duct work is buried until it enters the Ventilation Building. The buried ducting is cathodically protected with an active system.

2.5.4.2 Ventilation Condenser Cooling System. The closed-loop Ventilation Condenser Cooling System provides cooling for the primary tank ventilation exhaust air from the tanks.

The Ventilation Condenser Cooling System consists of an air-cooled liquid chiller, two circulation pumps, an expansion tank, an air separator, a condenser, and instruments for monitoring the closed-loop cooling system. The cooling medium used is a propylene glycol solution that is circulated between the chiller and the ventilation condenser. Instrumentation monitors the line for flow, inlet temperature, and outlet temperature. The main piping is carbon steel with welded fittings. A manual globe valve in the discharge piping adjusts the flow.

The closed-loop cooling system removes moisture from the gas stream and removes heat from the ventilation condenser. This process reduces the temperature of the vapor. The propylene glycol solution absorbs heat from the condenser and rejects heat in the air-cooled chiller.

2.5.4.2.1 Condenser. The condenser is a shell-and-tube heat exchanger located in the Vent Cell (Figure 2-2) of the Ventilation Building. The ventilation gas stream is cooled by 3800 L (1,000 gal) of 50% propylene glycol, 50% water solution through the tubes. Instrumentation monitors inlet temperature, outlet temperature, and pressure differential across the condenser.

2.5.4.2.2 Pumps. Two pumps (one active and one standby) circulate the propylene glycol solution through the condenser and the chiller cooler. The pumps also have suction and discharge local pressure indicators.

Pump operation is monitored through flow in the recirculation line. If low flow occurs, a flow switch activates the standby pump and an alarm sounds. If the flow is still low after the standby pump is activated, both pumps are shut down until they are reset. The flow switch is also used to send a signal to the chiller indicating that flow has been established.

The pumps are provided with current indication and alarms to show whether the pump is running or has failed. To facilitate equal pump wear, an indication of the pumps' total operating time is measured.

2.5.4.2.3 Chiller. An air-cooled liquid chiller removes heat from the propylene glycol solution as it returns from the ventilation condenser. The chiller is a complete, factory assembled, single-skid package, equipped with compressors, evaporator, condenser, refrigerant circuits, cooler, and controls.

The chiller is equipped with a common trouble alarm to indicate when there is an equipment failure. The chiller is also interlocked with the flow in the propylene glycol line to prevent operation during low flow.

2.5.4.3 High-Efficiency Mist Eliminator. The HEME is a cartridge type and is located in the Ventilation Building Vent Cell (Figure 2-2). The HEME will remove water droplets carried over from the condenser, and drain it into the condensate tank. Instrumentation monitors pressure differential across the HEME. In the case of high differential pressure, the filter can be changed.

All liquid collected in the HEME is drained to a seal pot, and then to catch tank 241-AZ-151.

2.5.4.4 Filtration Trains. The two independent filtration trains consist of a heater, HEPA filters, HEGA unit, and an exhaust fan. One operates as the primary train and the other a standby.

If the outlet valve to an operating filter train is not open, or is subsequently closed, the filter train will shut down and a failure alarm will be activated. Also, automatic switch over to the standby heater and filter train will occur.

2.5.4.4.1 Heaters. Upstream of each HEPA filter train is an electric heater system that heats the saturated air and prevents condensation on the filters. The heater capacity is based on the worst case scenario of loss of cooling and the resulting maximum gas stream conditions.

Each heater is equipped with an internal low flow switch, a high temperature cutout switch, and a manual cutout switch.

Instrumentation monitors temperature upstream of the heater and downstream of the HEPA filter train. Local temperature controllers for each heater are controlled by temperature differential controllers. The differential temperature is measured from the inlet of the heater to the outlet of the HEPA filter train. Low temperature differential will activate separate independent alarms. High temperatures on heater inlet or outlet will also activate alarms. Total airflow is monitored at the exhaust stack.

If the active heater fails, automatic switch over to the standby heater and filter train will occur and a failure alarm will be activated. If the inlet valve to an operating heater is not open or is subsequently closed, the heater will be shut down and a failure alarm will be activated. Switch over to the standby heater and filter train also will occur if the standby system is available.

2.5.4.4.2 High-Efficiency Particulate Air Filters. The filter system is designed for a high particulate removal efficiency. This will be achieved by using two HEPA filters in series. The filters have provisions for in-place efficiency testing. The filter bank can be isolated to facilitate filter change out or other maintenance procedures.

2.5.4.4.3 High-Efficiency Gas Adsorber Filter. The HEGA is a charcoal filter designed to remove organic carbon vapors and iodine gas. The carbon cartridges are located between stages of HEPA filters. The filter bank can be isolated to allow HEGA change out or other maintenance procedures.

2.5.4.4.4 Exhaust Fans. Each exhaust fan is belt driven with a variable speed motor. The maximum flow rate is 28 m^3/min (1,000 scfm), but is normally operated at 11 m^3/min (400 scfm). The fans are centrifugal type with low leakage construction. The fans are sufficient to cover all identified operating modes.

If a failure occurs in the operating exhaust fan, switch over to the standby fan will occur and an alarm will be activated. The fan can be isolated to facilitate change out or other maintenance actions.

2.5.5 Exhaust Stack

The primary tank ventilation exhaust stack is located just outside of the ventilation building, approximately 1 m (3.5 ft) from the external face of the building. The stack extends 16.8 m (55 ft) above grade and is the point of discharge for the primary tank ventilation system. The primary exhaust air stream is sampled and monitored for radioactive particulate before discharge through the stack. The exhausted air stream is also monitored for flow.

2.6 CONFINEMENT SYSTEMS

The 241-AZ-702 ventilation system has been designed to limit the release of radioactive and hazardous materials to the environment. This section provides an overview of confinement features incorporated into the design.

The underground ducting is comprised of individual underground ducts for each tank. Each individual tank is connected to a common header within each Tank Farm.

The 241-AZ-702 underground ducting is double contained from the Tank Farm tie-in to the connection at the ventilation building. Leak detection, for either condensate or pipe leakage is provided at low points between the outer and inner ducting.

2.7 SAFETY SUPPORT SYSTEMS

Safety support systems impacted by the 241-AZ-702 ventilation system consist of effluent monitoring and fire protection. These systems are discussed in the following subsections.

2.7.1 Effluent Monitoring

State-of-the-art instrumentation will monitor and analyze temperature and stack flows of the systems. The instrumentation and electrical systems will read out and/or alarm on the MCS in the control room.

The MCS provides monitoring and control for ventilation system processes and equipment as well as limited monitoring of tank processes in the AWF Tank Farms.

The primary tank ventilation exhaust system discharges the treated gas to the atmosphere. The effluent is monitored and sampled for radioactivity (Bauer 1994a and 1994b) before discharge into the atmosphere. High radioactivity levels will activate control alarms and enable interlocks to secure operation of the primary filter train and transfer to the secondary filter train thus maintaining continuous operation.

The building ventilation system stack is monitored and sampled for radioactivity before discharge of the air. The ventilation building HVAC system discharges the building exhaust air through the ventilation building exhaust stack. Interlocks from the radiation monitoring system cause the switch over to the standby bank on high radiation level. All annunciator response procedures require operator action to determine cause and corrective action.

2.7.2 Fire Protection Systems

The ventilation and generator service buildings are protected throughout by an automatic dry-pipe sprinkler system. The system complies with the requirements of NFPA 13, *Installation of Sprinkler Systems*, for ordinary hazard group occupancy classification (HNF-SD-WM-FHA-020, *Fire Hazards Analysis for Tank Farms*).

System fire alarm and supervisory signals for both buildings will annunciate at the fire alarm control panel located outside the 241-AZ-271 control room on the west wall. The fire alarm system for both buildings complies with the requirements of NFPA 72, *National Fire Alarm Code*. All alarm system components in both buildings are Underwriters Laboratories (UL) listed or Factory Mutual approved for the use intended. A radio fire alarm master box is located inside the 241-AZ-271 control room on the west wall. This master box transmits fire alarm and trouble signals to the Hanford Fire Department.

The control building is protected throughout by a wet pipe sprinkler system.

All sprinkler system components in both buildings are UL listed or Factory Mutual approved for the use intended.

2.8 UTILITY DISTRIBUTION SYSTEMS

Utility distribution systems impacted by the 241-AZ-702 ventilation system include the following:

- Water supply systems
- Electrical power distribution system.

Each system is discussed below.

2.8.1 Water Supply Systems

All water for the 200 East Area is supplied from the Hanford Site Export Water System (EWS). Water is distributed throughout the area by two separate systems, the Raw Water System (RWS) and the Sanitary Water System (SWS). Untreated, and unchlorinated raw water is used principally for cooling, and dilution systems. Sanitary water is treated (e.g., filtered, purified) water used for drinking and sanitary facilities. These provide water for sanitary, process, and fire protection uses.

The RWS supplies makeup water to the recirculation condenser cooling system and the evaporative coolers through the diesel generator building. The RWS consists of the duplex strainer, a pressure-reducing valve, a certified backflow preventer, and associated instrumentation.

The RWS routes raw water from a 30.5-cm (12-in.) polyvinyl chloride underground header into the diesel generator building through a 5.1-cm (2-in.) carbon steel line. The raw water enters the building through a duplex strainer and backflow preventer.

Instrumentation is provided to monitor differential pressure across the strainer and activate an alarm on high differential pressure. Upon detection of high differential pressure, maintenance personnel must manually switch to the standby filter. Local pressure gauges are provided upstream of the strainer and downstream of the backflow preventer. In addition, instrumentation is provided to monitor header flow rate, totalization, and pressure downstream of the backflow preventer. Upon detection of low pressure, an alarm is sent to the MCS, however, no automatic control is provided.

2.8.2 Electric Power Systems

Power is provided to the new facilities from an existing 13.8 kV aerial line to a newly-installed unit substation. In this substation, voltage is reduced by a 300 kVA transformer to 480/277 V ac for distribution to system loads. Standby power is available to the main ventilation train and the MCS.

Standby power is provided by a 325 KVA diesel generator through two automatic transfer switches to the service distribution switchboards, motor control centers (MCCs), transformers, and lighting and power panels. The automatic transfer switch will actuate and standby power will be supplied to the bus located in the MCC and bus located in the ventilation building. All non-motor loads such as lighting will be immediately energized. Critical motor loads will be automatically started in sequence to reduce the initial load on the generator. Non-critical loads will remain secured until manually started after return of normal power.

The diesel fuel storage tank is sized to provide at least 24 hours of fully loaded engine operation. The 241-AZ-702 ventilation system diesel generator is equipped with a 3 Kw jacket water heater that maintains the jacket water temperature above 32 °C (90 °F). The jacket water is not circulated unless the engine is running. The diesel generator building is cooled or heated to the approximate temperature range of 4 to 32 °C (40 to 90 °F).

An uninterruptible power supply is provided to maintain a continuous supply of power to the MCS during the transition from normal to standby power. The uninterruptible power supply is continuously on-line and will supply standby power on a loss of normal power.

2.9 AUXILIARY SYSTEMS AND SUPPORT FACILITIES

No systems or facilities other than those described in the previous sections were identified as requiring descriptions in this document.

Table 2-1. 241-AZ-702 Ventilation System Design Heat Loads and Tank Waste Temperatures.

Tank	AZ-101	AZ-102	AY-101	AY-102
Current heat load,[a] kW (Btu/h)	70.81 (241,600)	56.74 (193,600)	12.02 (41,000)	9.67 (33,000)
Design heat load removal with recirculation,[b] kW (Btu/h)	486.79 (1,661,000)	293.07 (1,000,000)	293.07 (1,000,000)	293.07 (1,000,000)
Ventilation flow rate allocated in the by-pass mode[a,c] m^3/min (cfm)	9.9 (350)	9.9 (350)	4.2 (150)	4.2 (150)
Supernate temperature with current tank contents and by-pass mode,[a] °C (°F)	65.6 (150)	61.1 (142)	41.7 (107)	38.9 (102)
Peak sludge temperature with current tank contents and by-pass mode,[a] °C (°F)	93.3 (200)	94.4 (202)	58.9 (138)	43.9 (111)

[a]HNF-SD-W030-ER-004, 1997, Evaluation of Waste Temperatures in Aging Waste Facility Tanks for By-Pass Mode Operation of the 702-AZ Ventilation System (Project W-030), Rev. 0, Numatec Hanford Corporation, Richland, Washington.

[b]WHC-SD-600-FDC-001, 1997, Functional Design Criteria for the Tank Farm Ventilation Upgrade, Project W-030, Rev. 4, Numatec Hanford Company, Richland, Washington.

[c]The by-pass mode is the lowest heat removal configuration. It involves no heat removal by the recirculation/cooling system (which is by-passed). The heat is only removed by the once-through air flow.

Table 2-2. Detailed Description of 241-AZ-702 Ventilation System TMACs Instrumentation Connections.

Tag Description	Detailed Description
AY FARM PRIM TK VENT LINES LEAK DETECTED	Leak detected in piping encasement associated with the 241-AY primary tank ventilation.
AY FARM RECIRC BLDGS LEAK DETECTED	Liquid detected on the floor of either the 241-AY-401 or 241-AY-402 buildings. Liquid likely condensate leaking from condenser, moisture separator, fan, or piping.
TK-AY-101 PRESS HI/LO	241-AY-101 tank pressure (head space) is outside its normal operating range.
TK-AY-102 PRESS HI/LO	241-AY-102 tank pressure (head space) is outside its normal operating range.
AZ FARM PRIM TK VENT LINES LEAK DETECTED	Leak detected in piping encasement associated with the 241-AZ primary tank ventilation.
AY FARM RECIRC BLDGS LEAK DETECTED	Liquid detected on the floor of either the 241-AZ-401 or 241-AZ-402 buildings. Liquid likely condensate leaking from condenser, moisture separator, fan, or piping.
TK-AZ-101 PRESS HI/LO	241-AZ-101 tank pressure (head space) is outside its normal operating range.
TK-AZ-102 PRESS HI/LO	241-AZ-102 tank pressure (head space) is outside its normal operating range.
CATCH TK 241-AZ-151 LEAK DETECTED	Liquid detected in either the piping encasement for the 241-AZ-702 condensate discharge line (piping to 241-AZ-151 from 241-AZ-702), or liquid detected in the piping encasement associated with the 241-AZ-151 catch tank ventilation line.
PRIMARY TK VENT STACK DISCHARGE RAD HI/FAIL	Either high levels of radiation have been detected by the 241-AZ-702 primary tank ventilation stack's beta/gamma CAM, or the CAM has failed.
PRIMARY TK VENT SAMPLE SYSTEMS FLOW HI/LO	The sample flow rate is too high or too low through the beta/gamma CAM, or the record sampler (which are associated with the 241-AZ-702 primary tank ventilation stack).
AZ702 BLDG VENT STACK DISCHARGE RAD HI/FAIL	Either high levels of radiation have been detected in the 241-AZ-702 building ventilation stack beta/gamma CAM, or CAM has failed.
AZ702 BLDG VENT SAMPLE SYSTEMS FLOW HI/LO	The sample flow rate is too high or too low through the beta/gamma CAM, or through the record sampler (which are associated with the 241-AZ-702 building ventilation stack).
AZ702 BLDG LEAK DETECTED	Liquid has been detected in the 241-AZ-702 cell's sump, or on the floor of Filter Room A, or on the floor of Filter Room B.

CAM = continuous air monitor.

3.0 HAZARD AND ACCIDENT ANALYSES

3.1 INTRODUCTION

The 241-AZ-702 ventilation system is designed to replace the existing 241-A-702 ventilation system for the Aging Waste Facility (AWF) waste storage tanks. These tanks contain radioactive materials in the form of liquid and sludges. The radionuclides, their concentrations, and the resulting unit liter doses (ULDs) used for radiological consequence calculations are found in WHC-SD-WM-SARR-037, *Development of Radiological Concentrations and Unit Liter Doses for TWRS FSAR Radiological Consequence Calculations*.

This section identifies and evaluates hazards associated with the operation of the 241-AZ-702 ventilation system. It evaluates the consequences of accidents from potential internal, external, and natural phenomena-related events that could potentially release hazardous materials. Potential consequences to the public and to workers are considered, as are the corresponding preventive and mitigative features.

The following safety analysis is based on a Preliminary Hazard Analysis (PHA) technique that qualitatively or semi-quantitatively evaluated the identified hazards. From this evaluation, design basis accidents are identified (Section 3.3, "Hazard Analysis Results") and analyzed. In addition, the 241-AZ-702 ventilation system is compared with the *Tank Waste Remediation System Basis for Interim Operation*, HNF-SD-WM-BIO-001, (BIO), accident scenarios (Section 3.4.2, "Design Basis Accidents" of this addendum). All the accident scenarios for further analysis are also contained in BIO, Section 5.3.2, "Accident Analysis Scenarios."

This addendum to the BIO and associated Technical Safety Requirements (TSRs), will be the basis for future Unreviewed Safety Question (USQ) (DOE 5480.21, *Unreviewed Safety Questions*) evaluations related to the ventilation system for the AWF.

3.2 REQUIREMENTS

The design codes, standards, regulations, and DOE Orders that are required for establishing the safety basis of the 241-AZ-702 ventilation system are as listed in the BIO. Only portions of these documents are relevant to this safety document, namely those that cover requirements pertinent to safety analysis.

3.3 HAZARD ANALYSIS RESULTS

Results of the hazard identification activities for the 241-AZ-702 ventilation system are provided in the following sections. Details of the hazard analysis are presented in the following appendices to this addendum.

- Appendix A, "Hazard Basis"
- Appendix B, "Hazard Analysis Summary"

- Appendix C, "Hazard Evaluation Result"
- Appendix D, "Control Allocation Tables."

The results of the hazard analysis were used to select candidate accidents for analysis and identify controls. The detailed methodology and results of the hazard analysis are recorded in Appendix B, "Hazard Analysis Summary," of this addendum.

Section 3.3.1 below discusses the methodology used for the hazard analysis summarized in the appendices. Section 3.3.2 below provides a summary of the hazard analysis results.

3.3.1 Methodology

The first step in performing an accident analysis is to identify and qualitatively assess the facility hazards. The results of the assessment are then used to determine the events that could initiate accidents with the potential to expose site personnel or the general public to radioactive or chemical materials. See Appendix B of this addendum for a more thorough description of methodology.

3.3.1.1 Hazard Identification. Hazard means a source of danger (i.e., material, energy source, or operation) with the potential to cause illness, injury, or death to personnel or damage to a facility or to the environment (without regards for the likelihood or credibility of accident scenarios or consequence mitigation). As in the BIO, the hazard identification methods and techniques include the following:

- Review of past safety documents
- Review of reportable event history (e.g., Hanford Site and Tank Waste Remediation System [TWRS] unusual occurrence reports)
- Review of historical records of similar operations (e.g., unusual occurrence reports from the existing 241-A-702 ventilation system, the SY farm ventilation system, the AN farm ventilation system, and the SX farm ventilation system)
- Participation by current and former operations and engineering personnel in the hazard analysis effort
- Use of standardized checklists of potential hazardous materials and energy sources
- Use of material at risk information
- Use of facilities and operations descriptions
- Use of existing TWRS hazard analyses.

3.3.1.2 Hazard Evaluation. The hazards analysis consists of the hazards identification and evaluation process performed for the AWF Tank Farms and includes the comprehensive evaluation of potential process-related hazards,

natural phenomena hazards, external hazards, and hazards intrinsic to the facility. These hazards arise from the type, form, location, and quantities of nuclear chemical waste stored in the aging waste underground storage tanks. The hazard identification and evaluation process provides a qualitative evaluation of the spectrum of potential accidents involving the hazards identified. This effort forms the basis for: 1) identifying any additional, unique facility worker protection issues and environmental considerations, and 2) selecting potential design basis accidents (DBAs) to be further developed and quantified in Section 3.4.2 below.

Those hazards identified as credible by the review team were recorded in the Hazard Summary Table Appendix B, Table B-1. Categories of hazardous materials evaluated included radioactive material, toxic materials, corrosive materials, reactive materials, asphyxiants, explosives, and combustibles and flammables. Types of energy sources evaluated included potential energy sources, kinetic energy sources, and radiant energy sources.

3.3.2 Hazard Analysis Results

Using the PHA and hazard and operability study (HazOp) techniques, a Hazard Analysis Summary table was constructed. Hazard Analysis Summary tables have been used to compile the results of the hazard identification and evaluation process for the 241-AZ-702 ventilation system. The tables are presented in Appendix B along with the supplemental information that was considered for each hazard category during the identification process.

3.3.2.1 Hazard Identification. The hazards identified for the 241-AZ-702 ventilation system are listed in Appendix B, Table B-1.

Review of past safety documents (e.g., unusual occurrence reports) indicates that no major accidents or hazardous situations that are ventilation related were identified for the AWF since 1985. No data was available before 1985. The hazards associated with the AWF waste storage tanks have been summarized in Tables 3-1 through 3-6.

3.3.2.2 Hazard Classification. The AWF Tank Farms have been identified in the BIO as Hazard Category 2 (BIO, Section 5.1, "Hazard Classification").

3.3.2.3 Accident Evaluation. In the PHA and HazOp study, estimates were made of the likelihood of each scenario (or class of accidents) to determine the frequency category of the scenario. There are four frequency categories. There are also four severity categories as previously defined. These values are used to establish a risk matrix bin number. Those events in bin numbers 1, 2, 3, 4, 5, and 7 are considered for accident selection (Table B-5).

The accidents having a potential severity category of S2 and S3 were grouped according to the accident scenarios (see Appendix B, Table B-4) for a definition of severity categories). This second grouping allows for the selection of a representative scenario to be developed in Section 3.4 below that will bound the other accidents within the group (Section 3.3.4.2).

3.3.2.3.1 Accidents Identified with the Monitor and Control System. The monitor and control system (MCS) was reviewed for hazards and accident initiators related to the 241-AZ-702 ventilation system. Hazards and accident initiators associated with the loss or malfunction of the MCS were identified as a loss of ventilation airflow, ventilation imbalance, excessive vacuum, excessive pressure, and excessive airflow. The associated accidents that would result from these have been included in (Table B-1, Event Numbers 28, 35, 36, and 39.

3.3.2.3.2 Accidents Identified with Instrumentation. The instrumentation was reviewed for its potential impact on the 241-AZ-702 ventilation system. The monitoring and alarm systems provide indications that the pressure, flow, radiation levels, etc., exceed trip limits. Lack of these indications, unless later identified as performing a safety function, was not identified as initiating any accident.

Reaching certain instrumentation trip limits results in ventilation configuration changes. An example of this would be exceeding the trip limit associated with differential pressure across the high-efficiency particulate air (HEPA) filters, resulting in an automatic change of the filter trains. Premature changes in configuration, failure to make the configuration changes, or slow changes in the configuration did not result in any identified hazards for the 241-AZ-702 ventilation system.

The instruments and equipment in regions of potential flammable gas concentrations meet the ignition source controls as defined in the BIO, Appendix E, "Flammable Gas/Slurry Growth Unreviewed Safety Question: Justification for Continued Operation for the Tank Farms at the Hanford Site."

3.3.2.3.3 Accidents Identified with Loss of Utilities. Accident initiators associated with the loss of utilities were evaluated. The only accident initiator from the loss of utilities that could seriously impact the 241-AZ-702 ventilation system was the loss of electrical power. This was evaluated and recorded in Table B-1, Event Number 28. Loss of water or instrument air (there are no natural gas or steam lines associated with the 241-AZ-702 ventilation system) did not result in any identified hazards.

3.3.2.3.4 Accidents Identified with Nuclear Criticality. A nuclear criticality accident within the AWF ventilation system was deemed to be beyond extremely unlikely (BEU) by the HazOp team (Appendix B, Table B-1, Event Number 43). Section 6.3, "Project Implementation" of this addendum provides additional information and detail to confirm the team's assessment for a criticality accident in the AWF ventilation system.

3.3.2.4 Accident Selection. Accident selection for hazards associated with the 241-AZ-702 ventilation system was performed by the hazards analysis team, as part of the hazards analysis process.

The hazards analysis team consisted of the 241-AZ-702 ventilation system designers, TWRS Tank Farm plant operators, and safety analysts. The hazards analysis team met and performed a PHA, HazOp, and hazard identification on the 241-AZ-702 ventilation system. Each component of the system was considered

for failure including the MOVs (PHA) and flow from each component (HazOp). The PHA emphasized the components of the design. The HazOp emphasized the processes involved with ventilation. Also, a checklist for all high energy sources in the system was performed (Table B-6). This was the method used to capture all the potential hazards and accidents associated with the system.

The hazards analysis scope included all aspects of the 241-AZ-702 ventilation system including the recirculation systems of the four tanks (241-AZ-101,-AZ-102, 241-AY-101,-AY-102), the chiller, chiller pumps, condenser, seal pot, 241-AZ-151 catch tank, HEME, both trains of electric heaters, HEPA, HEGA, fans, monitoring instrumentation, the buildings, the secondary HVAC in the ventilation building, the ducts, the hangers, and 55-ft exhaust stack.

Appendix B, Table B-1, provides summary results for the 241-AZ-702 ventilation system PHA and HazOp. Identified hazards were related to corresponding postulated accident scenarios. Each of the postulated accident scenarios were further evaluated by the hazards analysis team.

The results of the PHA analyses were a number of postulated abnormal events which were ranked by the team members with respect to safety consequences. The initial, qualitative, consensus estimates of the severity of the consequences were ranked according to the criteria shown in Appendix B, Table B-4, "Radiological and Chemical Consequence Evaluation Levels for Hazard Receptors."

The initial, qualitative, consensus estimates of the frequency of the abnormal events were also ranked by the hazards analysis team members. An alphanumeric system was used to designate the frequency as shown in Appendix B, Table B-3, "Frequency Evaluation Levels."

In the process of completing the PHA, risk matrix numbers were added to each column considering events both with and without mitigation. Table B-5, was used to help identify event scenarios that required further attention. The risk matrix numbers 1, 2, 3, 4, 5, and 7 indicated that accident analyses would be required to envelope postulated event consequences. These risk matrix numbers also indicated the need for consideration of safety structures, systems, and components, and interim operational safety requirements. Risk bin numbers 6, 8, and 9 indicated the need for consideration of administrative or operating specification level controls.

Those events which resulted in risk binning matrix numbers which indicated the need for further accident analyses included the following:

- Process vapor release to the atmosphere due to ducting failure, drain line failure, seal pot failure, etc. (facility worker only)
- Release of radiological and toxicological material due to Tank Bump
- Release of radiological and toxicological material due to dome collapse caused by flammable gas headspace deflagration
- Release of radiological and toxicological material due to dome collapse caused by excessive vacuum

- Release of radiological and toxicological material due to dome collapse caused by excessive pressure
- Criticality caused by buildup of radiological material in the ducting.

Safety analysts then further considered the above identified events. The criticality event was determined to be beyond extremely unlikely after consideration of the plutonium chemistry of high level neutralized wastes in the Hanford Site underground storage tanks. It was determined that the plutonium would not be subject to transport and accumulation in the tank ventilation systems (Section 6.0). The criticality event was thus eliminated from further consideration.

The remaining events were then reviewed to determine appropriate bounding, unique, and representative accident scenarios. The safety analysts determined that the following accidents are specific to the 241-AZ-702 ventilation system and were the appropriate bounding, unique, and representative accidents for analysis.

- HEPA filter failure - exposure to high temperature (filter fire)
- HEPA filter failure - exposure to high pressure
- Tank dome collapse (regarding ventilation)
- Flammable Gas Deflagration event
- Tank Bump.

3.4 ACCIDENT ANALYSIS

This section provides the analysis for the five accidents (HEPA filter failure - exposure to high temperature [filter fire], HEPA filter failure - exposure to high pressure, tank dome collapse, Flammable Gas Deflagration event, Tank Bump) that need to be revisited for the 241-AZ-702 ventilation system. To provide a complete picture of how the 241-AZ-702 ventilation system relates to the BIO accident scenarios, all other BIO accident scenarios are discussed with a focus on any interfaces with the 241-AZ-702 ventilation system (Table 3-7).

In accordance with DOE-STD-3009-94, each BIO accident used in the safety analysis was quantitatively evaluated and found to be applicable.

The five reanalyzed accidents are presented in the same order as that of the BIO. Note that only the new controls are shown in this addendum. The existing controls that remain applicable are provided by reference to the BIO.

It is important to note that the analysis addressing State Highway 240 transient populations that is outlined at the beginning of BIO Section 5.3.2, "Accident Analysis Scenarios," is also applicable to the 241-AZ-702 ventilation system analysis.

Section 3.4.1 below summarizes the important aspects of the consequence calculation methods common to the accidents analyzed.

3.4.1 Methodology

3.4.1.1 Radiological Dose and Toxicological Exposure Methodology. Five accidents previously analyzed in the BIO (HEPA filter failure - exposure to high temperature, HEPA filter failure - exposure to high pressure, tank dome collapse, Flammable Gas Deflagration, Tank Bump) were identified for analysis with respect to the 241-AZ-702 ventilation system. These accidents are addressed in this chapter. The methodology associated specifically with radiological dose and toxicological exposure is as detailed in WHC-SD-WM-SARR-037, WHC-SD-WM-SARR-011, *Toxic Chemical Considerations for Tank Farm Releases*, and WHC-SD-WM-SARR-016, *Tank Waste Compositions and Atmosphere Dispersion Coefficients for Use in Safety Analysis Consequence Assessments*, which comprise the same basis for the source terms used in the BIO. This section summarizes the radiological and toxicological consequence calculation values necessary and particular to the 241-AZ-702 ventilation system analyses of operational accidents, natural phenomena, and external events selected for further analysis in Section 3.3.2.4, "Accident Selection." Consequence calculation methods specific to individual accidents are summarized in the individual analyses presented in Section 3.4.2 below.

Accident consequences are combined with the accident frequency and compared to the risk guidelines as shown in Tables 3-8 and 3-9. Radiological risk guidelines for the 241-AZ-702 ventilation system, (Project W-030) are from Revision 1 of Section 7.0, "Risk," of WHC-CM-4-46[2].

Toxicological consequence calculation methodology is as shown in WHC-SD-WM-SARR-011. Toxicological risk guidelines are shown in Table 3-9. Application of these guidelines using the sum-of-fractions methodology means that all consequences with the sum-of-fraction values less than one (1) are within the risk guidelines.

3.4.1.2 Natural Phenomena Methodology. The process to analyze natural phenomena effects on facilities is twofold. First the facilities are analyzed for their failure with respect to natural phenomena and the associated consequences. Then the design is modified to preclude that failure, if necessary and possible, by designing the system to meet specified criteria as found in DOE 6430.1A and SDC 4.1 for each natural phenomenon (e.g., design basis earthquakes, wind loads, etc.).

---

[2]Refer to Appendix F, "Site-wide Controlled Manual Cross Reference Table," of the BIO for cross-walk between Site-wide controlled manuals (e.g., WHC-CM-X-XX) superseded by Fluor Daniel Hanford, Inc., Procedures (e.g., HNF-PRO-XXX).

3.4.2 Design Basis Accidents

The following accidents are specific to the 241-AZ-702 ventilation system and bound all other accidents resulting from hazards shown in the Hazards Analysis Summary Table B-1: HEPA filter failure - exposure to high pressure, HEPA filter failure - exposure to high temperature, tank dome collapse, Flammable Gas Deflagration, and Tank Bump. This section evaluates each of these accident scenarios and dispositions the balance of the BIO accidents with respect to the 241-AZ-702 ventilation system.

3.4.2.1 Nuclear Criticality. The BIO evaluated the potential for nuclear criticality and concluded that no credible scenario has been identified that leads to a criticality in a double-contained receiver tank (DCRT), double-shell tank(DST), or single-shell tank (SST), according to the existing inventory of plutonium that is in the Tank Farms.

Build-up of plutonium in the 241-AZ-702 ventilation system ductwork was considered but deemed BEU due to the low concentrations involved. See Section 6.3 of this addendum for a more detailed discussion.

3.4.2.1.1 Controls. No additional controls are needed. The other criticality controls listed in the BIO are still applicable.

3.4.2.2 High-Efficiency Particulate Air Filter Failure - Exposure to High Temperature or Pressure. Potential releases from HEPA filter failure - exposure to high temperature are evaluated in the BIO. The heat from a fire in close proximity to a ventilation system degrades the HEPA filter and causes a release of a portion of the waste that has accumulated on the filter. In addition, the failed filter is assumed to provide an unfiltered release pathway that continues to operate for up to one year. Bounding radiological and toxicological consequence calculations for the 241-AZ-702 ventilation system are provided in Addendum 1, "Tank 241-C-106 Sluicing Safety Analysis," Section 3.4.2.2.

A pressure differential of 2.5 kPa can fail HEPA filters. The high pressure events identified in the BIO are applicable to the 241-AZ-702 ventilation system. These scenarios are discussed in Section 3.4.2.2.2.

The 241-AZ-702 ventilation system (or the 241-A-702 if it is returned to service) is used to support operation of the Waste Retrieval Sluicing System that is discussed in Addendum 1. The normal storage operation accident (i.e., no sluicing) discussed here and in Section 5.3.2.2 of the BIO text, is bounded by the consequences shown in Addendum 1. Unlike sluicing, normal storage and transfer operations do not have the potential to greatly agitate the waste (both liquids and solids) and create an increased aerosol concentration in the headspace of Tank 241-AY-102. Addendum 1, Section 3.4.2.2, provides additional discussion regarding the accident and how it is impacted by sluicing activities.

3.4.2.2.1 High-Efficiency Particulate Air Filter Failure - Exposure to High Temperature Accident Scenario Assuming No Controls. The BIO indicates that high temperatures associated with an external fire (occurring in close proximity to a HEPA filter system) or the failure of an in-line heater could degrade the ventilation system filters. If the integrity of the filters was

compromised, the inventory of the filters could be released, followed by an unfiltered release from the tank vapor space. Releases from the unfiltered pathway are assumed to continue for up to one year in the BIO analysis. This one year unfiltered release is also assumed in the 241-AZ-702 ventilation system analysis. The radiological and toxicological consequences for this accident are bounded by those presented in Addendum 1, Section 3.4.2.2.

The estimated frequency for this accident scenario was determined to be anticipated (Table B-1, Event Number 40). The frequency of "anticipated" is based on the configuration of the ventilation system and the use of electric heaters.

Each of the two filter trains, containing two HEPAs and a HEGA filter, are housed separately, each train with its own heater. Only one train is used at a time, therefore only one is considered to be lost to fire. The HEME and the inlet HEPA are remotely located in the ventilation system and are not assumed to catch fire in this scenario.

3.4.2.2.1.1 Radiological Consequences. See Addendum 1, Section 3.4.2.2 for the radiological consequences of this accident.

3.4.2.2.1.2 Toxicological Consequences. See Addendum 1, Section 3.4.2.2 for the toxicological consequences of this accident.

3.4.2.2.1.3 HEPA Filter Failure - Exposure to High Temperature Accident Summary of Safety Class/Safety Significant SSCs and Technical Safety Requirements (TSRs). See Addendum 1, Section 3.4.2.2 for the safety SSCs and TSR controls that have been developed to address the risk associated with this accident.

3.4.2.2.2 High-Efficiency Particulate Air Filter Failure - Exposure to High Pressure. Accident Scenario Assuming No Controls - As described in the BIO, a pressure differential of 2.5 kPa (0.36 psi) can cause HEPA filter failure. The accidents identified in the BIO for the AWF tanks that could raise the tank pressure above 2.5 kPa (0.36 psi) include steam intrusions, Flammable Gas Deflagrations, organic solvent fire, and in-tank fuel fire/deflagrations. The 241-AZ-702 ventilation system hazard analysis (Appendix B) also identified excessive particulate loading in the filters and moisture on the filters as other potential initiators to the high pressure accident. The bounding analyses are presented in Addendum 1, Section 3.4.2.2. Unlike the HEPA filter failure from exposure to high temperature (discussed in Section 3.4.2.2.1), which assumed an unfiltered release for up to one year, the HEPA filter failure from high pressure involves high energy events which are not assumed to remain undetected. Therefore, a one year unfiltered release is not considered.

Radiological Consequences. The BIO has evaluated the accidents that could cause a HEPA filter failure because of high pressure (i.e., steam intrusions, Flammable Gas Deflagrations, organic solvent fire, and in-tank fuel fire/deflagrations) in the AWF tanks (with the 241-A-702 ventilation system). In addition, the HazOp in Appendix B considered excessive filter moisture and high particulate loading. The results presented in Addendum 1, Section 3.4.2.2 are bounding for the 241-AZ-702 ventilation system.

High-Efficiency Particulate Air Filter Failure - Exposure to High Pressure Accident Comparison to Guidelines. The accident consequences for the 241-AZ-702 ventilation system are presented in Addendum 1, Section 3.4.2.2.

High-Efficiency Particulate Air Filter Failure - Exposure to High Pressure Accident Controls. See Addendum 1, Section 3.4.2.2 for the safety SSCs and TSR controls that have been developed to address the risk associated with this accident.

The only accident associated with HEPA filter failure due to high pressure which requires the imposition of other ventilation controls (beyond the HEPA filter control program) is the Flammable Gas Deflagration accident. The controls required for this accident are discussed in more detail in Section 3.4.2.14.

3.4.2.2.3 High-Efficiency Particulate Air Filter Failure - Controls. See Addendum 1, Section 3.4.2.2 for the safety SSCs and TSR controls that have been developed to address the risk associated with this accident.

3.4.2.3 Fire In Contaminated Area. There are no contaminated areas associated with the 241-AZ-702 ventilation system that are routinely accessed, such as valve pits, pump pits, and diversion boxes. In the scenario analyzed in the BIO, fuel from a crane gas tank is spilled into a contaminated (and open) valve pit, where it catches fire. The analysis without controls showed that controls are required to protect the onsite worker. To protect the onsite worker, an ignition control program has been established. The elements of this program are shown in BIO, Table 5.3.2.3-2, "Technical Safety Requirement Controls for Fire in Contaminated Area." These controls are not directly applicable to the 241-AZ-702 ventilation system; however, they are applicable to the AWF in general.

3.4.2.4 Evaporator Dump. This accident involves a loss of electrical power to the evaporator, which results in a discharge of the contents of the evaporator to a DST. This scenario is not applicable to the AWF and therefore to the 241-AZ-702 ventilation system. Therefore, no additional controls, beyond those listed in the BIO, are required.

3.4.2.5 Steam Intrusion from Interfacing Systems. This accident involves steam jets that are used to transfer waste into the Tank Farms. As a result of operator error, steam is routed to the headspace of a waste tank, which results in a pressure increase and HEPA filter failure. This scenario applies to the 241-AZ-702 ventilation system and is addressed in Section 3.4.2.2.2 of this document. The controls as listed in Addendum 1, Section 3.4.2.2.3 apply.

3.4.2.6 Leak from Railcar/Tank Trailer. This scenario evaluates the effects of a railcar breach, as the railcar is about to enter the 204-AR Waste Unloading Facility. This scenario is not applicable to the 241-AZ-702 ventilation system. Therefore, no additional controls, beyond those listed in the BIO, are required.

3.4.2.7 Subsurface Leak Remaining Subsurface. Subsurface leaks that remain subsurface have been analyzed in the BIO for existing transfer routes. A leak from a single-walled direct-buried pipe was selected as the bounding accident in the BIO. This scenario was considered bounding because the leak flows

directly to the soil (i.e., there is no encasement) and the direct-buried pipe provides minimal soil shielding. This scenario is not applicable to the 241-AZ-702 ventilation system. Therefore, no additional controls, beyond those listed in the BIO, are required.

3.4.2.8 Unplanned Excavation in Cribs, Ditches, and Ponds. This accident considers inadvertent excavation in a crib, ditch, or pond that contains a large quantity of contaminated soil. This accident does not involve the 241-AZ-702 ventilation system. Therefore, no additional controls, beyond those listed in the BIO, are required.

3.4.2.9 Caustic Spray Leak. This accident involves a spray release of sodium hydroxide from a 1-in. Schedule 10 commercial steel pipe while the solution is being transferred to a waste tank. While this accident is associated with a waste tank, the scenario does not include the ventilation system of the tank, therefore this accident does not involve the 241-AZ-702 ventilation system. Therefore, no additional controls, beyond those listed in the BIO, are required.

3.4.2.10 Sodium Fire. This accident is specific to the 2727-W Building and does not involve the 241-AZ-702 ventilation system.

3.4.2.11 Mixing of Incompatible Material - Toxic Vapor Generation. The scenario assumes a rapid uncontrolled addition of caustic to a DCRT which increases the pH level and ultimately results in the release of ammonia. The analysis applies to DCRTs, DSTs, and SSTs. The BIO analysis results in no consequences and a single Defense-in-Depth control regarding the Industrial Hygiene Program, which ensures personnel safety during chemical additions to the waste tanks. The existing BIO analysis is adequate for the 241-AZ-702 ventilation system and no additional controls, beyond those listed in the BIO, are required.

3.4.2.12 Mixing of Incompatible Material - Tank Pressurization. This scenario assumes that an uncontrolled mixture of incompatible materials in a DCRT results in a tank pressurization and an airborne release. There is nothing unique to the ventilation system that introduces new and different accident scenarios for mixing incompatible materials. Since this occurs in a DCRT, this is not applicable to the 241-AZ-702 ventilation system. Therefore, the existing BIO analysis is adequate for the 241-AZ-702 ventilation system and no additional controls, beyond those listed in the BIO, are required.

3.4.2.13 Tank Failure Due to Excessive Loads. Postulated tank failure accidents, including tank dome failure, are analyzed in the BIO, Section 5.3.2.13, "Tank Failure Due to Excessive Loads." Tank dome collapses could be initiated by excessive dome loading or from a combination of internal (e.g., pressure, vacuum, waste level, temperature) and external (e.g., soil, equipment, seismic) loads. The only potential accident initiator identified in the BIO that is related to the 241-AZ-702 ventilation system is excessive vacuum caused by failures in the ventilation system with continued exhaust operation. Note that the potential for dome collapse caused by Flammable Gas Deflagrations is analyzed in Section 3.4.2.14.

The primary source of excessive vacuum would be from the main ventilation fans. The inlet breather subsystem for each tank includes pressure control valves to maintain tank pressure within the design limits and vacuum relief valves which protect against excessive negative pressure in the primary tank. A failure in the system that generated an excessive vacuum condition in the tank headspace (either fan over speed or inlet plugging) would actuate the vacuum relief valve. Subsequent failure of the vacuum relief valve could lead to excessive vacuum and tearing of the primary tank liner. However, this will not lead to a release of tank material (WHC-SD-TWR-RPT-002, *Structural Integrity and Potential Failure Modes of the Hanford High-Level Waste Tanks*).

The BIO concludes there is no need for a safety limit on excessive vacuum. It references several recent analyses which discuss accidents that could result in excessive vacuum. The bounding accident resulting in the highest vacuum is a solvent fire which results in a negative pressure of -55.16 kPa (-8 psig). Details of the accident analysis are contained in Section 5.3.2.13 of the BIO, WHC-SD-WM-TI-775, *Structural Assessment of Accident Loads*, and WHC-SD-TWR-RPT-002. The scenario is bounding because it results in a vacuum 4.4 times the maximum vacuum possible running the 241-AZ-702 system. The BIO also considered fan over speed and inlet plugging which were not bounding. The maximum vacuum on the fan curve for 241-AZ-702 fans plus the recirculation fan is a gauge pressure of -12.3 kPa (-49.5 in. water gauge or -1.8 psig) (Section 2.5.1.2). In the analysis for the BIO, the solvent fire results in tank failure but not in such a way as to provide a release to the environment. In addition, WHC-SD-WM-TI-775 suggests that some tank damage could occur at -6.9 kPa to -13.8 kPa (-1 to -2 psig), although there is no release due to this damage (WHC-SD-TWR-RPT-002). Protecting the tank is a programmatic issue; there is no safety issue since the worst case excessive vacuum does not result in onsite, offsite, or environmental consequences.

3.4.2.13.1 Controls. Because excessive vacuum results in no release, no controls are required for the 241-AZ-702 ventilation system for this accident. The other controls established in the BIO are unrelated to ventilation and thus are unaffected by the presence of the 241-AZ-702 ventilation system (BIO, Tables 5.3.2.13-2, "Technical Safety Requirement Controls for Load Drops" and 5.3.2.13-3, "Defense-in-Depth, Control for Load Drops")

3.4.2.14 Deflagration Accident. The deflagration accident for the aging waste tanks (with the 241-A-702 ventilation system) has been analyzed in the BIO, Section 5.3.2.14, "Flammable Gas Deflagrations." This analysis (as will be shown below) is also bounding for the 241-AZ-702 ventilation system.

3.4.2.14.1 Deflagration Accident Scenario. Steady state flammable gas generation is expected from all of the AWF tanks. Steady state flammable gas generation is dependent on several parameters including heat load, waste temperature, total organic carbon (TOC) content, aluminum content, and nitrate/nitrite content. The exact influence these parameters have on flammable gas generation is unknown. However, it is estimated that, with current AWF conditions, a condition > 25% of the lower flammability limit (LFL) in the tank dome space can not occur in less than 24 days after the loss of active ventilation (HNF-SD-WM-CN-117, *Calculation of Hydrogen Release Rate at Steady State for Double-Shell Tanks*). This calculation is not considered

to be a "design basis analysis" because of the considerable uncertainty associated with it and because it uses non-bounding assumptions for tank and waste conditions. Rather it is the best available quantitative basis for the prediction that interruption of ventilation flow does not result in imminent danger of deflagration (assuming current tank contents).

Note that the ventilation system mitigates for steady-state flammable gas accumulation but does not mitigate for gas release events (i.e., waste intrusive activities or spontaneous release events). Waste intrusive activities are discontinued on loss of ventilation. Also, ventilation is not credited for gas release event (GRE) protection. The ventilation function addresses steady state release and accumulation.

No credit was taken in the BIO analysis for any beneficial effects that flammable gas monitoring, ignition control practices, or ventilation could have to either prevent or mitigate an accident. An unmitigated, unprevented deflagration accident frequency was determined to be anticipated (Table B-1, Event Numbers 33 and 34).

3.4.2.14.2 Deflagration Accident Source Term. Because the accident scenario analyzed in the BIO (for the 241-A-702 ventilation system) assumes no controls (i.e., no ventilation), the only source term change that will result from applying the same analysis to the 241-AZ-702 ventilation system is in the HEPA filter inventory. However, the analysis for the 241-A-702 ventilation system (documented in Attachment 5 of HNF-SD-WM-CN-099, *Radiological and Toxicological Analyses of Tank 241-AY-102 and Tank 241-C-106 Ventilation Systems*) documents the total quantity of material released from the ventilation system to be 3.6×10^{-2} L, while the 241-AZ-702 system has a total release from the ventilation system of 2.3×10^{-3} L (HNF-SD-WM-CN-099). This shows that the total material released from the 241-AZ-702 system is bounded by the amount released from the 241-A-702 system. It should also be noted that the HEPA filter contribution to the total dose consequences is several orders of magnitude less than the other contributors for both radiological and toxicological consequences and does not impact the total consequences. Thus, the BIO results for the accident without controls are still bounding for the 241-AZ-702 ventilation system. These results are shown in Section 3.4.2.14.3 below and the BIO, Table 5.3.2.14-1, "Results Assuming No Controls Accident Scenario for Flammable Gas Deflagrations."

3.4.2.14.3 Deflagration Accident Comparison to Guidelines. The radiological and toxicological risk guidelines (Table 3-8) are exceeded for the onsite receptor for the AWF tank headspace deflagration scenario. The radiological and toxicological risk guidelines for the offsite receptor, however, are met for the DST and AWF tank headspace deflagration scenarios assuming that burn pressures do not exceed the tank structural limits (i.e., lead to dome collapse). However, due to the technical uncertainties associated with the open flammable gas USQ, this assumption cannot be rigorously defended and cannot be relied upon to yield bounding results. Nevertheless, the BIO results clearly imply a need to institute controls to prevent or mitigate hazards associated with flammable gas in the AWF tanks.

Requirements to Remain Within the Risk Evaluation Guidelines. The requirements and strategy to remain within the risk guidelines are summarized in the BIO, Section 5.3.2.14, "Flammable Gas Deflagrations".

Experience indicates that other site ventilation systems have historically been adequate to sweep out the steady state generated gases. The 241-AZ-702 ventilation system has no operational history upon which to base the claim that it will also provide adequate ventilation. However, calculations (HNF-SD-WM-CN-117) show that, for best-estimate current conditions, no more than 0.057 m^3/min (2 scfm) is required to keep flammable gas concentrations below 25% of the LFL. Therefore, the nominal design flow rate of the 241-AZ-702 ventilation system is expected to be adequate. To confirm this, flammable gas monitoring will be used for a short time after full start up (steady state conditions attained) of the 241-AZ-702 ventilation system to confirm the system's ability to keep flammable gas concentrations below 25% of the LFL. The risk of this approach is low since the best-estimate calculations show a large margin between what is required and what is provided (2.83 m^3/min [100 scfm] nominal). A temporary monitoring program shall be established to benchmark the ability of the 241-AZ-702 ventilation system to sweep out flammable gas due to steady state generation. As a backup, the higher capacity 241-A-702 system will not be decommissioned until the monitoring is complete.

3.4.2.14.5 Deflagration Accident Summary of Safety-Class/ Safety-Significant Structures, Systems, and Components and Technical Safety Requirements Controls. Because of the open status of the USQ TF-96-0433, *Consolidation of Flammable Gas/Slurry Growth Unreviewed Safety Question Issues*, and the technical uncertainties associated with the flammable gas safety issue, it is assumed that all installed equipment necessary to implement the flammable gas controls merit a Safety-Class designation. Additional analysis may provide refinement to this approach. The flammable gas controls are provided in the BIO TSRs. The operation of the 241-AZ-702 ventilation system does not require any new flammable gas controls beyond those already established in the BIO.

To apply the BIO controls, a process is followed to specify the allowed safe conditions and control requirements to address the flammable gas hazards as described in the FG JCO (BIO, Appendix E, "Flammable Gas/Slurry Growth Unreviewed Safety Question: Justification for Continued Operation for the Tank Farms at the Hanford Site"). The following is the description of the application of this process to the 241-AZ-702 ventilation system equipment.

Inlet Filter Assembly. The inlet filter assembly was found to meet requirements except for four elements. A review of the equipment layout drawings and characteristics of various components was conducted which identified four components which were not in compliance with the FG JCO requirements.

The control/electrical box houses potential sparking components (switches) but is not of explosion proof design, and is located within 18 diameters of the filter opening. The HEPA filter differential pressure switch is normally sparking, not of explosion proof design, and is located within 18 diameters of the filter opening. Heat trace wiring is not qualified to National Fire Protection Association (NFPA) Class I, Division 2, Group B requirements for temperature limited operation and provides temperature control for piping in proximity to the filter opening. The air stream electrical heater is located in the filter opening and vendor data shows that

the heater could exceed the 416 °C (781 °F) temperature limit for a dome intrusive region, which is an unacceptable design.

For these components, several alternatives were provided to meet requirements, with equivalency rulings based on administratively-controlled shutdown during globally waste disturbing activities for the control/electrical box, HEPA filter differential pressure switch, and heat tracing. Administrative shutdown of unqualified components during time periods which require application of controls renders the applied condition of the equipment compliant. The air stream heater is required to meet Ignition Source Control Set 2 requirements at all times; therefore, the temperature of the heater surface would require control to limit temperature and be vapor tight or be de-energized or replaced since a fault would trip the ground fault circuit interrupter (GFCI). This is based on design of heat tracing that meets NFPA Class I, Division 2, Group B requirements.

For the heat tracing, metallic sheathing of the heat tracing with GFCI connection of the sheath was also found to provide an equipment equivalency. Addition of a grounded metallic sheath was found to provide equivalent safety by eliminating potential electrical sparking as a potential ignition source.

Recirculation Module. The recirculation module was found compliant except for the recirculation fan. The fan did not meet Air Movement Contractor Association (AMCA) 99, Standards Handbook, Type C requirements for application under Ignition Source Control Set 2 requirements. The FGEAB found that equivalent safety would be provided if an axial stop plate were included in the design to prevent fan blade mechanical sparking on the fan housing. This modification to the fan was found to be equivalent to the AMCA requirement to prevent axial restraint of the fan blades. The fan was found to have suitable radial shaft restraint to meet requirements.

Tie-Ins to Existing Equipment. Equipment tie-ins were found to meet requirements under applied controls and practices with the exception of the 20-in. riser tie-in. For the 20-in. tie-in, a reciprocating cutter application was proposed, which the FGEAB found to be a potential mechanical spark source. The FGEAB recommended that an alternative cutting technique be employed. Project W-030 personnel have identified a pipe cutting tool which was tested to satisfy the FGEAB that the maximum pipe temperature which could be reached during cutting is below 80% of autoignition and that hot particle releases, when cutting penetrates the pipe wall, would not provide a potential mechanical spark source. The tests provided pipe temperature data which was clearly bounded by 80% of the hydrogen autoignition temperature and showed that the shavings from cutting would not provide a hot particle spark inside the pipe (cuttings were continuous, rather than particle ejections).

Equipment Past First Mixing Point. Because this equipment is beyond the first mixing point, this equipment was identified to not require application of Ignition Source Controls.

3.4.2.15 Organic Solvent Fire. Some waste tanks contain separable organic solvent phases. If ignited, the burning organic can liberate sufficient energy to release hazardous material from the tank. The oxygen in the tank is the limiting parameter for this scenario. Tanks not yet vapor space sampled are assumed to contain organic solvents. The AWF tanks are considered

potential Organic Solvent containing tanks. The accident analysis presented in the BIO, Section 5.3.2.15, "Organic Solvent Fire" is a parametric analysis that evaluates the worst case configurations for DST/AWF tanks. The change from the 241-A-702 to the 241-AZ-702 ventilation system does not change the worst case configuration, and the BIO analysis remains bounding. Further discussion relative to source term differences between the analysis presented in the BIO and that available with the 241-AZ-702 ventilation system is presented in Addendum 1, Section 3.4.1.

3.4.2.16 In-Tank Fuel Fire/Deflagration. This scenario postulates that a motor vehicle shears off one or more tank risers and ruptures the vehicle fuel tank. The change from the 241-A-702 to the 241-AZ-702 ventilation system does not change the worst case scenario analyzed in the BIO, Section 5.3.2.16, "In-Tank Fuel Fire/Deflagrations," and the BIO analysis remains bounding. Further discussion relative to source term differences between the analysis presented in the BIO and that available with the 241-AZ-702 ventilation system is presented in Addendum 1, Section 3.4.1.

3.4.2.17 Organic Salt-Nitrate Reaction. Organic complexants were used during past Hanford operations and were discharged to the tank where they were mixed with sodium hydroxide, sodium nitrate, and other inorganic diluent already present in the tank. Organic complexants will react with these types of oxidizing materials. The reaction can be accelerated to a rapid combustion by heating to high temperatures by an initiator of sufficient energy. A combustion front would be generated by such a condition and would spread through the combustible waste releasing significant energy and gases. The dose due to the HEPA filter release is insignificant when compared to the results of the main reaction. This accident is applicable to the AWF per the BIO, Section 5.3.2.17, "Organic Salt-Nitrate Reaction." Safety Limit 2.1.1, "Waste Temperature" of the TSRs and the controls for the Flammable Gas Deflagrations and Tank Bump scenarios as called for in the BIO (Sections 5.3.4.2.14, "Flammable Gas Deflagrations," and 5.3.4.2.22, "Tank Bump") remain unchanged as a result of the operation of the 241-AZ-702 ventilation system.

3.4.2.18 Surface Leak Resulting In Pool. Surface leaks that result in pools have been analyzed in the BIO for transfer routes. A misrouting of waste to a valve pit was analyzed as the bounding case in the BIO, Section 5.3.2.18, "Surface Leak Resulting In the Pool." This accident is not applicable to ventilation systems, therefore the BIO analysis is bounding for the 241-AZ-702 ventilation system.

3.4.2.19 Subsurface Leak Resulting In Pool. Transfer line leaks at high flow rates that are in excess of the natural infiltration rate of the soil can result in surface pools of waste. These waste pools are a safety concern because they can cause significant onsite and offsite inhalation doses and produce significant shine and skyshine doses to the onsite receptor. However, this analysis is not applicable to the 241-AZ-702 ventilation system which services the vapor space of the AWF tanks.

3.4.2.20 Spray Leak in Structure or From Overground Transfer Line. Spray leaks have been analyzed in the BIO for existing transfer routes. A breach of containment during a transfer could result in a pressurized spray release. A spray leak in a valve pit was analyzed as the bounding case in the BIO.

These spray releases are a safety concern because, depending on the waste pressure and leak dimensions, they can be relatively efficient generators of respirable-sized aerosols. Spray leaks also apply to the DSTs and including the AWF. The BIO (Section 5.3.2.20, "Spray Leak in Structure or From Overground Waste Transfer Line") requires a Safety-Class exhaust stack continuous air monitor (CAM) interlock to the exhaust fan. This is required for the 241-AZ-702 ventilation system also.

3.4.2.21 Spray Leak From Underground Waste Transfer Lines. A construction excavation accident could conceivably breach a waste transfer line and cause a spray leak or a surface leak that results in a pool. However, this analysis is not applicable to the 241-AZ-702 ventilation system which services the vapor space of the AWF tanks.

3.4.2.22 Tank Bump Accident. A tank waste thermal rollover phenomenon, known as a Tank Bump, is a rapid steam pressurization of tank headspace. A Tank Bump is a safety concern because of the potential for a release of aerosolized waste to the environment. The Tank Bump accident has been analyzed in the BIO, and as will be shown below, the BIO results are bounding for the 241-AZ-702 ventilation system.

3.4.2.22.1 Analysis Strategy. For those tanks that pose a Tank Bump threat, the upper bound on heat load and radionuclide content is found in the Aging Waste Tanks. Tank 241-AZ-101 has nearly twice the heat load of any other AWF tank and therefore was evaluated in the BIO as the bounding tank.

3.4.2.22.2 Tank Bump Accident Scenario Assuming No Controls. Since no controls are assumed and Tank 241-AZ-101 was evaluated as the bounding tank, the BIO results do not need to be revisited for the 241-AZ-702 ventilation system. The results presented in the BIO, Table 5.3.2.22-1, "Consequences of a Tank Bump Assuming No Controls," indicate that controls are required.

3.4.2.22.3 Tank Bump Accident Comparison to Guidelines. The BIO contains the required comparison. The Tank Bump accident is considered unlikely.

3.4.2.22.4 Tank Bump Accident Controls. The Safety-Class and Safety-Significant SSCs selected in the BIO Table 5.3.2.22-2, "Safety Structures, Systems, and Components for Tank Bump," include the tank waste temperature monitoring system and the tank waste level detection system (DSTs and AWF tanks). These safety SSCs do not involve ventilation and thus are unaffected by the 241-AZ-702 ventilation system.

The TSR controls presented in BIO, Table 5.3.2.22-3, "Technical Safety Requirement Controls for Tank Bumps," involve maintaining the temperature in the AWF tanks $\leq$ 91 °C (195 °F) for all waste levels or $\leq$ 91 °C (195 °F) in the top 4.6 m (15 ft) and $\leq$ 102 °C (215 °F) in the waste below 4.6 m (15 ft). In addition, waste transfer controls and controls on process instrumentation and measuring and test equipment (to ensure that instrumentation to monitor tank temperature is maintained) are imposed. Since no TSR controls were imposed on ventilation systems for the Tank Bump scenario, the 241-AZ-702 ventilation system has no impact on the TSR controls in the BIO for this accident.

The Defense-in-Depth controls for Tank Bumps are shown in the BIO, Table 5.3.2.22-4, "Defense-in-Depth Controls for Tank Bumps," and include maintaining active ventilation. The 241-AZ-702 ventilation system will provide this capability.

Conclusion. The 241-AZ-702 ventilation system has no impact on the Tank Bump analysis as presented in the BIO, nor does its operation require the establishment of additional controls beyond those selected in the BIO.

3.4.2.23 Natural Phenomena. Natural phenomena analyzed in the BIO include high winds, lightning, and earthquakes. The accidents discussed in the BIO applicable to the 241-AZ-702 ventilation system are the seismically-induced gas release event and deflagration due to lightning. The seismically-induced GRE is bounded by the deflagration accident already discussed in the addendum. The lightning accident is bounded by the Flammable Gas Deflagration, the organic solvent fire, and the organic salt-nitrate reaction accidents. The Flammable Gas Deflagration and organic solvent fire are discussed in this addendum (Section 3.4.2.2.2). The organic salt-nitrate reaction accident is not applicable to the AWF (Section 3.4.2.17). The BIO further indicates that no Safety-Class or Safety-Significant structures, systems, and components are associated with lightning and seismic protection. The existing BIO analysis is adequate for the 241-AZ-702 ventilation system and no additional controls, beyond those listed in the BIO and Addendum 1, Section 3.4.2.2, are required.

3.4.3 Beyond Evaluation Basis Accidents

An analysis of Beyond Evaluation Basis accidents events will be documented in the Final Safety Analysis Report.

Table 3-1. Aging Waste Facility Hazards Identification.[a]

Energy Classification	Aging Waste Facility Hazards	
	Potentially Present Inside Tanks	Potentially Present Elsewhere in or Adjacent to Facility
Corrosive	Caustic, high temperature waste	Caustic
Explosive/pyrophoric	Hydrogen, ammonia, methane, nitrates	Hydrogen
Nuclear criticality	High fissile material concentration in waste	N/A
Flammable materials	Hydrogen, ammonia, methane	Rags, gasoline, lube oil, diesel fuel, grease, other
Thermal radiation	Radionuclides in tank	N/A
Chemical reactions	Uncontrolled chemical reactions	N/A
Friction	Bearings, fans, motors, other	Belts, bearings, fans, gears, motors
Electrical	Wiring, pumps, motors, electrical equipment	Battery banks, transformers, wiring, switchgear, underground wiring, cable runs, service outlets/fittings, pumps, motors, heaters, electrical equipment, high voltage, transmission lines
Kinetic-rotational	Motors, pumps	Motors, pumps, fans
Kinetic-linear	N/A	Cars, trucks, buses, obstructions, crane loads, pressure vessel blowdown, other
Mass, gravity, Height	Pits	Lifts and cranes, trucks, scaffold and ladders, pits, excavations
Pressure-volume	Stressed members, negative pressure collapse, positive pressure release	N/A
Thermal (except radiant)	N/A	Heaters

[a]The hazards identification represents the hazards that could potentially cause an uncontrolled release of radioactive or hazardous materials only. Hazards only resulting in personnel injury are not included.

N/A = not applicable.

Table 3-2. Tank Waste Liquids and Solids Analyte Concentrations.[a]

Composites concentrations (g/L)		
Analyte	DST Solids	DST Liquids
Ammonia (NH3)	6.6 E+00	7.1 E+00
Antimony (Sb)	9.2 E-01	6.4 E-03
Arsenic (As)	5.7 E+00	1.1 E-02
Barium (Ba)	5.9 E+00	3.3 E-02
Beryllium (Be)	2.4 E-01	3.8 E-03
Cadmium (Cd)	2.6 E+01	7.0 E-02
Calcium (Ca)	2.6 E+01	1.3 E+00
Cerium (Ce)	2.6 E+00	5.8 E-02
Chromium (Cr+3)	1.5 E+02	[b]
Cobalt (Co)	4.4 E+00	8.8 E-03
Cyanide (Cn)	4.7 E-01	9.1 E-02
Dysprosium (Dy)	[b]	
Lanthanum (La)	3.0 E+01	1.0 E+00
Mercury (Hg)	1.2 E-01	2.4 E-04
Neodymium (Nd)	7.0 E+00	5.6 E-03
Oxalate (C2O4)	2.8 E+02	[b]
Selenium (Se)	1.9 E+00	2.8 E-01
Sodium hydroxide (NaOH)	2.3 E+02	2.1 E+02
Sodium (Na) - NaOH[b]	3.5 E+02	2.1 E+02
Tellurium (Te)	9.3 E-01	2.7 E-03
Thallium (Tl)	1.5 E+01	3.7 E-02
TOC-oxalate[c]	7.5 E+01	4.0 E+01
Uranium (U)	4.4 E+01	1.1 E+01
Vanadium (V)	1.2 E-01	2.1 E-03

DST = double-shell tank.
TOC = Total organic carbon.

[a]The information in this table is from WHC-SD-WM-SARR-011, 1996, Toxic Chemical Considerations for Tank Farm Releases, Rev. 2, Westinghouse Hanford Company, Richland, Washington.

[b] = The best available data indicates there is not significant concentrations of this analytes in this composite.

[c] = To avoid counting the same analyte twice, the oxalate concentration was subtracted from the TOC concentration and NaOH was subtracted from the Na concentration.

Table 3-3. Headspace Gas Composite Concentrations.[a]

	Worst Case Composite[b]	
Gas	Concentration (ppmv)	Concentration (mg/m^3)[cb]
Acetonitrile	13	21.8
Ammonia	61,300	40,000
Benzene	0.4	1.3
1,3 Butadiene	0.1	0.19
Butanol	58	164
Dodecane	45	296
2-Hexanone	0.8	2.7
Methylene chloride	2	22
Nitrous oxide	67,000	110,000
Propanenitrile	5	11
Tributyl phosphate	1	12
Tridecane	50	390

[a]The information in this table is from WHC-SD-WM-SARR-011, 1996, Toxic Chemical Considerations for Tank Farm Releases, Rev. 2, Westinghouse Hanford Company, Richland, Washington.

[b]Based on worst case composites including slurry gas released.

[c]The conversion from ppmv to mg/m^3 assumes a temperature of 38 °C (100 °F) and a pressure of 740 torr (0.1 MPA).

Table 3-4. In-Tank Concentrations of the 11 Radionuclides Chosen for Inclusion in Accident Analysis.[a]

Isotope	Bq/L	ULD (Sv/L)	% dose	Bq/L	ULD (Sv/L)	% dose
	Aging Waste Facility Liquids			Aging Waste Facility Solids		
^{60}Co	7.71 E+05	4.56 E-02	0.0	4.9 E+08	2.9 E+01	0.0
^{90}Sr	5.60 E+09	3.62 E+02	25.4	2.9 E+12	1.9 E+05	10.8

Table 3-6. Aging Waste Facility Energy Sources.

Energy	Location	Form and Quantity
Electrical (Ignition sources and high voltage)	• Dome space • Ventilation buildings • Ventilation system • External equipment • Pump • Pump pit/valve pit • Aboveground (near risers)	• Various electrical equipment • Ventilation fans • Monitoring and instrumentation • Material with potential electrostatic charge buildup
Mechanical (including spark sources)	• Dome space • Ventilation system • External equipment • Pump • Tank intrusive activities	• Tools with spark potential • Air motion caused by active ventilation • Ventilation fans, kinetic energy (recirculation and main) • Moving parts with kinetic energy (pumps, motors, etc.)
Mechanical (potential energy)	• Tank waste	• Potential energy stored in gas bubbles compressed by hydrostatic head • Potential energy stored as saturated liquid (Tank Bump potential)
Chemical	• Tank • Vehicles (on or near tanks) • Tank farm • Ventilation buildings	• Diesel and gasoline • Lubricants
Radiant	• Transfer lines • Tank waste	• Radionuclides in tank waste
External events	• Tank farms	• Lightning • Tornadoes/high winds • Heavy rains • Earthquakes/volcanoes • Range fires

Note: A more detailed listing of the energy sources evaluated in the hazards and operability study can be found in Appendix B, Table B-6.

Table 3-7. BIO Accident Comparison Summary. (3 sheets)

No.	BIO Accident	241-AZ-702 Section	BIO Section	241-AZ-702 Comparison	TSR	Comment	Justification
1	Nuclear Criticality	3.4.2.1 and Section 6.3	5.3.2.1	Bounded by the BIO	Nuclear Criticality Safety Program	N/A	There is no mechanism to increase the plutonium concentration in the ductwork sufficiently to cause a criticality.
2a	HEPA Filter Failure - High Temp. Unfiltered Release	3.4.2.2.1	5.3.2.2	Bounding consequence analysis provided in Addendum 1, Section 3.4.2.2	LCO 3.1.4A AC 5.18.2b AC 5.18.2c AC 5.18.2e	N/A	N/A
2b	HEPA Filter Failure - High Pressure	3.4.2.2.2	5.3.2.2	Bounding consequence analysis provided in Addendum 1, Section 3.4.2.2	AC 5.18.2b AC 5.18.2c AC 5.18.2e	BIO 5.3.2.2 points to other accidents for actual consequences.	N/A
3	Fire in a Contaminated Area	3.4.2.3	5.3.2.3	Not applicable to 241-AZ-702 ventilation system in particular - no contaminated areas as described in BIO.	Ignition Control Program	Generally applicable to AWF	No (open) contaminated areas in which to spill fuel.
4	Evaporator Dump	3.4.2.4	5.3.2.4	Not applicable	N/A	N/A	N/A
5	Steam Intrusion from Interfacing Systems	3.4.2.5	5.3.2.5	Bounded by the BIO; see HEPA filter failure - due to high pressure	AC 5.18.2b AC 5.18.2c AC 5.18.2e	(see item 2 above)	(see item 2 above)
6	Leak from Railcar/ Tank Trailer	3.4.2.6	5.3.2.6	Not applicable	N/A	N/A	N/A
7	Subsurface Leak remaining Subsurface	3.4.2.7	5.3.2.7	Not applicable	N/A	N/A	N/A
8	Unplanned Excavation/ Drilling in Pond/ Ditch/Crib	3.4.2.8	5.3.2.8	Not applicable	N/A	N/A	N/A

Table 3-7. BIO Accident Comparison Summary. (3 sheets)

No.	BIO Accident	241-AZ-702 Section	BIO Section	241-AZ-702 Comparison	TSR	Comment	Justification
23	Natural Phenomena - High wind - Lightning - Seismic	3.4.2.23	5.3.2.23	Bounded by the BIO	Controls as listed for the seismically induced GREs and lightning strikes.	General applicability to the AWF	N/A

AC = Administrative Control.
AWF = Aging Waste Facility.
BIO = HNF-SD-WM-BIO-001, 1997, Tank Waste Remediation System Basis for Interim Operation, Rev. 1, Duke Engineering and Services, Hanford, Richland, Washington.
CAM = continuous air monitor.
DCRT = double-contained receiver tank.
GRE = gas release event.
HEGA = high-efficiency gas adsorber.
HEME = high-efficiency mist eliminator.
HEPA = high-efficiency particulate air (filter).
LCO = Limiting Condition for Operation.
N/A = not applicable.
SL = Safety Limit.

Table 3-8. Radiological Risk Guidelines.[a]

Frequency Category	Frequency Range (yr^{-1})	Effective Dose Equivalent (rem)	
		Onsite	Offsite
Anticipated	$>10^{-2}$	.5	0.1
Unlikely	$10^{-4} < f \leq 10^{-2}$	5	0.5
Extremely unlikely	$10^{-6} < f \leq 10^{-4}$	10	4

[a]The information in this table is from WHC-CM-4-46, Safety Analysis Manual, Section 7.0, "Risk," Rev. 1, Westinghouse Hanford Company, Richland, Washington.

Refer to Appendix F, "Site-wide Controlled Manual Cross Reference Table," of the BIO for cross-walk between Site-wide controlled manuals (e.g., WHC-CM-X-XX) superseded by Fluor Daniel Hanford, Inc., Procedures (e.g., HNF-PRO-XXX).

Table 3-9. Toxicological Risk Evaluation Guidelines.[a]

Frequency Category	Frequency Range (yr^{-1})	Primary Concentration Guidelines	
		Onsite	Offsite
Anticipated	$>10^{-2}$	$\leq$ ERPG-1	$\leq$ PEL-TWA
Unlikely	$10^{-4} < f \leq 10^{-2}$	$\leq$ ERPG-2	$\leq$ ERPG-1
Extremely unlikely	$10^{-6} < f \leq 10^{-4}$	$\leq$ ERPG-3	$\leq$ ERPG-2

ERPG = Emergency Response Planning Guideline.
PEL-TWA = permissible exposure limit-time weighted average.

[a]The information in this table is from WHC-CM-4-46, Safety Analysis Manual, Section 7.0, "Risk," Rev. 4, Westinghouse Hanford Company, Richland, Washington.

Refer to Appendix F, "Site-wide Controlled Manual Cross Reference Table," of the BIO for cross-walk between Site-wide controlled manuals (e.g., WHC-CM-X-XX) superseded by Fluor Daniel Hanford, Inc., Procedures (e.g., HNF-PRO-XXX).

This page intentionally left blank.

4.0 SAFETY STRUCTURES, SYSTEMS, AND COMPONENTS

The safety classifications for the 241-AZ-702 ventilation system structures, systems, and components (SSCs) are presented in the following sections. Safety classifications for Tank Waste Remediation System (TWRS) facility SSCs are described in the HNF-SD-WM-BIO-001, *Tank Waste Remediation System Basis for Interim Operation*, (BIO), Section 2.1, "Structures, Systems, and Components Important to Safety."

4.1 INTRODUCTION

The controls selected for each accident are described in Section 3.0, "Hazard and Accident Analyses." The selection process follows the SSC classification methodology described in WHC-CM-4-46[1],, *Safety Analysis Manual*.

The SSCs included in this report are divided into two categories, Safety-Class SSCs and Safety-Significant SSCs. See the BIO, Section 2.1, "Structures, Systems and Components Important to Safety" for definitions of all the terms used to categorize SSCs.

4.2 REQUIREMENTS

DOE Orders and standards that provide requirements and guidance for safety classification of SSCs are as listed in the BIO.

4.3 SAFETY-CLASS STRUCTURES, SYSTEMS, AND COMPONENTS

This section provides information about the Safety-Class SSCs identified in Section 3.0 "Hazard and Accident Analyses" of this addendum. Table 4-1 provides a categorization of those SSCs.

4.3.1 Safety-Class Structures, Systems, and Components

The following is a discussion of the Safety-Class considerations associated with the 241-AZ-702 ventilation system and the exhaust continuous air monitor (CAM) interlock.

---

[1]Refer to Appendix F, "Site-wide Controlled Manual Cross Reference Table," of the BIO for cross-walk between Site-wide controlled manuals (e.g., WHC-CM-X-XX) superseded by Fluor Daniel Hanford, Inc., Procedures (e.g., HNF-PRO-XXX).

4.3.1.1 Safety Function. The deflagration accident described previously in Section 3.4.2.14, "Deflagration Accident" requires the provision of tank ventilation flow to be a Safety-Class function. Components that would be designated Safety-Class are those whose failure could block the flow path or deprive the flow of its motive force (e.g., ducting, valves, filters, fans, electrical distribution system). In addition, instrumentation critical to sensing flow are designated Safety-Class. See HNF-SD-WM-SEL-040.

The safety function is achieved by the 241-AZ-702 ventilation system SSCs which were originally designated to meet Safety-Significant criteria. The bases for this Safety-Significant designation were developed before the declaration of the Flammable Gas Unreviewed Safety Question (USQ) TF-96-0433. Therefore, the design, procurement and construction of the 241-AZ-702 ventilation system meets, as a minimum, applicable Safety-Significant criteria.

Another control is a result of the spray leak accident, described previously in Section 3.4.2.20, "Spray Leak in Structure or From Overground Transfer Line." This accident requires a continuous air monitor (CAM) interlock on the exhaust stack to shut down the exhaust fan should the exhaust high-efficiency particulate air (HEPA) filters breakthrough.

4.3.1.2 System Descriptions. The 241-AZ-702 ventilation system maintains adequate flow by continuous operation of the fans and provisions for switching to an alternate fan and filter bank during maintenance. Section 2.5 "Process Description" of this addendum provides a detailed description of the ventilation system.

The exhaust stack CAM interlock transfers the flow from one train to the other upon CAM alarm. This is slightly different than the interlock described in the BIO, but is allowed under the compensatory measures for BIO Implementation (Technical Safety Requirements [TSR] Limiting Condition for Operation [LCO] 3.1.4A, "Ventilation Stack Continuous Air Monitor [CAM] Interlock Systems").

4.3.1.3 Controls (Technical Safety Requirements). The additional control for the 241-AZ-702 ventilation system required to support the SSCs for the 241-AZ-702 ventilation system is in place within the TSRs which is summarized in the BIO, Table 6-1, "Hazard and Accident Analyses; Safety Structures, Systems, and Components; and Technical Safety Requirement Cross Reference."

The Administrative Control (TSR AC 5.18, "HEPA Filter Controls") governing HEPA filter loading requires the addition of the 241-AZ-702 ventilation system high-efficiency mist eliminator (HEME) loading maximum of 800 mrem/hr and replacement of the high-efficiency gas adsorber (HEGA) filter before the upstream HEPA filter in the associated filter train has been replaced 20 times. Additionally, an efficiency requirement is placed on the HEPA filters upstream of the HEGA.

There are no changes required to LCO 3.1.4A, except to include its applicability to the 241-AZ-702 ventilation system.

4.4 SAFETY-SIGNIFICANT STRUCTURES, SYSTEMS, AND COMPONENTS

4.4.1 Safety-Significant Structures, Systems, and Components

There are no unique Safety-Significant SSCs designated for the 241-AZ-702 ventilation system.

This page intentionally left blank.

Table 4-1. Safety-Class SSCs for the 241-AZ-702 Ventilation System.

SSC	Accident(s)	Safety Functions
Ventilation System - Safety-Class[a] (by designation) - Safety-Significant (by design)	Deflagration	Maintain flammable gas concentrations in the tank dome spaces, due to steady-state releases, below 25% of the LFL.
CAM Interlock - Safety-Class for spray leak accident - Safety-Significant for HEPA filter failure accident	HEPA filter failure - high temperature Spray leak in structure or from overground waste transfer line	Mitigate radiological and toxicological releases to the environment.

CAM = continuous air monitor.
HEPA = high-efficiency particulate air (filter).
LFL = Lower Flammability Limit.

[a]The actual 241-AZ-702 ventilation system configuration, consistent with original design requirements, meets Safety-Significant design criteria. Allocation of design margins may demonstrate that certain Safety-Class requirements are met by the original design.

This page intentionally left blank.

5.0 DERIVATION OF TECHNICAL SAFETY REQUIREMENTS

5.1 INTRODUCTION

The existing operating envelope for the Tank Waste Remediation System (TWRS) is defined by the Technical Safety Requirements (TSRs) listed in Chapter 6.0, "Operational Controls" of HNF-SD-WM-BIO-001, *Tank Waste Remediation System Basis for Interim Operation*, (BIO). These controls are implemented through HNF-SD-WM-TSR-006, *Tank Waste Remediation System Technical Safety Requirements*, prepared using the guidance of U.S. Department of Energy (DOE) 5480.22, *Technical Safety Requirements*. The purpose of this section is to identify the TSRs that must be added to the BIO to bring the W-030 ventilation upgrade within the TWRS safety envelope.

5.2 REQUIREMENTS

The DOE Orders required for establishing the safety basis for the 241-AZ-702 ventilation system are as listed in the main body of the BIO.

5.3 TECHNICAL SAFETY REQUIREMENTS COVERAGE, AND DERIVATIONS

The accident analysis in Section 3.0, "Hazard and Accident Analyses" along with the designation of safety Structures, Systems, and Components (SSCs) and the associated TSRs in Section 4.0, "Safety Structures, Systems and Components" indicated that operation of the 241-AZ-702 ventilation system is bounded by the TWRS TSRs. However, an addition to the TSR Administrative Control (AC) 5.18, "HEPA Filter Controls" program is required to limit the inventories on high-efficiency particulate air (HEPA), high-efficiency gas adsorber (HEGA), and high-efficiency mist eliminator (HEME) filters and prefilters to protect the source term assumptions in the accident analyses. This control has been added to BIO, Table 6-1, "Hazard and Accident Analysis; Safety Structures, Systems, and Components; and Technical Safety Requirement Cross Reference," to account for the reanalyzed accident scenarios and allows the BIO to envelope operation of the 241-AZ-702 ventilation system. The BIO, Table 6-1, "Hazard and Accident Analyses; Safety Structures, Systems, and Components; and Technical Safety Requirements Cross Reference," correlates the reanalyzed accident scenarios with the necessary controls and includes the Safety-Class and Safety-Significant SSCs, the type of TSR control (i.e., Limiting Condition for Operation [LCO] or AC) and the specific location of the control within the TSR (e.g., LCO 3.2.1 "DST and AWF Ventilation System" or AC 5.18), and a summary of the key elements of the TSR derivation basis.

The Administrative Control (BIO TSR AC 5.18, "HEPA Filter Controls") governing HEPA filter loading requires the addition of the 241-AZ-702 ventilation system HEME loading maximum of 800 mrem/hr and replacement of the HEGA filter before the upstream HEPA filter in the associated filter train has been replaced 20 times. Additionally, an efficiency testing requirement is placed on the HEPA filters upstream of the HEGA.

Other TSRs required for the 241-AZ-702 ventilation system are not unique to the 241-AZ-702 ventilation system and are covered by TSRs previously identified in the BIO.

5.4 DERIVATION OF FACILITY MODES

The operational modes for the TWRS facility are defined in the TSRs. Operation of the 241-AZ-702 ventilation system does not change any of these definitions of facility operating modes.

5.5 INTERFACE WITH TECHNICAL SAFETY REQUIREMENTS FROM OTHER FACILITIES

The TSRs for the 241-AZ-702 ventilation system are contained within the TSRs for the TWRS. Any interfaces between the TWRS TSRs and the TSRs from other facilities will be determined in the Final Safety Analysis Report.

6.0 PREVENTION OF INADVERTENT CRITICALITY

This section contains information relevant to prevention of inadvertent criticality as a result of operation of the 241-AZ-702 ventilation system. See Sections 4.3, "Criticality Protection" and 5.3.2.1, "Nuclear Criticality" of the *Tank Waste Remediation System Basis for Interim Operation*, (BIO), HNF-SD-WM-BIO-001 for further information on the TWRS specific criticality safety and protection program. The program ensures that sufficient controls are in place to reduce the likelihood of inadvertent nuclear criticality excursions as a result of the activities performed within the Tank Waste Remediation System (TWRS) facilities.

6.1 REQUIREMENTS

See the BIO, Sections 4.3 and 5.3.2.1 for requirements.

6.2 FACILITY IMPLEMENTATION

See the BIO, Sections 4.3 and 5.3.2.1 for facility implementation.

6.3 PROJECT IMPLEMENTATION

The WHC-SD-WM-TI-725, *Tank Farm Nuclear Criticality Review*, evaluated the possibility of a nuclear criticality occurring in tank farm facilities. Considering current plutonium inventories and operating conditions, it was concluded that a nuclear criticality accident was not credible in Hanford Site double-contained receiver tanks (DCRTs), double-shell tanks (DSTs), and single-shell tanks (SSTs). The discussion then presented an analysis of a hypothetical criticality accident resulting from the transfer of new plutonium inventory into the tank farms. No new conditions or configurations of plutonium are introduced into the tank farms by the 241-AZ-702 ventilation systems, and there is no change in the likelihood of a criticality for normal storage and operations at tank farms due to the implementation of this system.

The potential for criticality within the ventilation system itself has also been considered. The largest duct in the system has a 25.4 cm (10-in.) diameter. An infinitely long 25.4 cm diameter duct would need to be filled with waste material containing about 22 g Pu/liter (1.4 lb Pu/ft^3) in order to achieve criticality. All the waste in tanks exhibits plutonium concentrations substantially less than the subcritical limit of 2.6 g Pu/liter (0.16 lb Pu/ft^3). In fact the maximum concentration observed in tanks is about 0.35 g Pu/liter (0.022 lb Pu/ft^3) (although there was a single sample of 0.7 g Pu/liter [0.044 lb Pu/ft^3]). Most of the tanks exhibit concentrations substantially less. Thus any explosion or other excursion which might be postulated to force waste material into the ventilation system would not, by itself, result in a criticality concern.

From the foregoing discussion, it can be concluded that a mechanism capable of increasing plutonium concentration by a factor of 60-100 or more would necessarily have to function in order to achieve a condition of potential criticality. Plutonium buildup in ventilation systems such as that experienced at the Rocky Flats facility or at the Hanford Plutonium Finishing Plant (Z Plant) (PFP) involves either the transport of material which was highly concentrated to begin with, e.g., plutonium metal or concentrated oxide, or which was highly volatile, e.g., plutonium hexafluoride. Neither of these conditions pertain to the material in the Hanford tanks. The plutonium in high level neutralized waste is sorbed with the neutralized oxyhydroxides; thus it is neither easily airborne nor volatile.

Thermally driven increases in plutonium concentration can also be considered, i.e., those driven by fire in the tank. However, the aging waste facility (AWF) tanks have not been identified as organic nitrate tanks and thus the waste will not burn. Thus plutonium segregation and/or concentration due to combustion of organic nitrate is not a concern for operation of the 241-AZ-702 ventilation system.

To date none of these tanks have been identified as organic solvent containing tanks, although sampling has not yet been completed to verify that for the tanks of concern. Further, solvent fires primarily involve the solvent itself, and minimal impact on the sludge would be expected. Hence solvent fires are not expected to be a source of plutonium segregation and/or concentration for these tanks.

Finally, existing ventilation data was sought to determine if any plutonium segregation was indicated. There is comparatively little data available upstream of the high-efficiency particulate air (HEPA) filters. Some gamma spectrometry has been performed on the HEPA filters. This data usually indicates the presence of large amounts of ^{137}Cs, but gamma spectrometry cannot distinguish the weak gammas of plutonium in the presence of stronger gamma emitters. More complete analyses are performed downstream of the HEPAs and are reported in the annual *Radionuclide Air Emissions Report for the Hanford Site, Calendar Year 1995* , (DOE/RL-96-37). The ratios of common, non-volatile isotopes to plutonium for various tank farm stack samples can be compared to similar ratios for the source term reported in the BIO as a rough indicator of plutonium concentration by the ventilation process. The non-volatile isotope is taken as an indicator of the behavior of all the non-volatile, non-plutonium constituents of waste. If the ratios of a non-volatile isotope to plutonium in the ventilation system are similar to those found in the tank waste, this can be taken as an indicator that no concentration of plutonium is occurring in the ventilation process. The ^{90}Sr was chosen since it is relatively non-volatile and is present in most ventilation samples. The range of $^{90}Sr/^{239}Pu$ for the source term in the BIO is 33 to 6600 (HNF-SD-WM-CN-108, *Calculation of Isotopic Ratios in Tank Farms Ventilation Systems*). The range of $^{90}Sr/^{239}Pu$ for the 1995 stack release data is 37 to 2200, a similar range of values. This rough comparison does not suggest any notable segregation or reconcentration of plutonium in the ventilation system.

Based on understanding of the relevant phenomena and the limited data discussed above, it is concluded that there is no potential for criticality in the 241-AZ-702 ventilation system.

7.0 RADIATION PROTECTION

This section identifies the requirements for radiation protection for Tank Waste Remediation System (TWRS) facilities and operations and the implementing program documents.

7.1 REQUIREMENTS

See *Tank Waste Remediation System Basis for Interim Operation*, (BIO), HNF-SD-WM-BIO-001, Section 4.4, "Radiological Protection" for requirements.

7.2 FACILITY IMPLEMENTATION

See the BIO, Section 4.4 for facility implementation.

7.3 PROJECT IMPLEMENTATION

The radiation dose and dose rate design limits are delineated in project functional design criteria, WHC-SD-600-FDC-001, *Functional Design Criteria for the Tank Farm Ventilation Upgrade, Project W-030*, and WHC-SD-W030-RD-001, *Supplemental Definition of Requirements for Tank Farm Ventilation Upgrade, Project W-030*. Design details required to comply with the criteria are verified in calculations completed by the architect-engineer/constructor. Programmatic elements of radiation protection are governed by existing Site and facility programs. Descriptions of radiation monitoring and instrumentation are given in the System Description of this document. No requirements above those identified in the programmatic documents were required for the 241-AZ-702 ventilation system.

This page intentionally left blank.

8.0 HAZARDOUS MATERIAL PROTECTION

This section identifies the requirements for hazardous material protection other than radiological hazards for Tank Waste Remediation System (TWRS) facilities and operations and the implementing program documents.

8.1 REQUIREMENTS

See *Tank Waste Remediation System Basis for Interim Operation*, (BIO), HNF-SD-WM-BIO-001, Section 4.5, "Hazardous Material Protection" for requirements.

8.2 FACILITY IMPLEMENTATION

See the BIO, Section 4.5 for facility implementation.

8.3 PROJECT IMPLEMENTATION

No project-specific requirements related to hazardous material protection were identified for the 241-AZ-702 ventilation system.

This page intentionally left blank.

9.0 RADIOACTIVE AND HAZARDOUS WASTE MANAGEMENT

This section lists the requirement documents for the radioactive and hazardous waste management for the 241-AZ-702 ventilation system.

9.1 REQUIREMENTS

See *Tank Waste Remediation System Basis for Interim Operation*, (BIO), HNF-SD-WM-BIO-001, Section 4.6, "Radioactive and Hazardous Material Waste Management" for requirements.

9.2 FACILITY IMPLEMENTATION

See the BIO, Section 4.6 for facility implementation.

9.3 PROJECT IMPLEMENTATION

No additional requirements relating to radioactive and hazardous waste management were identified for the 241-AZ-702 ventilation system.

This page intentionally left blank.

10.0 INITIAL TESTING, IN-SERVICE SURVEILLANCE, AND MAINTENANCE

This section identifies the requirements for initial testing, in-service surveillance, and maintenance for Tank Waste Remediation System (TWRS) facilities and operations and their implementing program documents.

10.1 REQUIREMENTS

See *Tank Waste Remediation System Basis for Interim Operation*, (BIO), HNF-SD-WM-BIO-001, Section 4.7, "Testing, Surveillance, and Maintenance" for requirements.

10.2 FACILITY IMPLEMENTATION

See the BIO, Section 4.7 for facility implementation.

10.3 PROJECT IMPLEMENTATION

10.3.1 Initial Testing

10.3.1.1 Testing Program. Organizational responsibilities for initial testing phases of the project are defined in WHC-SD-W030-SUP-001, *Startup Plan - Tank Farm Ventilation Upgrade Project W-030*. The initial testing program is described in WHC-SD-W030-SUP-003, *Startup Test Plan - Tank Farm Ventilation Upgrade W-030*.

Three phases of testing are performed during startup of the 241-AZ-702 ventilation system. These are the acceptance test procedures (ATPs), the pre-operational test procedures (POTPs), and the operational test procedures (OTPs). The ATPs and POTPs are performed before initial system operation while the OTPs are performed after system startup. Eight POTPs are performed; seven of the eight POTPs test individual sub-systems. The eighth POTP tests the overall system, checking for interactions between the sub-systems and for instabilities of total system operation. Completion of the POTPs establishes the stable operational settings of the system. The parameters evaluated in the test and their acceptance criteria are defined in WHC-SD-W030-SUP-003.

10.3.1.2 System Construction. System construction is performed under the current Authorization Basis and is not covered under this safety analysis document. Work packages are reviewed using the USQ process (HNF-IP-0842, *TWRS Administration*, Volume IV, Section 5.4) and the applicable Authorization Basis. A key component of the Authorization Basis against which construction was evaluated is Standing Order 97-01, *Compensatory Measures to Address Flammable Gas Hazards (East Tank Farms)*.

10.3.1.3 System Tie-In. The 241-AZ-702 ventilation system hot tie-in will be accomplished per the WHC-SD-W030-SUP-004, *Hot Tie-In Plan, Tank Farm Ventilation Upgrade Program*.

10.3.1.4 Temporary Flammable Gas Monitoring. A temporary monitoring program shall be established to benchmark the ability of the 241-AZ-702 ventilation system to sweep out flammable gas due to steady state generation. A plan has been prepared providing the details of the testing to demonstrate compliance with the following criterion (HNF-SD-W030-TC-001).

> Criterion: The 241-AZ-702 ventilation system shall be considered successful at maintaining tank flammable gas concentrations within acceptable levels if the flammable gas concentration is less than 25% of the LFL (BIO, Section 4.7).

In order to demonstrate compliance with this criterion a mix of sampling, and online (Standard Hydrogen Monitoring System [SHMS] or gas chromatograph [GC]) or portable instruments (combustible gas meter [CGM] and Organic Vapor Meter [OVM] may be used. At least two samples must be taken to validate each instrument used.

The data must be collected after the tank has had time to approach steady state conditions and shall be used to calculate a one-sided 95% upper confidence interval based on the precision and accuracy of the instrument used. As a backup, the higher capacity 241-AZ-702 system shall not be deactivated until the monitoring is complete and the above requirements have been met.

The flammable gas monitoring plan for the 241-AZ-702 ventilation system (Fowler 1997) discusses measurement of the flammable gas concentrations in the exhaust stream, temperatures of the waste and flow rates of the system to document the ability of the new system to mitigate flammable gas build up due to steady-state generation. The instruments, calibration requirements, collection frequencies and procedures to follow are defined in the plan. A discussion is included on how the data will be used to define the concentrations (e.g., modeling methods). The monitoring will occur after system startup.

10.3.2 In-Service Surveillance

Procedures for surveillance testing will be developed in accordance to U.S. Department of Energy (DOE) 5480.19, *Conduct of Operations Requirements for DOE Facilities.*

10.3.3 Maintenance

Procedures for maintenance will be developed in accordance to DOE 5480.19.

11.0 OPERATIONAL SAFETY

This section identifies requirements for conduct of operations, Aging Waste Facility (AWF) fire protection, and the implementing program documents directly resulting from the installation/operation of the 241-AZ-702 ventilation system.

11.1 REQUIREMENTS

See *Tank Waste Remediation System Basis for Interim Operation*, (BIO), HNF-SD-WM-BIO-001, Sections 4.8, "Conduct of Operations," 4.9, "Work Control," and 4.10, "Fire Protection Program" for requirements.

11.2 FACILITY IMPLEMENTATION

See the BIO, Section 4.8, 4.9, and 4.10 for facility implementation.

11.3 PROJECT IMPLEMENTATION

A revision to HNF-SD-WM-FHA-020, *Fire Hazards Analysis for Tank Farms*, was performed for the 241-AZ-702 ventilation system. The conclusion from this analysis is as described below.

The risk of fire loss in the three-building facility is well managed through the placement of walls of fire rated construction and through the use of fire sprinkler systems for fire suppression throughout. Combustible material loadings are held to a minimum in each fire area and exposure dangers are mitigated by physical separation. The protection of this facility and its contents, as well as the safety of its occupants, appear to be more than adequately assured. Water supplies for this location do not have a second supply as required by U.S. Department of Energy (DOE) 6430.1A. A second water source will be provided by Project B-604 to meet this DOE 6430.1A requirement for the entire 200 East and West Areas.

This page intentionally left blank.

12.0 PROCEDURES AND TRAINING

This section lists the requirements for the procedures and training programs for the 241-AZ-702 ventilation system.

12.1 REQUIREMENTS

See *Tank Waste Remediation System Basis for Interim Operation*, (BIO), HNF-SD-WM-BIO-001, Section 4.11, "Training and Procedures" for requirements.

12.2 FACILITY IMPLEMENTATION

See the BIO, Section 4.11 for facility implementation.

12.3 PROJECT IMPLEMENTATION

Responsibility for training on the new systems before commencement of operations is defined in WHC-SD-W030-SUP-001. Training and procedure development are to be conducted per existing site and facility requirements. Procedures and training requirements for areas specifically related to the 241-AZ-702 ventilation system will be developed in accordance with U.S. Department of Energy (DOE) 5480.19 and the results of the accident analysis of this addendum (Section 3.0 "Hazard and Accident Analysis").

This page intentionally left blank.

13.0 HUMAN FACTORS

Human factors requirements are defined for this facility in the *Tank Waste Remediation System Basis for Interim Operation*, (BIO), HNF-SD-WM-BIO-001, Section 4.18, "Human Factors." Specific requirements for the 241-AZ-702 ventilation system related to human factors above those specified in the reference are noted below.

This section lists the requirements for a human factors program to demonstrate that human factors are considered in facility design where human actions are relied upon for preventive or mitigative actions.

13.1 REQUIREMENTS

See the BIO, Section 4.18 for requirements.

13.2 FACILITY IMPLEMENTATION

See the BIO, Section 4.18 for facility implementation.

13.3 PROJECT IMPLEMENTATION

A human factors analysis for the instrument/control room and control systems was completed for the project. Results of this analysis were included in the design of the Project W-030 systems (WHC-SD-W030-ANAL-001, *Human Factors Analysis & Design Guidelines for the Tank Farm Ventilation Upgrade of AY-AZ Farms*). System design is summarized in the System Description section of this document. The human factors analysis provided location and sizes for workspace design such as monitors, keyboards, desk space area, floor space, and maintenance access. The analysis also provided for printer, monitor and label font sizes for optimal viewing and alarm size and color (and decibel level) for optimal response. Guidelines were provided for lighting, temperature and humidity control which were used in design.

14.0 QUALITY ASSURANCE

This section lists the requirements for a quality assurance program to ensure the safety of personnel and the public, for environmental protection, and for the implementing program documents.

14.1 REQUIREMENTS

See *Tank Waste Remediation System Basis for Interim Operation*, (BIO), HNF-SD-WM-BIO-001, Section 4.12, "Quality Assurance" for requirements.

14.2 FACILITY IMPLEMENTATION

See the BIO, Section 4.12 for facility implementation.

14.3 PROJECT IMPLEMENTATION

Implementation of specific quality assurance requirements for the 241-AZ-702 ventilation system is controlled by WHC-SD-W030-QAPP-001, *Project Specific Quality Assurance Plan, W-030, Tank Farm Ventilation Upgrade*.

- Personnel performing work on the 241-AZ-702 ventilation system have been and will continue to be trained and qualified in accordance with the above-referenced quality assurance programs and DOE 5480.20A, *Personnel Selection, Qualification, and Training Requirements for Nuclear Facilities*.

- Quality improvement processes described in the quality assurance programs are provided for the detection and correction of quality problems throughout the design and construction of this project.

- Documents and records associated with this project have been and will be independently reviewed for completeness and accuracy. A record index is available to classify all quality assurance records to aid in retrieval.

- Work processes associated with this project have been and will be strictly adhered to in accordance with this quality assurance program. Appropriate administrative procedures have been developed and approved to control key aspects in the design and construction of this project.

- Designs associated with this project have been or will be independently reviewed and approved. Completed construction will be accurately depicted by as-built drawings upon project completion.

- Procurement of Safety-Class and Safety-Significant items for this project are in compliance with this quality assurance program. Such items have been purchased from qualified suppliers where applicable and all stated requirements have been or will be met as verified through independent inspections, tests, and assessments. Certified Vendor Information has been or will be received and appropriately indexed and filed to support continuity of service for this project.

- Inspection and testing of items associated with this project will meet required standards as verified by properly trained and qualified personnel and records supplied on project turnover will attest to accuracy and completeness.

- Periodic management assessment of this project has been and/or will be conducted to ensure this project is compliant with this quality assurance plan and the objectives stated therein.

- Independent assessments will be planned, scheduled, and conducted to confirm that project deliverables and service quality are adequate to meet operational objectives.

15.0 EMERGENCY PREPAREDNESS PROGRAM

This section identifies the requirements for the emergency preparedness functions and response at the site of the 241-AZ-702 ventilation system.

15.1 REQUIREMENTS

See *Tank Waste Remediation System Basis for Interim Operation*, (BIO), HNF-SD-WM-BIO-001, Section 4.13, "Emergency Preparedness" for facility implementation.

15.2 FACILITY IMPLEMENTATION

See the BIO, Section 4.13 for facility implementation.

15.3 PROJECT IMPLEMENTATION

No additional project-specific requirements related to emergency preparedness were identified as unique (in addition to those identified in the BIO) to the 241-AZ-702 ventilation system in Sections 3.0, "Hazard and Accident Analyses" 4.0, "Safety Structures, Systems, and Components," and 5.0, "Derivation of Technical Safety Requirements," of this addendum.

This page intentionally left blank.

16.0 PROVISIONS FOR DECONTAMINATION AND DECOMMISSIONING

This section describes provisions that facilitate future decontamination and decommissioning of the facilities with respect to the 241-AZ-702 ventilation system.

16.1 REQUIREMENTS

See *Tank Waste Remediation System Basis for Interim Operation*, (BIO), HNF-SD-WM-BIO-001, Section 4.14, "Decontamination and Decommissioning" for requirements.

16.2 IMPLEMENTATION

See the BIO, Section 4.14 for requirements.

16.3 PROJECT IMPLEMENTATION

Decontamination and decommissioning was considered in the design of the 241-AZ-702 ventilation system (WHC-SD-W030-RD-001). It requires all equipment and surfaces exposed to, or containing, radioactive materials, to be designed to minimize cracks and crevices. Materials and surfaces were specified to minimize surface contamination and enhance washdown. Because of this, the 241-AZ-702 ventilation system provides modular components, lifting rings, and access ports for decontamination.

This page intentionally left blank.

17.0 MANAGEMENT, ORGANIZATION, AND INSTITUTIONAL SAFETY PROVISIONS

This section provides the requirements specific to this section and pertinent to the safety analysis, and the implementing program documents.

17.1 REQUIREMENTS

See *Tank Waste Remediation System Basis for Interim Operation*, (BIO), HNF-SD-WM-BIO-001, Section 4.1, "Organizational Structure and Management Responsibilities" for requirements.

17.2 FACILITY IMPLEMENTATION

See the BIO, Section 4.1 for requirements.

17.3 PROJECT IMPLEMENTATION

No additional management, organization, and institutional safety provisions, above those currently in place for the Aging Waste Facility (AWF) 241-A-702 ventilation system, were introduced or required by the 241-AZ-702 ventilation system.

APPENDIX A

HAZARD BASIS

This page intentionally left blank.

Table A-1. Event Categories and Relationship to Hazard Energy and Material Sources.

Event Category	Event Category Description	Hazard Energy and Material Groups
E-1	Fire	Electrical Thermal Friction Pyrophoric material Spontaneous combustion Open flame Flammable Combustibles Chemicals
E-2	Explosion	Potential (pressure) Explosive materials Chemical reactions
E-3	Loss of Containment or Confinement	Radiological Material Hazardous Material
E-4	Direct Radiological Exposure	Ionizing radiation sources
E-5	Nuclear Criticality	Fissile material
E-6	External Hazards	Non-facility events Vehicles in motion Crane
E-7	Natural Phenomena	Natural Phenomena

Note: Material at risk can be found in the BIO, since the presence of the 241-AZ-702 ventilation system does not change the TWRS material at risk.

APPENDIX B

HAZARD ANALYSIS SUMMARY

This page intentionally left blank.

APPENDIX B

HAZARD ANALYSIS SUMMARY

Note: This appendix is presented for information about the initial development of the accident analyses. It was performed before the development of the *Tank Waste Remediation System Basis for Interim Operation*, (BIO), HNF-SD-WM-BIO-001, and references the former Authorization Basis documents (i.e., Interim Operational Safety Requirements [IOSRs]) which are no longer applicable. The BIO controls and Defense-in-Depth requirements take precedence. Because of this, disregard the entries in the Defense-in-Depth column. Also disregard the reference to AC 5.19 of the IOSRs in the entries associated with the Tank Bump accident which is analyzed in Section 3.4.2.22 of this addendum. Other references to IOSR administrative controls have corresponding administrative controls in the BIO TSRs (i.e., IOSR AC 5.3 is TSR AC 5.7, IOSR AC 5.13 is TSR AC 5.18, IOSR AC 5.22 is TSR AC 5.16, IOSR AC 5.24 is TSR AC 5.19, and IOSR AC 5.29 is TSR AC 5.9, 5.10, and 5.11).

B1.0 HAZARD ANALYSIS SUMMARY

Table B-1 provides the summary for the Preliminary Hazard Analysis (PHA) and Hazards and Operability (HazOp) study that was performed for the Project W-030 ventilation system. A PHA technique was used to evaluate the hazards for the Project W-030 ventilation upgrade for the Aging Waste Facility (AWF). This technique consists of first identifying the hazards (e.g., radioactive sources, wastes, and chemicals) in terms of form, quantity, and location. Additional characterization identifies the mechanisms for their accidental releases. Tables B-6 and B-7 provide an energy source checklist and a summary of hazardous events used during the evaluation. Finally, the risks from accidents associated with these hazards are evaluated in a qualitative or semi-quantitative way, depending upon the accident scenario.

The hazard evaluations address consequences to the public, collocated workers, and immediate workers. Accidental releases can result from internal events, external events, or natural phenomena. Consequences of common industrial accidents are not included, unless they: 1) initiate a release of hazardous material, or 2) worsen the consequences of a hazardous material release. Industrial accidents which could cause only occupational injuries or illnesses are addressed by the Industrial Hygiene and Safety Program, which is a required element identified in the Administrative Controls section of the IOSRs.

A HazOp study was also performed to confirm and validate the results of the PHA. The hazard definition guide shown in Table B-2 describes the process variables and the guide words used to perform the HazOp. The HazOp emphasizes the processes involved with the ventilation system and not just the individual components. Also, a check list was used to capture and evaluate all high energy sources and natural hazards that impact the Project W-030 ventilation system. The results of the PHA and HazOp are recorded in Table B-1.

B2.0 METHODOLOGY

B.2.1 Hazard Identification

This hazards analysis describes the hazards identification and evaluation process performed for the Aging Waste Facility (AWF) Tank Farms and presents the comprehensive evaluation of potential process-related hazards, natural phenomena hazards, and external hazards. These hazards arise from the form, location, and quantities of nuclear chemical waste stored in the aging waste Underground storage tanks. Operations, maintenance, testing, and construction have been considered. The hazard identification and evaluation process provides a thorough and complete qualitative evaluation of the spectrum of potential accidents involving the hazards identified. This effort forms the basis for: 1) understanding facility worker protection and environmental features, and 2) selecting potential design basis accidents (DBAs) to be further developed and quantified in Section 3.4.2 "Design Basis Accidents."

The major classification of accident categories for the ventilation system were identified as loss of containment, loss of confinement, waste disposal, criticality, natural phenomena, fire and explosion, interface, maintenance and testing, and injury to personnel. Those hazards identified as credible by the review team were recorded in the Hazard Summary Table (Table B-1). Hazardous materials evaluated included radioactive material, toxic materials, corrosive materials, reactive materials, asphyxiants, explosives, and combustibles and flammables.

B.2.1.1 Loss of Containment/Confinement. Loss of containment as a hazard will be considered as breach of ventilation system barriers resulting in the release (non-airborne) of radioactive materials or hazardous chemicals.

B.2.1.2 Loss of Confinement. Loss of confinement as a hazard category will be considered as the breach of a ventilation system barrier resulting in the release of gaseous or airborne radioactive materials or hazardous chemicals.

B.2.1.3 Waste Disposal. Consideration of waste handling and disposal hazards will be limited to those hazards involving the waste that is generated under the ventilation function and incidental to the performance of the waste storage and treatment mission at the tank farms.

The scope of this hazard identification and analysis effort specifically will not include the hazards associated with the transportation, treatment and disposal of waste materials generated incidental to the performance of the waste storage mission.

A gaseous or airborne waste effluent stream results from filtered stack exhaust through active ventilation systems (primary, annulus, and portable exhausters) and filtered exhaust through tank ventilation inlet/outlet risers in passive ventilation systems. An additional airborne waste effluent stream may be associated with filtered exhaust through ventilation inlet risers in active ventilation systems during events that result in loss of negative pressure in the tank headspace.

B.2.1.4 Criticality. The hazard identification and analysis team assumed that insufficient fissile material carryover from the tank headspace to the ventilation system takes place that could result in a significant accumulation of fissile materials in the ventilation system (Section 6.3 "Project Implementation").

B.2.1.5 Natural Phenomena. The hazards associated with natural phenomena can be considered from two different perspectives based on the effects of the event. These are the direct effects to personnel (such as direct physical consequence) and those effects that result from a sequence of events leading to a release of hazardous material that is initiated by natural phenomena as the energy source.

B.2.1.6 Fire and Explosion. Hazards associated with fire and explosion considered in the context of the ventilation function were found to be represented by two classes: 1) those hazards that result in a direct physical effect to personnel caused by the fire or explosion, and 2) those hazards that result from the release of hazardous materials that may result from a sequence of events that are initiated by the fire or explosion.

Potential concerns related to initiation of fires or explosions internal to the ventilation system components are associated with either the carryover of crystallized flammable chemicals that may accumulate in ventilation system filters and components (active and passive ventilation systems) or exhaust of gases from the tank headspace through the ventilation system (active and passive).

B.2.1.7 Interfaces. The hazards associated with interfaces with utilities and other AWF tank equipment were considered.

B.2.1.8 Maintenance and Testing. The hazards associated with maintaining and testing the Project W-030 ventilation system were included in the PHA evaluation effort.

B.2.2 Hazard Evaluation

Using the PHA and HazOp evaluation techniques, a Hazard Analysis Summary table was constructed (Table B-1). Hazard Analysis Summary tables have been used to compile the results of the hazard identification and evaluation process for the AWF Project W-030 ventilation upgrade system. The hazard tables of Table B-1 are structured using columns to present information about the hazardous materials, energy sources, and general environmental and occupational hazards associated with tank farm operations. Each column in the hazard tables is described below.

- **Hazard.** Identifies the hazard evaluated for the given entry.
- **Event Number.** Identifies sequence for the hazards evaluated.
- **Event Category.** Provides an event category descriptor based on Table A-1.

- **Postulated Event Description.** Provides details on how the hazard can occur.

- **Significant Causes or Energy Sources.** Identifies the hazard or accident initiators.

- **Receptor.** Identifies the affected party.

  Note: This Hazard Analysis Summary Table includes the immediate onsite worker; the regulations do not evaluate this receptor and it is not included in the consequence analyses of Section 3.0, "Hazard and Accident Analyses," of this addendum.

- **Credited Prevention.** Identifies engineered or administrative features that would prevent or reduce the probability of the hazard/accident from occurring.

- **Event Frequency.** Discusses qualitative or semi-quantitative assessment of the frequency of occurrence of the hazard with and without preventative features. Values found in this column are based on Table B-3.

- **Credited Mitigation.** Identifies engineered or administrative features that would mitigate or reduce the consequences of the hazard/accident.

- **Consequences.** Discusses qualitative or semi-quantitative assessment of the consequences of the hazard with and without mitigative features. Values found in this column are based on Table B-4.

- **Risk Bin Number.** Assigns a risk number based on the frequency, the consequences, and the receptor. Values found in this column are based on Table B-5.

- **Defense-in-Depth Controls.** Lists the key preventative and mitigative features used to provide a Defense-in-Depth to minimize the occurrence and/or occurrence of the identified hazard.

B.2.3 Hazard Evaluation Results. The hazard analysis results were recorded and transmitted in a letter report (Kelly 1996) which is included as an attachment to this section of the addendum. Attachment 1 to this report is the same as Tables A-1 in the previous section of this addendum and Tables B-3 through B-6 of this addendum. Attachment 2, "Hazard Summary Table," is found in Table B-1 of this section.

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
Hazard - Radiological and toxicological material in the ventilation process stream and exhaust stream													
1	E-7	Process vapor release to the atmosphere due to ducting failure, drain line failure, seal pot failure, etc.	Seismic event	Public	Engineered Features: - Double encase piping - Seismic design of system is SC-2 Administrative Features: - None identified	F2	F1	Engineered Features: - Double encased ducting Administrative Features: - None Identified	S0	S0	4	2	- Hardened building
				Co-located Worker	- Same as for the public			- Same as for the public	S0	S0	4	2	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S1	S1	8	5	- Same as for the public
				Rationale for frequency of event: Seismic event at the Hanford Site has a frequency of F2 Potential for contamination of the environment: E0, slight to negligible									
2	E-7	Process condensate release to the soil due to ducting failure, drain line failure, seal pot failure, etc.	Seismic event	Public	Engineered Features: - Double encased piping - Seismic design of system is SC-2 Administrative Features: - None identified	F2	F1	Engineered Features: - Double encased ducting Administrative Features: - Alarm response procedures	S0	S0	4	2	- Sloped ducting to drain to tank or sump - Pipe annulus liquid monitoring - Hardened building
				Co-located Worker	- Same as for the public			- Same as for the public	S0	S0	4	2	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S0	S0	4	2	- Same as for the public
				Rationale for frequency of event: Seismic event at the Hanford Site has a frequency of F2 Potential for contamination of the environment: E0, slight to negligible									

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
Hazard – Radiological and toxicological material in the ventilation process stream and exhaust stream													
3	E-7	Process condensate release to the soil due to ducting failure, drain line failure, seal pot failure, etc.	Tornado Tornado generated missiles High winds	Public	Engineered Features: - Building hardened to SC-2 winds (80 mph) - Lines buried 2.4 m (8 ft) deep - Double encased ducting Administrative Features: - Emergency response procedures - Tie down (AC)	F2	F1	Engineered Features: - Double encased ducting - Hardened building Administrative Features: - Emergency response procedures	S0	S0	4	2	- Cathodic protection
				Co-located Worker	- Same as for the public			- Same as for the public	S0	S0	4	2	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S0	S0	4	2	- Same as for the public
				Rationale for frequency of event: Tornado/high wind event at the Hanford Site has a frequency of F2 Potential for contamination of the environment: E0, slight to negligible									
Hazard – Radiological and toxicological material in the ventilation process stream and exhaust stream													
4	E-7	Process vapor release to the atmosphere due to ducting failure, drain line failure, seal pot failure, etc.	Tornado Tornado generated missiles High winds	Public	Engineered Features: - Building hardened to SC-2 winds (80 mph) - Lines buried 2.4 m (8 ft) deep - Double encased ducting Administrative Features: - Emergency response procedures - Tie down (AC)	F2	F1	Engineered Features: - Double encased ducting Administrative Features: - Emergency response procedures	S0	S0	4	2	- Cathodic protection
				Co-located Worker	- Same as for the public			- Same as for the public	S0	S0	4	2	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S1	S1	8	5	- Same as for the public
				Rationale for frequency of event: Tornado/high wind event at the Hanford Site has a frequency of F2 Potential for contamination of the environment: E0, slight to negligible									

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
Hazard - Radiological and toxicological material in the ventilation process stream and exhaust stream													
5	E-7	Process condensate release to the soil due to ducting failure, drain line failure, seal pot failure, etc.	Other externally generated missiles (e.g., compressed gas cylinders during maintenance or construction, falling light poles, etc.)	Public	Engineered Features: - Ducting is double encased - Ducting is buried - Hardened facility Administrative Features: - Emergency response procedure	F2	F1	Engineered Features: - Ducting is double encased Administrative Features: - Emergency response procedure	S0	S0	4	2	- All lines are sloped to tank or sump - Ducting is schedule 40 pipe - Ducting is SC-2

				Immediate Worker	- Same as for the public			- Same as for the public	S0	S0	4	2	- Same as for the public
				Rationale for frequency of event: Compressed gas is used only during maintenance and other maintenance activities give a frequency of F2 Potential for contamination of the environment: E0, slight to negligible									

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
Hazard – Radiological and toxicological material in the ventilation process stream and exhaust stream													
6	E-7	Process vapor release to the atmosphere due to ducting failure, drain line failure, seal pot failure, etc.	Other externally generated missiles (e.g., compressed gas cylinders during maintenance or construction, falling light poles, etc.)	Public	Engineered Features: - Ducting is double encased - Ducting is buried - Hardened facility - Ducting is schedule 40 pipe - Ducting is SC-2 Administrative Features: - Emergency response procedure	F2	F1	Engineered Features: - Ducting is double encased Administrative Features: - None identified	S0	S0	4	2	- Ducting is schedule 40 pipe - Ducting is SC-2
				Co-located Worker	- Same as for the public			- Same as for the public	S0	S0	4	2	Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S1	S1	8	5	Same as for the public
				Rationale for frequency of event: Compressed gas is used only during maintenance and other maintenance activities give a frequency of F2 Potential for contamination of the environment: E0, slight to negligible									
Hazard – Radiological and toxicological material in the ventilation process stream and exhaust stream													
7	E-3	Process condensate release to the soil due to ducting failure, drain line failure, seal pot failure, etc.	Corrosion of ducting, weld cracks, etc.	Public	Engineered Features: - Cathodic protection - Stainless steel piping Administrative Features: - Initial weld inspections - Initial pressure testing	F3	F2	Engineered Features: - Double encased piping - Pipe annulus monitoring Administrative Features: - Alarm response procedure	S0	S0	7	4	- All lines are sloped back to tank or sump
				Co-Located Worker	- Same as for the public			- Same as for the public	S0	S0	7	4	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S0	S0	7	4	- Same as for the public
				Rationale for frequency of event: Corrosion is anticipated to significantly degrade the piping (without prevention or mitigation) during the life of the facility; this makes it a frequency of F3 Potential for contamination of the environment: E0, slight to negligible									

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
Hazard - Radiological and toxicological material in the process stream and exhaust stream													
13	E-6	Process condensate release to the soil due to ducting failure, drain line failure, seal pot failure, etc.	Ventilation system overburden (external loading)	Public	Engineered Features: - Control density fill - Double encased ducting Administrative Features: - Excavation permit required (AC 5.24) - Dome loading limited (AC 5.22) - Shift manager controls vehicle access/route for heavy equipment	F3	F2	Engineered Features: - Double encased ducting Administrative Features: - None Identified	S0	S0	7	4	- Ducting buried 8 ft deep - All lines are sloped to tank or sump
		Process vapor release to the atmosphere due to ducting failure, drain line failure, seal pot failure, etc.		Co-located Worker	- Same as for the public			- Same as for the public	S0	S0	7	4	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S0	S0	7	4	- Same as for the public
				Rationale for frequency of event: The frequency of heavy equipment moving within tank farms makes this event an F3 Potential for contamination of the environment: E0, slight to negligible									

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
14	E-6		Ventilation system overburden (external loading)	Public	Engineered Features: - Control density fill - Double encased ducting Administrative Features: - Excavation permit required (AC 5.24) - Dome loading limited (AC 5.22) - Shift manager controls vehicle access/route for heavy equipment	F3	F2	Engineered Features: - Double encased ducting Administrative Features: - None Identified	S0	S0	7	4	- Ducting buried 2.4 m (8 ft) deep
				Co-located Worker	- Same as for the public			- Same as for the public	S0	S0	7	4	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S1	S1	11	8	- Same as for the public
				Rationale for frequency of event: The frequency of heavy equipment moving within tank farms makes this event an F3 Potential for contamination of the environment: E0, slight to negligible									
Hazard - Radiological and toxicological material in the process stream and exhaust stream													
15	E-6	Process condensate release to the soil due to ducting failure, drain line failure, seal pot failure, etc.	External dropped equipment	Public	Engineered Features: - Hardened aboveground - Double encased Administrative Features: - Major lifts require a USQ screening - AC/procedure on all lifts	F3	F2	Engineered Features: Administrative Features:	S0	S0	7	4	- Ducting buried 2.4 m (8 ft) - Double encased lines - All lines are sloped to tank or sump
				Co-located Worker	- Same as for the public			- Same as for the public	S0	S0	7	4	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S0	S0	7	4	- Same as for the public
				Rationale for frequency of event: The frequency of crane operations and heavy lifts within tank farms makes this event an F3 Potential for contamination of the environment: E0, slight to negligible									

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
16	E-6	Process vapor release to the atmosphere due to ducting failure, drain line failure, seal pot failure, etc.	External dropped equipment	Public	Engineered Features: - Hardened aboveground - Double encased Administrative Features: - Major lifts require a USQ screening - AC/procedures on all lifts	F3	F2	Engineered Features: - None Identified Administrative Features: - None Identified	S0	S0	7	4	- Ducting buried 2.4 m (8 ft)
				Co-located Worker	- Same as for the public			- Same as for the public	S0	S0	7	4	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S1	S1	11	8	- Same as for the public
				Rationale for frequency of event: The frequency of crane operations and heavy lifts within tank farms makes this event an F3 Potential for contamination of the environment: E0, slight to negligible									
Hazard – Radiological and toxicological material in the ventilation process stream and exhaust stream													
17	E-6	Process condensate release to the soil due to ducting failure, drain line failure, seal pot failure, etc.	Excavation operations	Public	Engineered Features: None Identified Administrative Features: - AC 5.24, Excavation permit program - HNF-IP-0842[1] manual requires hand digging - HNF-IP-0842[1] manual requires scanning the area before digging - RCT and PIC present during activity and	F3	F2	Engineered Features: - None Identified Administrative Features: - None Identified	S0	S0	7	4	- Ducting buried 2.4 m (8 ft) - Yellow tape marker has been placed 0.6 m (2 ft) above ducting - All lines are sloped to tank or sump - Ducting is located inside fence
				Co-located Worker	- Same as for the public			- Same as for the public	S0	S0	7	4	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S0	S0	7	4	- Same as for the public
				Rationale for frequency of event: The frequency of excavations in tank farms makes this event an F3 Potential for contamination of the environment: E0, slight to negligible

19	E-6	Process condensate release to the soil due to ducting failure, drain line failure, seal pot failure, etc.	Ground creep and movement	Public	Engineered features: - Controlled density fill - Expansion loops Administrative Features: - None identified.	F3	F2	Engineered Features: - None identified. Administrative Features: - None identified.	S0	S0	7	4	- All lines are sloped to tank or sump - Double encased ducting
				Co-located Worker	- Same as for the public			- Same as for the public	S0	S0	7	4	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S0	S0	7	4	- Same as for the public
				Rationale for frequency of event: The frequency of ground movement or ground creep makes this event an F3 Potential for contamination of the environment: E0, slight to negligible									

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
Hazard – Radiological and toxicological material in the ventilation process stream and exhaust stream													
20	E-6	Process vapor release to the atmosphere due to ducting failure, drain line failure, seal pot failure, etc.	Ground creep and movement	Public	Engineered Features: - Controlled density fill - Expansion loops Administrative Features: - None identified	F3	F2	Engineered Features: - None identified. Administrative Features: - None identified.	S0	S0	7	4	- Double encased ducting
				Co-located Worker	- Same as for the public			- Same as for the public	S0	S0	7	4	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S1	S1	11	8	- Same as for the public
				Rationale for frequency of event: The frequency of ground movement or ground creep makes this event an F3 Potential for contamination of the environment: E0, slight to negligible									
Hazard – Radiological and toxicological material in the ventilation process stream and exhaust stream													
21	E-6	Process condensate release to the soil due to ducting failure, drain line failure, seal pot failure, etc.	Vehicular collision with above grade ventilation system components	Public	Engineered Features: - Hardened facility - Recirculation modules Administrative Features: - Spotter required for vehicles backing up within tank farms	F3	F2	Engineered Features: - None identified. Administrative Features: - None identified.	S0	S0	7	4	- All lines are sloped to tank or sump - Components are not readily vulnerable
				Co-located Worker	- Same as for the public			- Same as for the public	S0	S0	7	4	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S0	S0	7	4	- Same as for the public
				Rationale for frequency of event: The frequency of vehicular operation within tank farms makes this event an F3 Potential for contamination of the environment: E0, slight to negligible									

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
22	E-6	Process vapor release to the atmosphere due to ducting failure, drain line failure, seal pot failure, etc.	Vehicular collision with above grade ventilation system components	Public	Engineered Features: - Hardened facility - Recirculation modules Administrative Features: - Spotter required for vehicles backing up within tank farms	F3	F2	Engineered Features: - None Identified Administrative Features: - None Identified	S0	S0	7	4	- Components are not readily vulnerable
				Co-located Worker	- Same as for the public			- Same as for the public	S0	S0	7	4	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S1	S1	11	8	- Same as for the public
				Rationale for frequency of event: The frequency of vehicular operation within tank farms makes this event an F3 Potential for contamination of the environment: E0, slight to negligible									
Hazard – Radiological and toxicological material in the ventilation process stream and exhaust stream													
23	E-6	Process condensate release to the soil due to ducting failure, drain line failure, seal pot failure, etc.	Freezing and thawing of ventilation system components that contain liquid	Public	Engineered Features: - Components have drains - Seal loops below frost line Administrative Features: - Freeze protection/ winterization procedure	F3	F3	Engineered Features: Administrative Features: - Freeze protection plan for AWF	S0	S0	7	4	- Sloped ducting back to sump/tank - Double encased - Electric heaters - Can by-pass condenser and/or HEME - Airflow from condenser limits exit temperature to 1 °C (34 °F)
				Co-located Worker	- Same as for the public			- Same as for the public	S0	S0	7	4	- Same as for public
				Immediate Worker	- Same as for the public			- Same as for the public	S0	S0	7	4	- Same as for public
				Rationale for frequency of event: The frequency of freezing weather conditions on the Hanford Site makes this event an F3 Potential for contamination of the environment: E0, slight to negligible									

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
Hazard – Radiological and toxicological material in the ventilation process stream and exhaust stream													
24	E-6	Process vapor release to the atmosphere due to ducting failure, drain line failure, seal pot failure, etc.	Freezing and thawing of ventilation systems that contain liquid	Public	Engineered Features: - Components have drains - Seal loops below frost line Administrative Features: - Freeze protection/ winterization procedure - Freeze protection plan for AWF	F3	F3	Engineered Features: None Identified Administrative Features: - Freeze protection plan for AWF	S0	S0	7	7	- Double encased ducting - Electric heaters - Can by-pass condenser and/or HEME - Airflow exit temperature limited to 1 °C (34 °F)
				Co-located Worker	- Same as for the public			- Same as for the public	S0	S0	7	7	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S1	S1	11	11	- Same as for the public
				Rationale for frequency of event: The frequency of freezing weather conditions on the Hanford Site makes this event an F3 Potential for contamination of the environment: E0, slight to negligible									
Hazard – Radiological and toxicological in the tank													
25	E-3	Release of radiological material due to Tank Bump	Loss of tank cooling due to failure of the tank recirculation system fan	Public	Engineered Features: - Exhaust system fans - Air lift circulators - Main ventilation system has backup Administrative Features: - Shut off heat generating equipment (mixer pumps, etc.) - Temperature monitoring	F3	F2	Engineered Features: - None identified Administrative Features: - AC 5.19, Tank heat load limit	S3	S3	16	15	- Annulus ventilation system available - Ancillary exhaust connectors available - Cooling provided by main ventilation system
				Co-located Worker	- Same as for the public			- Same as for the public	S3	S3	16	15	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S3	S3	16	15	- Same as for the public
				Rationale for frequency of event: The frequency of fan failures makes this event an F3 Potential for contamination of the environment: E3									

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
Hazard - Radiological and toxicological material in the tank													
26	E-3	Release of radiological material due to Tank Bump	Loss of ventilation due to failure of one of the main ventilation system fans	Public	Engineered Features: - Redundant ventilation trains Administrative Features: - Time to repair	F3	F2	Engineered Features: Administrative Features: - AC 5.19, Tank heat load limit	S3	S3	16	15	- Electrical backup - Redundant fans - Ancillary exhaust connectors - Main ventilation systems (primary and backup) are separately located - Manual settings of system can be made - ALC operation available
				Co-located Worker	- Same as for the public			- Same as for the public	S3	S3	16	15	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S3	S3	16	15	- Same as for the public
				Rationale for frequency of event: The frequency of fan failures makes this event an F3 Potential for contamination of the environment: E3									

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
Hazard - Radiological and toxicological material in the tank													
27	E-3	Release of radiological material due to Tank Bump	Loss of ventilation due to failure of both of the main ventilation system fans	Public	Engineered Features: - Scenario requires two independent failures (redundant ventilation trains) Administrative Features: - Temperature monitoring	F2	F1	Engineered Features: - None Identified Administrative Features: - AC 5.19, Tank heat load limit	S3	S3	15	13	- Standby diesel generator provides electrical power - Main ventilation systems (primary and backup) are separately located - Ancillary ventilation connector - Days or weeks available to respond before Tank Bump occurs - ALC operation available
				Co-located Worker	- Same as for the public			- Same as for the public	S3	S3	15	13	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S3	S3	15	13	- Same as for the public
				Rationale for frequency of event: The frequency of two fan failures makes this event an F2 Potential for contamination of the environment: E3									

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
Hazard — Radiological and toxicological material in the tank													
28	E-3	Release of radiological material due to Tank Bump	Loss of ventilation due to loss of AC power	Public	Engineered Features: - Standby diesel generator Administrative Features: - None identified	F3	F2	Engineered Features: - None identified Administrative Features: - AC 5.19, Tank heat load limit	S3	S3	16	15	- Standby diesel generator provides electrical power - Main ventilation systems (primary and backup) are separately located - Ancillary ventilation connector - Days or weeks available to respond before Tank Bump occurs - ALC operation available
				Co-located Worker	- Same as for the public			- Same as for the public	S3	S3	16	15	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S3	S3	16	15	- Same as for the public
				Rationale for frequency of event: The frequency of loss of AC power has a frequency of F3 Potential for contamination of the environment: E3									

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
Hazard – Radiological and toxicological material in the tank													
29	E-3	Release of radiological material due to Tank Bump	Loss of ventilation due to blockage of the tank inlet breather	Public	Engineered Features: - Pressure monitoring system Administrative Features: - Temperature monitoring - AC for pressure drop across inlet breather (OSD limit) - Temperature monitoring - Flow monitoring (for low flow) - Alarm response procedure)	F3	F2	Engineered Features: - None Identified Administrative Features: - AC 5.19, Tank heat load limits	S3	S3	16	15	- Air lift circulators available - Vacuum relief valve is set at -1.5 kPa (6 in. w.g.) - Recirculation system can maintain waste temperature - Heaters protect filters from freezing
				Co-located Worker	- Same as for the public			- Same as for the public	S3	S3	16	15	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S3	S3	16	15	- Same as for the public
				Rationale for frequency of event: Total blockage of the inlet breather (ice, tumbleweed, plastic bag, particulate build-up, or other means) is expected to occur during the life of the facility; this makes the event frequency an F3 Potential for contamination of the environment: E3								

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
30	E-3	Release of radiological material due to Tank Bump	Loss of ventilation due to blockage of the exhaust system HEME	Public	Engineered Features: - Seal pot has level alarm - HEME can be bypassed Administrative Features: - Pressure drop tested periodically across HEME	F3	F2	Engineered Features: - None identified Administrative Features: - AC 5.19, Tank heat load limit	S3	S3	16	15	- HEME has capability of being replaced (modular) - Temperature monitoring of waste - Water spray prevent HEME filter from drying out - ALC operation available
				Co-located Worker	- Same as for the public			- Same as for the public	S3	S3	16	15	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S3	S3	16	15	- Same as for the public
				Rationale for frequency of event: Total blockage of the HEME (particulate build-up) and without prevention or mitigation is expected to occur during the life of the facility; this makes the event frequency an F3 Potential for contamination of the environment: E3									
31	E-3	Release of radiological material due to Tank Bump	Loss of ventilation due to blockage of the exhaust system HEPA/HEGA filters	Public	Engineered Features: - Redundant ventilation train - High pressure drop across filters switches systems Administrative Features: - High pressure drop across HEPA/HEGA - Temperature monitoring - Alarm response procedures	F3	F2	Engineered Features: - None Identified Administrative Features: - AC 5.19, Tank heat load limit	S3	S3	16	15	- Temperature monitoring of waste - 200 mrem/h maximum filter loading (800 mrem/h for HEME) - ALC operation available
				Co-located Worker	- Same as for the public			- Same as for the public	S3	S3	16	15	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S3	S3	16	15	- Same as for the public
				Rationale for frequency of event: Total blockage of the HEPA/HEGA (particulate build-up) and without prevention or mitigation is expected to occur during the life of the facility; this makes the event frequency an F3 Potential for contamination of the environment: E3									

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
Hazard – Radiological and toxicological material in the tank													
32	E-3	Release of radiological material due to Tank Bump	Loss of ventilation due to failure of the seal pot allowing water to back up to HEME and/or exhaust system condenser	Public	Engineered Features: - Liquid level probes (high and low levels) Administrative Features: - Alarm response procedures	F3	F2	Engineered Features: - None identified Administrative Features: - AC 5.19 Tank heat load limit	S3	S3	16	15	- Temperature monitoring - Time available for maintenance response - ALC operation available
				Co-located Worker	- Same as for the public			- Same as for the public	S3	S3	16	15	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S3	S3	16	15	- Same as for the public
				Rationale for frequency of event: Total blockage of the seal loop (Without prevention or mitigation) is expected to occur during the life of the facility; this makes the event frequency an F3 Potential for contamination of the environment: E3									
Hazard – Radiological and toxicological material in the tank													
33	E-1	Release of radiological material due to dome failure caused by flammable gas headspace deflagration	Accumulation of flammable gas from steady state generation and ignition source	Public	Engineered Features: - Operating ventilation system (airflow through the tanks) prevents flammable gas accumulation - Flow monitoring is Safety-Class Administrative Features: - AC 5.29, Flammable gas controls	F3	F2	Engineered Features: - Operating ventilation system (airflow through the tanks) mitigates flammable gas accumulation Administrative Features: - None Identified	S3	S3	16	15	- None identified
				Co-located Worker	- Same as for the public			- Same as for the public	S3	S3	16	15	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S3	S3	16	15	- Same as for the public
				Rationale for frequency of event: Radioactive waste generates flammable gases in all AWF tanks; without prevention or mitigation, flammable conditions within the tank are expected to occur in days, weeks, or months depending on initial tank conditions; an ignition source is assumed to be present; this makes the event frequency an F3 Potential for contamination of the environment: E3									

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
Hazard – Radiological and toxicological material in the tank													
34	E-1	Release of radiological material due to dome failure caused by flammable gas headspace deflagration	Accumulation of flammable gas resulting from a GRE and ignition source	Public	Engineered Features: - Flow monitoring is Safety-Class - Lock out recirculation system for suspect tank(s) Administrative Features: - AC 5.29, Flammable gas controls	F3	F2	Engineered Features: - Operation of ventilation will purge tank of flammable gases Administrative Features: - None Identified	S3	S3	16	15	- ALC operation available
				Co-located Worker	- Same as for the public			- Same as for the public	S3	S3	16	15	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S3	S3	16	15	- Same as for the public
				Rationale for frequency of event: Tanks identified as GRE potential tanks are, by definition, those tanks which could have a release that exceeds 25% of the LFL; an accumulation of flammable mixtures is anticipated in these tanks during the life of the facility; an ignition source is assumed to be present; this makes the event frequency an F3 Potential for contamination of the environment: E3								
Hazard – Radiological and toxicological material in the tank													
35	E-7	Release of radiological material due to dome failure or collapse caused by excessive vacuum	Blocked inlet breather. Overspeeding exhaust fan. Excessively open exhaust valve.	Public	Engineered Features: - Vacuum relief valve Administrative Features: - Pressure drop across inlet breather - Vacuum monitoring - Flow monitoring	F2	F1	Engineered Features: - None Identified Administrative Features: - Alarm response procedure	S3	S3	15	13	- Inlet heater protect against ice on filters - Flow monitoring
				Co-located Worker	- Same as for the public			- Same as for the public	S3	S3	15	13	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S3	S3	15	13	- Same as for the public
				Rationale for frequency of event: Total blockage of the inlet breather (ice, tumbleweed, plastic bag, particulate build-up, or other means) is expected to occur during the life of the facility and has a frequency an F3; this event also requires the simultaneous failure of the pressure relief valve; these to failures make the frequency an F2 Potential for contamination of the environment: E3								

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
Hazard – Radiological and toxicological material in the tank													
36	E-6	Release of radiological material due to dome failure or collapse caused by excessive vacuum	Ventilation imbalance	Public	Engineered Features: - Flow monitoring Administrative Features: - Pressure monitoring - Alarm response procedure	F2	F1	Engineered Features: - Tank vacuum relief valve Administrative Features: - Alarm response procedure	S3	S3	15	13	- Valve settings can be manually set
				Co-located Worker	- Same as for the public			- Same as for the public	S3	S3	15	13	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S3	S3	15	13	- Same as for the public
				Rationale for frequency of event: Failure of the ventilation system to create a dome failure is unlikely because of the presence of the inlet system and pressure relief valves (these would also have to fail) Potential for contamination of the environment: E3									
37	E-6	Release of radiological material due to dome collapse caused by excessive pressure	Excessive air supply to air lift circulators	Public	Engineered Features: Administrative Features: - Interlock to shut off ALC on high pressure - High pressure alarm - Alarm response procedure	F2	F1	Engineered Features: - Manifolded to other AWF tanks and main ventilation system - System is to be operable and operating Administrative Features: - Alarm response procedure	S3	S3	15	13	- Pressure monitoring
				Co-located Worker	- Same as for the public			- Same as for the public	S3	S3	15	13	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S3	S3	15	13	- Same as for the public
				Rationale for frequency of event: Normal operation of the ALC results in 0.04 m^3/s (80 cfm) being introduced into the tank; the tank is manifolded to the other three tanks; the inlet filter system is rated for 0.24 m^3/s (500 cfm); the frequency of the given event is deemed to be F2 Potential for contamination of the environment: E3									

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
Hazard - Radiological and toxicological material in the process stream													
38	E-6	Release of radiological material due to a leak in the recirculation ventilation cooling system or the exhaust ventilation cooling system	Corrosion of shell or tubes	Public	Engineered Features: - Failure requires failure of both the propylene glycol system and cooling tower (two failures) - Cooling fluid is at a higher pressure than the process gas (ventilation airstream) Administrative Features: - None identified)	F1	F1	Engineered Features: - None identified Administrative Features: - None identified	S0	S0	7	4	- System components are modular
				Co-located Worker	- Same as for the public			- Same as for the public	S0	S0	7	4	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S0	S0	7	4	- Same as for the public
				Rationale for frequency of event: Corrosion of both the shell and the tubes of the condenser put the frequency in the F1 range Potential for contamination of the environment: E0, slight to negligible									

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
Hazard – Radiological and toxicological material in the exhaust stream and built up on the HEPA filters													
39	E-6	Release of radiological material due to HEPA filter AZ-K1-4-1A blow out	High dP due to excessive HEPA filter loading, excessive system moisture carryover, high tank pressure, etc.	Public	Engineered Features: - Heater - Redundant HEPA filters Administrative Features: - Pressure drop across HEPA filter tested annually	F1	F1	Engineered Features: - Redundant HEPA filters Administrative Features: - Filters to be replaced if they fail dP testing - Filters to be replaced if they fail radioactive load surveillance	S1	S1	5	5	- Limits on radioactive loading on filters (200 mrem/h, 800 mrem/h for HEME) - Recirculation system, condenser, and HEME remove moisture and particulate loading from airstream - Redundant ventilation trains
				Co-located Worker	- Same as for the public			- Same as for the public	S1	S1	5	5	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S1	S1	5	5	- Same as for the public
				Rationale for frequency of event: Event requires the failure of two HEPA filters in series; this makes the event frequency in the F1 range Potential for contamination of the environment: E1									

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
Hazard - Radiological and toxicological material in the exhaust stream and built up on the HEPA filters													
40	E-1	Release of radiological material due to HEPA filter failure	HEPA filter failure caused by: - External fire in the vicinity of the HEPA filters - Fire in the ventilation system caused by flammable gas buildup and ignition - Fire from electrical failure of the heaters in the common exhaust system, etc. - Damage to HEPA filters from an external event, dropping of a heavy load, etc.	Public	Engineered Features: - Backflow prevention on fan housing - Firewall between systems - Temperature monitoring isolates upon high temperature Administrative Features: - None identified	F1	F1	Engineered Features: - None identified Administrative Features: - Limits on radioactive loading	S1	S1	5	5	- Maximum filter loading is limited to 200 mrem/h contact (800 mrem/h for HEME)
				Co-located Worker	- Same as for the public			- Same as for the public	S1	S1	5	5	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S1	S1	5	5	- Same as for the public
				Rationale for frequency of event: Event requires the fire (located at or near the HEPA filters) and the ignition of the HEPA filters; this puts the event frequency in the F1 range Potential for contamination of the environment: E1									

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
Hazard – Radiological and toxicological material in the exhaust stream													
41	E-6	Release of radiological material due to reduced efficiency of the HEPA filters	- HEPA filter seal failure - Defective HEPA filter - Deteriorated HEPA filter	Public	Engineered Features: - Requires double failure of HEPA filters for loss of containment Administrative Features: - Filter leak tests - Delta pressure drop testing of the filters annually - Filter leak test before and after installation and	F1	F1	Engineered Features: - None Identified Administrative Features: - None Identified	S0	S0	2	2	- Maximum filter loading is limited to 200 mrem/h contact (800 mrem/h for HEME) - Exhaust stack radiation monitor and alarm - Pressure monitoring - Exhaust stack height
				Co-located Worker	- Same as for the public			- Same as for the public	S0	S0	2	2	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S0	S0	2	2	- Same as for the public
				Rationale for frequency of event: Event requires the failure of two HEPA filters in series; this makes the event frequency in the F1 range Potential for contamination of the environment: E0, slight to negligible									

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
Hazard – Radiological and toxicological material on the HEPA filters													
42	E-7	Occupational radiation exposure	HEPA filter radioactive particle accumulation	Public	Engineered Features: - HEPA filters are SC-2 Administrative Features: - AC 5.13, Radiation protection program	F3	F3	Engineered Features: - None identified Administrative Features: - Filters to be replaced if they fail dP testing - Filters to be replaced if they fail radioactive load surveillance	S0	S0	7	7	- Recirculation system washes out particulates of airstream and returns condensate to AWF tank - HEME washes out particulates of airstream and returns condensate to catch tank - Maximum radiological loading on filters limited to 200 mrem/h and 800 mrem/h on HEME
				Co-located Worker	- Same as for the public			- Same as for the public	S0	S0	7	7	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S1	S1	11	11	- Same as for the public
				Rationale for frequency of event: HEPA filter are designed to trap particulates; this makes the event frequency anticipated or in the F3 Potential for contamination of the environment: E0, slight to negligible									

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
Hazard – Radiological and toxicological material in the ventilation ducting													
43	E-5	Release of radiological material and exposure to radiation	Criticality caused by buildup of radioactive material in the ducting	Public	Engineered Features: - Geometry of ventilation system not conducive to criticality Administrative Features: - AC 5.3, Criticality prevention program	F0	F0	Engineered Features: - None identified Administrative Features: - None identified	S0	S0	1	1	- None Identified
				Co-located Worker	- Same as for the public			- Same as for the public	S0	S0	1	1	- Same as for the public
				Immediate Worker	- Same as for the public			- Same as for the public	S3	S3	10	10	- Same as for the public
				Rationale for frequency of event: Event requires the failure of two HEPA filters in series; this makes the event frequency in the F1 range Potential for contamination of the environment: E0, slight to negligible									

Table B-1. Hazards Analysis Summary. (30 sheets)

Event No.	Event Category	Postulated Event Description	Significant Causes or Energy Sources	Receptor	Credited Prevention (Attributes that Lower Frequency)	Event Frequency		Credited Mitigation (Attributes that Lower Consequences)	Consequences		Risk Bin Number		Defense-in-Depth Controls
						Without Prevent	With Prevent		Without Mitigat	With Mitigat	Without Prevent Mitigat	With Prevent Mitigat	
Hazard – Leaking Ethylene Glycol into AWF tank													
44	N/A	Coolant leakage from recirculation cooling unit leaks into tank	Corrosion or mechanical failure	Public	Engineered Features: - Coolant lines are made of stainless Administrative Features: - None identified	A	A	Engineered Features: - None Identified Administrative Features: - None Identified	N	N	12	12	
				Co-located Worker	- Same as for the public				N	N	12	12	
				Immediate Worker	- Same as for the public				N	N	12	12	
				Potential for contamination of the environment: E0, slight to negligible									

AC = Administrative Control.
ALC = airlift circulators.
AWF = Aging Waste Facility.
GRE = gas release event.
HEGA = high-efficiency gas adsorber.
HEME = high-efficiency mist eliminator.
HEPA = high-efficiency particulate air (filters).
OSD = Operating Specifications Document.
RCT = radiological control technician.
PIC = person-in-charge.
USQ = Unreviewed Safety Question.

Note: [1]HNF-IP-0842, 1997, TWRS Administration, Lockheed Martin Hanford Corporation, Richland, Washington.

Table B-2. HazOp Definition Guide.

Guide Words / Process Variables	No, Not, Non	Less, Low, Short	More, High, Long	Part of	As Well As, Also	Other Than	Reverse
Flow	No Flow	Low Rate, Low Total	High Rate, High Total	Missing Ingredient	Misdirection, Impurities	Wrong Material	Backflow
Pressure	Open to Atmosphere	Low Pressure	High Pressure				Vacuum
Temperature	Freezing	Low Temperature	High Temperature				Auto-refrigeration
Level	Empty	Low Level	High Level	Low Interface			
Agitation	No Mixing	Poor Mixing	Excessive Mixing	Mixing Interruption	Mixing Interruption		Phase Separation
Reaction	No Reaction	Slow Reaction	Runaway Reaction	Partial Reaction	Partial Reaction	Wrong Reaction	Decomposition
Time Procedure	Skipped or Missing Step	Too short, Too Little	Too Long, Too Much	Action(s) Skipped	Extra Action(s) (Short cuts)	Wrong Action	Out of Order, Opposite
Speed	Stopped	Too Slow	Too Fast	Out of Synch		Web or belt Break	Backward
Special	Utility Failure	External Leak	External Rupture	Tube Leak	Tube Rupture	Startup, Shut down, Maintenance	

Table B-3. Frequency Evaluation Levels.

Acronym	Description	Frequency Level (per yr^{-1})
A (F3)	Anticipated, Expected	$>10^{-2}$
U (F2)	Unlikely	$10^{-4}<f\leq 10^{-2}$
EU (F1)	Extremely Unlikely	$10^{-6}<f\leq 10^{-4}$
BEU (F0)	Beyond Extremely Unlikely	$\leq 10^{-6}$

Note: The information in this table is from WHC-CM-4-46, Safety Analysis Manual, Section 7.0, "Risk," Rev. 3, Westinghouse Hanford Company, Richland, Washington.

Table B-4. Radiological and Chemical Consequence Evaluation Levels for Hazard Receptors.

Consequence Level (Abbreviation) ↓	Consequences to the Public, Workers, or Environment
High (H) or S3	May cause deaths onsite; loss of the facility or operation; major injuries or illness offsite; radiation exposure to offsite individuals in excess of annual limits; or severe impact on the environment.
Moderate (M) or S2	May cause severe injuries or severe occupational illness onsite; radiation exposure to onsite individuals in excess of annual limits; major damage to a facility or operation; minor illness or injury offsite; exposure of offsite individuals to radiation below annual limits; or major impact on the environment.
Low (L) or S1	May cause minor injuries or minor occupational illness onsite; exposure of onsite individuals to radiation below annual limits; negligible impact offsite; or minor impact on the environment.
Negligible (N) or S0	Will not result in injury; occupational illness; exposure onsite or offsite; or result in significant impact on the environment.

Note: The information in this table is from WHC-CM-4-46, Safety Analysis Manual, Section 7.0, "Risk," Rev. 3, and WHC-SD-WM-SARR-011, 1995, Toxic Chemical Considerations for Tank Farm Releases, Rev. 1, Westinghouse Hanford Company, Richland, Washington.

Table B-5. Risk Binning Matrix.

Frequency → / Radiological or Toxicological Consequence ↓	Beyond Extremely Unlikely (F0) ($\leq 10^{-6}$/yr)	Extremely Unlikely (F1) ($10^{-6} < f \leq 10^{-4}$/yr)	Unlikely (F2) ($10^{-4} < f \leq 10^{-2}$/yr)	Anticipated (F3) ($>10^{-2}$/yr)
High (S3)	10	7	4	1
Moderate (S2)		8	5	2
Low (S1)		9	6	3
Negligible (S0)	11	12		

Key:

→ Risk Bins 1,2,3,4,5,7: Accident Analysis required; may require safety structures, systems, and components (SSC); may require interim operation safety requirements

→ Risk Bins 6,8,9: may require administrative or OSD level controls

Table B-6. Energy Source Checklist from DOE.[a] (4 sheets)

Type of Hazard	Form of Hazard	Comment
Electrical	Battery banks	Uninterruptible Power Source, 208 V rectified, sealed lead-acid battery, because of seal not a source for toxic and loss of it covered in PHA as power loss.
	Diesel units	Battery Charger for batteries for diesel - 125 KW output, in a vented building; no buildup of hydrogen. Covered in PHA as total loss of power
	High lines	None
	Transformers	Yes, one 300 KW in yard (1380 V and down to 120 V), outside fence and not covered in PHA
	Wiring	241-AY-101,-102, 241-AZ-101,-102 in trays, not covered in W-030 PHA, but covered in TWRS PHA
	Switchgear	Outside the tank farms and fence, except diesel switchgear in closed building
	Underground wiring	None for W-030 PHA, but in 241-AY-101,-102 and 241-AZ-101,-102 TWRS PHA
	Cable runs	Instruments - 120 V
	Service outlets and fittings	Yes, welding receptacles in tank farms covered in TWRS PHA
	Pumps	Yes, pumps wired per codes for W-030 additions; other pumps 241-AY-101,-102, 241-AZ-101,-102 covered in TWRS PHA
	Motors	Covered by pumps
	Heaters	Fire covered in W-030 PHA, wired per code, 480 V/code
	Power tools	None
	Small equipment	Instrumentation 120 V or lower.
	Electrical equipment	241-AY-101,-102, 241-AZ-101,-102 covered in TWRS PHA
	Hot plates	None
	High voltage	Yes, covered for sources of W-030 equipment
	Locomotive, electrical	None
	Transmission lines	None
	Other	Switchgear for diesel
Nuclear Criticality	Vaults/pits	None
	Temporary storage areas	None
	Receiving areas	None
	Shipping areas	None
	Casks	None
	Burial grounds	None
	Storage tanks	241-AY-101,-102, 241-AZ-101,-102 and pits
	Canals and basins	None
	Reactor in-tank storage areas	None
	Dollies	None
	Trucks	None
	Hand carry	None
	Cranes	None
	Lifts	None
	Shops	None
	Hot cells	None
	Assembly areas	None
	Inspection areas	None
	Laboratories	None
	Pilot plants	None
Nuclear (in-reactor)	Reactors	None
	Critical facilities	None
	Subcritical facilities	None

Table B-6. Energy Source Checklist from DOE.[a] (4 sheets)

Type of Hazard	Form of Hazard	Comment
Kinetic/linear (in plant)	Fork lifts	None
	Carts	None
	Dollies	None
	Railroad	None
	Surfaces	None
	Obstructions (collision with)	Stack, covered in W-030 PHA
	Shears	None
	Presses	None
	Crane loads in motion	Tie-ins, riser damage if shield plug drops
	Pressure vessel blowdown	None
	Power assisted driving tools	Construction, pipe wrench, little or no damage
	Cars	Stack inlet stations - maintenance, impossible to get to
	Trucks	Stack inlet stations - maintenance, impossible to get to
	Buses	None
	Heavy equipment	Cranes, guzzler trucks
	Centrifuges	None
	Motors	With pumps
	Pumps	241-AY, AZ-101,102, outside of farm
	Cooling tower fans	Outside fence
	Cafeteria equipment	None
	Laundry equipment	None
	Gears/compressors	None/motor operated valves
	Shop equipment (grinders, saws, brushes, etc.)	Construction
	Fans	Chiller fans, protected from doing damage
PV-KD (pressure, tension)	Boilers/chillers	None/2 by 2 stage refrigeration Compressor, covered in W-030 PHA
	Heated surge tanks	None
	Autoclaves	None
	Test loops and facilities	None
	Gas bottles	Construction
	Pressure vessels	None
	Negative pressure, collapse	241-AY, 241-AZ-101,-102/air inlets and relief valves mitigate
	Stressed members	None
	Steam Headers and lines	None
MGH (falls and drops)	Human effort	Maintenance
	Vent cells	Maintenance/short time
	Bucket and ladders	None
	Trucks	Maintenance
	Hoists and elevators	None
	Jacks	None
	Scaffold and ladder	Maintenance
	Excavations	Construction - tie-ins, per codes
	Pits	None
	Elevated doors	None
	Raw water lines	None
	Canals	None
	Vessels	None
	Lifts	Construction maintenance
	Cranes	Construction maintenance, carbon filters weigh only 150 pounds

Table B-6. Energy Source Checklist from DOE.[a] (4 sheets)

Type of Hazard	Form of Hazard	Comment
MGH (falls and drops) (Cont'd)	Packing materials	None
	Rags	None
	Gasoline	None
	Paint solvent	None
	Diesel fuel	Inside building 701-AZ (FHA), fill per codes
	Hydrogen	241-AY, 241-AZ-101,-102/Battery charger - building ventilated
	Organics	None
	Nitric acid	None
	Gases	241-AY, 241-AZ-101,-102
		None
Corrosive	Acids	Batteries/UPS, vented/sealed
	Caustic	241-AY-101,-102, 241-AZ-101,-102
	Natural chemicals	241-AY-101,-102, 241-AZ-101,-102
	Decon solution	None
	High temperature waste	241-AY-101,-102, 241-AZ-101,-102/241-AZ-102[b], covered in Tank Bump and flow in W-030 PHA
	Plug storage	None
Radioactivity	Storage areas	None
	Storage buildings	None
	Radioactive sources	241-AY-101,-102, 241-AZ-101,-102, covered in Tank Bump and filter blowout in W-030 PHA
	Building	Tank ventilation
	Filters	Covered in W-030 PHA
	Condenser cell	Yes
Radioactivity (Cont'd)	Electric furnace	None
	Blacklight (e.g., magniflux)	None
	Laser	None
	Medical x-ray	None
	Radiography equipment and sources	None
	Electron beam	None
	Equipment noise	Some noise will be generated by the heating, ventilating, and air-conditioning system and the chiller system. However, rotating equipment, diesel generator designed for minimum noise
	Ultrasonic cleaners	None
Thermal radiation	Furnaces	None
	Boilers	None
	Steam lines	None
	Lab and pilot plant equipment	None
	Sun	Sun is often present on the Hanford Site, but does not effect Project W-030
Thermal (except radiant)	Convection	Cooling towers
	Heavy metal weld preheat	None
	Exposed steam pipes	None
	Electric heaters	Ventilation inlet and main system - Maintenance, covered in W-030 PHA
	Fire boxes	None
	Lead melting pot	None
	Electrical wiring and equipment	Wired per code and does not present a thermal energy - covered above as equipment

Table B-6. Energy Source Checklist from DOE.[a] (4 sheets)

Type of Hazard	Form of Hazard	Comment
Explosive pyrophoric	Caps	None
	Primer cord	None
	Dynamite	None
	Power metallurgy	None
	Dusts	None
	Hydrogen (including battery banks and water decomposition)	241-AY-101,-102, 241-AZ-101,-102. Diesel building battery charger (ventilated)
Explosive pyrophoric	Peroxides - superoxides	None
	Acetone	None
	Fluorides	None
	Carbon monoxide	None
	Lead	None
	Ammonia and compounds	Possible waste in tanks: Part of toxicological constituents of SARR-011
Other	Dusts and particulates	Environmental dusts could be present, but not considered in PHA
	Pesticides-herbicides-insecticides	Spray each spring for pesticides and herbicides-minimal affect and not covered in PHA
	Bacteria	None
	Beryllium and compounds	None
	Chlorine and compounds	None
	Sandblast	None
	Metal plating	None
	Asphyxiation-drowning	None

FHA = Fire Hazards Analysis.
PHA = Preliminary Hazard Analysis.
TWRS = Tank Waste Remediation System.

[b]WHC-SD-WM-SARR-011, 1995, Toxic Chemical Considerations for Tank Farm Releases, Rev. 1, Westinghouse Hanford Company, Richland, Washington.

Table B-7. Summary of Hazardous Events.

Hazardous Event	Definition of Event
Loss of containment	For the hazard identification task, loss of containment was considered as the breach of a barrier resulting in the release of hazardous liquid material (radioactive and/or toxic chemical).
Loss of confinement	For the hazard identification task, loss of confinement was considered as the breach of a barrier resulting in the release of hazardous gaseous or airborne material (radioactive and/or toxic chemical).
Waste disposal	Consistent with the requirements of DOE 5480.23 (DOE 1992) consideration of hazards associated with waste disposal and handling were limited to those hazards involving the waste that is generated incidental to the performance of functions related to the waste storage and treatment mission at tank farms.
Criticality	The hazards associated with criticality were identified considering two different perspectives based upon the effects of the event. These were the direct effects to personnel (such as direct radiation exposure) and the effects that result from a sequence initiated by criticality as an energy source that may lead to a release of hazardous material.
Natural phenomena	The hazards associated with natural phenomena were identified considering two different perspectives based upon the effects of the event. These were the direct effects to personnel (such as physical injury and the effects that result from a sequence initiated by natural phenomena such as an energy source that may lead to a release of hazardous material.
Fire and deflagration	The hazards associated with fires and explosions were identified considering two different perspectives based upon the effects of the event. These were the direct effects to personnel (such as physical injury) and the effects that result from a sequence initiated by a fire or deflagration of an energy source that may lead to a release of hazardous material.
Interfaces	This category was used to identify hazards that may be associated with interfaces between the major functional segment under consideration and operations/activities related to the other major functional segments. Hazards that did not fit within the context of the other hazard categories were included under interfaces.
Extrinsic hazards	Hazards associated with facilities or activities outside of tank farms. No impact to existing extrinsic hazards was identified in this assessment and therefore no further action was taken.
Testing, surveillance, and maintenance	This category was used to identify hazards that are uniquely associated with the testing, surveillance, and maintenance activities associated with the major functional segment under consideration. The hazards considered were related to both personnel exposure to hazardous materials (radioactive and toxic chemical) and potential personnel injury.
Industrial	Injury to operating personnel – This category was used to identify the general occupational hazards (radiological, hazardous chemical and general industrial) associated with the major functional segment under consideration.

Westinghouse Hanford Company **Internal Memo**

8M400-JEK-96015

From: Consequence Analysis
Phone: 376-9219 A3-34
Date: September 27, 1996
Subject: VALIDATION OF THE W-030 PROJECT PHA

To: R. L. Guthrie A3-37

cc: S. M. Stahl A3-37
JEK File/LB

Reference: WHC-CM-6-32, Section WP-4.6, Rev. 1, Hazard Analysis, Safety Analysis and Nuclear Engineering Work Procedures

Monday and Tuesday, September 23 and 24, 1996 we met to verify the existing PHA for the W-030 Project. Those that met at these meetings included the following:

Frank T. Clifton
Richard L. Guthrie
Morgan D. Harding
Mark G. Hunn
John E.kelly
Scott R. Pierce
Paul D. Rice
Gary R. Tardiff

Brief resumes for these gentlemen appear attached to this report. Initially, we developed a DOE-RL approved Energy Source Checklist. We went through the list and determined what energy sources are affected by the W-030 Project. Included are those energy sources either not part of the project or the reasoning for not developing them further in the W-030 PHA. This checklist is attached. We also verified which of these events should be included in the W-030 PHA. We went through each Event Category, Postulated Event Description, Significant Causes of Energy Source including any new events in the PHA and affirmed that the information was correct. Next, the accident frequency and mitigation feature was verified for each event. Some of the Engineering attributes that lower the frequency were found to be incorrect and were removed. We then verified what was used to reduce the frequency and made sure that these items were not included in the Defense in Depth Column. Table F-5 of reference 1 was used for the frequency ranges. Where necessary, the consequences were updated using Table F-3 of reference 1. Finally, the Risk Bin Numbers were updated to the latest Risk Matrix Bin Numbers found in Table F-6 of reference 1.

HAZARD ANALYSIS PARTICIPANTS

The following contains the names and experience of the Hazard Analysis Participants for the W-030 project SARR.

Frank T. Clifton - Westinghouse Hanford Company - Principal Engineer

Mr. Clifton is a Mechanical Engineer assigned to TWRS Engineering and to the W-030 Project. He has 25 years in the nuclear industry including 20 years at Hanford; assigned to a variety of major projects, with primary responsibilities related to the design of nuclear ventilation systems.

Richard L. Guthrie - Westinghouse Hanford Company - Principal Engineer

Mr. Guthrie has over 19 years experience in Mechanical Engineering. Three and one half of those years have been spent at Hanford. Richard is a Registered Professional Engineer in Mechanical Engineering and a Certified Safety Professional in System Safety Aspects. He has performed PHAs and FTAs with companies like Loral Space Information Systems, Morton Thiokol, General Dynamics, and the Superconducting Super Collider. His TWRS experience includes numerous unreviewed safety evaluations and a HAZOP for the light duty utility arm. Richard is currently working in the TWRS SAR Engineering Group of the Safety Analysis and Nuclear Engineering Division.

Morgan D. Harding - Westinghouse Hanford Company

Mr. Harding has 11 years experience in the nuclear industry. The past six of those years have been in tank farms. Prior to that he was at N-Reactor. He has for the past 4 years been part of the TWRS management team managing planners for the Operations support group and Major Maintenance. Managed east tank farms Operations Field Support Group. His latest management position as Operations interface to construction forces, has given him over 2 years in the field working with the construction forces that have built and installed equipment for projects such as W-030 Aging Waste Ventilation System, W-320 106-C Sluicing System, W-151 101-AZ Retrieval Project, and the 107-AN Mixer Pump and Caustic Injection system. All of the above experience and knowledge of tank systems has brought him to the W-030 Project team as the operations representative for system start-up. This was to include development and implementation of procedures, training programs, system acceptance, etc.

Mark G. Hunn - Contract Engineer (Self) - Mechanical Engineer

Eighteen years experience in the armed forces and nuclear industries as a technical manager, project engineer, and field

crew supervisor. Background includes work on safety documentation, environmental cleanup and decontamination projects, supervision of operational nuclear reactors, and major system maintenance.

John E. Kelly - Westinghouse Hanford Company - Fellow Engineer

Mr. Kelly has 30 years experience in system safety reliability engineering with 6 years experience at Hanford including the N-Reactor PRA. He is a internationally recognized expert in system safety analysis and probabilistic safety assessments and a licensed Safety Engineer in the state of California. His experience in the DOE complex includes hazard and risk analysis work for the Savannah River Site, Sandia National Laboratories, Lawrence Livermore National Laboratory, and taught classes at Brookhaven and Argonne National Laboratories.

Scott, R. Pierce - Westinghouse Hanford Company - Cognizant Engineer W-030 Project

- Provided technical oversight for startup and future operation of the 5 million dollar ventilation facility.
- Coordinate preparation of 18 Operating Procedure, 50 Maintenance Procedures, 22 Alarm Response Procedures, and 8 Emergency Response Procedures.
- Provided technical input to planning and performing the system's 11 Acceptance Tests, 8 Pre-Operational Tests, and 2 Post-Operating Tests.
- Determined process and alarm set points for system operation.
- Developed operator surveillance of new facility.
- Participated on Formal Design Review team for Westinghouse's acceptance of system design.
- Held position on Project W-030 Test Review Board.

Paul D. Rice - ICF Kaiser Hanford - Senior Principal Engineer

Mr. Rice has been a Registered Mechanical Engineer since 1971, and has been employed at Hanford since 1970. He has been the lead HVAC design engineer for the W-030 project since its beginning, and was directly involved in the development and testing of the 1/7 scale process ventilation prototype. Mr. Rice has twenty eight years of diverse experience in the field of Mechanical Engineering, with particular emphasis on energy conservation, HVAC, and on mechanisms. Experience related to HVAC has included analysis, design, and field inspection of systems for nuclear processing facilities, research laboratories, and office buildings. Mechanisms experience includes preliminary design for reactor maintenance systems and special equipment. Other engineering experience has included aircraft HVAC systems, wind tunnel model design, and artificial kidney machine design.

Gary R. Tardiff - Westinghouse Hanford Company - Principal Engineer

Mr. Tardiff has 15 years experience at Hanford with 12 years at PUREX and 3 years at Tank Farms. Gary currently works in the East Tank Farm Engineering as a Project Cognizant Engineer. Previous work experience includes two years experience for E.I. Dupont de Nemours doing design, cost estimating, and development of pilot scale equipment, he also worked on production of experimental fluorocarbons for marketing and toxicological purposes. He worked for W.R. Grace for five years in production and process development of chelating agents for product yield increase and purification. He has a Bachelor of Science degree in Chemical Engineering and has participated in several HAZOPS including Project W-151, 204-AR Facility, Project W-030 and TWRS FSAR HAZOPs.

In the process of performing the PHA for the W-030 Project, we used the Energy Source Checklist from DOE. In the comment section of this table, we concluded whether the energy source was covered in the was unique to the W-030 Project and should be covered by the W-030 Project PHA, or whether this energy source does not affect the ventilation project and therefore coverage in the TWRS FSAR PHA and HAZOP analyses. This is also shown in the comment section. The checklist is attached.

MIXER PUMP TEST
(241-AZ-101)
SAFETY ANALYSIS

ADDENDUM 4

September 1998

This page intentionally left blank.

EXECUTIVE SUMMARY

ES.1 FACILITY BACKGROUND AND MISSION

The purpose of this document is to describe and analyze the mixer pump test for Aging Waste Facility (AWF) Tank 241-AZ-101 and to address the "yes/maybe" responses marked for evaluation questions identified in Unreviewed Safety Question (USQ) Evaluation TF-94-0266. The scope of this document is limited to the performance of the mixer pump test for Tank 241-AZ-101. Unreviewed Safety Question Determination (USQD) TF-96-0018 verified that the installation of two mixer pumps into Tank 241-AZ-101 was within the current Tank Waste Remediation System (TWRS) Authorization Basis. USQDs TF-96-0461, TF-96-0448, and TF-96-0805 verified that the installation of the in-tank video camera, thermocouples, and Ultrasonic Interface Level Analyzer (URSILLA), respectively, were within the current TWRS Authorization Basis. USQD TF-96-1041 verified that the checkout testing of the installed equipment was within the current TWRS Authorization Basis. Installation of the pumps and equipment has been completed. This document provides an evaluation of safety considerations associated with operation of the mixer pumps for the mixer pump test. This document augments the existing AWF authorization basis as defined in the TWRS Basis for Interim Operation (BIO) (LMHC 1997), and as such, will use the TWRS Technical Safety Requirements (TSRs) of Noorani 1997 to adequately control the mixer pump test. The TSRs now include "Air Lift Circulator" controls which have been converted from the AWF Interim Operational Safety Requirements (Heubach 1996) to newly incorporated TWRS TSR controls, as identified in Wagoner 1997. The hazard and accident analysis is limited to the scope and impact of the mixer pump test, and therefore, does not address hazards already addressed by the current AWF authorization basis.

The mixer pump test has been evaluated to cover the use of either the existing ventilation system (241-A-702) or the ventilation system upgrade provided by Project W-030. Analysis of Project W-030 is outside of the scope of this document and is addressed in BIO Addendum 3 which, should the W-030 system be in service at the time of the mixer pump test, will have been approved and made a part of the TWRS authorization basis.

The test will use two high-capacity mixer pumps in various configurations and modes to demonstrate solids mobilization of waste in Tank 241-AZ-101. The information and experience gained during the test will provide data for comparison with sludge mobilization prediction models; provide data to estimate the number, location, and cycle times of the mixer pumps; and provide indication of the effects of mixer pump operation on the AWF tank systems and components. The slurry produced will be evaluated for future pretreatment processing. This process test does not transfer waste from the tank; the waste is mixed and confined within the existing system. At the completion of the mixer pump test, the mixer pumps will be stopped and normal tank operations, maintenance, and surveillance will continue. Periodic rotation of the mixer pumps and motor shafts, along with bearing greasing, is required to maintain the pumps following the mixer pump test.

ES.2 FACILITY OVERVIEW

An overview of the AWF, including a description of the facility mission and stage of life-cycle, is provided in the TWRS Basis for Interim Operations (BIO) HNF-SD-WM-BIO-001 and in Chapter 2 of this addendum. General TWRS and Hanford Site information is provided via reference to the approved TWRS BIO. Likewise, specific information pertaining to the AWF tanks is provided via reference to the approved TWRS BIO. Aspects of the mixer pump test and facility test configuration relevant to this safety evaluation are documented in Chapter 2 of this addendum.

ES.3 FACILITY HAZARD CLASSIFICATION

TWRS facilities, including the AWF, have been designated as Hazard Category 2 facilities (Table 5.1-1 of the TWRS BIO). The mixer pump test does not impact the Hazard Classification assumptions of Tank 241-AZ-101 (no change to the inventory or amount of the material at risk). Thus, Tank 241-AZ-101 remains classified as Hazard Category 2.

ES.4 SAFETY ANALYSIS OVERVIEW

Hazards associated with operation were evaluated using process hazard analysis and Hazards and Operability (HazOp) evaluation techniques. From the results of the hazard analysis, six postulated events were identified as representative of the significant hazards. These events are: (1) a ventilation system high-efficiency particulate air (HEPA) filter failure, (2) backflow through open tank riser, (3) leakage via failed vent ducting, (4) a breach of the tank due to internal or external mechanisms, (5) a nuclear criticality induced by mixer pump operation, and (6) a seismic event. These postulated events were evaluated, based on specific causes and conditions associated with the mixer pump test as described in Section 3.3.2.4 of this addendum. This evaluation resulted in the identification of four design basis accidents that are analyzed in Section 3.4.2 of this addendum. These accidents are: (1) unfiltered release of radionuclide and toxic aerosols from the tank, (2) tank bump, (3) breach of containment, and (4) over-pressurization caused by criticality. The various causes and conditions associated with each of these accident scenarios are identified in Table 3-5 of this addendum. A summary of the accident consequences and a comparison to the risk evaluation guidelines are provided in Table ES-1 of this addendum. A summary of the preventive and mitigative features is provided in Table ES-2 of this addendum.

ES.5 ORGANIZATIONS

Prior to October 1, 1996, Westinghouse Hanford Company and ICF Kaiser Hanford were responsible for design, construction, and testing associated with the mixer pump test. Westinghouse Hanford Company was also responsible for operations, project management, and safety analysis. Since October 1, 1996, Fluor Daniel Hanford, Inc., has acted as management contractor and is ultimately responsible for contract performance, which includes protecting the public, workers, and environment from anticipated hazards associated with

Hanford Site operations, and for being the focal point for interaction with the U.S. Department of Energy (DOE) and the stakeholders. Fluor Daniel Northwest, Inc., has been responsible for design, construction, and testing; Lockheed Martin Hanford Corporation has been responsible for operations; Numatec Hanford Corporation has been responsible for project management; and Duke Engineering and Services Hanford, Inc., has been responsible for the nuclear safety analysis and licensing process.

ES.6 SAFETY ANALYSIS CONCLUSIONS

It is concluded that the mixer pump test can be safely conducted using currently-approved TSRs in conjunction with Air Lift Circulator TSR controls, converted from Heubach 1996 as identified in Wagoner 1997, thus ensuring protection of the workers and the public.

ES.7 DOCUMENT ORGANIZATION

This document is organized in the format of DOE-STD-3009-94. General information pertaining to TWRS or the entire Hanford Site and specific information pertaining to the AWF tanks, but not directly relevant to the mixer pump test, are provided via reference to the approved TWRS BIO.

Table ES-1. Summary of Accident Consequences.

Design Basis Accident Scenario	Mixer pump test Design Basis Accident consequences				Risk evaluation guidelines
			without prevention/ mitigation	with prevention/ mitigation*	
Unfiltered release of radionuclides or toxic aerosols (Section 3.4.2.1)					
HEPA filter failure due to over-pressure (Section 3.4.2.1.2) Frequency: EU	Radiological (rem)	Offsite	**	3.9 E-3	4
		Onsite	**	2.8	10
	Toxicological (SOF)	Offsite	**	2.7 E-5	1 (ERPG-2)
		Onsite	**	3.4 E-1	1 (ERPG-3)
Reverse flow through tank due to tank dome collapse and breach of confinement (Section 3.4.2.3.6) Frequency: BEU (see Breach of Containment)	This event is determined to be beyond extremely unlikely for mixer pump test.	Offsite and Onsite	None	N/A	N/A
Tank Bump (Section 3.4.2.2) Frequency: U	Radiological (rem)	Offsite	.22	None	0.5
		Onsite	250	None	5
	Toxicological (SOF)	Offsite	0.73	None	1 (ERPG-1)
		Onsite	4.9E+03	None	1 (ERPG-2)
Breach of containment (Section 3.4.2.3)					
Flammable Gas Deflagration (Section 3.4.2.3.1) Frequency: Accident prevented through TSR AC 5.9. 5.10. 5.11. Open USQ prevents quantification. Natural phenomena frequencies probably drive this to EU.	Radiological (rem)	Offsite	0.004	None	0.1
		Onsite	4.4	None	0.5
	Toxicological (SOF)	Offsite	0.7	None	1
		Onsite	820	None	1
Tank Dome Collapse (Section 3.4.2.3.6) Frequency: BEU	This event determined to be BEU for mixer pump test structural loadings.	Offsite and Onsite	None	N/A	N/A
Seismic during pumps operation (Section 3.4.2.3.7) Frequency: BEU	Analysis shows that pump support and riser configuration acceptable for applied design requirements.	Offsite and Onsite	None	N/A	N/A
Material degradation due to high temperature (Section 3.4.2.3.5) Erosion (Section 3.4.2.3.4) Missiles from the pumps (Section 3.4.2.3.3) Frequencies: BEU	Analyses show that these events are prevented and not credible.	Offsite and Onsite	None	N/A	N/A
Criticality (Section 3.4.2.4) Frequency: BEU	This event determined to be BEU for mixer pump test.	Offsite and Onsite	None	N/A (no preventive or mitigative features identified)	N/A

*Mitigation actions reduce numerical consequences. Prevention actions denoted by column entry of "None", since consequences are prevented. See Table ES-2 on the following page for specific Mitigation/Prevention actions.

**See Section 3.4.2.1.2.1 for discussion of unmitigated consequences.

(Note: Section numbers are sections in this addendum.)

A = anticipated (1/yr - 10^{-2}/yr)
BEU = beyond extremely unlikely ($\leq 10^{-6}$/yr)
EU = extremely unlikely (10^{-4}/yr - 10^{-6}/yr)
U = unlikely (10^{-2}/yr - 10^{-4}/yr)
N/A = not applicable
SOF = sum-of-fractions

Table ES-2. Summary of Preventive/Mitigative Actions.

Accident Scenario	Preventive or Mitigative Actions during mixer pump test	Applicable Control or Other Document
Unfiltered release of radionuclides and toxic aerosols from the tank (Section 3.4.2.1)	• Limiting the maximum activity on each filter to a level that gives an equivalent dose rate of 200 mrem/h on contact controls the amount of particulates that could be expelled.	TSR AC 5.18
Tank Bump (Section 3.4.2.2)	• Localized high temperatures may be caused by mixer pump operation. The mixer pumps will be turned off if the top 15 feet of waste reaches 195 °F or the waste below 15 feet reaches 215 °F. ALCs will be operated to provide more uniform temperature distributions per limits described below.	TSR LCO 3.3.2, 3.3.4
	• Upon loss of the primary ventilation system the mixer pump(s) will be turned off to control gas and heat buildup in the tank.	TSR LCO 3.2.1
	• During normal operation of the pump(s) and at the end of the test while the pumps are turned off, the waste temperature will be monitored and the air lift circulators operated as soon as the temperature reaches 230 °F for waste below 20 feet and 190 °F for the average waste solution.	TSR LCO 3.3.4
Breach of Containment (Section 3.4.2.3)	• High temperature (3.4.2.3.5):	
	- Primary tank exhaust ventilation system shall be operable.	TSR LCO 3.2.1, 3.3.2
	• Flammable gas deflagration (3.4.2.3.1):	
	- Implementation of Ignition Source Controls as well as monitoring for flammable gas are preventive measures against deflagration, breach of the tank, and breach of ventilation confinement in the event that an episodic gas release exceeds 100% of the lower flammability limit.	TSR AC 5.9, 5.10, 5.11
	- LCO 3.2.1 requires ventilation operability to prevent flammable gas accumulations. The vent system operation also prevents tank pressurization and an unfiltered release.	TSR LCO 3.2.1
	• Tank dome collapse due to overload (3.4.2.3.6):	
	- This event is deemed beyond extremely unlikely for the mixer pump test based on analysis of dead load, live load, jet impingement, and seismic loads. All components of the support system were found adequate to support the mixer pumps for both service and extreme conditions.	TSR AC 5.16
	• Seismic (3.4.2.3.7):	
	- Structural analysis of seismic loads shows that the pump support and riser configuration are acceptable for the applied design requirements.	Moody 1996
Criticality (Section 3.4.2.4)	• A Criticality Safety Evaluation Report prepared for Project W-151 identified no scenario associated with the mixer pump test that could credibly lead to criticality.	TSR AC 5.7

(Note: Section numbers are sections in this addendum.)

1.0 SITE CHARACTERISTICS

1.1 INTRODUCTION

The objective of this chapter is to describe any changes to the site characteristics of the Hanford Site provided in Appendix C of HNF-SD-WM-BIO-001, *Tank Waste Remediation System Basis for Interim Operation* (TWRS BIO) (LMHC 1997) due to the performance of the mixer pump test. Tank 241-AZ-101 is located in the Aging Waste Facility (AWF) of the Tank Waste Remediation System (TWRS) in the 200 East Area of the Hanford Site. See Chapter 2 of this addendum for the changes to the facility descriptions provided in Appendix B of the TWRS BIO and for the process descriptions of the mixer pump test.

It is not the intent of this chapter (including its references to the TWRS BIO) to provide all of the information suggested by the guidance of DOE-STD-3009-94. The objective of this chapter is to provide the information necessary to describe the facility's location, identify any hazards due to that location, and identify critical parameters used in Chapter 3 of this addendum.

1.2 REQUIREMENTS

See Appendix C, Section 1.2 of the TWRS BIO for the requirements for Hanford Site characterization in support of safety analysis and design. There are no changes to these requirements as a result of the performance of the mixer pump test.

1.3 SITE DESCRIPTION

See Appendix C, Section 1.3 of the TWRS BIO for the Hanford Site description. There are no changes to the site description as a result of the performance of the mixer pump test.

1.4 ENVIRONMENTAL DESCRIPTION

See Appendix C, Section 1.4 of the TWRS BIO for a discussion of the meteorology, hydrology, and geology of the Hanford Site. There are no changes to the environmental description as a result of performance of the mixer pump test. This data from the TWRS BIO is used to calculate radiological and toxicological impacts to receptors (onsite and offsite) from accident scenarios outlined in Chapter 3 of this addendum.

1.5 NATURAL PHENOMENA THREATS

See Appendix C, Section 1.5 of the TWRS BIO for a description of the natural phenomena threats. There are no changes to the natural phenomena threats as a result of performance of the mixer pump test.

1.6 EXTERNAL MAN-MADE THREATS

See Appendix C, Section 1.6 of the TWRS BIO for a description of the external man-made threats. There are no changes to the external man-made threats as a result of the performance of the mixer pump test.

1.7 NEARBY FACILITIES

See Appendix C, Section 1.7 of the TWRS BIO for a description of nearby facilities. There are no changes to the potential effects on Tank Waste Remediation System (TWRS) facilities from nearby facilities as a result of performance of the mixer pump test. Accidents associated with performance of the mixer pump test with the potential to affect the maximum onsite individual (which may include people at some of the facilities listed in Section 1.7.1 of Appendix C of the TWRS BIO) are discussed in Chapter 3 of this addendum.

1.8 VALIDITY OF EXISTING ENVIRONMENTAL ANALYSES

Project W-151 and the performance of the mixer pump test were evaluated by the U.S. Department of Energy, Richland Operations Office (RL) (Gerton 1990) and found to be within the scope of the existing Environmental Impact Statement (EIS) DOE-EIS-0113, "Disposal of Hanford Defense High-Level, Transuranic, and Tank Wastes." The site characteristics data are in agreement with the data contained in the TWRS Environmental Impact Statement (DOE-EIS-0189).

2.0 FACILITY DESCRIPTION

2.1 INTRODUCTION

The purpose of this chapter is to describe any changes to the description of the Tank Waste Remediation Systems (TWRS) Aging Waste Facility (AWF) provided in Section 2.4.4.1.1 of Appendix B of the *Tank Waste Remediation System Basis for Interim Operations* (TWRS BIO), HNF-SD-WM-BIO-001, due to the performance of the mixer pump test. The mixer pump test is similar in concept to previous mixer pump operations performed in Hanford waste tanks (Wicks 1997). However, the size and power of the mixer pumps used during this test will be considerably larger than those used in the past (300 hp vs. 75 hp), necessitating this safety analysis to be performed because of the increased thermal output and potential accident consequences. This chapter describes the process test to be performed in Tank 241-AZ-101. The facility and process descriptions (both in this chapter and the TWRS BIO) support the assumptions used in Chapter 3 of this addendum.

The scope of this document is limited to the performance of the mixer pump test. Unreviewed Safety Question Determinations (USQDs) TF-96-0018, TF-96-0461, TF-96-0448, and TF-96-0805 verified that the installation of the two mixer pumps, the in-tank camera system, the profile thermocouples, and the Ultrasonic Interface Level Analyzer (URSILLA), respectively, into Tank 241-AZ-101 were within the current TWRS authorization basis. USQD TF-96-1041 verified that checkout testing of the installed equipment was within the current TWRS authorization basis. Safety considerations associated with performance of the mixer pump test are evaluated by this BIO Addendum.

This document augments the current TWRS authorization basis. This document does not evaluate removal of the mixer pumps since no decision had been made regarding pump removal at the time that this BIO Addendum was approved. Safety considerations for removal of the pumps will be addressed by separate safety documentation if the decision is made to remove the pumps.

The mixer pump test has been evaluated to cover use of the existing ventilation system (241-A-702) or the ventilation system upgrade provided by Project W-030. Analysis of Project W-030 is outside of the scope of this document and is addressed in BIO Addendum 3. Should the Project W-030 ventilation system upgrade be in service at the time of the mixer pump test, BIO Addendum 3 will have been approved and made available as a referenceable source for additional information on the W-030 ventilation system equipment and safety analyses. The hazard and accident analysis within this BIO Addendum is limited to the scope and impact of the mixer pump test, and therefore, does not address hazards already addressed within the current authorization basis and not related to or affected by the mixer pump test.

The mixer pump test will use two high-capacity mixer pumps to demonstrate solids mobilization on Hanford waste in Tank 241-AZ-101 (Figure 2-1 of this addendum). The information and experience gained during the test will provide data for comparison with sludge mobilization prediction models; provide data to estimate the number, location and cycle times of the mixer pumps; and provide indication of the effects of mixer pump operation on the AWF Tank

systems and components. The slurry produced will be evaluated for future pretreatment processing. This process test does not transfer waste from or to the tank; the waste is mixed and confined within the existing system. At the completion of the mixer pump test; Tank Farm Operations will stop the mixer pumps and resume normal tank operations, maintenance and surveillance. Periodic rotation of the mixer pumps and motor shafts, along with bearing greasing, is required to maintain the pumps following the mixer pump test. The test is equivalent to any maintenance testing of pumping equipment, and provides a gradual operation of the system to determine maximum and minimum effectiveness.

2.2 REQUIREMENTS

See Project W-151 Functional Design Criteria (FDC) (Nordquist 1997), which has been approved by the U.S. Department of Energy, Richland Operations Office (RL) for identification of design codes, standards, regulations, and the U.S. Department of Energy (DOE) orders relevant to the design and construction of Project W-151.

2.3 FACILITY OVERVIEW

Project W-151 and the mixer pump test do not impact the currently defined mission of the TWRS facilities or the basic processes in use, as defined in Section 2.3.1 of Appendix B of the TWRS BIO. The following discussion is limited to providing information applicable to Project W-151 and the mixer pump test. Information provided here consists of any and all changes to the Aging Waste Facility (AWF) configuration and process description provided in Appendix B of the TWRS BIO.

The AWF tanks currently contain a mixture of liquid and sludge with both radioactive and hazardous compounds. The current waste inventory for Tank 241-AZ-101 is presented in Hodgson 1995. The current heat generation rate associated with Tank 241-AZ-101, without the mixer pumps, is 70,806 W (241,600 Btu/h) (Hodgson 1995). The 300 hp mixer pumps have a thermal input to the waste of 201,000 W (687,000 Btu/h) each (Nordquist 1997), resulting in a total heat load for the tank, with both mixer pumps, of 472,806 W (1,613,000 Btu/h).

2.4 FACILITY STRUCTURE

The following discussion is limited to providing information applicable to mixer pump test equipment. Information provided here consists of any and all changes to the AWF equipment description provided in Appendix B, Sections 2.4.3 and 2.4.4 of the TWRS BIO.

Figure 2-1 of this addendum provides a top-view of the tank and locates the mixer pumps and temperature monitoring equipment within the tank provided by Project W-151. See Appendix B of the TWRS BIO for additional information on AWF tank temperature monitoring equipment.

A brief listing of the characteristics of each mixer pump is provided in Table 2-1 of this addendum. Additional pump information is provided in Nordquist 1997, and WHC 1996a and WHC 1996b. The following is an excerpt from Nordquist 1997: "Each mixer pump shall take in fluid from the tank bottom and discharge the fluid horizontally through two opposing nozzles located 12 to 18 inches above the tank bottom. The nozzle assembly shall oscillate rotationally (180 °) or rotate 360 ° at 0.05 to 0.2 rpm to sweep the entire projected area of the tank bottom." The two mixer pumps are installed in Tank 241-AZ-101 through existing 1.1 m (42-in.) risers in the tank (see Figure 2-2 of this addendum). The mixer pumps are driven by 300 hp induction motors and rotation of the whole assembly is performed by 1/3 hp induction motors with a 900:1 gear reduction. The design life of the individual mixer pump components is five years or 44,000 hours. The design life of the permanent modifications of Tank 241-AZ-101 and non-replacement ancillary and support equipment is consistent with the remainder of the 50-year design life of the 241-AZ tank farm, which was completed in 1976. Replaceable equipment and components may have a shorter design life, but generally not less than five years.

Analysis of pump-to-pump interaction has been completed in the vendor supplied information (Nordquist 1996). Pump effects, which included the effects of pump operational and environmental conditions, were found to be much greater on the smaller equipment already existing in the tank than for pump-to-pump interaction.

To determine the effects of pump operation on in-tank equipment, structural analyses were performed. Waters and Heimberger 1993 states that for the small number of cycles involved, the stress levels on in-tank components (including the air lift circulators [ALCs]) are well below the allowable limits. Additional analysis (Julyk 1997) states there is a potential for some damage to the thermocouples attached to the ALCs (not safety related equipment) if there are agglomerations of hardened sludge adhering to the thermocouples. Tank 241-AZ-101 has 22 ALCs used to establish convective currents within the tank's supernatant region, and to some degree, mobilize the sludge which settles to the bottom of the tank. During the mixer pump test, the ALCs will be left off as much as possible to determine the effectiveness of the mixer pumps. For the steam coil installed in Tank 241-AZ-101, an analysis was performed to determine the allowable number of stress cycles that could be withstood to support mixer pump operation at the steam coil's current location (Crass 1996). The number of stress cycles are determined by multiplying the mixer pump's rotational speed (the speed at which the entire mixer pump unit rotates about its vertical axis in the oscillating mode) by the time of the mixer pump operation. The rotational speed of the mixer pump assembly, including the casing, is relatively slow as compared to the pump impeller speeds (0.05 to 0.2 rpm, as compared to 1,200 rpm). Initially, it was thought that the steam coil would have to be raised out of the path of pump discharge. However, at the current location of the steam coil (approximately 53 cm [21-in.] from the tank bottom), the allowable stress cycles are 200,000. These 200,000 stress cycles at a rotational speed of 0.1 rpm translates to 16,600 hours. At a maximum rotational speed of 0.2 rpm the pumps can safely operate for 160,000 cycles or 6,650 hours (Crass 1996) versus a test duration of approximately 1,300 hours.

In addition, the potential for pump operation to result in erosion of the tank liner is addressed in Section 3.4.2.3.4 of this addendum. Erosion of in-tank equipment is considered to be bounded by that of the tank liner analysis. Erosion of in-tank equipment will not affect equipment operability and therefore is considered acceptable for the duration of the test.

Mixer pump system components and assemblies located at or within the double-shell tank (DST) are designed to withstand the anticipated radiation environment as specified in Nordquist 1997. In addition, mixer pump system components and assemblies that will contact the waste are compatible with the waste fluid properties present in the tank as specified in Nordquist 1997. Those in-tank parts of the mixer pumps and other in-tank equipment submerged in the liquid may potentially be exposed to waste at temperatures from 40 °C to 100 °C (104 °F to 212 °F) during normal operations.

2.5 PROCESS DESCRIPTION

Other than the addition of the mixer pumps, Project W-151 and the mixer pump test do not impact the facility's currently defined mission or the basic processes in use. This section describes the mixer pump test.

2.5.1 Mixer Pump Testing

Tank 241-AZ-101 has been selected for the first full-scale demonstration testing of a mixer pump system. The tank currently holds over 3.63 ML (960 Kgal) of neutralized current acid waste, including approximately 31.8 cm (12.7 in) of settling solids (sludge) at the bottom of the tank (Hodgson 1995).

The mixer pump test goals are to provide actual in-tank operations of mixer pumps, effectively mobilize solids within the supernatant, provide empirical data for determination of the mixer pump effective cleaning radius (distance out from pump discharge at which the effectiveness of the pump in mobilizing tank solids significantly decreases), and provide further justification for use of mixer pumps on other DSTs. The mixer pump test may consist of three pump configuration phases, including:

- Single Pump - Fixed Mode
- Single Pump - Oscillating Mode
- Two Pumps - Oscillating Mode.

In addition to the pumping or mixing modes, two other tank conditions during the mixer pump test are considered in this BIO Addendum and discussed as "modes":

- Pump Shutdown - Initial Waste Settling Phase (up to one month)
- Long-Term Re-compaction of solids (up to one year).

The mixer pumps are designed to operate in a fixed position (fixed mode during the single pump portion of the test) or to continuously oscillate from ± 180 ° to 0 ° (oscillating mode). In the oscillating mode, the effective rotation rate of the jet nozzles will be operated from 0.05 rpm to 0.2 rpm during the mixer pump test. Testing will also initially include slowly increasing from 700 rpm to 1,200 rpm instead of increasing directly to full power in order to evaluate the accuracy of modeling conclusions. The duration of each of the modes is contingent on the success (or lack thereof) of sludge mobilization. Within each accident analysis in Chapter 3 of this addendum, the worst case mode was chosen for evaluation. It is expected that a reasonable duration of mixing to achieve maximum mobilization is from 10 to 20 days (Symons and Staehr 1996). Due to a loss of mixer pump test data, the mixer pumps will be turned off whenever all of the air lift circulators are running.

2.6 CONFINEMENT SYSTEMS

The mixer pump test was analyzed to cover the use of either the ventilation system upgrade provided by Project W-030 or the 241-A-702 ventilation system. The current ventilation system for Tank 241-AZ-101 is the 241-A-702 AWF ventilation system described in Appendix B, Section 2.4.3.7.1 of the TWRS BIO (Figure 2-2 of this addendum). However, Project W-030 will provide a ventilation system upgrade for the AWF (which includes Tank 241-AZ-101) as described in BIO Addendum 3. Since there is uncertainty about which of these ventilation systems will be operational during the mixer pump test, the safety analyses provided in this document evaluate both ventilation systems and the accident consequences were considered for the bounding case condition. Either ventilation system can remove the calculated heat load for bulk waste temperatures (Sathyanarayana 1994, Rice 1992a, Rice 1992b, Collins 1992) for mixer pump operation (see Table 2-2 and Section 3.4.2.2 of this addendum for additional information).

2.6.1 241-AY and 241-AZ (Aging Waste Facility) Tank Farm Ventilation System - Project W-030

See BIO Addendum 3, as well as Figures 2-3, 2-4, and 2-5 of this addendum for a description of the Project W-030 ventilation system. There are no changes to this ventilation system as a result of performance of the mixer pump test.

2.6.2 241-AY and 241-AZ (Aging Waste Facility) Tank Farm Ventilation System - 241-A-702

See Appendix B, Section 2.4.3.7.1 of the TWRS BIO, and Figure 2-6 of this addendum for a description of the 241-A-702 AWF ventilation system. There are no changes to this ventilation system as a result of the operation of the mixer pump test.

2.6.3 Annulus Exhaust Flow Description

See Appendix B, Section 2.4.3.7.1 of the TWRS BIO, and Figure 2-7 of this addendum for a description of the AWF annulus ventilation system. There are no changes to this ventilation system as a result of operation of the mixer pump test. Currently, the annulus exhauster is non-operational, and the conservative assumption has been made for the thermal analyses of Chapter 3 of this addendum that it will remain unavailable during the mixer pump test. Should it be returned to service prior to the mixer pump test, additional tank cooling would be provided by the system, and all tank thermal margins to operational and safety limits would be increased.

2.7 SAFETY SUPPORT SYSTEMS

Existing equipment in Tank 241-AZ-101 monitors and records selected parameters during the mixer pump test. The following describes (1) the appropriate section of the TWRS BIO where descriptions of the existing equipment may be located, and (2) the Tank 241-AZ-101 mixer pump system equipment.

2.7.1 Existing Equipment

See Section 2.4.11 of Appendix B of the TWRS BIO for a description of the existing equipment within Tank 241-AZ-101 which will be used to monitor and record parameters during the mixer pump test. Any changes or additional cautions involved with using this equipment during the mixer pump test are discussed below.

2.7.1.1 Liquid Level Measurement System. During the mixer pump test, liquid level measurement will be taken either manually using a tape or by using an ENRAF(TM) gauge to comply with TWRS TSR Limiting Condition for Operation (LCO) 3.3.4, "Air Lift Circulators (ALCs)." Caution is to be taken during mixer pump operation because the ENRAF(TM) liquid level detector could be damaged when lowered into the tank during mixer pump operation. The ENRAF(TM) liquid level is a micro-processor-controlled tank gauge which accurately measures the liquid level. During testing, liquid level measurement with an ENRAF(TM) gauge will be taken when the mixer pump(s) is off, or by other means (e.g., manual tape). For the mixer pump test, level data will be measured and manually logged.

2.7.1.2 Temperature Monitoring. Temperature monitoring in the waste tanks is required to maintain tank operating conditions. For the mixer pump test, as described in the mixer pump test plan (Symons and Staehr 1996), the temperature data, collected and analyzed, provides information about the waste temperature within the tank before, during and after the mixer pump test. This system provides one method of identifying any potential localized "hot spots" leading to tank bump conditions (refer to Section 3.4.2.2 of this addendum).

In accordance with Symons and Staehr 1996, the tank bottom thermocouples, profile thermocouples, air lift circulator thermocouples, and sludge

thermocouples may be used to monitor the growth of the effective cleaning radius area when the mixer pumps are operating. The thermocouple data will be monitored before, during, and after pump operation. See Section 2.4.11.4.2 of Appendix B of the TWRS BIO for a description of AWF tank temperature monitoring equipment and locations.

Several different temperatures relating to the mixer pump test and Tank 241-AZ-101 are to be used throughout this BIO Addendum. Some of these temperatures result from predicted temperature responses of the waste to the mixer pump action, some relate to saturation temperatures of the tank solids, supernate, or mixed slurry, and some relate to design and/or safety limits. For clarity, Table 2-3 of this addendum is provided to outline all of these temperatures.

2.7.1.3 Hydrogen Monitoring. Monitoring requirements for flammable gas accumulation in tank headspace are specified in the TWRS TSR AC 5.11. A Standard Hydrogen Monitoring System (SHMS) cabinet has been installed on Tank 241-AZ-101, which will be used to take hydrogen concentration readings, as required, during the testing. Data from the SHMS will be recorded manually, as specified in Symons and Staehr 1996.

2.7.1.4 Tank Pressure Monitoring. The pressure/vacuum within the 241-AZ-101 primary tank (i.e., vapor space) is continuously monitored as discussed in Section 2.4.11.7 of Appendix B of the TWRS BIO.

2.7.1.5 Air Lift Circulator System. The air lift circulator system consists of air lift circulators (ALCs) in each of the aging waste tanks and a compressed air system. The compressed air system provides process air to operate the ALCs. Instrument air is also generated to operate critical valves on the 702-A ventilation system. The compressed air system includes the following items:

- Air lift circulators
- Piping between the compressor building and the individual tanks
- Air receiver (TK-801)
- Air accumulator for instrument air (TK-802)
- Portable separator and dryer
- Permanent duplicate sets of air separators and dryers
- Permanent air compressors
- Portable diesel air compressor.

2.7.1.5.1 Air Lift Circulators. The air lift circulator system is composed of the process air (described above) and 22 air lift circulators (ALCs) in each of the 241-AY and 241-AZ Tanks. See Section 2.4.4.1.1 of the TWRS BIO Appendix B for a brief general description of the ALCs. Additional ALC system details are provided below.

The ALCs are relatively simple devices consisting of two basic components: a vertical lift riser pipe 76 cm (30-in.) in diameter, and a foot piece (air nozzle) located within and near the lower end. A 15 cm (6-in.) pipe suspends the lift riser from the tank dome and concentrically extends to a 3.8 cm (1.5-in.) inner diameter nipple. A 2.5 cm (1-in.) pipe, which supplies the motive air, is a removable insert that extends within the 15 cm (6-in) pipe to 5 cm (2-in.) below the swaged nipple. This is the one component which can be replaced in the event of a plug. The entire unit is of mild steel construction. The lower ends of all the lift risers are 76 cm (30-in) above the tank bottom.

Air is injected into the lift riser at the foot of the air lift, draws in liquid from the bottom of the tank, and pushes the fluids up the circulator and out the top. The large liquid flow rates generated with the circulators will create turbulent flow in the tank contents. Liquids flowing along the bottom of the tank and up the draft tubes will carry solid particles out the top of the circulator as they are discharged in the upper region of the tank. The vertical fluid motion decreases the temperature differential between the top and bottom of the tank by transporting warm liquids and solids from the bottom of the tank to the cooler regions at the top. A computer analysis of the adequacy of the circulator capabilities for suspending and mixing was made by Pacific Northwest Laboratory (Fineman 1984). This analysis compiles several modeling reports which show the air lift circulators are capable of keeping the solids suspended and maintaining a more even temperature distribution, preventing tank bumps (see Section 3.4.2.2 of this addendum).

2.7.1.5.2 Air Compressor Building. Process and instrument air is supplied to the 241-AY and 241-AZ Tank Farms from the 241-A-701 Compressor Building. The 241-A-701 Building compressed air system was upgraded from late 1993 to 1995. It contains two Ingersoll-Rand glycol/water cooled electric air compressors. Each compressor is powered by a 125 hp electric motor and will supply about 2.1×10^{-1} m^3/s (440 cubic feet per minute [CFM]) at 1.0 MPa (150 lbf/in^2 gauge). Normally one compressor will be operated, and the other acts as a backup. They will be rotated to ensure that they have about the same amount of use and that they remain operable. A dedicated portable diesel driven air compressor is available at the Compressor Building as backup. A portable air separator and air dryer system is available (in use) outside of 241-A-701 building.

Air from the compressors passes through a cooler and separator to remove moisture and droplets. The air goes to an air receiver tank located behind 241-A-701. For instrument air, the air is routed through a separator and air dryer to further remove water droplets, particulates, and vapors. For process air, these dryers and filters are bypassed.

Process air is reduced to 0.3 MPa (41 lbf/in^2 gauge) through a pressure reducing valve and then one 7.6 cm (3-in.) line is routed to the 241-AX, AY, and AZ tank farms. Process air is piped to the 801 buildings in the 241-AZ and 241-AY Tank Farms. Another pipeline leaves the Compressor Building to the 241-A tank farm.

Instrument air from 241-A-701 is routed to an air accumulator, reduced in pressure to 0.2 MPa (35 lbf/in^2 gauge) and then to the 241-A-702 ventilation

building. Instrument air is routed to 241-AX, AY and AZ farms through a 2.5 cm (1-in.) line.

Rotameters located in the 241-AY-801A and 241-AZ-801A Instrument Buildings are used to indicate the air flow rate to the individual circulators. An adjoining raw water header (and associated valves) are provided at these locations for water flushing of the ALC lines. Connections are available for the emergency diesel air compressor at the air headers in the 241-AY-801A and 241-AZ-801A buildings, if required.

2.7.2 Tank 241-AZ-101 Mixer Pump System Equipment

The process control system for the mixer pump test consists of:

- Pump column water pressure normal and low indicators
- Pump column supply filter normal and high indicators
- Motor bearing high temperature alarm, and motor bearing maximum temperature alarm and interlock
- Motor winding maximum temperature alarm and interlock
- High pump current alarm, and maximum pump current alarm and interlock.

In addition, the mixer pump test will use three existing safety control systems in support of process control. These existing systems are:

- Tank vapor pressure alarm and tank low vacuum alarms
- Maximum tank temperature alarm
- Tank liquid level minimum, absolute minimum, and maximum alarms

The mixer pump motors and connections are above tank farm grade (i.e., in an area without direct connection or exposure to tank headspace) and contain no accumulation areas for flammable gas buildup around the motors. To provide cooling and lubrication, the mixer pump line shaft bearings are enclosed in a water column, which also prevents sparking. In addition, the volute and impeller are 304 stainless steel and the process bearing is submerged in the waste, which prevent sparks (Crass 1993).

As noted in Section 2.5 of this addendum, the mixer pumps are being started slowly as part of the mixer pump process test. This will serve as a preventive measure against a sudden gas release, although gas pockets within the sludge are not expected (Hodgson 1996). In addition, the mixer pump test procedure (Ross 1997) contains requirements to comply with the flammable gas requirements of the TWRS BIO and TSRs (AC 5.9, 5.10, and 5.11). Prior to startup of a mixer pump or change in the mixing test mode, the tank's exhaust or headspace must be sampled for flammable gas to verify it to be <25% of the lower flammability limit (LFL) (see TWRS TSR AC 5.11).

The waste profile thermocouples and transfer pump are carbon steel and are installed in carbon steel risers. Normally, there is no movement of any of these pieces of equipment. However, due to mixer pump operation, they may sway (Waters and Heimberger 1993). The flammable gas hazard has been evaluated in Chapter 3, Section 3.4.2.3.1 of this addendum.

A closed-circuit television system, with videocassette recorder capabilities, will be installed in the tank headspace and will be monitored for information purposes to determine whether any in-tank equipment has been damaged or is being damaged by the mixer pumps. The use of the camera has been determined to be a prudent measure for defense-in-depth. (Analyses have shown safety equipment to be within allowable stress margins, though Julyk 1997 recommended that the ALCs be monitored by camera to avoid flow-induced resonant vibration coupling for more than a duration of one hour. Julyk 1997 also states that resonant coupling is not likely in the tank because of the non-uniform nature of the flow patterns.) It is intended that the closed-circuit television be operated during the entire mixer pump test. But, if the functionality of the camera is lost during the mixer pump test, the test may be continued, once the reason for the camera failure has been determined, since the camera is not needed to fulfill a safety function.

The surveillance camera is housed in a stainless steel, purged enclosure. This enclosure is designed, in accordance with the requirements of TWRS TSR flammable gas controls (AC 5.9, 5.10, and 5.11) and approved by the Flammable Gas Equipment Advisory Board (Smet 1997), to provide a continuously isolated (purged and pressurized) environment for a potentially sparking camera system (either the electronics of the camera itself or the direct current pan and tilt motor for the unit) from a potentially flammable gas environment. Upon loss of purge, the in-tank camera equipment will shut down automatically, deenergizing the system and stopping all sparking potential.

Two gamma profilers may be installed in existing drywell locations to help determine the mixer pump effective cleaning radius during the test and the degree of solids distribution within the supernatant. These pieces of equipment are manually operated (i.e., raised and lowered in the drywell manually) and the readings may be taken during mixer pump operation. The flammable gas administrative controls of the TWRS BIO and TSRs require that the drywells be checked for flammable gas accumulation to ensure integrity of the well on a monthly basis. The housing of the profilers are made from stainless steel and all electrical connections are above tank farm grade (i.e., in an area without direct connection or exposure to tank headspace).

Strain gauges installed on the profile thermocouple trees will monitor the impingement jet force from the mixer pump. The strain gauges are used while the mixer pumps are in operation. The collected data will be measured and stored in a personal computer data spreadsheet program, maintained by the operators. The strain gauges on the profile thermocouple trees are non-sparking during normal operation and all electrical connections are above tank farm grade (i.e., in an area without direct connection or exposure to tank headspace). The strain gauges are also isolated from the tank's vapor space with a welded cover.

Vibration of the mixer pump assembly will be measured by the use of a vibration switch mounted to the pump motor, which is preset to provide indication, should vibrations exceed vibration set-points.

The ultrasonic interface level analyzer (URSILLA) (Royce Model 2511) system consists of three individual units that use an ultrasonic ranging technique to measure the depth of the sludge interfaces within the supernatant. The URSILLA will be operated continuously, and collected data measured and stored in a personal computer data spreadsheet program, maintained by the test engineers. The URSILLA's sensors will be located approximately 4.5 m (15 ft) off the tank bottom, and will be housed and sealed from the tank's atmosphere and waste in 5.1-cm dia (2-in) stainless steel housings and all electrical connections are above tank farm grade (i.e., in an area without direct connection or exposure to tank headspace). The three units provide a high degree of redundancy for process data. The mixer pump test plan only requires two of the three units to be operational during the mixer pump test.

Instrumentation monitors the following:

- Mixer pump motor and bearing temperature
- Pressure readings on pump bearing/seal lubrication water pressure
- Electrical parameters including current, voltage, and frequency
- Rotary position to determine pump orientation
- Bending of selected in-tank equipment through the use of strain gauges (Figure 2-1 of this addendum).

2.8 UTILITY DISTRIBUTION SYSTEMS

Utility distribution systems impacted by Project W-151 include the following:

- Water Supply Systems and
- Electrical Power Distribution System.

2.8.1 Water Supply Systems

All water for the 200 East Area is supplied from the Hanford Site export water system. Export water is defined as water that is pumped from the Hanford Site reservoir to reservoirs located in the 200 East and West areas. Water is distributed throughout the area by two separate systems, the raw water system and the sanitary water system. Raw water is untreated, and unchlorinated, and is used principally for cooling, flushing, and dilution systems. Sanitary water is treated (filtered, purified, etc.) and used for drinking and sanitary facilities, process, and fire protection.

For Project W-151, raw water is provided for mixer pump mechanical seals and bearings. Heat trace of the water piping from the raw water connection to the mixer pump is provided. Flushing of the mixer pump for decontamination during potential failed equipment removal and replacement would be provided by tanker-supplied hot water from the power house.

2.8.2 Electric Power Systems

An electrical substation and pump control facility was installed for Project W-151. The substation replaced the previous transformer (C8-S27) and, in addition to the existing C8-S27 loads, has the capacity to supply power for the two mixer pumps and associated equipment.

2.9 AUXILIARY SYSTEMS AND SUPPORT FACILITIES

No systems or facilities other than those described in the previous sections of this addendum were identified as requiring descriptions in this document.

Table 2-1. Project W-151 Mixer Pump Characteristics.

Pump type	Vertical line shaft drive mixer pump
Motor type	Induction-type, 300 hp, 1,200 rpm, 480V/3 Phase/60HZ weather-protected enclosure
Total pump weight	12,247 kg (27,000 lb) (water column filled)
Pump dimensions	17 m by 41 cm (56 ft by 16 in) (from support connection to bottom of the screen)
Number of jet nozzles	(2) 180 ° opposed
Diameter of each nozzle	15 cm (6 in)
Max Flow rate of each nozzle	19,680 L/minute (5,200 gpm)
(Velocity) x (nozzle diameter)	2.7 m^2/s (29.4 ft^2/s)
Jet flow direction	Horizontal
Nozzle centerline distribution above floor	43 cm (17 in.)
Pump rotation	Fixed, or 180 ° oscillating at 0.05 to 0.2 rpm

Table 2-2. Heat Generation and Removal.

241-AZ-101 Heat Generation without Mixer Pumps[1]	241-AZ-101 Heat Generation with one Mixer Pump	241-AZ-101 Heat Generation with two Mixer Pumps[2]	241-A-702 Heat Removal Capacity[3]	W-030 Ventilation System Heat Removal Capacity[4]
70,806 W (241,600 Btu/h)	271,806 W (928,600 Btu/h)	472,806 W (1,613,000 Btu/h)	1,172,284 W (4,000,000 Btu/h)	486,791 W (1,661,000 Btu/h)

3.0 HAZARD AND ACCIDENT ANALYSIS

3.1 INTRODUCTION

This chapter identifies and evaluates the hazards associated with the mixer pump test in Tank 241-AZ-101. In addition, it evaluates the consequences of potential accidents that could lead to a release of radioactive and hazardous materials. Potential consequences to the offsite public and onsite individuals are considered, as are the corresponding preventive and mitigative features. This chapter is limited to the scope and impact of the Tank 241-AZ-101 mixer pump test and therefore does not address all of the hazards analyzed and presented in the Tank Waste Remediation System (TWRS) Basis for Interim Operation (BIO), HNF-SD-WM-BIO-001 (LMHC 1997).

3.2 REQUIREMENTS

The standards and U.S. Department of Energy (DOE) Orders that are required for establishing the safety basis of the mixer pump test are listed below, and are consistent with those listed in Chapter 5 of the TWRS BIO. Only portions of these documents are relevant to this safety document; namely, those requirements pertinent to safety analysis.

- DOE 5480.22, *Technical Safety Requirements* (1992)
- DOE 5480.23, *Nuclear Safety Analysis Reports*, Change 1, (1994)
- DOE 6430.1A, *General Design Criteria* (1989)[1]
- DOE Standard 1027-92, *Hazard Categorization and Accident Analysis Techniques for Compliance with DOE Order 5480.23, Nuclear Safety Analysis Reports*
- DOE Standard 3009-94, *Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports*
- DOE Standard 3011-94, *Guidance for Preparation of DOE-5480.22 (TSR) and DOE-5480.23 (SAR) Implementation Plans.*

[1]Non-safety related sections of DOE 6430.1A will be phased out/canceled upon meeting the implementation conditions of DOE O 430.1. The portions of DOE 6430.1A related to nuclear safety for non-reactor nuclear facilities are canceled by DOE O 420.1. As of this writing, the new orders have not been transmitted for compliance and therefore, compliance with DOE 6430.1A is required.

3.3 HAZARDS ANALYSIS

3.3.1 Methodology

The methodology used to perform this safety analysis is described in Section 5.2.1 of the TWRS BIO. The purpose of this safety analysis is to analyze the specific hazards related to the operation of two 300 hp mixer pumps in Tank 241-AZ-101 and also to assess the changes (i.e., assumptions and conclusions) in the current analysis due to the performance of the test.

The hazards analyzed were those identified in the Hazards and Operability (HazOp) effort presented in Appendix 3A enhanced by subsequent evaluation and comparison with hazards analyses performed for the TWRS BIO and Tanks 241-SY-101 and 241-AP-102 mixer pump additions (Section 3.3.2.4 of this addendum). Sabotage and terrorism are not included. Single and multiple failures (equipment and human errors) are considered as well as common-cause failures.

3.3.1.1 Hazard Identification. The hazard identification procedure used is consistent with that described in Section 5.2.1.1 of the TWRS BIO. Radiological hazards (excerpted from Table 5.3-4 of the TWRS BIO) are listed in Table 3-8 of this addendum, and toxicological hazards (excerpted from Table 5.3-6 of the TWRS BIO) are listed in Table 3-11 of this addendum.

3.3.1.2 Hazard Evaluation. The technique chosen for the mixer pump test hazards evaluation was the HazOp study which is the method used in the TWRS BIO. Additional analysis has been performed in conjunction with the BIO for non-operational hazards (for example, flammable gas) and the analysis is unchanged for the mixer pump test. Refer to the TWRS BIO Section 5.2.1.2.

3.3.1.3 Worker Health and Safety Requirements. This safety analysis addresses the risks to hypothetical onsite individuals at 100 m (330 ft) and to the public at the Site boundary, and provides for safety equipment and administrative controls to reduce such risks to within risk evaluation guidelines (see Tables 5.3-2 and 5.3-3 of the TWRS BIO). Included are the risks from radioactive materials, toxic gases, and toxic chemicals. The risk evaluation guidelines for the workers and the public are those defined in Tables 5.3-2 and 5.3-3 of the TWRS BIO (see Tables 3-3 and 3-4 of this addendum). The onsite receptor is assumed to be 100 m (330 ft) from the source of releases. This safety analysis does not specify any new controls necessary to protect workers who are located closer than 100 m (330 ft) to the activity. The current controls that protect workers during operations within 100 m (330 ft) are defined in the *Hanford Site Radiological Control Manual* (HSRCM-1 1995) and the *Tank Farm Health and Safety Plan* (HASP) (Hewitt 1996). The controls necessary to protect the workers against uncontrolled releases are documented in the TWRS BIO Section 5.4 and Chapter 5 of this addendum.

There is a potential for worker exposure to high concentrations of toxic gases during tank intrusive work around open tank risers or from emissions from the ventilation exhauster, including ammonia, nitrous oxide, and various organic species. Concentrations of these gases in the tank vapor space during the mixer pump operation work may be in excess of Occupational Safety and

Health Administration (OSHA)-allowed values. Because the tank vapor space will be exhausted to the ambient air above the tank, a pathway for worker exposure is recognized to exist. Assessment of the hazards from these materials and protection of the workers is provided as required by the HASP. Significant elements of this plan include monitoring of the work area for organic vapors, ammonia, and other chemical species whenever there is a potential for elevated employee exposure levels (i.e., above the established administrative action level defined by TWRS Industrial Health & Safety, which is one-half of the lower of either the Permissible Exposure Limit [PEL] or the Threshold Limit Value [TLV]). In addition, personnel monitoring is performed on those tasks which are judged to have the highest potential for exposure. The potential for elevated employee exposure is determined from a specific job hazards analysis performed on each work package prior to the work performed in the field, evaluating the potential levels of exposure from the baseline sample data available for the specific facility.

The Tank Farms are considered to be a Resource Conservation and Recovery Act (RCRA) Treatment, Storage and Disposal (TSD) facility, and all work in Tank Farms must comply with the HASP. The TWRS Industrial Hygiene staff has responsibility for implementation of the HASP, including monitoring and personnel sampling. Trained industrial hygiene technicians perform monitoring during each task. If any tank vapor levels are detected that present a possibility of employee over-exposure, the industrial hygiene technicians will take appropriate actions (as defined in the TWRS HASP), including the use of personal protective equipment or suspending the activity to ensure that no employee over-exposures occur.

It is important to note that the analysis addressing State Route 240 transient populations outlined at the beginning of TWRS BIO Section 5.3.2 is also applicable to the 241-AZ-101 mixer pump process test analysis.

3.3.2 Hazard Analysis Results

The following section presents and evaluates the results of the HazOp for the mixer pump test.

3.3.2.1 Hazard Identification. See TWRS BIO Section 5.2.2. There are no new hazards presented by the mixer pump test. See Table 3-8 of this addendum for the radionuclide hazards and Table 3-11 of this addendum for the toxicological hazards which are tables excerpted from the TWRS BIO, Tables 5.3-4 and 5.3-6 respectively.

3.3.2.2 Hazard Classification. The hazard category, as defined in DOE-STD-1027-92 for Tank 241-AZ-101, which is a Double-Shell Aging Waste Tank, has been determined to be Category 2 (Table 5.1-1 in the TWRS BIO). Since the mixer pump test does not segment the facility, change the type or form of waste being stored within the tank, and does not change its location (other than mobilizing the waste within the tank), the hazard classification remains Category 2.

3.3.2.3 Hazard Evaluation. The hazards evaluated in the TWRS BIO were re-evaluated for potential changes as a result of the mixer pump test.

Results of the HazOp (Appendix 3A of this document) were also considered during this re-evaluation and subsequent accident selection.

3.3.2.4 Accident Selection. The results of the HazOp are a number of postulated abnormal events that are ranked with respect to severity and frequency of occurrence. The Event Severity Index and Event Frequency Index are provided in Tables 3A-2 and 3A-3, respectively, of Appendix 3A of this addendum. These tables are reproduced in this section, as Tables 3-1 and 3-2.

The complete product of the HazOp study is presented as a series of tables (Appendix 3A of this addendum) showing the results of the study.

Using the HazOp evaluation techniques, a Hazard Analysis Summary table (Appendix 3B of this addendum) was constructed. Hazard Analysis Summary tables have been used to compile the results of the hazard identification and evaluation process for this test. Each column in the hazard tables is described below.

Event Number. Sequential identification for the hazard or accident evaluated.

Event Category. Event category descriptor.

Postulated Event Description. Details on how the hazard or accident can occur.

Significant Causes or Energy Sources. Hazard or accident initiators.

Receptor. Identifies the affected party (facility worker, onsite worker, public).

Credited Prevention. Engineered or administrative features that would prevent or reduce the probability of the hazard/accident from occurring.

Event Frequency. The qualitative or semi-quantitative assessment of the frequency of occurrence of the hazard/accident with and without preventive features.

Credited mitigation. Engineered or administrative features that would mitigate or reduce the consequences of the hazard/accident.

Consequences. The qualitative or semi-quantitative assessment of the consequences of the hazard/accident with and without mitigative features.

Risk Bin Number. Risk number based on the frequency, the consequences, and the receptor. This number, as used in the HazOp, was an arbitrary numbering system to gather together accidents of similar risk.

Defense-in-Depth Controls. Preventive and mitigative features not credited in the accident analyses.

HazOp study estimates were made for the likelihood of occurrence (frequency) for each accident shown in the HazOp study tables. There are

four frequency categories. Also shown are four severity categories. These categories were used along with common release mechanisms to categorize or bin accidents with common attributes (i.e., accidents that would benefit from the same control and protection strategy). Bin numbers were generated during the HazOp as an arbitrary method of gathering together accidents of similar risk potential, and are shown on the HazOp study tables.

An accident scenario was developed which bounds all common attribute accidents assigned to a bin. Only those accidents with a severity category of S3 and S2 were selected for further accident analysis (Section 5.2.1.3 "Accident Selection" in the TWRS BIO). The accidents appearing in these categories for further analysis were grouped according to release mechanisms that could result in dispersal of contaminants to an occupied area of the facility, and/or to the onsite and/or offsite receptor. Six bins were identified and therefore, six bounding (candidate) accident scenarios were developed from the HazOp.

The HazOp study detailed in Appendix 3A resulted in the identification of six postulated events which were binned from all the postulated accidents. These events and their related causes and conditions are identified in Appendix 3B. These six postulated events are: (1) a ventilation system High Efficiency Particulate Air (HEPA) filter failure, (2) backflow through open tank risers, (3) leakage via failed vent ducting, (4) a breach of the tank due to internal or external mechanisms, (5) a nuclear criticality induced by mixer pump operations, and (6) a seismic event.

The next step in the accident selection process involved an evaluation of the specific causes and conditions associated with the postulated events. Using the results of the HazOp as a starting point, and evaluating the events identified with the analyses of the BIO and other analyses performed in support of the similar mixer pump additions to Tanks 241-SY-101 and 241-AP-102 (though these pumps are smaller than the 241-AZ-101 mixer pump, many of the hazards are the same), a reconciliation was performed between the HazOp and these other analyses to arrive at an integrated set of design basis accidents (using updated information from these later analyses to update the results of the HazOp). The HazOp and Hazards Evaluation Tables are included for historical reference. This evaluation identified causes and conditions related and not related to the mixer pump test. Postulated events that involve causes and conditions not related to the mixer pump test are not analyzed. In addition, postulated events bounded by similar accidents are not analyzed. For example, leakage via failed vent ducting is not analyzed since the causes of this accident are not related to the mixer pump test and the accident is bounded by the HEPA filter failure.

This evaluation process resulted in the identification of four design basis accidents requiring further analysis: (1) unfiltered release of radionuclides and toxic aerosols from the tank, (2) tank bump, (3) breach of containment, and (4) over-pressurization caused by criticality. The unfiltered release includes an evaluation of HEPA filter failure and reverse flow through the tank.

The tank bump accident scenario is considered separately from the unfiltered release. The breach of containment accident scenario includes many

causes and conditions, with the most significant being flammable gas deflagration.

Table 3-5 of this addendum provides the four design basis accidents, causes and conditions of the accident scenarios, and mapping of the postulated events to the accident analysis in Section 3.4 of this addendum.

Table 3-1. Event Severity Index.

Safety class category designation	Description
S3	Potential significant radiological dose consequences or chemical exposure to the offsite receptor.
S2	Potential significant radiological dose consequences or chemical exposure to the onsite co-located worker.
S1	Potential industrial injury, radiological dose consequences or chemical exposure to the facility worker.
S0	No effect outside the facility confinement systems and no safety concerns for the facility worker, the onsite worker, or members of the general public.

Table 3-2. Event Frequency Index.

Frequency category designation	Numeric definition	Word definition
F3	$> 10^{-2}$/year	Anticipated
F2	$> 10^{-4}$ to $\leq 10^{-2}$/year	Unlikely
F1	$> 10^{-6}$ to $\leq 10^{-4}$/year	Extremely unlikely
F0	$\leq 10^{-6}$/year	Beyond extremely unlikely

3.4 ACCIDENT ANALYSIS

This section presents the formal development of potential accidents. Section 3.4.1 refers to the relevant sections of the TWRS BIO for the description of the consequence calculation methods common to the accidents analyzed. Section 3.4.2 presents analyses of the design basis accidents (DBA). No beyond design basis accidents (BDBA) were evaluated for the mixer pump test, for the reasons stated in Section 3.4.3.

3.4.1 Methodology

This section summarizes the radiological and toxicological consequence calculation assumptions used in the mixer pump test related accidents selected for further analysis in Section 3.3.2.4 of this addendum.

The calculation methods of the BIO as derived in Van Keuren 1996 and Van Keuren et al. 1996 have been applied to determine health effects. Where

assumptions vary from those of the TWRS BIO because of the mixer pump test, consequence calculations are summarized in Sections 3.4.2 and 3.4.3. Accident consequences are combined with the accident frequency and compared to the risk evaluation guidelines as shown in Tables 3-3 and 3-4 (excerpts of Tables 5.3-2 and 5.3-3 of the TWRS BIO).

Table 3-3. Radiological Risk Evaluation Guidelines.
(Excerpted from TWRS BIO Table 5.3-2)

Frequency category	Frequency range (yr^{-1})	mSv (rem)	
		Onsite	Offsite
Anticipated	$>10^{-2}$ to $\leq 10^{0}$	5 (0.5)	1 (0.1)
Unlikely	$>10^{-4}$ to $\leq 10^{-2}$	50 (5)	5 (0.5)
Extremely unlikely	$>10^{-6}$ to $\leq 10^{-4}$	100 (10)	40 (4)

Table 3-4. Toxicological Risk Evaluation Guidelines.
(Excerpted from TWRS BIO Table 5.3-3)

Frequency category	Frequency range (yr^{-1})	Primary concentration guidelines	
		Onsite	Offsite
Anticipated	$>10^{-2}$ to $\leq 10^{0}$	≤ ERPG-1	≤ PEL-TWA
Unlikely	$>10^{-4}$ to $\leq 10^{-2}$	≤ ERPG-2	≤ ERPG-1
Extremely unlikely	$>10^{-6}$ to $\leq 10^{-4}$	≤ ERPG-3	≤ ERPG-2

ERPG = Emergency Response Planning Guidelines
PEL = Permissible Exposure Limit
TWA = Time-Weighted Average

Table 3-5. Accident Selection and Mapping to Analysis. (2 sheets)

Accident	Cause or condition due to mixer pump operation	Map to accident analysis
1. Unfiltered release of radionuclides and toxic aerosols from the tank (Section 3.4.2.1)	HEPA filter failure due to:	
	• Aerosol generation from chemical reaction	Waste is not to be added by or during this process test. Therefore, this scenario is not relevant to this analysis.
	• Ignition of flammable gases in dome void space	See Flammable Gas discussion in Section 3.4.2.3.1. This scenario is presumed to cause an over-pressure peak that damages the ventilation equipment and is analyzed in Section 3.4.2.1.2.
	• Increased aerosol generation due to mixer pump action and heat input	Aerosol generation during the mixer pump process test is analyzed in Section 3.4.2.1.1.
	• Plugging of filters with particulates or moisture	Increased particulates and moisture generated due to mixer pump operation that would result in a HEPA filter plugging is analyzed in Section 3.4.2.1.1.
	• Tank bump	A tank bump resulting in HEPA filter blowout is analyzed in Section 3.4.2.2. The tank bump scenario is not considered representative of this class of accident and is therefore analyzed separately.
	• Tank dome collapse and breach of containment	Tank dome collapse is analyzed in Section 3.4.2.3.7.
	• Breach of vent ducting due to seismic event	The consequences of a breach of vent ducting leading to continuous unfiltered release are bounded by the HEPA filter failure (3.4.2.1.2 of this addendum), and are within guidelines for an unlikely event (seismic initiator). Therefore, this scenario is not analyzed further.
2. Tank bump (Section 3.4.2.2)	Uncontrolled waste overheating above saturation temperature:	The tank bump scenario is analyzed in Section 3.4.2.2.
	• Waste re-distribution causing poor heat transfer from the sludge to the liquid or potential ALC draft tube blockage	
	• Loss of ventilation	
	• Increased waste temperature due to mixer pump operation heat input	
	• Seismic event during pump operation	

Table 3-5. Accident Selection and Mapping to Analysis. (2 sheets)

Accident	Cause or condition due to mixer pump operation	Map to accident analysis
3. Breach of containment (Section 3.4.2.3)	Excess vacuum draw down	Tank buckling that would result in a breach of containment is not a credible scenario. The waste level in the tank prevents buckling. Waste will not be added or removed during the test. (No change from BIO analysis due to mixer pump operation.)
	Pressure from a flammable gas burn	See Flammable Gas discussion in Section 3.4.2.3.1.
	Equipment dropped into the tank during installation or removal	USQDs TF-96-0018, TF-96-0461, TF-96-0448, and TF-96-0805 address equipment installation. This analysis only deals with the mixer pump process test (Section 3.4.2.3.2) and does not address installation or removal of equipment.
	Missiles from pumps (pump impeller failure)	Internal missiles are analyzed in Section 3.4.2.3.3.
	Erosion during mixer pump operation	A breach of containment from erosion caused by mixer pump operation is analyzed in Section 3.4.2.3.4.
	Material degradation due to high temperature	The analysis of this scenario is addressed in Section 3.4.2.3.5.
	Tank dome collapse due to overloading	The analysis of this scenario is addressed in Section 3.4.2.3.6.
	Seismic event during pumping operations	A seismic event leading to failure of the mixer pump support assembly, riser extension, and/or spray wash system is analyzed in Section 3.4.2.3.7.
4. Over-pressurization caused by criticality (Section 3.4.2.4)	Mixer pump action during operation	Criticality is analyzed in Section 3.4.2.4.
	Waste settling after mixer pump shutdown	Criticality is analyzed in Section 3.4.2.4.

ALC = air lift circulator.
HEPA = high-efficiency particulate air (filter).
USQD = Unreviewed Safety Question Determination.

3.4.1.1 Radiological Consequence Calculation Methodology. The radiological consequence calculation methodology is provided in Section 5.3.1.1 of the TWRS BIO. This section provides the assumptions and data applicable to the consequence calculations for the mixer pump test. This specific information is provided in Tables 3-6 through 3-10.

The radionuclide concentration data in Table 3-8 above represents bounding activity concentrations for dose assessments and were used to derive the ULDs of Table 3-9. The data are bounding for all the AWF tanks and are, therefore, conservative for 241-AZ-101.

Tank 241-AZ-101 contains radioactive materials in the form of liquid and sludge. Table 3-9 below presents the inhalation and ingestion Unit Liter Doses (ULD)s for the liquid and solid constituents of AWF tank waste. The inhalation and ingestion ULDs were reported in Cowley 1996. They were calculated with dose conversion factors in EPA 1988 using the GENII computer program (Napier et al. 1988).

Table 3-6. Centerline Atmospheric Dispersion Coefficients.
(Excerpt from Van Keuren 1996)

Maximum individual	Bounding (99.5 percentile) integrated χ/Q' (s/m^3)	Bounding integrated χ/Q' (s/m^3) with PM*	Maximum puff χ/Q ($1/m^3$)
Onsite (sector and distance)	3.41 E-02 (E 100 m)	1.13 E-02 (ESE 100 m)	9.85 E-03 (E 100 m)
Offsite (sector and distance)	2.83 E-05 (N 8,760 m)	2.12 E-05 (N 8,760 m)	1.14 E-07 (NNW 8,690 m)

*NRC Regulatory Guide 1.145 (NRC 1982) plume meander correction applied.

Table 3-7. Chronic Annual Average Atmospheric Dispersion Coefficients for 200 Area Tank Farms.
(excerpt from Van Keuren 1996)

Maximum individual	Integrated χ/Q' (s/m^3)
Onsite (sector and distance)	4.03 E-04 (ESE 100 m)
Offsite (sector and distance)	1.24 E-07 (E 12,630 m)

Table 3-8. In-Tank Concentration of the 11 Radionuclides Chosen for Inclusion in Accident Analysis.
(excerpt from Table 5.3-4 of the TWRS BIO)

Nuclide	Activity concentration (Bq/L)	
	AWF liquids	AWF solids
^{60}Co	7.7 E+05	4.9 E+08
^{90}Sr	5.6 E+09	2.9 E+12
^{90}Y	5.6 E+09	2.9 E+12
^{137}Cs	8.8 E+10	9.8 E+10
^{154}Eu	a	1.1 E+10
^{237}Np	9.2 E+04	9.9 E+08
^{238}Pu	2.8 E+03	6.7 E+07
^{239}Pu[b]	1.2 E+06	4.4 E+08
^{241}Pu	3.4 E+05	1.7 E+09
^{241}Am	1.1 E+06	1.1 E+10
^{244}Cm	1.1 E+04	6.1 E+07

a) No valid sample result exists. Analysis indicates this isotope, in the liquids, is a negligible contributor to dose.
b) The ^{239}Pu activity concentration also includes ^{240}Pu.

AWF = Aging Waste Facility

Table 3-9. Unit Liter Doses for Inhalation and Ingestion.
(Excerpt from Table 5.3-5 of the TWRS BIO)

Composite	Inhalation ULD (Sv/L)	Ingestion ULD* (Sv-m3/s-L)
AWF liquids	1.4 E+03	0.092
AWF solids	1.7 E+06	8.1

*Includes 24 hour ingestion of fruits and vegetables, ground shine, inadvertent soil ingestion, and inhalation of material re-suspended from the ground.

Table 3-10. Release Durations for which the Maximum Puff χ/Q can be Applied.

Release	Duration
Onsite receptor, ground-level release	≤3.5s
Offsite receptor, ground-level release	≤250s

NOTE: The information in this table is from Van Keuren et al. 1996.

3.4.1.2 Toxicological Consequence Calculation Methodology. The toxicological consequence calculation methodology is provided in Section 5.3.1.2 of the TWRS BIO and defined as the toxicological sum-of-fractions (SOF) methodology. This methodology is based on the methodology provided in Van Keuren et al. 1996. This section provides the assumptions and data applicable to the consequence calculations for the mixer pump test. This specific information is provided in Tables 3-11 and 3-12.

Since the toxicological SOF methodology does not directly correlate to single, chemical-specific emergency response planning guideline (ERPG) values, the toxicological SOF values calculated for a specific accident do not provide

enough information for emergency response purposes. Depending upon the type, form, and location of waste released, the 24 analytes used in the toxicological SOF methodology may be reduced to a smaller set of peak contributors to be initially considered for emergency response purposes. For example, in double-shell tank liquids, there are five peak analytes (Na, NaOH, NH3, TOC, and U). For double shell tank solids, there are twelve peak analytes (Na, Cd, NaOH, Co, Oxalate, Cr, As, Tl, U, Be, TOC, and Se). Determination of emergency response actions relies upon the location of the release, the potential release quantity, consideration of the primary (peak) analytes, and the location of any potentially affected individuals (onsite or offsite).

Table 3-11. Tank Waste Liquids and Solids Analyte Concentrations

Analyte	Composite concentration (g/L)	
	DST solids[c]	DST liquids[c]
Ammonia (NH_3)	6.6 E+00	7.1 E+00
Antimony (Sb)	9.2 E-01	6.4 E-03
Arsenic (As)	5.7 E+00	1.1 E-02
Barium (Ba)	5.9 E+00	3.3 E-02
Beryllium (Be)	2.4 E-01	3.8 E-03
Cadmium (Cd)	2.6 E+01	7.0 E-02
Calcium (Ca)	2.6 E+01	1.3 E+00
Cerium (Ce)	2.6 E+00	5.8 E-02
Chromium (Cr^{+3})	1.5 E+02	a
Cobalt (Co)	4.4 E+00	8.8 E-03
Cyanide (CN)	4.7 E-01	9.1 E-02
Dysprosium (Dy)	a	a
Lanthanum (La)	3.0 E+01	1.0 E+00
Mercury (Hg)	1.2 E-01	2.4 E-04
Neodymium (Nd)	7.0 E+00	5.6 E-03
Oxalate (C_2O_4)	2.8 E+02	a
Selenium (Se)	1.9 E+00	2.8 E-01
Sodium hydroxide (NaOH)	2.3 E+02	2.1 E+02
Sodium (Na) - NaOH[b]	3.5 E+02	2.1 E+02
Tellurium (Te)	9.3 E-01	2.7 E-03
Thallium (Tl)	1.5 E+01	3.7 E-02
Total organic carbon (TOC)-oxalate[b]	7.5 E+01	4.0 E+01
Uranium (U)	4.4 E+01	1.1 E+01
Vanadium (V)	1.2 E-01	2.1 E-03

NOTE: The information in this table is from Table 5.3-6 from the TWRS BIO.
a) The best available data indicates there is not a significant concentration of this analyte in the composite.
b) To avoid counting the same analyte twice, the oxalate concentration was subtracted from the TOC concentration and NaOH was subtracted from the Na concentration.
c) The Aging Waste Facility tanks, including 241-AZ-101, are grouped with the other double-shell tanks for toxicological analysis.

DST = double-shell tank.

Table 3-12. Sum-of-Fractions for Risk Evaluation Guidelines for a Unit Release of Waste Chemicals. (excerpt from Table 5.3-8 of the TWRS BIO)

Tank waste type	Maximum individual	Sum-of-fractions (s/L) as a function of accident frequency (1/yr)		
		$1 - 10^{-2}$	$10^{-2} - 10^{-4}$	$10^{-4} - 10^{-6}$
DST solid or liquid continuous release				
DST liquids	Onsite	1.0 E+04	7.5 E+02	2.1 E+02
	Offsite	8.4 E+00	8.4 E+00	6.2 E-01
DST solids	Onsite	1.8 E+04	3.3 E+03	6.3 E+02
	Offsite	1.9 E+02	1.5 E+01	2.8 E+00
DST solid or liquid puff release				
DST liquids	Onsite	2.9 E+03	2.2 E+02	6.0 E+01
	Offsite	3.4 E-02	3.4 E-02	2.5 E-03
DST solids	Onsite	5.2 E+03	9.7 E+02	1.8 E+02
	Offsite	7.7 E-01	5.9 E-02	1.1 E-02

Note: The Aging Waste Facility tanks are grouped with the other double-shell tanks for the toxicological analysis.

3.4.2 Design Basis Accidents

3.4.2.1 Unfiltered Release of Radionuclides and Toxic Aerosols From the Tank.

3.4.2.1.1 HEPA Filter Plugging Due to Mixer Pump Aerosols Generation. The consequences resulting from HEPA filter plugging and subsequent damage caused by moisture overload are reduced by TWRS TSR AC 5.18. This requirement includes limiting the radioactive material inventories on HEPA filters and to ensure the capability of the HEPA filters to mitigate the consequences of specific accident scenarios. Surveillances are also performed by checking the pressure drop across the filters. Therefore, any trending toward HEPA filter plugging due to mixer pump and/or ALC operation will be detected, and corrective action taken. The following paragraphs discuss the process by which this conclusion was reached.

Wong and Waters 1994 attempted to evaluate the ability of a ventilation system to provide adequate de-entrainment of liquid and solid aerosols during mixer pump operations, and to determine if the radioactive aerosols will overload the HEPA filters.

Wong and Waters 1994 concluded that insufficient data exist to confidently estimate the magnitude of aerosol generation during tank waste mixer pump operations. However, it was noted by Wong and Waters 1994 that, qualitatively, aerosol generation would not be expected to be a severe problem during full-scale operations due to (1) the existing cooling system being able to handle the additional heat generated from mixer pump operations so that significant vapor rates are not expected to carry aerosols beyond the condensers (20,000,000 Btu/h cooling capacity), (2) aerosol testing conducted during mixer pump testing in Tank 241-AP-102 did not indicate a significant increase in aerosols (also, surface agitation as viewed by a camera indicated less disturbance than that produced by air lift circulators), and

(3) development tests indicate that Project W-030 will also adequately control the aerosol generation (BIO Addendum 3).

In addition, as stated in a letter report by Ligotke et al. 1994, analysis shows the operation of the two mixer pumps may increase the generation of aerosols slightly over normal storage operations without air lift circulators (ALCs) operating but that the aerosol generation would be less than that expected for normal storage operation with ALCs operating. Temperature variations are considered to be small contributors to aerosol generation, as compared to physical agitation, so that these analyses adequately bound worst-case expected temperature conditions in the tank.

The values used in this document to calculate the amount of aerosolized liquid in the vapor space bound operations with the mixer pumps alone, the ALCs alone, and the mixer pumps and ALCs together. The release fraction information is found in Section 3.4.2.1.2.3B of this addendum. Since the consequences do not approach the risk evaluation guidelines, confirmation testing is not required at this time.

Two off-normal situations are considered. The first is the failure of the ventilation system heater (in either the 241-A-702 or W-030 systems). This failure would result in condensation build-up in the ventilation ducting. The second failure scenario considered is the situation where mixer pump and/or ALC aerosol generation rates exceed the upstream equipment's (de-entrainers in the 241-A-702 system, or the high-efficiency mist eliminator [HEME] and high-efficiency gas absorber [HEGA] in the W-030 system) capabilities to prevent wetting of HEPA filters (by allowing increased liquid carryover). This could then create an excessive differential pressure across the HEPA filters and subsequent failure of the filters, resulting in a release of radioactive particulates. This release is mitigated through the implementation of BIO AC 5.18, addressing radioactive material maximum loading on HEPA filters (Section 3.4.2.1.2).

3.4.2.1.2 HEPA Filter Failure Due to Over-pressure.

3.4.2.1.2.1 HEPA Filter Failure Due to Over-pressure Accident Scenario. The HEPA Filter Failure due to over-pressure accident is an AWF Design Basis Accident documented in Section 5.3.2.2 of the TWRS BIO and supported by Ryan 1996, which was used in the BIO analysis. However, this accident scenario requires additional evaluation due to the assumption that mixer pump operation could result in the release of solids entrained in the liquid during a continuous unfiltered release. Thus, the potential release of solid (as well as liquid) waste requires a re-assessment of the consequences calculated in the TWRS BIO.

This section evaluates the consequences of an unprevented HEPA filter failure due to over-pressure accident scenario using the same initial assumptions as were used in the TWRS BIO analysis (i.e., using the maximum radionuclide loading on HEPA filters equating to a dose rate of 200 mrem/h). Therefore, all consequences given in this BIO Addendum for this scenario are considered to contain some degree of mitigation. Filter failure due to over-pressure is postulated to require a mechanism such as hydrogen deflagration, which is an anticipated event without controls (Section 5.3.2.14 of the TWRS

BIO). The estimated frequency for this accident scenario (deflagration in Tank 241-AZ-101 during the mixer pump test with a complete filter failure due to over-pressure), was determined to be extremely unlikely. This frequency determination is based on the configuration of the ventilation systems and the duration of the mixer pump test as well as the assertion that the potential for a waste disturbance to generate a gas release event of sufficient magnitude to be beyond the capabilities of the tank ventilation system is very small (based on available characterization data for Tank 241-AZ-101, refer to Section 3.4.3.2.1, "Gas Release Event," of this addendum). For the Project W-030 ventilation system (see BIO Addendum 3 for additional details), there are four filtration elements in series (a HEME, two HEPA filters, and a HEGA), remotely located from each of the AWF tanks that would have to fail to varying degrees for this accident scenario. The varying degrees of failure for these pieces of equipment relate to the physical mechanisms involved for each component during a pressure pulse. For the HEME and the HEGA, which are not designed specifically for particulate filtration, the pressure pulse results in a temporary decrease in decontamination efficiency and carryover of additional liquids through the equipment. For the analysis regarding the HEPA filters, however, the pressure pulse results in a permanent rupture of the filtration media. For the 702-A ventilation system, the pressure pulse from a deflagration accident would be dampened by approximately one-quarter mile of 20-inch diameter ventilation ducting and two de-entrainers (similar "failure" mechanism as discussed above for a HEGA and/or a HEME) (Section 2.4.3.7.1 of Appendix B of the TWRS BIO for additional details). The accident frequency is further reduced when considering that the mixer pump test has an anticipated duration of 1,300 hours, or 0.15 year. Based on the above considerations, the likelihood of a deflagration event occurring during the approximate 1,300 hour time period of the mixer pump test with a sufficiently powerful pressure pulse to fail the HEPA filters is considered to be extremely unlikely (frequency of 10^{-4} to 10^{-6} per year). These findings are also applicable to the currently anticipated W-030 ventilation system (four elements in series that would have to fail to varying degrees).

In this scenario, the failure due to over-pressure of a single bank of ventilation system filters is assumed to be followed by the active ventilation of the tank headspace. This would be a puff release (i.e., the loss of the HEPA filters) followed by a continuous release of unfiltered airflow as the system continues to operate for 24 hours. A 24 hour release is equivalent to two shift changes. It is assumed that the filter failure due to over-pressure goes without intervention (is undetected) during this time.

The accident involving failure due to over-pressure of the inlet HEPA filters (only existing on the W-030 ventilation system) was considered during the HazOp study. It is true that this accident has a higher frequency than the accident involving the downstream filters, but the consequences are significantly lower. The consequences of the HEPA filter failure due to over-pressure evaluated in this BIO Addendum derive from two separate source terms: (1) radioactivity previously entrained on the HEPA filters and released during the accident, and (2) radioactivity released from continued 24 hours operation of the ventilation system with no filtration. The consequences are dominated by the 24-hour release scenario. It is unlikely that the inlet HEPA filter would be as heavily loaded as the downstream HEPA filters, but even if it were, the consequences of an inlet filter failure due to over-pressure would

be about three orders of magnitude less than a complete failure of the downstream filtration system. The ventilation system would continue to operate, provide negative pressure on the tank, and exhaust tank headspace vapors through the downstream HEPA filters.

The first step of the analysis is to evaluate the HEPA filter loading of particulates. To determine the consequences of releasing the accumulated particulates in a puff release, it is assumed that only liquid waste constituents accumulate on the filters during normal service (i.e., waste which re-condenses downstream of the de-entrainers or the HEME/HEGA (241-A-702 or W-030 ventilation systems, respectively). The next step is to evaluate the continuous flow contribution, conservatively assuming mixed waste aerosols (term "mixed waste" used in this document to denote a composite of liquids and solids as opposed to the regulatory usage of radioactive and hazardous wastes) are released due to mixer pump re-suspension. The final step is to determine the radiological and toxicological consequences of this accident scenario.

3.4.2.1.2.2 HEPA Filter Failure Due to Over-pressure Accident Source Term.

A. Source Term from the Filter

The consequences of a HEPA filter failure due to over-pressure are dependent upon the initial filter loading and the loading in the ventilation ductwork and other components. For the ventilation system upgrade provided by Project W-030, the amount of material released would be that from a single bank of filters (two HEPA filters in series in one of two independent, parallel ventilation trains, with only one filter bank will be used at a time), and three additional volume equivalents to account for the loading in the HEME, HEGA, and the ventilation duct work. Therefore, the number of HEPA filter volumes released for Project W-030 would be 4. For the 241-A-702 ventilation system, Van Vleet 1996a assumes the number of HEPA filter volumes is 30, considering 6 banks of 5 HEPA filter volume equivalents (2 HEPAs, 2 de-entrainers, and one volume equivalent for ductwork), which is more limiting. This is conservative since 5 of the banks contain only 2 HEPAs and no de-entrainers.

From the same calculation note, the maximum total amount of material potentially released is found to be 5.62 E-3 L. This result is based on considering ^{137}Cs as the predominant gamma emitter for the AWF source material for the liquids (the other gamma emitters have much smaller concentrations). However, because of the agitation of the tank solids into the supernatant, this analysis must take into account gamma contributors from the solids within the tank as well as the contributors from the liquids. Therefore, the ULD (radiological) and SOF (toxicological) values used in this analysis will be a weighted average of the values given in the BIO for AWF liquids and solids (4% solids and 96% liquid as derived from the TWRS BIO, Appendix B, Table - 2-3), adjusted to account for only one of the four Aging Waste Tanks being affected by the agitation (i.e., solids aerosols emanating from only one of the four tanks). In addition, a maximum loading on the filter is assumed to be no greater than the activity that would result in 200 mrem/h on contact for each filter or component, based on maximum allowable loading before filter change-out (TWRS TSR AC 5.18). The amount of material on the filter will be

taken from the Van Vleet 1996a calculation note, as this bounds the amount of material which could be on the filter (i.e., addition of solids in the aerosol would result in a lesser volume of deposited material achieving the 200 mrem/h contact reading).

B. Source Term Released from Unfiltered Operation of the Ventilation System

For the ventilation system upgrade provided by Project W-030, the design airflow through the ventilation system is 4.7×10^{-1} m^3/s (1,000 cubic feet per minute [CFM]). Also for Project W-030, the rate used for the unfiltered continuous release of the ventilation system assumes the simultaneous operation of both fans or 9.4×10^{-1} m^3/s (2,000 CFM) to bound the scenario. For the 241-A-702 ventilation system, the design airflow through the system is 1.89 m^3/s (4,000 CFM), which is more limiting.

With the mixer pumps running in Tank 241-AZ-101 during unfiltered operation of the ventilation system, it is assumed that the supernatant and sludge is homogeneously mixed. This requires modification of the ULDs listed in Table 3-9 of this addendum to reflect the presence of sludge particles in aerosols released to the tank headspace. The ULDs for the liquid/sludge mixture are calculated using the liquid and solid ULDs given in Table 3-9 of this addendum and the volume fractions of liquid and sludge in Tank 241-AZ-101,

$$ULD_{mix} = (f_1 \times ULD_{liq}) + (f_2 \times ULD_{sol})$$

where:

f_1 = 0.96, volume fraction of liquid in Tank 241-AZ-101 (data from TWRS BIO, Appendix B, Table 2-3)

f_2 = 0.04, volume fraction of solids in Tank 241-AZ-101 (data from TWRS BIO, Appendix B, Table 2-3)

ULD_{liq} = unit liter dose for AWF liquids (Table 3-9 of this addendum)

ULD_{sol} = unit liter dose for AWF solids (Table 3-9 of this addendum)

Using the above formula, the Inhalation and Ingestion ULDs for Tank 241-AZ-101 mixed liquids and solids are calculated to be:

Inhalation ULD_{mix} (Sv/L) = 6.9×10^4

Ingestion ULD_{mix} (Sv-m^3/s-L) = 0.4

The source term released from unfiltered operation of the ventilation system is drawn from all four AWF tanks, but the mixer pumps operate only in one tank. Therefore, the ULDs for the unfiltered release must be adjusted to represent the aerosols from one mixed tank and three unmixed tanks,

$$ULD'_{mix} = (0.25 \times ULD_{mix}) + (0.75 \times ULD_{liq})$$

The Inhalation and Ingestion ULDs for the aerosols released from unfiltered operation of the ventilation system are calculated to be:

Inhalation ULD'_{mix} (Sv/L) = 1.8×10^4

Ingestion ULD'_{mix} (Sv-m^3/s-L) = 0.17

3.4.2.1.2.3 HEPA Filter Failure Due to Over-pressure Accident Offsite Radiological Consequence Analysis.

A. Offsite Radiological Consequence for a Puff Release from Filter Failure Due to Over-Pressure

The TEDE for inhalation for offsite consequences for the loss of a HEPA filter can be found using the following equation:

$$D_{inh\text{-}filter}(Sv) = Q(L) \times \frac{\chi}{Q'}\left[\frac{s}{m^3}\right] \times R\left[\frac{m^3}{s}\right] \times ULD_{inh}\left[\frac{Sv}{L}\right]$$

where:

$D_{inh\text{-}filter}$ = dose due to inhalation

Q = respirable source term

χ/Q' = atmospheric dispersion coefficient

R = breathing rate

ULD_{inh} = inhalation unit liter dose

The type of material accumulating on the AWF filters is from the AWF liquids and solids being deposited on the filter from normal ventilation air flow. The total effective dose equivalent (TEDE) for offsite consequence is found to be:

$D_{inh\text{-}filter}$ = $(5.62 \times 10^{-3}$ L) x $(2.83 \times 10^{-5}$ s/m^3) x $(3.3 \times 10^{-4}$ m^3/s) x $(1.8 \times 10^4$ Sv/L)

$D_{inh\text{-}filter}$ = 9.5×10^{-7} Sv (9.5×10^{-5} rem)

where:

Q = $V_{released}$ (Section 3.4.2.1.2.2 of this addendum) = 5.62×10^{-3} L

χ/Q' (Table 3-6 of this addendum, bounding offsite) = 2.83×10^{-5} s/m^3

R = acute breathing rate (Van Keuren 1996) = 3.3×10^{-4} m^3/s

$ULD'_{liquid\text{-}inh}$ (Section 3.4.2.1.2.2 of this addendum) = 1.8×10^{4} Sv/L

These inputs are consistent with those used in Ryan 1996 as input for the TWRS BIO consequence analysis.

The TEDE for ingestion for offsite consequences for the loss of a HEPA filter can be found using the following equation:

$$D_{ing}(Sv) = Q(L) \times \frac{\chi}{Q'} \left[\frac{s}{m^3}\right] \times ULD_{ing} \left[\frac{Sv\,m^3}{s\text{-}L}\right]$$

where:

D_{ing} = dose due to ingestion

Q = respirable source term

χ/Q' = atmospheric dispersion coefficient

ULD_{ing} = ingestion unit liter dose

The TEDE for offsite consequence is found to be:

$D_{ing\ filter}$ = $(5.62 \times 10^{-3}$ L) x $(2.83 \times 10^{-5}$ s/m^3) x (0.17 Sv-m^3/s-L)

$D_{ing\ filter}$ = 2.7×10^{-8} Sv (2.7×10^{-6} rem)

where:

$ULD'_{liquid\text{-}ing}$ (Section 3.4.2.1.2.2 of this addendum) = 0.17 Sv-m^3/s-L

B. Offsite Radiological Consequence for 24 Hour Continuous Venting After Filter Failure due to Over-pressure

The duration of 24 hours was selected to represent the continued venting of the system since this represents two shift changes. Radioactive material is carried from the tank waste material into the tank vapor space atmosphere through several physical processes. Only a fraction of the liquid waste constituents, the partition fraction (PF), in a tank will migrate into the vapor space atmosphere. The PF for AWF tanks is found to be 1×10^{-8} under the worst case liquid waste agitation conditions (Ryan 1996, Appendix A), as used in the TWRS BIO consequence analysis. The value bounds severe waste surface agitation, such as ALC operation and tank boiling.

The amount of mixed waste released by operating the ventilation system can be found by:

$V_{release\ rate} = V_{rate} \times PF$

$V_{release\ rate} = (1.89 \times 10^{3}\ L/s) \times (1 \times 10^{-8})$

$V_{release\ rate} = 1.89 \times 10^{-5}\ L/s$

where:

$V_{rate} = 1.89 \times 10^{3}\ L/s$ (4,000 CFM)

PF (Ryan 1996) = 1×10^{-8}

The dispersion coefficients (χ/Q') to be used for the 12-hour and 24-hour releases are calculated from the methodology presented in Van Keuren 1996.

χ/Q', Offsite (24-hour)

To determine the χ/Q' for the 24-hour release, the logarithmic interpolation procedure described in Van Keuren 1996 is used to correctly identify the proper χ/Q' to be used. The χ/Q' used for the 2-hour release is 2.12×10^{-5} s/m^3 to account for plume meander (Table 3-6 of this addendum). Using the equation from Van Keuren 1996 yields:

$$\frac{\log(2.12 \times 10^{-5}) - \log(\chi/Q'\ 24\text{-hour})}{\log(2.12 \times 10^{-5}) - \log(1.24 \times 10^{-7})} = \frac{\log(2\text{-hour}) - \log(24\text{-hour})}{\log(2\text{-hour}) - \log(8{,}760\text{-hour})}$$

The offsite χ/Q' (24-hour) is 4.62×10^{-6} s/m^3.

The TEDE for inhalation for offsite consequences for the continued operation for 24 hours after the loss of a HEPA filter can be found using the same equation as was used for inhalation consequences in Section 3.4.2.1.2.3.A of this addendum.

TEDE for offsite consequence for 24 hour exposure is found to be:

$D_{inh\ vent} = (1.89 \times 10^{-5}\ L/s) \times (4.62 \times 10^{-6}\ s/m^3) \times (2.7 \times 10^{-4}\ m^3/s) \times (1.8 \times 10^{4}\ Sv/L) \times (24\ h) \times (60\ min/h) \times (60\ s/min)$

$D_{inh\ vent} = 3.7 \times 10^{-5}$ Sv (3.7×10^{-3} rem)

where:

$Q = V_{release\ rate} = 1.89 \times 10^{-5}$ L/s

χ/Q' (offsite 24-hour) = 4.62×10^{-6} s/m^3

R = chronic breathing rate (Van Keuren 1996) = 2.7×10^{-4} m^3/s

$ULD'_{mix\text{-}inh}$ (Section 3.4.2.1.2 of this addendum) = 1.8×10^{4} Sv/L.

The TEDE for ingestion for offsite consequences for the continued operation for 24 hours after the loss of a HEPA filter can be found using the same equation as was used for ingestion consequences in Section 3.4.2.1.2.3.A of this addendum.

The TEDE for offsite consequence is found to be:

$$D_{ing\ vent} = (1.89 \times 10^{-5}\ L/s) \times (4.62 \times 10^{-6}\ s/m^3) \times (0.17\ Sv\text{-}m^3/s\text{-}L) \times (24\ h) \times (3{,}600\ s/h)$$

$$D_{ing\ vent} = 1.3 \times 10^{-6}\ Sv\ (1.3 \times 10^{-4}\ rem)$$

where:

$ULD'_{mix\text{-}ing}$ (Section 3.4.2.1.2 of this addendum) = 0.17 Sv-m^3/s-L

C. Total Offsite Radiological Consequence

Total offsite consequences ($D_{offsite}$) for HEPA filter failure due to over-pressure is the sum of the filter offsite consequences and the unfiltered operation of the ventilation system offsite consequences. The total offsite consequence is found to be:

$$D_{offsite} = D_{inh\text{-}filter} + D_{ing\ filter} + D_{inh\ vent} + D_{ing\ vent}$$

$$D_{offsite} = 9.5 \times 10^{-7}\ Sv + 2.7 \times 10^{-8}\ Sv + 3.7 \times 10^{-5}\ Sv + 1.3 \times 10^{-6}\ Sv$$

$$D_{offsite} = 3.9 \times 10^{-5}\ Sv\ (3.9 \times 10^{-3}\ rem)$$

3.4.2.1.2.4 HEPA Filter Failure Due to Over-pressure Onsite Radiological Consequence.

A. Onsite Radiological Consequence For a Puff Release from Filter Failure Due to Over-Pressure

The TEDE for onsite consequences for the HEPA filter is found using the same methodology and equation (Section 3.4.2.1.2.3.A of this addendum) as for the offsite. The TEDE for onsite consequence is found to be:

$$D_{inh\text{-}filter} = (5.62 \times 10^{-3}\ L) \times (3.41 \times 10^{-2}\ s/m^3) \times (3.3 \times 10^{-4}\ m^3/s) \times (1.8 \times 10^{4}\ Sv/L)$$

$$D_{inh\text{-}filter} = 1.1 \times 10^{-3}\ Sv\ (1.1 \times 10^{-1}\ rem)$$

where:

Q = $V_{released}$=5.62 x 10^{-3} L

χ/Q' (Table 3-6 of this addendum, bounding onsite) = 3.41 x 10^{-2} s/m^3

R = acute breathing rate (Van Keuren 1996) = 3.3 x 10^{-4} m^3/s

$ULD'_{liquid\text{-}inh}$ (Section 3.4.2.1.2.2 of this addendum) = 1.8 x 10^{4} Sv/L

B. Onsite Radiological Consequence for 24 Hour Continuous Release After Filter Failure Due to Over-pressure

Since shifts are limited to 12 hours, this is assumed to be the maximum exposure to the onsite receptor.

χ/Q', Onsite (12-hour)

To determine the χ/Q' for the 12-hour release, the logarithmic interpolation procedure described in Van Keuren 1996 is used to correctly identify the proper χ/Q' to be used. The χ/Q' used for the 2-hour release is 1.13×10^{-2} s/m^3 to account for plume meander (Table 3-6 of this addendum). Using the equation from Van Keuren 1996 yields:

$$\frac{\log(1.13 \times 10^{-2}) - \log(\chi/Q' \text{ 12-hour})}{\log(1.13 \times 10^{-2}) - \log(4.03 \times 10^{-4})} = \frac{\log(\text{2-hour}) - \log(\text{12-hour})}{\log(\text{2-hour}) - \log(\text{8,760-hour})}$$

The onsite χ/Q' (12-hour) is 5.54×10^{-3} s/m^3.

Using the same equations as in Section 3.4.2.1.2.3 of this addendum, the TEDE for onsite consequences from the continuous release is found to be:

$$D_{inh\ vent} = (1.89 \times 10^{-5}\ L/s) \times (5.54 \times 10^{-3}\ s/m^3) \times (3.3 \times 10^{-4}\ m^3/s) \times (1.8 \times 10^{4}\ Sv/L) \times (12\ h) \times (3{,}600\ s/h)$$

$$D_{inh\ vent} = 2.7 \times 10^{-2}\ Sv\ (2.7\ rem)$$

where:

$Q = V_{release\ rate} = 1.89 \times 10^{-5}$ L/s

χ/Q' (onsite 12-hour) $= 5.54 \times 10^{-3}$ s/m^3

R = acute breathing rate (Van Keuren 1996) $= 3.3 \times 10^{-4}$ m^3/s

$ULD'_{mix\text{-}inh}$ (Section 3.4.2.1.2 of this addendum) $= 1.8 \times 10^{4}$ Sv/L

C. Total Onsite Radiological Consequence

Total onsite consequences (D_{onsite}) for HEPA filter failure due to over-pressure is the sum of the puff and the continuous releases. This is found to be:

$$D_{onsite} = D_{inh\text{-}filter} + D_{inh\ vent}$$

$$D_{onsite} = 1.1 \times 10^{-3}\ Sv + 2.7 \times 10^{-2}\ Sv$$

$$D_{onsite} = 2.8 \times 10^{-2}\ Sv\ (2.8\ rem)$$

3.4.2.1.2.5 HEPA Filter Failure Due to Over-pressure Toxicological Consequences. The toxicological consequences for the HEPA filter failure due to over-pressure can be found using the method outlined in Section 5.3.1.2 of the TWRS BIO and the assumptions listed in Section 3.4.1.2 of this addendum. The unmitigated, unprevented HEPA filter failure due to over-pressure accident frequency was determined to be extremely unlikely. The amount of material released from the filter was determined to be 5.62×10^{-3} L and is a puff type release. The release rate for operation of the ventilation system without filters is 1.89 m^3/s (4,000 CFM) and is a continuous type release.

A. HEPA Filter Failure Due to Over-pressure Toxicological Consequences Due to a Puff Release

As with the radiological source term, the type of material accumulating on Tank 241-AZ-101 filters is from liquids and solids being deposited on the filters from normal air flow (Sections 3.4.2.1.2.3 and 3.4.2.1.1 of this addendum). To obtain the SOF for the release of the liquids and solids on the filter media, the SOF for the AWF liquids and solids for the puff release for the extremely unlikely event (Table 3-12 of this addendum) must be adjusted (as in Section 3.4.2.1.2.2 of this addendum) to account for the percentage of solids in the aerosol stream as well as the fact that only one of the four tanks in the Aging Waste Facility will be emitting the increased solids levels as a result of the mixer pump test. This adjusted SOF can be obtained from:

$$SOF_{mix\ puff\ off} = (f_1 \times SOF_{liq\ puff\ off}) + (f_2 \times SOF_{sol\ puff\ off})$$

Using the above equation, the SOF for the liquid/solid mix is calculated to be:

$$SOF_{mix\ puff\ off} = 2.8 \times 10^{-3}\ L^{-1}$$

As in Section 3.4.2.1.2.2 of this addendum, this SOF must be adjusted to account for the fact that ventilation is drawn from all four AWF tanks, but the mixer pumps operate in only one tank. Therefore, the SOF must be adjusted to represent the aerosols from the one mixed tank and three unmixed tanks,

$$SOF'_{mix\ puff\ off} = (0.25 \times SOF_{mix\ puff\ off}) + (0.75 \times SOF_{liq\ puff\ off})$$

Using the above equation, the SOF for the liquids and solids resulting from the mixer pump test is calculated to be:

$$SOF'_{mix\ puff\ off} = 2.6 \times 10^{-3}\ L^{-1}$$

The consequences for the offsite receptor from a filter failure due to over-pressure unmitigated puff release is:

$T_{puff\ off} = V_{released} \times SOF'_{mix\ puff\ off}$

$T_{puff\ off} = (5.62 \times 10^{-3}\ L) \times (2.6 \times 10^{-3}\ L^{-1})$

$T_{puff\ off} = 1.5 \times 10^{-5}$

where:

$V_{release} = 5.62 \times 10^{-3}$ L (Section 3.4.2.1.2 of this addendum)

For the onsite receptor, the SOF for an extremely unlikely event are also calculated in the same fashion as for the offsite receptor.

The consequence for the onsite receptor from a filter failure due to over-pressure unmitigated puff release is:

$T_{puff\ on} = V_{released} \times SOF'_{mix\ puff\ on}$

$T_{puff\ on} = (5.62 \times 10^{-3}\ L) \times (6.1 \times 10^{1}\ L^{-1})$

$T_{puff\ on} = 3.4 \times 10^{-1}$

B. HEPA Filter Failure Due to Over-pressure Toxicological Consequences Due to a Continuous Release Following the Filter Failure

For the continuous release, the SOF for an extremely unlikely event are calculated considering a liquid/sludge mixture source term.

$SOF_{mix\ cont\ off} = (f_1 \times SOF_{liq\ cont\ off}) + (f_2 \times SOF_{sol\ cont\ off})$

where:

f_1 = 0.96, volume fraction of liquid in Tank 241-AZ-101 (data from TWRS BIO, Appendix B, Table 2-3)

f_2 = 0.04, volume fraction of solids in Tank 241-AZ-101 (data from TWRS BIO, Appendix B, Table 2-3)

$SOF_{liq\ cont\ off}$ = for DST liquids (Table 3-12 of this addendum) = 6.2×10^{-1} s/L

$SOF_{sol\ cont\ off}$ = for DST solids (Table 3-12 of this addendum) = 2.8×10^{0} s/L

Using the above formula, the SOF for Tank 241-AZ-101 mixed liquids and solids is calculated to be:

$SOF_{mix\ cont\ off} = 7.1 \times 10^{-1}$ s/L

The toxic chemical release from unfiltered operation of the ventilation system is drawn from all four AWF tanks, but the mixer pumps operate only in one tank. Therefore, the SOF for the unfiltered release must be adjusted to represent the aerosols from one mixed tank and three unmixed tanks.

$$SOF'_{mix\ cont\ off} = (0.25 \times SOF_{mix\ cont\ off}) + (0.75 \times SOF_{liq\ cont\ off})$$

$$SOF_{mix\ cont\ off} = 7.1 \times 10^{-1} s/L$$

$$SOF_{liq\ cont\ off} = \text{for DST liquids (Table 3-12 of this addendum)}$$
$$= 6.2 \times 10^{-1} s/L$$

The SOF for the aerosols released from unfiltered operation of the ventilation system is calculated to be:

$$SOF'_{mix\ cont\ off} = 6.4 \times 10^{-1} s/L$$

The consequence for the offsite receptor from the loss of an AWF filter is:

$$T_{cont\ off} = V_{released} \times SOF'_{mix\ cont\ off}$$

$$T_{cont\ off} = (1.89 \times 10^{-5}\ L/s) \times (6.4 \times 10^{-1} s/L)$$

$$T_{cont\ off} = 1.2 \times 10^{-5}$$

For the onsite receptor, the SOF for an extremely unlikely event is also calculated in the same fashion as for the offsite receptor for the liquid/sludge mixture.

$$SOF_{mix\ cont\ on} = (f_1 \times SOF_{liq\ cont\ on}) + (f_2 \times SOF_{sol\ cont\ on})$$

where:

f_1 = 0.96, volume fraction of liquid in Tank 241-AZ-101 (data from TWRS BIO, Appendix B, Table 2-3)

f_2 = 0.04, volume fraction of solids in Tank 241-AZ-101 (data from TWRS BIO, Appendix B, Table 2-3)

$SOF_{liq\ cont\ on}$ = for DST liquids (Table 3-12 of this addendum)
$= 2.1 \times 10^{2} s/L$

$SOF_{sol\ cont\ on}$ = for DST solids (Table 3-12 of this addendum)
$= 6.3 \times 10^{2} s/L$

Using the above formula, the SOF for Tank 241-AZ-101 mixed liquids and solids is calculated to be:

$$SOF_{mix\ cont\ on} = 2.3 \times 10^{2} s/L$$

The toxic chemical release from unfiltered operation of the ventilation system is drawn from all four AWF tanks, but the mixer pumps operate only in one tank. Therefore, the SOF for the unfiltered release must be adjusted to represent the aerosols from one mixed tank and three unmixed tanks.

$SOF'_{mix\ cont\ on} = (0.25 \times SOF_{mix\ cont\ on}) + (0.75 \times SOF_{liq\ cont\ on})$

$SOF_{mix\ cont\ on} = 2.3 \times 10^{2} s/L$

$SOF_{liq\ cont\ on}$ = for DST liquids (Table 3-12 of this addendum)
$= 2.1 \times 10^{2} s/L$

The SOF for the aerosols released from unfiltered operation of the ventilation system is calculated to be:

$SOF'_{mix\ cont\ on} = 2.2 \times 10^{2} s/L$

The consequence for the onsite receptor from the loss of an AWF filter is:

$T_{cont\ on} = V_{released} \times SOF'_{mix\ cont\ on}$

$T_{cont\ on} = (1.89 \times 10^{-5} L/s) \times (2.2 \times 10^{2} s/L)$

$T_{cont\ on} = 4.2 \times 10^{-3}$

C. Sum of the Offsite Toxicological Consequence

The sum of the offsite puff release toxicological consequence and the offsite continuous release toxicological consequence gives the total offsite toxicological consequence:

$T_{total\ off} = T_{puff\ off} + T_{cont\ off}$

$T_{total\ off} = 1.5 \times 10^{-5} + 1.2 \times 10^{-5}$

$T_{total\ off} = 2.7 \times 10^{-5}$

D. Sum of the Onsite Toxicological Consequence

The sum of the onsite puff release toxicological consequence and the onsite continuous release toxicological consequence gives the total onsite toxicological consequence:

$T_{total\ on} = T_{puff\ on} + T_{cont\ on}$

$T_{total\ on} = 3.4 \times 10^{-1} + 4.2 \times 10^{-3}$

$T_{total\ on} = 3.4 \times 10^{-1}$

3.4.2.1.2.6 HEPA Filter Failure Due to Over-pressure Accident Comparison to Guidelines. Table 3-13 shows that both radiological and toxicological consequences of a HEPA filter failure due to over-pressure fall within the risk guidelines for the extremely unlikely frequency category.

Table 3-13. Radiological and Toxicological Consequences of a HEPA Filter Failure Due to Over-Pressure Accident, with Comparison to Risk Guidelines.

Receptor	Radiological		Toxicological	
	Consequence	Guideline	Consequence (SOF)	Guideline (SOF)
Onsite	2.8×10^{-2} Sv (2.8 rem)	0.1 Sv (10 rem)	3.4×10^{-1}	1 (ERPG-3)
Offsite	3.9×10^{-5} Sv (3.9×10^{-3} rem)	0.04 Sv (4 rem)	2.7×10^{-5}	1 (ERPG-2)

3.4.2.1.2.7 HEPA Filter Failure Due to Over-pressure Accident Summary of Safety Class/Safety Significant Structures, Systems, and Components (SSC)s and Technical Safety Requirement (TSR) Controls. There are no new Safety SSCs required by this project to either the existing AWF ventilation system (241-A-702) or the upgraded ventilation system to be provided by Project W-030, associated with preventing or mitigating the consequences of the HEPA filter failure due to over-pressure accident.

The TWRS TSR control (AC 5.18) is still required to ensure the consequences of a HEPA filter failure due to over-pressure accident remain within the risk evaluation guidelines:

- TWRS TSR AC 5.18 requires the HEPA filters to be maintained such that the dose rate from them is < 200 mrem/h. This ensures that HEPA filter loadings do not exceed the values assumed in this report.

3.4.2.2 Tank Bump Accident.

3.4.2.2.1 Aging Waste Facility Tank Bump Accident Scenario. The thermal phenomenon known as a tank bump occurs when steam stored in the waste causes a waste rollover and a rapid steam pressurization of the tank headspace. The Aging Waste Facility Tank Bump Accident Scenario analysis strategy is addressed in Section 5.3.2.22 of the TWRS BIO. A tank bump is a safety concern because of the potential for a release of aerosolized waste to the environment. The following tank bump scenario description, used as a basis for the Tank 241-AZ-101 mixer pump test analysis, is summarized from Section 5.3.2.22 of the TWRS BIO.

The initial conditions for a tank bump accident to occur are those leading to local saturation temperature and steam buildup within the waste. Those require:

(1) a heat generation rate greater than 7,600 W (26,000 Btu/h), assuming no active ventilation, to reach waste saturation temperature 104 °C (220 °F) at atmospheric pressure,

Note: For Tank 241-AZ-101, the saturation temperature would be 126 °C (258 °F) at the bottom of the tank (accounting for hydrostatic pressure) and 104 °C (220 °F) at the surface (Sathyanarayana 1994),

(2) an amount of non-convective and highly viscous sludge holding steam bubbles, and

(3) an in-tank waste heat removal system failure.

In addition to this, the higher the waste level is, the higher the saturation temperature and the energy stored before a bump.

3.4.2.2.2 Tank Bump Scenario Analysis and Controls for Tank 241-AZ-101 Mixer Pump Test. Tank 241-AZ-101 currently contains waste with a heat generation rate of approximately 70,806 W (241,600 Btu/h) (Hodgson 1995). The operation of the two 300 hp mixer pumps will raise the tank heat generation rate significantly (i.e., by 402,000 W [1,374,000 Btu/h] for a total heat generation rate of 472,806 W [1,613,000 Btu/h] from Nordquist 1997). This is well above the minimum heat load value (7.6 kW [26,000 Btu/h]) that may lead, in certain conditions, to waste saturation temperatures; therefore, 241-AZ-101 is judged to have the conditions necessary for a tank bump.

For the unmitigated and unprevented accident scenario, it was postulated that the cooling capability of the primary tank active ventilation system for Tank 241-AZ-101 would be lost for an indefinite amount of time. The annulus ventilation system is under repair as of this writing, and is therefore, not available to provide additional cooling for the tank waste. The conservative assumption has been made that this system would not be available during the mixer pump test. This results in a bounding analysis in that, should the annulus system be made available, all safety margins would be increased over analyzed values. Therefore, considering the assumption of the loss of the primary ventilation system, the frequency of a Tank 241-AZ-101 tank bump during the mixer pump test was categorized as an unlikely event (due to the short duration of the test). This is based on the fact that a similar ventilation system on 101-SY was determined to have a probability of failure of 4.8×10^{-3} (LANL 1996, Appendix J, Section 2.1.1).

A. Normal Operation of the Pumps and the Primary Ventilation System

In addition to the heat introduced by the operation of the mixer pumps in Tank 241-AZ-101, an increase in waste temperature may occur due to changes in heat transfer characteristics within the waste. These changes may result from re-suspension of solid particulates within the liquid waste as well as non-mobilized sludge areas (even with two pumps operating, it has yet to be determined how long it might take before the sludge becomes completely mixed). When the pumps are turned off at the end of the test or during test interruptions, the bottom of the tank could potentially experience a temperature excursion due to reduced thermal conductivity as the waste solids resettle. This effect is expected even with the primary ventilation system operating normally.

The tank bump protection strategy is one of prevention and relies on air lift circulator (ALC) operation to prevent the potential for heat and steam bubble buildup within the sludge. Several tanks during the history of aging waste tanks (Bendixsen 1990) have had tank bumps. These tank bump accidents only occurred in "boiling" tanks (from 1 to 7 Million Btu/h, and sludge temperatures well above 115.6 °C [240 °F]) prior to ALC full implementation (the cases involved situations in which either no ALCs were operating, only 4 ALCs were operating, or a case in which the ALCs had been stopped and were in the process of being re-started at the time of the bump). In most of the cases, these tanks were not provided with any active cooling ventilation system at the time of the bump. During over 40 years of Hanford Site operation, the ALCs have been the most successful method used to prevent "boiling" tanks from bumping. Several studies have been performed to assess ALC use for tank bump prevention. Among these are Fineman and Lawler 1982, which measured ALC convective flow rates, and Fineman 1984, which contains a Pacific Northwest National Laboratory (PNNL) modelling evaluation of the minimum number of ALCs necessary to prevent tank bumps in full-scale, partial tank laboratory experiments. The latter study also included some modelling for in-tank equipment effects on ALC use (no effect was noted). The lack of effect of in-tank hardware (such as drywells, thermocouples, etc.) on ALC operation can also be seen in photographic evidence (PNL 1979) in which the surface of the liquid waste can clearly be seen to be entirely disturbed by the ALC operation, with no null areas visible. Tank 241-AZ-101 was constructed with 22 ALCs and, using established procedures for ALC use, has never experienced a tank bump. The AWF Interim Operational Safety Requirement (IOSR) (Heubach 1996, LCO 3.4.4), converted to TWRS TSR LCO 3.3.4, requires that the ALCs be operated as soon as the temperature reaches 110 °C (230 °F) for the sludge (or the bottom of the tank) and 87.8 °C (190 °F) for the average waste solution temperature. Thus, the normal operation of the mixer pumps requires no additional controls. This TWRS TSR LCO also requires that a minimum number of ALCs be available for operation, should the temperatures exceed the TSR LCO temperature limits.

B. Off-normal Situations

A prolonged and total loss of primary ventilation could result in tank waste conditions conducive to a thermal bump. This scenario is very unlikely given the existing backup ventilation system, as well as the existence of connection ports for hook-up of an alternate exhauster. However, in the case of a total loss of ventilation, the pumps will be turned off in accordance with TWRS TSR LCO 3.2.1 which requires that all waste disturbing operations and activities within the tank stop upon a loss of ventilation in order to prevent further buildup of heat and gases. The tank bump potential arises because the ALCs are interlocked to turn off when the ventilation system is down. TWRS TSR LCO 3.2.1 requires that, whenever active ventilation is lost within a waste storage tank, actions be initiated immediately to restore ventilation.

For these off-normal situations, very conservative scoping thermal calculations (Sathyanarayana 1997) have shown that the time for the waste temperature to increase from maximum estimated initial conditions and reach local saturation is significantly greater than historical time periods of ventilation loss (previous AWF IOSR 3.4.1 time requirements of 40 hours if

ALCs were not required to be operating per AWF IOSR 3.4.4 and 16 hours if ALCs were required to be operating per AWF IOSR 3.4.4 are considered to be indicative of maximum historical ventilation outage periods). Indeed, the analysis considers the hypothetical case of having half of the area of the tank's sludge (approximately 31.5 cm [12.5 inches] thick) being non-mobilized during the mixer pump test, and being covered by freshly settled solids from the other half of the tank with loss of power, and hence loss of mixer pumps, ventilation, and ALCs. This fraction of sludge mobilization results in the maximum postulated thickness of sludge buildup in the non-mobilized zone. This would normally be an additional 15.75 cm (6.25 inches) of sludge, since it would be distributed over the entire tank area, but an additional conservatism is included that the sludge volume may be increased (or fluffed) by up to a factor of 2 because of the pumping action. This results in an additional 31.5 cm (12.5 inches) of sludge deposition, for a conservative value of 63 cm (25 inches) for the scenario. For this scenario, the time for the sludge temperature to increase from a maximum anticipated sludge temperature of 110 °C (230 °F) to sludge saturation temperature (125.6 °C [258 °F]) is greater than 53 hours, well in excess of the historical maximum for ventilation outages (16 hours). (Higher sludge temperatures before accident onset would have resulted in ALC operation, equilibrating sludge temperatures to a value closer to supernatant levels.) Moreover, this 53 hour minimum time needed to reach sludge saturation temperature conservatively assumes an instantaneous settling time for sludge after waste disturbance has ceased (actual settling time is more on the order of several days, based on sludge sample from Tank 241-AZ-101) (Gray et al. 1993).

In addition to this scoping study, empirical data from previous Tank 241-AZ-101 ALC shutdown testing show no bottom temperature peaks close to waste saturation temperatures (Winkler 1995). The average sludge temperature rose 14.9 °C (5.2 °F) over 1,296 hours (with primary ventilation on and annulus ventilation off). These data lend credence to the assertion that current controls are adequate for the performance of the Tank 241-AZ-101 mixer pump test without the need for additional controls.

3.4.2.2.3 Tank Bump Offsite and Onsite Radiological and Toxicological Consequences Analysis and Comparison to Risk Guidelines. The bounding accident analysis in Section 5.3.2.22.3 of the TWRS BIO is consistent with the Tank 241-AZ-101 assumptions. The associated calculations are documented in Board 1996.

The results are presented in Table 3-14.

The values of 2.2×10^{-3} Sv (2.2×10^{-1} rem) for the offsite radiological dose meets risk guidelines, but the value of 2.5×10^{0} Sv (2.5×10^{2} rem) for onsite radiological doses exceed the risk guidelines for the unlikely event of an unprevented, unmitigated AWF tank bump accident analyzed in the TWRS BIO.

The offsite toxicological value is below one and is within the risk guidelines. The onsite toxicological dose is above one and exceeds the risk guidelines for an unprevented, unmitigated tank bump accident.

The safety control and prevention strategy regarding the tank bump accident is to rely on the current TWRS TSR LCO 3.3.2 for temperature limits.

TWRS TSR LCO 3.3.4 for ALC operation provides additional control and prevention based on prior history of its use as AWF IOSR LCO 3.4.4 (Heubach 1996). This LCO provides an enveloping set of controls covering the behavior of the waste during and after the mixer pump test, as well as the heat load additions from the pumps and waste mobilization effectiveness.

Given several uncertainties with respect to the heat load brought to the waste by the pumps and the waste mobilization effectiveness of the pumps (i.e., amount of sludge initially mobilized and time necessary to achieve maximum waste mobilization), the safety control strategy is to: (1) maintain operation of the primary ventilation system, (2) monitor the waste temperatures (and shut-off mixer pumps per TWRS TSR LCO 3.3.2), and (3) maintain availability of the ALCs to prevent steam bubble formation and turn on ALCs if the waste temperature below 20 feet reaches 110 °C (230 °F) (in the bottom region of the tank after the pumps are turned off, or in non-mobilized areas) per TWRS TSR LCO 3.3.4.

Table 3-14. Tank Bump Radiological and Toxicological Consequences. (Excerpt from Table 5.3.2.22-1 of the TWRS BIO)

Receptor	Radiological		Toxicological	
	Consequence	Guideline	Consequence (SOF)	Guideline (SOF)
Onsite	2.5 Sv (250 rem)	5×10^{-2} Sv (5 rem)	4.9×10^{3}	1 (ERPG-2)
Offsite	2.2×10^{-3} Sv (0.22 rem)	5×10^{-3} Sv (0.5 rem)	0.73	1 (ERPG-1)

3.4.2.2.4 Tank Bump Accident Summary of Safety Class/Safety Significant SSCs and TSR Controls. The safety SSCs associated with this accident are the ALC system (Section 2.7.1.5 of this addendum), which prevents steam accumulation and rollover occurrences, and the primary tank exhaust ventilation system. Both of these systems are safety significant SSCs. Note, the TWRS BIO currently classifies the primary tank exhaust ventilation system as safety class based on the flammable gas deflagration accident. Therefore, the postulated tank bump accident described in this addendum does not change the primary tank exhaust ventilation system safety classification.

The following existing controls are preventive measures against the AWF tank bump (note, there are no mitigative controls):

- Monitor waste temperature and turn off mixer pumps when the top 15 feet of waste reaches 90.6 °C (195 °F) or the waste below 15 feet reaches 101.7°C (215 °F) (TWRS TSR LCO 3.3.2);
- Monitor waste temperature and operate ALCs when the waste temperature below 20 feet reaches 110 °C (230 °F) and the average waste solution temperature reaches 87.8 °C (190 °F) (TWRS TSR LCO 3.3.4);
- Upon total loss of the ventilation system, turn off the mixer pump(s) to control heat addition to the tank and potential tank

over-pressurization and comply with requirements of TWRS TSR LCO 3.2.1.

3.4.2.3 Breach of Containment. The following mechanisms (i.e., flammable gas deflagration, dropped equipment, internal missiles, erosion, and material degradation due to high temperatures) due to mixer pump operation result in scenarios already discussed in Squires 1987 and the TWRS BIO. Therefore, no additional consequence calculations were performed.

3.4.2.3.1 Flammable Gas Deflagration. This section discusses the hazards and controls associated with the generation, accumulation, storage, release, and postulated combustion of flammable gases in the tank headspace. This hazard was first identified as an Unreviewed Safety Question (USQ) in 1990. This USQ was updated on November 1, 1996 (Serrano 1996) to account for increased understanding of the nature of the hazard and the affected facilities. The updated USQ addresses potential flammable gas hazards in the AWF tanks. The flammable gas USQ remains open for the AWF (Serrano 1996) as of this writing.

The Flammable Gas Justification for Continued Operation has been incorporated in the BIO as Appendix E and in the TSRs as Administrative Controls (AC) 5.9, 5.10, and 5.11. This BIO Addendum affirms the applicability of the RL approved controls for the mixer pump test. This affirmation is required for two reasons. First, the initiation of the mixer pump test has the potential to release any flammable gas that has accumulated in the waste matrix and is trapped beneath the waste surface. Second, operation of the mixer pumps will increase waste temperature and will, therefore, increase the rate of flammable gas generation. This results in an increase in the chronic (or "steady state") gas release rate to the tank vapor space.

Radioactive waste generates hydrogen through the radiolysis of water, thermolytic decomposition of organic compounds, and corrosion of the tank's carbon steel walls. Radiolysis and thermolytic decomposition also generate ammonia. Additional flammable gases (such as methane) and an oxidizer (nitrous oxide) are generated by chemical reactions between various degradation products of organic chemicals originally present in the tank. Volatile or semi-volatile organic chemicals also produce organic vapors.

The gas generated through these processes may be released continually to the tank vapor spaces (historically referred to as steady state flammable gas generation) or be retained by the tank's waste matrix, potentially resulting in an episodic gas release event (GRE). Steady state flammable gas generation from radiolysis, chemical decomposition, and corrosion is expected from all of the AWF tanks. With a GRE, gas is retained in the tank's waste matrix until it is spontaneously released or a release is induced during waste disturbing activities, such as mixer pump operations.

An accident scenario for a representative flammable gas deflagration resulting from a GRE in an AWF tank is provided in the TWRS BIO, Section 5.3.2.14.1. The source terms and consequences associated with this event were developed in Van Vleet 1996b. The representative GRE accident analysis assumes the release and ignition of sufficient trapped gas such that

the resulting energy creates unfiltered release paths, but is insufficient to collapse the tank dome. A gas release of this size has never been observed, and is not expected for the current waste contents of Tank 241-AZ-101. Therefore, the energy associated with the deflagration of such a release is considered bounding for Tank 241-AZ-101 with its current waste contents.

The source term selected for the representative GRE accident analysis is based on the assumption that only the liquid component of the waste would be released by the deflagration event. While likely to be valid for a quiescent initial waste condition, the liquid source term assumption may be questioned for the condition where mixer pump operation mobilizes a significant portion of the waste solids. In this case, it may be argued that some fraction of the release due to a deflagration consists of waste solids. As seen in Van Keuren 1996, the existence of a solids component in the source term would result in an increased radiological dose at the receptor locations. Determination of the fraction of solids that may be entrained in the release is an additional uncertainty associated with this event.

As indicated in the TWRS BIO, the consequence analysis for the representative GRE is not considered bounding. However, at this point in the resolution process of the open USQ, the analysis serves to indicate the need for an Authorization Basis control strategy. As provided in the current authorization basis (TWRS BIO), the control strategy is prevention. Controls related to monitoring and ignition sources are assigned to specific facilities and tanks on the basis of observed and estimated gas release behavior. These controls are not specifically derived from GRE consequence analysis, and would not be changed by variations in the magnitude of the calculated consequences presented in the TWRS BIO. For information, the TWRS BIO analysis results are summarized in Table 3-15 of this addendum, excerpted from Table 5.3.2.14-1 of the TWRS BIO. The detailed discussion of the consequence analysis is provided in Section 5.3.2.14 of the TWRS BIO.

The specific monitoring and ignition source controls applicable to the AWF tanks are driven by assignment of the AWF tanks to flammable gas Facility Group 2 (TWRS BIO) and the nature of activities and operations performed in the tanks. The mixer pump test does not alter the assignment of Tank 241-AZ-101 to Facility Group 2. In addition, performance of the test falls within the authorization basis definitions for the nature and location of activities and operations. Therefore, with respect to GRE behavior that may be associated with the mixer pump test, the existing authorization basis monitoring and ignition source controls continue to apply.

Thus, the strategy to prevent or mitigate potential hazards associated with flammable gas in Tank 241-AZ-101 during the performance of the mixer pump test involves implementation of the controls detailed in the TWRS BIO. The BIO strategy is to expeditiously implement achievable and practical controls to manage postulated flammable gas risks. While doing so, progress towards safety issue resolution and USQ closure will continue to concentrate on remaining uncertainties regarding the quantification of risk and effectiveness of control strategies.

The controls are aimed primarily at prevention of ignition of flammable gas (although certain aspects of the control strategy are mitigative in

nature). Provisions for ventilation serve to prevent accumulation of chronically released gases and possibly reduce the time at risk assuming the occurrence of a spontaneous or induced gas release. Flammable gas monitoring requirements serve to validate ventilation effectiveness as well as prevent or halt manned activities when margin of safety is considered to be insufficient (i.e., conditions are such that the flammable gases exist in concentrations greater than 25% of the lower flammability limit). Ignition controls related to work practices and equipment requirements serve to eliminate, to the greatest extent practical, ignition sources.

This three-pronged control strategy (ventilation, monitoring, and ignition source control) is assumed to be effective in preventing the accumulation of flammable gases where ignition sources may be present or to eliminate ignition sources where flammable gases may potentially be present.

Steady State Generation

The performance of the tests associated with running the mixer pumps could potentially affect the steady state generation of flammable gases. Steady state flammable gas generation is dependent on several parameters including decay heat load, waste temperature, organic complexant chemical concentrations, and nitrate/nitrite concentration. Running the mixer pumps will increase the waste temperature, potentially resulting in increased steady state flammable gas generation.

The implementation of the TWRS BIO/TSR control strategy during mixer pump operation in Tank 241-AZ-101 provides ventilation to prevent accumulation resulting from a steady state gas release. However, the safety margin provided by compliance with the ventilation requirements of the TWRS TSR flammable gas controls (TSR AC 5.9, 5.10, and 5.11) may be decreased as a result of the mixer pump test. This is due to the expected increases in waste temperature resulting from mixer pump heat input as well as a possible reduction in waste heat conduction during a potential fluffed sludge condition (see Section 3.4.2.2.2B of this addendum) during initial settling following operation of the mixer pumps. The increased waste temperature can result in an increased hydrogen generation rate.

In order to provide some degree of confidence that the ventilation flow and TWRS TSRs for ventilation restoration are adequate to prevent a flammable gas deflagration resulting from the increased hydrogen generation rate, a brief review was performed of the BIO supporting calculation (Hu 1997). This calculation note provides a numerical analysis for estimating the steady-state hydrogen release rate for double-shell tanks. This numerical analysis provides various equations for the three contributors of hydrogen generation; radiolysis, thermolysis, and corrosion. Of the three, thermolysis will vary according to temperature as indicated in the following equation (Hu 1997 Equation 6):

$$G_{chemical}=G_{bl} * M * \left(\frac{TOC}{TOC_{bl}}\right) * \left(\frac{Al}{Al_{bl}}\right) * \exp\left[-\frac{Ea}{R} * \left(\frac{1}{T}-\frac{1}{T_{bl}}\right)\right]$$

where:

bl	=	baseline tank, 241-SY-103
G	=	hydrogen generation rate, mole/(kg * day) (baseline 3.5 E-7)
M	=	total mass of liquid, kg
TOC	=	total organic carbon concentration
Al	=	total aluminum concentration
Ea	=	baseline tank hydrogen generation activation energy (91,000 J)
R	=	gas constant (8.314 J/mole/ °K)
T	=	temperature, °K (baseline = 304.7 °K)

Using the numbers contained in the calculation note for 241-AZ-101 but substituting 110 °C (230 °F) as a bounding temperature for the mixer pump test yields 1.77E-5 m^3/s (0.0376 CFM). This added to the other two hydrogen generation components yields 2.63E-5 m^3/s (0.0557 CFM).

Equation 8 of Hu 1997 determines the time to reach a specified hydrogen concentration and Equation 9 determines the minimum ventilation flow rate to keep the hydrogen concentration below a specified limit. Using the revised flow rate above yields 8.25 days to reach 25% of the LFL (8.09 days using Project W-030's high heat flow rate of 0.24 m^3/s [500 CFM]). The 7 day limit of 241-SY-101 still bounds the completion time of Recovery Action A.3 of TWRS TSR LCO 3.2.1. The minimum flow rate to keep the hydrogen concentration below 25% of the LFL is 2.8 E-3 m^3/s (5.9 CFM).

This evaluation provides some confidence in the adequacy of the ventilation system to prevent the steady state accumulation of flammable gas to levels above the LFL since the minimum ventilation flow rate provided by the existing 241-A-702 AWF ventilation system ranges from approximately 400 to 600 CFM and the minimum ventilation flow rate provided by the W-030 ventilation system is approximately 100 CFM.

The increased gas generation rates will be reduced to their prior values after temperatures have re-stabilized to the lower, typical values measured today (within 30 days, extrapolating data from Sathyanarayana 1997).

Thus, the implementation of the TWRS BIO/TSR control strategy during mixer pump operation in Tank 241-AZ-101 in conjunction with the application of the TWRS TSRs provides adequate controls to prevent a flammable gas deflagration as a result of steady state flammable gas generation.

Gas Release Event

The performance of the mixer pump test could also potentially result in a gas release event (GRE). This test involves running the mixer pumps which is defined as a global waste disturbing operation (TWRS BIO). Waste disturbing activities represent the primary means of releasing gas retained in the waste matrix resulting in a GRE.

The controls required by the TWRS BIO are graded based on the tank Facility Group assignment and the nature of the operation or activity. The AWF tanks are assigned Facility Group 2 status. However, the assignment of Facility Group 2 is based on consideration for future use of the tanks rather than current waste inventory. This facility assignment means that GRE controls are focused on dome space intrusive and waste intrusive regions during non-waste disturbing or local waste disturbing operations. Controls are extended to ex-tank intrusive regions during global waste disturbing operations. This test involves running the mixer pumps which is defined as a global waste disturbing operation. Therefore, the expanded controls are required during operation of the mixer pumps.

The equipment, materials, and work practices associated with this project were evaluated by the Flammable Gas Equipment Advisory Board (FGEAB) (Smet 1997) to verify compliance with the Ignition Source Control Sets #1 and #2 as detailed in the TWRS BIO. The FGEAB evaluation of the equipment, materials, and work practices associated with this project determined that the applicable Ignition Source Control Sets were satisfied in all cases, including the case of carbon steel profile thermocouples and/or transfer pumps swaying in the carbon steel risers (Smet 1997). This determination also concluded the 300 hp induction drive motor and the 1/3 hp induction rotation motors mounted on top of the risers met the applicable Ignition Source Control Sets.

Comprehensive compliance with the applicable Ignition Source Control Sets not only minimizes the potential for an ignition source following a steady state gas release, but also minimizes the potential for an ignition source following a GRE. This control implementation provides an additional level of safety in order to prevent a flammable gas deflagration even if a large GRE were to occur. However, a large GRE is not expected to occur during mixer pump operation. These expectations are based on the following information:

- Tank 241-AZ-101 currently contains only a small amount of sludge, approximately 35,000 gallons, which limits the maximum amount of potentially retained gas to small amounts (Hodgson 1995).

- A conservative scoping analysis indicates that if the sludge in Tank 241-AZ-101 retained and released flammable gas in the same volumetric proportion as did Tank 241-SY-101 (prior to mitigation), then a GRE would be insufficient to cause a well mixed headspace to exceed 25% of the LFL (Hodgson 1996). This scoping analysis uses barometric pressure versus tank level rise to estimate the amount of trapped gas. The gas release event used in Hodgson 1996 assumed 25% of the trapped gas was released and its hydrogen concentration was 97% unless data supported a reduction. Analysis of Tank 241-AZ-101 resulted in a steady-state gas generation of 0.16% LFL and a worst case episodic release of 20% of the LFL (Hodgson 1996 Table 2-1). Also, Hodgson 1996 reported no correlation seen between barometric pressure changes and surface level rise for Tank 241-AZ-101 (i.e., minimal amounts of trapped gas).

- An evaluation of actual amounts of retained gas using the limited data available indicates that the amounts of retained gas in Tank 241-AZ-101 are very small to non-existent (Hodgson 1996).

- Even though mixer pump operation is defined as global waste disturbing, the test is performed in phases of increasing expected sludge mobilization. Complete and rapid mobilization of all of the sludge is not expected during the first phases of the test.

- After the sludge has been re-distributed and settled, it should not retain significantly more gas than prior to the test.

In the time period between waste sludge mobilization and complete settling, the sludge volume may be larger than it is currently. That is, it will be less compacted. This may result in an increase in the total amount of retained gas and may alter the retention and release (i.e., GRE) behavior postulated as the basis for the flammable gas controls. GRE behavior in the partially settled sludge is not postulated to be worse than the "small" spontaneous GRE or the "large" induced GRE postulated for Facility Group 2 tanks in the TWRS BIO.

Thus, the implementation of the TWRS BIO/TSR control strategy during mixer pump operation in Tank 241-AZ-101 provides adequate control to prevent a flammable gas deflagration as a result of a GRE, even though a large GRE is not expected to occur.

Table 3-15. Radiological and Toxicological Consequences of a Flammable Gas Deflagration. (excerpted from Table 5.3.2.14-1 of the TWRS BIO)

Receptor	Radiological		Toxicological	
	Consequence	Guideline	Consequence (SOF)	Guideline (SOF)
Onsite	4.4×10^{-2} Sv (4.4 rem)	5×10^{-3} Sv (0.5 rem)	8.2×10^{2}	1 (ERPG-1)
Offsite	4×10^{-5} Sv (4×10^{-3} rem)	1×10^{-3} Sv (0.1 rem)	0.7	1 (PEL-TWA)

3.4.2.3.2 Dropped Equipment. Consequences of scenarios for dropped equipment were not analyzed in this addendum. No equipment is planned to be installed or removed during the test. Structural and fatigue analysis for other in-tank components is contained in Section 2.4.4 of the TWRS BIO Appendix B. If non-safety-related in-tank process equipment is damaged through the use of the mixer pumps, an evaluation will be performed to determine the impact of restarting or continuing the test.

3.4.2.3.3 Internal Missile. The pumps have an installed screen (5 cm [2 in] openings) to keep out items that have the potential for damaging the impeller (Nordquist 1997). Any debris items smaller than the screen openings would pass directly through the pump, and have the potential to exit the pump discharge at approximately 18 m/s (58 ft/s). An assessment has been made, based on qualitative engineering judgement, that these potential missiles

could not damage the tank wall or safety-related in-tank equipment. This assessment is based on: (1) the discharge height of the mixer pump from the tank bottom (43 cm [17 in]) is below the level of any safety-related equipment; (2) the pump discharge is horizontal (i.e., does not angle upward); and (3) the tank wall is greater than 4.6 m (15 ft) distant from the discharge points of the pump. This distance, combined with the discharge velocity and the 5 cP assumed viscosity of the waste (Nordquist 1997) makes it highly unlikely that any potential missile will retain sufficient energy to impart damage to a 1.3 cm (1/2 in) tank wall.

An assessment was performed to determine whether a pump impeller failure (the largest potential missile) would penetrate the pump housing and subsequently penetrate the tank wall. It was determined in LANL 1996 that, at an approximate impeller speed of 1,200 rpm (the maximum pump speed) the resulting fragment could not penetrate the pump casing and therefore, could not impact the tank. It was also concluded in the same analysis that if the entire pump impeller (13.0 kg [28.7 lb]) were separated from the shaft and dropped axially downward in the tank, the mass of the impeller would not be large enough to penetrate the tank. The mass of the 241-AZ-101 mixer pump impeller is 65.7 kg (144.5 lb) but is much closer to the tank bottom (50 cm for 241-AZ-101 versus 370 cm for 241-SY-101). The 241-AZ-101 mixer pump impeller is not expected to achieve any significant velocity from dropping due to its short height above the floor. Another conclusion reached in LANL 1996 was that the dropping of small parts up to a mass of 45.4 kg (100 lb) would not affect the tank's integrity.

3.4.2.3.4 Erosion. Smith and Elmore 1992 evaluated the effect of an impinging slurry jet on the corrosion rate of the tank wall and floor. Results of the tests indicate that, because of the action of the mixer pump slurry jets, the mixer pump activity will moderately accelerate corrosion of the tank wall and floor. A time averaged corrosion rate of approximately 4 mils/yr was calculated for the highest jet velocity tested for the Neutralized Current Acid Waste (NCAW) test (4.6 m/s [15 ft/s]). The maximum total base metal loss for the 150-day NCAW test was approximately 1.6 mils. Analysis of the weight loss data from the NCAW test coupons with the oxide layer intact indicates it is likely that a lower corrosion rate of 2.5 mils/yr or less may occur over the long term during actual waste mixer pump operations. This reduction in the corrosion rate is due to the thickness of the oxide layer within the tank. The tank surfaces are heavily oxidized following fabrication as a result of the stress relief process and since their fabrication the tanks have contained corrosive wastes to further increase the impermeability of the layer.

For the mixer pump test, approximately only 1,300 hours are planned, including many hours at reduced jet velocities. Smith and Elmore 1992 also provides data at 42 days, which is representative of the planned mixer pump test duration. The 42-day results are less than 17% of the 150-day values. Therefore, for the mixer pump test, between 0.27 and 0.68 mils of base metal loss is predicted, depending on which of the above 150-day values is used. For the short duration use of the mixer pumps addressed by this safety analysis, and tank walls in Tank 241-AZ-101 that were constructed to be a minimum of 1.3 cm (1/2 inch [500 mil]) thick, the predicted erosion-corrosion of the tank steel is insignificant.

3.4.2.3.5 Material Degradation due to High Temperatures. The TWRS TSR controls include a waste temperature limit of 121.1 °C (250 °F) (TWRS TSR Safety Limit [SL] 2.1.1) to protect against runaway exothermic organic nitrate chemical reactions. This limit is less than the previous AWF IOSR limit of 148.9 °C (300 °F), which was designed to preserve the concrete tank wall integrity from temperature excursions above 176.7 °C (350 °F) (AWF IOSR SL 2.2). The risk associated with exothermic organic nitrate chemical reactions is minimal for the mixer pump test in Tank 241-AZ-101 because of three things: (1) the low organic content of the tank of approximately 0.92 weight percent in the solids and 0.09 weight percent in the liquid (Hodgson 1995), (2) none of the mixer pump activities have any potential for reducing the water content of the waste solids, and (3) the use of TWRS TSR LCO 3.3.2 provides protection for TWRS TSR SL 2.1.1 as described in the bases for TWRS TSR LCO 3.3.2 (Noorani 1997).

3.4.2.3.6 Tank Dome Collapse Accident due to Overload. The mixer pump test increases the tank dome load substantially. However, the total of the previous load and the new load placed on the tank by the Project W-151 equipment is below the enhanced total load limit permitted by JCO 1995. A structural analysis was performed (Moody 1996) that includes design calculations for the concrete pad, the steel support frame, the extension riser and riser lifting bails, and the 20.7 MPa (3,000 lbf/in^2) spray wash piping system (refer to Figure 2-2 of this addendum for mixer pump support). Dead load, live load, jet impingement and seismic loads were considered. The mixer pump and mounting plate are bolted to the support frame that is anchored to a concrete pad. A tank riser extension is provided to connect the existing tank riser with the pump support assembly. The pump support system is designed to prevent the transfer of loads directly from the pump to the riser. Thus, the pump is supported by its own on-grade foundation, and is independent of the buried AZ-101 pits and risers.

The Project W-151 Functional Design Criteria (Nordquist 1997) and Supplemental Design Requirements Documents (Kohlman 1993) establish the design basis loads and load combinations by reference to the Hanford Plant Standards Standard Design Criteria (SDC) 4.1[2]. SDC 4.1 requires dynamic analysis for Safety Class 2 systems unless otherwise justified. The mixer pump support assembly and riser extension have been classified as Safety Class 2 (Kidder 1994). (See Chapter 4 of this addendum for a correlation between the previous Hanford Site safety class numbering system and the DOE STD 3009-94 system.) Because of this, the mixer pump support assembly and riser extension were analyzed using a "static equivalent" safety class 2 approach.

The mixer pump support foundation earthquake design loading (0.25 g Peak Horizontal Ground Acceleration) complies with SDC 4.1, Rev. 11 for Safety Class systems. A Peak Acceleration factor of 0.25 g was also applied to the concrete foundation since both of these foundations support the Safety Class 2 riser extension (Kidder 1994). Calculations of the earthquake loads transferred from the 241-AZ-101 mixer pump to the support frame and concrete foundation are included in the directional load combinations (Moody 1996).

---

[2]Hanford Plant Standards Standard Design Criteria (SDC) 4.1 has been replaced by GC-LOAD-01, "Design Loads For Facilities."

Since the mixer pump assembly is designated safety class 3, loading criteria of Conrads 1996 were used to determine the magnitude of load transfer. Using 0.25 g peak, criteria of Conrads 1996, and the fact the mixer pumps are flexible resulted in the following acceleration or "g" factors used in the analysis: (1) Horizontal = 0.675 g and (2) Vertical = 0.45 g, both in excess of those required for Safety Class 2 components.

The results of the analysis show that all components of the support system are structurally adequate to support the mixer pump for both normal service and extreme loading conditions. Therefore, the Tank Dome Collapse accident is classified as being Beyond Extremely Unlikely, and no consequences are calculated.

3.4.2.3.7 Seismic. The results of the HazOp study given in Appendix 3A show that the deformation or failure of the mixer pump shaft due to a seismic event is extremely unlikely. Moody 1996 evaluated the mixer pump support assembly, riser extension, concrete pad, steel support frame, riser lift bails, and the 20.7 MPa (3,000 lbf/in^2) spray wash piping system. Dead load, live load, jet impingement, and seismic loads are considered in the design calculations.

The 241-AZ-101 mixer pump support assembly, extension riser, and spray wash system structural analysis results show that the pump support and riser configuration are acceptable for the applied design requirements. (See Section 3.4.2.3.6 of this addendum for an additional seismic discussion.)

A breach of containment caused by the deformation or the failure of the mixer pump shaft due to a seismic event is then Beyond Extremely Unlikely and no consequences are calculated.

During and after a seismic event, the scenario could occur wherein the primary ventilation fails (as described in the TWRS BIO Section 5.3.2.23) either through electrical power outage or ventilation system mechanical failure, but the mixer pumps are left running, either through human error or a situation in which the operator is prevented, for some reason, from stopping the pumps (injury, etc.). In this scenario, the concern would be for the continued addition of pump energies to the tank with a reduced heat removal capability from the tank to raise the waste temperatures to the point where tank bump would become a potential. The risk associated with this scenario, however, is bounded by that of the HEPA filter failure due to over-pressure, discussed in Section 3.4.2.1.2 of this addendum. The frequency of the design basis earthquake, from the TWRS BIO, is 1×10^{-3}. This frequency, combined with the frequency reduction associated with the pump being left running after the seismic event in which the ventilation system is lost (contrary to controls), brings the accident into the extremely unlikely category. The consequences of this accident are bounded by the 24 hour emission calculated for the HEPA failure scenario, since Tank Farms Emergency Response personnel, whose function it is to verify equipment status (in this case, that the mixer pumps are off in accordance with requirements) would have completed their checks well before the 24 hour period. Also, the onset of any potential tank bump will be alleviated by the mixer pump action over that of a quiescent tank. Because of these prevention/mitigation factors, this accident is felt to be adequately bounded, and no further analysis is required.

3.4.2.4 Criticality. The Criticality Safety Evaluation Report (CSER) (Vail 1997) documents an evaluation of the criticality safety implications of the mixer pump test to be performed in Tank 241-AZ-101. The CSER does not identify a scenario associated with the mixing test that could lead to a criticality. It is concluded that testing the mixer pumps will not sufficiently increase the concentration of plutonium in any portion of the waste contained in 241-AZ-101 to pose a criticality safety concern.

Mixing the waste will disperse the plutonium, and none of the mechanisms capable of increasing plutonium concentration appear capable of overcoming the dispersal and blending mechanisms. The calculated k-effective (k_{eff}), when limited experimental data exist for a similar system and relatively large but reasonable interpolations or extrapolations are necessary, shall not exceed 0.95 (WHC-CM-4-29). For solid tank waste with a conservative composition, as defined in Rogers 1993, the plutonium concentration corresponding to a k_{eff} of 0.95 is 2.6 g/L. This concentration of plutonium is known as the subcritical limit with respect to tank waste.

A comparison of the concentration of plutonium in 241-AZ-101 sludge and the subcritical limit is valid when the actual solids are shown to be less reactive than the composition of the conservative waste model (Rogers 1993). The measure of reactivity is determined by comparing the macroscopic absorption cross section of the waste in Tank 241-AZ-101 to the macroscopic absorption cross section of the conservative waste model solids. The absorption cross section of the waste based on sample analysis is more than double the cross section of the conservative waste model solids. So, the subcritical limit for the actual waste solids will be higher than 2.6 g/L and a correlation between actual and calculated plutonium concentrations in the waste to the subcritical limit is conservative.

Based on waste transfer data reported in Vail 1997, the highest measured plutonium concentrations from sample analysis in the supernate and the sludge of Tank 241-AZ-101 are 0.000019 g/L and 0.175 g/L, respectively, and the highest plutonium concentration in a waste batch transferred into the tank was 0.0242 g/L. The transfer data also indicates that a very thin layer of solids may reside in the tank with a plutonium concentration of up to 0.63 g/L. It follows that the sample data and waste transfer data support the conclusion that the margin of criticality safety in the undisturbed solids in the tank ranges from a factor of 4.1 to 14.8. Also, the waste composition based on the sample analysis indicates that the neutron absorbing capacity of the non-fissile constituents is 16 times the amount of absorbers necessary to assure sub-criticality for any plutonium concentration.

The primary criticality safety aspect of mixing the waste solids is whether the plutonium remains intimately associated with the neutron poisons while the solids are suspended, and after settling. The exact mechanism which holds the plutonium in the 241-AZ-101 solids is not known, but it is reasonable to suggest that many different mechanisms contribute (i.e., precipitation, adsorption, agglomerated solids, etc.). The preferential segregation of Pu from the other hydroxides is most likely prevented by solid agglomerates containing Pu at very large absorber-to-Pu ratios. Whyatt et al. 1996 explains that hot-cell settling tests and flocculation calculations lead to the conclusion that particles are flocculated under

normal waste tank conditions, and interaction potentials promote a very rapid flocculation rate, even after the agglomerates are broken up by hydraulic forces such as mixer pumps. The investigation into Pu chemistry in waste tank environments does not lead to any scenario which suggests a criticality in the solid phase of the waste is possible.

An evaluation of the criticality safety aspects of mixing the waste in 241-AZ-101 must also investigate the consequences of Pu segregation due to the waste containing discrete particles of PuO_2. Serne et al. 1996 provides "...calculations that show, for the most realistic cases, that the level of segregation of fissiles from neutron absorbers was about a factor of 2.5." This value is the result of particle segregation predictions using the Transient Energy Momentum and Pressure Equations Solutions in Three Dimensions (TEMPEST) Fluid Dynamic Model, the Subsurface Transport Over Multiple Phases (STOMP) code (a simplified one-dimensional stagnant settling model), and mixing experiments which assess particle segregation due to size. For a plutonium concentration increase by a factor of 3 due to particle segregation during settling, the highest plutonium concentration for a thin layer is 1.889 g Pu/L, which is less than the subcritical limit.

Another angle of investigation includes a determination of the consequences of pulling waste with the highest estimated Pu concentration into the mixer pump. The expectation is that the waste layer with the calculated 1.889 g Pu/L will mix with layers of lower Pu concentration resulting in an overall lower average, but the conservative approach is an evaluation which assumes that only the high Pu concentration waste is in the pump. The volume of the mixer pump housing is approximately 134 L (Nordquist 1996). So, at the highest plutonium concentration of 1.889 g Pu/L, only 253 g of plutonium can reside in the pump at any one time. Hence the plutonium concentration is less than the subcritical limit of 2.6 g Pu/L and the total mass of plutonium in the pump is less than the minimum critical mass of plutonium of 520 g.

Modeling used in the CSER was conducted with extremely conservative assumptions:

- The realities of agglomerate formation and their behavior were ignored.
- The presence of neutron absorbers was ignored.
- Mixing of AY-102 and AZ-101 by operation of the air lift circulators (ALCs) was ignored.
- The highest plutonium concentration of the four layers in C-106 was used for modeling.

Based on these assumptions, modeling was conducted with the TEMPEST three-dimensional code to predict the maximum plutonium concentration in the initial settling of solids, the maximum concentration in the pump housing, and the maximum concentration in settled solids after pumping. A one-dimensional code was also used to bound simple settling phenomena, although the one-dimensional approach is not considered realistic, as described in the preceding section.

A summary of the principal concentration factors (CF) used in the modeling is as follows:

- Highest CF in 1-dimensional model using the reported size range of particles for C-106, AZ-101, and AY-102: 10 (rounded from 9.3)
- Highest CF in 3-dimensional TEMPEST model: 3 (rounded from 2.5)
- Highest CF in large pump housing (AZ-101): ~50%
- Effective CF used for all three tanks: 18 (a CF of 6 is used to account for the maximum/average concentration in any layer in the tank and is combined with an additional CF of 3 to account for the maximum segregation by settling as predicted by the TEMPEST code for the largest of particulates).

Finally, an attempt was made to determine if undisturbed waste presently stored in tanks exhibits any indication of increasing plutonium concentration at the bottom of settled sludge. The first such review was made by Braun et al. 1994. That review concluded that no correlation of plutonium concentration with vertical displacement in the tanks could be shown.

Another attempt to determine a plutonium concentration correlation with depth in tank sludge was carried out in support of the CSERs for the W-320 and W-151 projects. Data was requested from the TWRS Characterization Data Base for sludge tanks from which full depth sample cores had been obtained and analyzed for either plutonium concentration or gross alpha activity. Three such tanks were found: B-203, B-204, and U-105. Plots of alpha activity against segment number (proportional to core depth) are shown in Figures 3-1 through 3-3 of this addendum.

Tanks B-203 and B-204 received metal wastes from B-plant through the 224B concentrator. Both tanks are 50,000 gallon capacity, both are near full, and both are administratively stabilized and isolated. Neither tank has been jet pumped. Both tanks received their last transfers in 1976. They are reasonably good examples of undisturbed sludge tanks. As readily observed from Figures 3-1 and 3-2 of this addendum, there is no evidence of plutonium tending to concentrate more toward the bottom.

Tank U-105 once held T-Plant waste, but that was sluiced out for uranium recovery in 1956. Since 1956 there have been three different regions of waste added to the tank; (1) Redox high level waste (coating waste) was added from 1956 to 1961, (2) The tank then received evaporator bottoms from 242-T, and (3) After 1975 the tank again received high level waste from Redox. The profile shown in Figure 3-3 of this addendum is consistent with this history. Redox high level waste is expected to contain about 0.4% of the plutonium in the irradiated fuel. However the 242-T evaporators processed waste tank supernate containing very little plutonium and resulting in relatively low plutonium concentrations even in the evaporator bottoms.

It appears most likely that the actual behavior of plutonium in tanks is typified by B-203 and B-204, namely that there is no evidence of a trend to concentrate plutonium closer to the bottom of a tank. Similarly, the

differences in concentration shown by Tank U-105 in Figure 3-3 of this addendum can be completely explained by the historical waste receipt record. If it is argued that the "trend" exhibited for the lower half of U-105 is due in whole or in part to a plutonium concentrating mechanism, then such concentration is roughly consistent with the CF value used in the analyses, i.e., a factor of 18.

The scenarios evaluated, the data presented, and analysis of actual tank data support the conclusion that a large margin of criticality safety exists in waste Tank 241-AZ-101 and the mixer pump test will not pose a criticality safety concern. An added layer of conservatism to this conclusion is that allowances for the quantity of ^{240}Pu in plutonium concentrations has not been taken. Plutonium-240 has a substantial neutron capture cross section, and so will decrease the reactivity of the waste.

Because this scenario is considered to be beyond extremely unlikely, no further study is required.

3.4.3 Beyond Design Basis Accidents

No BDBAs were evaluated for the mixer pump test. Because the test procedure is of relatively short duration (approximately 1300 hours), the identification and evaluation of BDBAs was judged to be unnecessary. This judgement is consistent with the graded approach implementation of DOE 5480.23.

Figure 3-1. Tank B-203 Alpha Activity by Core Segment. (Sludge)

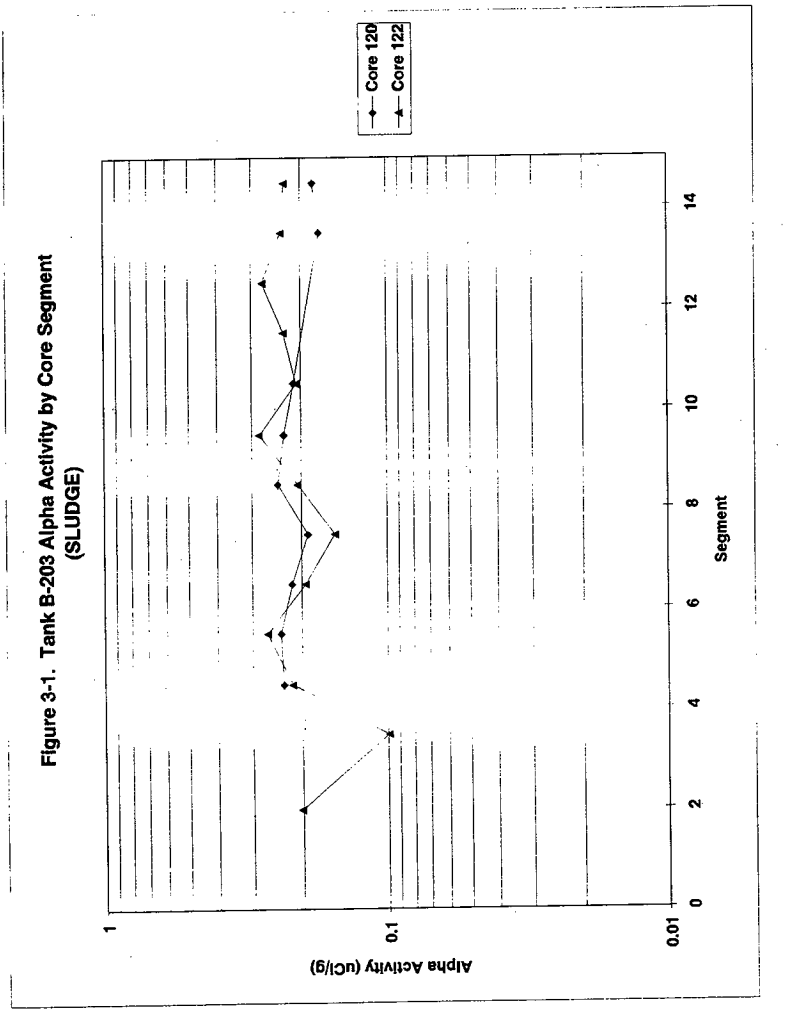

Figure 3-2. Tank B-204 Alpha Activity by Core Segment. (Sludge)

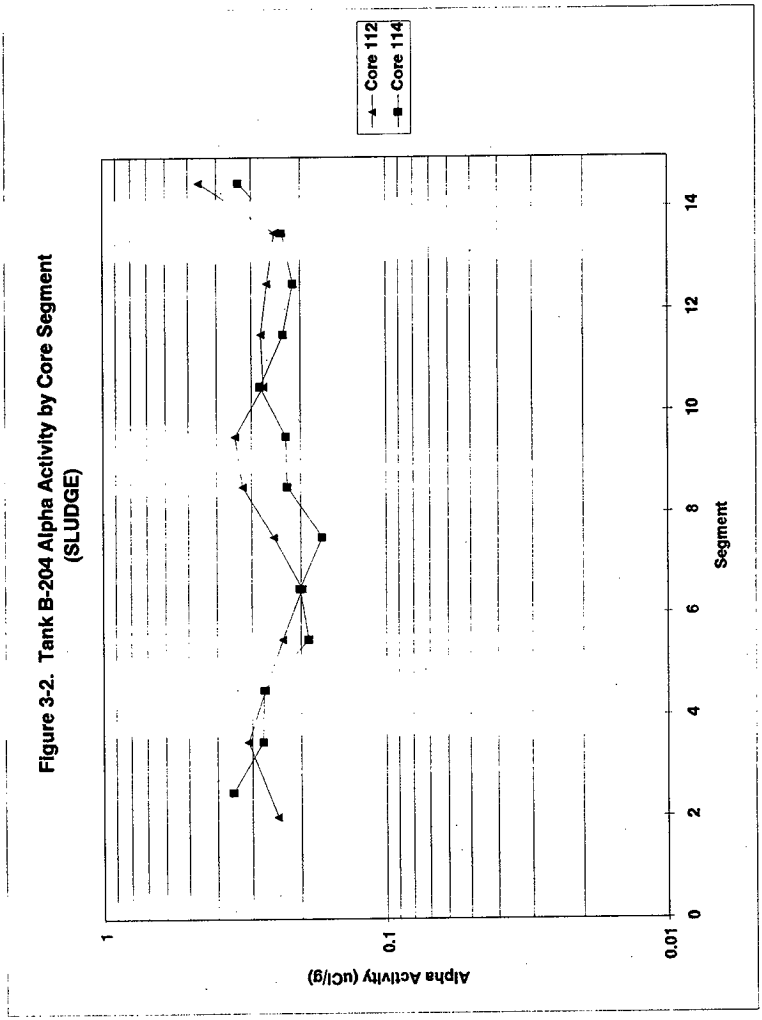

Figure 3-3. Tank U-105 Alpha Activity by Core Segment (Sludge: Fusion Digest).

4.0 SAFETY SYSTEMS, STRUCTURES, AND COMPONENTS

The safety classifications for the Project W-151 systems, structures, and components (SSC)s were determined in the project preliminary safety analysis report (Bourger 1993) and remain unchanged as a result of this safety document. As documented in Chapter 3 of this addendum, failure of the added equipment does not cause unacceptable consequences. Since all previous analyses for the 241-AZ-101 mixer pump test have used the former WHC safety classification class 1, 2, and 3 system, the use of the term "Safety-Significant" as delineated in DOE-STD-3009-94 is used interchangeably with Safety-Class 2 (SC-2) and Safety-Class 3 (SC-3) for the new SSCs added for the 241-AZ-101 mixer pump test. The highest safety classification assigned was Safety-Class 2 which was assigned to the mixer pump support system, though this system was analyzed to equivalent Safety-Class 1 seismic criteria. Refer to Table 4-1 following for an excerpted listing of the added project SSCs from Bourger 1993. Refer to Section 2.1 of the TWRS BIO for conversion to safety significant.

The existing tank farm SSCs remain unchanged except for the air lift circulator system for Tank 241-AZ-101. As a result of safety analysis in Chapter 3 of this addendum, the air lift circulator system and the air lift circulators in Tank 241-AZ-101 require a designation change, previously identified as IOSR related equipment (Kidder 1994) but now perform a Safety-Class 2 or Safety-Significant function based on the outcome of the tank bump scenario (the mixer pump process test does not change the tank bump outcome described in the TWRS BIO). This equipment (including support and ancillary equipment systems as discussed in Section 2.7.1.5 of this addendum) is currently installed and can be verified as meeting the requirements for performing their Safety-Significant function.

This page intentionally left blank.

Table 4-1. Preliminary Safety Equipment List.
(Excerpt from Bourger 1993 Table A)

Component	Safety Function	Safety Class	MRP 5.46/EP-1.4 Criterion
Mixer Pumps	Required for sludge mobilization	3	Failure does not satisfy any of the Safety-Class criteria for SC 1 or 2 listed in Table 1 of MRP 5.46 Rev. 4.
Mixer pump power supply	Required for supply of power to mixer pumps	3	Cause significant harm to facility workers due to industrial safety hazards.
Mixer pump instrumentation	Required to monitor pump operation	3	Failure does not satisfy any of the Safety-Class criteria for SC 1 or 2 listed in Table 1 of MRP 5.46 Rev. 4.
Mixer pump water supply	Required for insertion and rotation of pumps during startup	4	Failure has no significant importance to safety, health, or environmental protection.
Mixer pump support system	Required for support of mixer pumps during operation.	2	Failure could prevent a separate Safety-Class 2 system, component, structure, from performing its safety function, either by loss of control function or by damage.
Shielding plugs		3	Failure could preclude implementing ALARA principles for exposure to radiological or nonradiological hazardous materials.
Four profile thermocouples	Required to monitor tank temperatures	3	Failure does not satisfy any of the Safety-Class criteria for SC 1 or 2 listed in Table 1 of MRP 5.46 Rev. 4.
Sludge thermocouples	Required to monitor tank temperatures	3	Failure does not satisfy any of the Safety-Class criteria for SC 1 or 2 listed in Table 1 of MRP 5.46 Rev. 4.

Note: For conversion from SC-2, SC-3, and SC-4 to Safety-Class and Safety-Significant (as defined in DOE STD-3009), refer to Jensen et al. 1997.

This page intentionally left blank.

5.0 DERIVATION OF TECHNICAL SAFETY REQUIREMENTS

The 241-AZ-101 mixer pump test hazards and accidents identified in Chapter 3 are safely mitigated or prevented using currently-approved TSRs (Noorani 1997) in conjunction with Air Lift Circulator TSR controls, converted from Heubach 1996 as identified in Wagoner 1997, thus ensuring protection of the workers and the public.

Table 5-1 on the following page summarizes the preventive or mitigative actions identified for each of the accidents analyzed in Chapter 3 of this addendum, and identifies the applicable TWRS TSR controls or other document which implements the required actions.

The air lift circulator control, discussed in the first paragraph of this section, is specifically converted from the AWF Interim Operational Safety Requirement (IOSR) LCO 3.4.4, Air Lift Circulators and its surveillance requirements to TSR LCO 3.3.4 along with its surveillance requirements. TSR LCO 3.3.4 prevents the tank bump and its subsequent unmitigated, unprevented on-site consequences over the risk evaluation guidelines.

This page intentionally left blank.

Table 5-1. Summary of Preventive/Mitigative Actions.

Accident Scenario	Preventive or Mitigative Actions during mixer pump test	Applicable TSR Contr or Other Document
Unfiltered release of radionuclides and toxic aerosols from the tank (Section 3.4.2.1)	• Limiting the maximum activity on each filter to a level that gives an equivalent dose rate of 200 mrem/h on contact controls the amount of particulates that could be expelled.	TSR AC 5.18
Tank Bump (Section 3.4.2.2)	• Localized high temperatures may be caused by mixer pump operation. The mixer pumps will be turned off if the top 15 feet of waste reaches 90.6 °C (195 °F) or the waste below 15 feet reaches 101.7 °C (215 °F). ALCs will be operated to provide more uniform temperature distributions per limits described below. • Upon loss of the primary ventilation system, the mixer pump(s) will be turned off to control gas and heat buildup in the tank. • During normal operation of the pump(s) and at the end of the test while the pumps are turned off, the waste temperature will be monitored and the air lift circulators operated as soon as the temperature reaches 110 °C (230 °F) for waste below 20 feet and 87.8 °C (190 °F) for the average waste solution.	TSR LCOs 3.3.2, 3.3.4 TSR LCO 3.2.1 TSR LCO 3.3.4
Breach of Containment (Section 3.4.2.3)	• High temperature (3.4.2.3.5): - Primary tank exhaust ventilation system shall be operable. • Flammable gas deflagration (3.4.2.3.1): - Implementation of Ignition Source Controls as well as monitoring for flammable gas are preventive measures against deflagration, breach of the tank, and breach of ventilation confinement in the event that an episodic gas release exceeds 100% of the lower flammability limit. - LCO 3.2.1 requires ventilation operability to prevent flammable gas accumulations. The vent system operation also prevents tank pressurization and an unfiltered release. • Tank dome collapse due to overload (3.4.2.3.6): - This event is deemed beyond extremely unlikely for the mixer pump test based on analysis of dead load, live load, jet impingement, and seismic loads. All components of the support system were found adequate to support the mixer pumps for both normal service and extreme conditions. • Seismic (3.4.2.3.7): - Structural analysis of seismic loads shows that the pump support and riser configuration are acceptable for the applied design requirements.	TSR LCO 3.2.1 TSR AC 5.9, 5.10, 5.1 TSR LCO 3.2.1 TSR AC 5.16 Moody 1996
Criticality (Section 3.4.2.4)	• A Criticality Safety Evaluation Report prepared for Project W-151 identified no scenario associated with the mixer pump test that could credibly lead to criticality.	TSR AC 5.7

AC = Administrative Control
AWF = Aging Waste Facility
LCO = Limiting Condition for Operation
TSR = Technical Safety Requirement (TWRS)

(Section number refers to sections of this addendum.)

This page intentionally left blank.

6.0 PREVENTION OF INADVERTENT CRITICALITY

This section contains information relevant to prevention of inadvertent criticality as a result of the operation of the mixer pump test. For further information on the Tank Waste Remediation Systems (TWRS) specific criticality safety and protection program, see Section 4.3 of the TWRS BIO. The program ensures that sufficient controls are in place to reduce the likelihood of inadvertent nuclear criticality excursions as a result of the activities performed within the TWRS facilities.

6.1 REQUIREMENTS

See Section 4.3 of the TWRS BIO for requirements.

6.2 FACILITY IMPLEMENTATION

See Section 4.3 of the TWRS BIO for facility implementation.

6.3 PROJECT IMPLEMENTATION

Vail 1997 evaluates the safety aspects of the mixer pump test. The Criticality Safety Evaluation Report is necessary to address the potential that mixing, suspension, and settling of tank fissile material may result in a criticality safety concern. See Section 3.4.2.4 of this addendum for further discussion on criticality.

This page intentionally left blank.

7.0 RADIATION PROTECTION

This section identifies the requirements for radiation protection as a result of the operation of the mixer pump test.

7.1 REQUIREMENTS

See Section 4.4 of the TWRS BIO for requirements.

7.2 FACILITY IMPLEMENTATION

See Section 4.4 of the TWRS BIO for facility implementation.

7.3 PROJECT IMPLEMENTATION

Design of the upgrades necessary for the mixer pump test followed the requirements of Westinghouse Hanford Company Controlled Manual WHC-CM-4-9, *Radiological Design*, which has since been canceled by Evans 1994. A review of Nordquist 1997 shows that the uncontrolled area dose rate limit of 0.5 mrem from WHC-CM-4-9 was used for the design. This limit is conservative from the standpoint of the upgrades being in a controlled tank farm facility. The current dose rate limit from Evans 1994 for controlled full-time use is 2.5 μSv (0.25 mrem). The only designs impacted by this change are the radiation shields built for the new equipment (mixer pumps and new thermocouples). Access to the top of the mixer pumps is very difficult due to the motor and installed support equipment. Full-time exposure above the thermocouples is not expected either during the normal operations or potential abnormal operations.

There were no project specific requirements related to radiation protection during construction of the project equipment as all work activities were performed per Section 4.4 of the TWRS BIO.

This page intentionally left blank.

8.0 HAZARDOUS MATERIAL PROTECTION

This section identifies the requirements for hazardous material protection other than radiological hazards for the mixer pump test.

8.1 REQUIREMENTS

See Section 4.5 of the TWRS BIO for requirements.

8.2 FACILITY IMPLEMENTATION

See Section 4.5 of the TWRS BIO for facility implementation.

8.3 PROJECT IMPLEMENTATION

No project-specific requirements related to hazardous material protection were identified for the mixer pump test.

This page intentionally left blank.

9.0 RADIOACTIVE AND HAZARDOUS WASTE MANAGEMENT

This section lists the requirement documents for the radioactive and hazardous waste management for the mixer pump test.

9.1 REQUIREMENTS

See Section 4.6 of the TWRS BIO for requirements.

9.2 FACILITY IMPLEMENTATION

See Section 4.6 of the TWRS BIO for facility implementation.

9.3 PROJECT IMPLEMENTATION

No additional requirements relating to radioactive and hazardous waste management were identified for the mixer pump test. The equipment removed from the tank to accomplish the mixer pump test was managed as mixed waste.

This page intentionally left blank.

10.0 INITIAL TESTING, IN-SERVICE SURVEILLANCE, AND MAINTENANCE

This section identifies the requirements for testing, surveillance, and maintenance for the mixer pump process test equipment.

10.1 REQUIREMENTS

See Section 4.7 of the TWRS BIO for requirements.

10.2 FACILITY IMPLEMENTATION

See Section 4.7 of the TWRS BIO for facility implementation.

10.3 PROJECT IMPLEMENTATION

10.3.1 Initial Testing

USQD TF-96-1041 verified that the checkout testing of the installed equipment was within the current TWRS Authorization Basis.

10.3.2 In-Service Surveillance

New in-service surveillance procedures were not required as a result of the mixer pump test equipment. All new surveillances will only be required during the operation of the mixer pump test and will be documented in the test plan.

10.3.3 Maintenance

New preventive maintenance procedures were not required as all of the new equipment are covered by existing maintenance procedures. Specific maintenance items such as periodicity and types of lubricants were itemized by the various vendors and input into the existing maintenance program as identified in Section 4.7 of the TWRS BIO.

This page intentionally left blank.

11.0 OPERATIONAL SAFETY

This section identifies requirements for conduct of operations, Aging Waste Facility (AWF) fire protection, and the implementing program documents directly resulting from the performance of the mixer pump test.

11.1 REQUIREMENTS

See Sections 4.8, 4.9, and 4.10 of the TWRS BIO for requirements.

11.2 FACILITY IMPLEMENTATION

See Sections 4.8, 4.9, and 4.10 of the TWRS BIO for facility implementation.

11.3 PROJECT IMPLEMENTATION

No project-specific requirements related to operational safety or fire protection were identified for the mixer pump test. Per the requirements of DOE 5480.7, no project-specific fire hazards analysis was required. Motors overheating are already potential fire hazards for Tank Farms. These motors do not represent anything new. The motors are in the open where the damage would be limited only to the motors. The mixer pump operations have been evaluated by the Flammable Gas Equipment Advisory Board (Smet 1997).

This page intentionally left blank.

12.0 PROCEDURES AND TRAINING

This section lists the requirements for the procedures and training programs for the mixer pump test.

12.1 REQUIREMENTS

See Section 4.11 of the TWRS BIO for requirements.

12.2 FACILITY IMPLEMENTATION

See Section 4.11 of the TWRS BIO for facility implementation.

12.3 PROJECT IMPLEMENTATION

There are specific training requirements for operation of the mixer pumps including on-the-job training cards, required reading, and additional certifications for the nuclear power operators for operating the new equipment. These requirements are specified in Bohan 1996.

The procedure to perform the mixer pump test is TF-210-OTP-001 (Ross 1997).

This page intentionally left blank.

13.0 HUMAN FACTORS

This section lists the requirements for a human factors program to demonstrate that human factors are considered in facility design where human actions are relied upon for preventive or mitigative actions.

13.1 REQUIREMENTS

See Section 4.18 of the TWRS BIO for requirements.

13.2 FACILITY IMPLEMENTATION

See Section 4.18 of the TWRS BIO for facility implementation.

13.3 PROJECT IMPLEMENTATION

The application of human factors is graded on project risk, complexity, and level of involvement of the operator at the facility. A human factors systematic inquiry was not required for the mixer pump test. Within TWRS, human factors are considered in the development of procedures and controls, staffing, interface with Safety systems, structures and components, surveillance, maintenance, and Safety Analyses. For the mixer pump test, various human factors were used including development of a written mixer pump test procedure, validation of the procedure, qualification and training of the nuclear power operators, and design of the test monitoring console with design improvement feedback from the operators. Since this is a one-time test, no comparisons were made regarding allocation of mixer pump control functions between the operators versus automatic devices.

This page intentionally left blank.

14.0 QUALITY ASSURANCE

This section lists the requirements for a quality assurance program to ensure the safety of personnel and the public, for environmental protection, and for the implementing program documents.

14.1 REQUIREMENTS

See Section 4.12 of the TWRS BIO for requirements.

14.2 FACILITY IMPLEMENTATION

See Section 4.12 of the TWRS BIO for facility implementation.

14.3 PROJECT IMPLEMENTATION

Implementation of specific quality assurance requirements for the mixer pump process test equipment was controlled by Manthei 1994.

The Quality Assurance Program consists of the following:

- Personnel performing construction on this project were trained and qualified in accordance with the above quality assurance program plan and DOE 5480.20A.
- Quality Improvement processes described in the quality assurance programs provided for the detection and correction of quality problems throughout the design and construction of this project.
- Documents associated with this project have been independently reviewed for completeness and accuracy. A record index is available to classify all quality assurance records to aid in document retrieval.
- Work processes associated with this project have been and will be strictly adhered to in accordance with this quality assurance program plan. Appropriate administrative procedures have been developed and approved to control key aspects in the design and construction of this project.
- Designs associated with this project were independently reviewed and approved. Completed construction is accurately depicted by as-built drawings.

- Procurement of safety-class and safety-significant items for this project were in compliance with this quality assurance program in that such items have been purchased from qualified suppliers where applicable and all stated requirements have been met as verified through independent inspections, tests, and assessments. All required Certified Vendor Information has been received and appropriately indexed and filed to support continuity of service.

- Inspection and testing of items associated with this project met required standards as verified by properly trained and qualified personnel. Records are on file to attest to accuracy and completeness of the inspection and testing.

- Periodic management assessment of this project was established to ensure this project is compliant with this quality assurance program plan and the objectives stated within met required performance objectives.

- Independent assessments were planned, scheduled, and conducted to confirm that project deliverables and service quality are adequate to meet operational objectives.

15.0 EMERGENCY PREPAREDNESS PROGRAM

This section identifies the requirements for the emergency preparedness functions and response at the site of the mixer pump test.

15.1 REQUIREMENTS

See Section 4.13 of the TWRS BIO for requirements.

15.2 FACILITY IMPLEMENTATION

See Section 4.13 of the TWRS BIO for facility implementation.

15.3 PROJECT IMPLEMENTATION

No project-specific requirements related to emergency preparedness were identified for the mixer pump test.

This page intentionally left blank.

16.0 PROVISIONS FOR DECONTAMINATION AND DECOMMISSIONING

This section describes provisions that facilitate future decontamination and decommissioning (D&D) of the facilities.

16.1 REQUIREMENTS

See Section 4.14 of the TWRS BIO for requirements.

16.2 FACILITY IMPLEMENTATION

See Section 4.14 of the TWRS BIO for implementation.

16.3 PROJECT IMPLEMENTATION

This document does not evaluate removal of the mixer pumps and future D&D. D&D considerations were left to the future D&D of the tank farms as there are other in-tank components which will need similar evaluation. Safety considerations for removal of the pumps will be addressed by separate safety documentation once that portion of the mission is defined. At this time removal of the mixer pumps following the mixer pump test is not anticipated. It is expected, following an acceptable test, that the pumps will be used in the future for waste retrieval purposes, supporting the TWRS strategy. If the mixer pumps fail during the test, the test will be concluded.

The design of the installed mixer pumps does include provisions for decontamination and decommissioning, such as a spray ring in the extended riser, capability for installing a flexible receiver to provide tank confinement during mixer pump removal, minimizing cracks and crevices, and using stainless steel for material contacted by tank waste for ease in decontamination.

This page intentionally left blank.

17.0 MANAGEMENT, ORGANIZATION, AND INSTITUTIONAL SAFETY PROVISIONS

This section provides the requirements specific to this chapter and pertinent to the safety analysis and for the implementing program documents.

17.1 REQUIREMENTS

See Section 4.1 of the TWRS BIO for requirements.

17.2 FACILITY IMPLEMENTATION

See Section 4.1 of the TWRS BIO for facility implementation.

17.3 PROJECT IMPLEMENTATION

No project-specific requirements related to management, organization, and institutional safety provisions were identified for the mixer pump test.

This section specifically refers to the TWRS BIO: Section 4.2 regarding Standards/Requirements Identification Document, Section 4.15 regarding Configuration Management and Control, Section 4.16 regarding Occurrence Reporting, and Section 4.17 regarding Unreviewed Safety Questions.

This page intentionally left blank.

APPENDIX 3A

HAZARDS AND OPERABILITY STUDY FOR PROJECT W-151

This page intentionally left blank.

1.0 INTRODUCTION

Project W-151 has been established for the purpose of the installation and process testing of two 300 horsepower mixer pumps weighing 12,247 kg (27,000) each in Aging Waste Facility (AWF) Waste Tank 241-AZ-101. The mixer pumps are intended to mix 90% of the sludge with the supernate in the tank. TWRS SAR Engineering will have the primary role in performing the hazards and accident analysis for the Safety Evaluation. The Safety Evaluation is scheduled to be completed in fiscal year 1996.

The first step in performing an accident analysis is to identify and qualitatively assess the facility hazards. The results of the assessment are used to determine which abnormal events could initiate accidents with the potential to expose site personnel or the general public to radioactive or chemical hazards.

A number of systematic techniques for hazards identification are available. The technique chosen for Project W-151 hazards identification was the Hazards and Operability (HazOp) Study. The HazOp methodology is specifically designed for chemical processing and storage areas. It is one of the most exhaustive techniques available because it is designed to examine process deviations in exhaustive detail, and also because it uses a multi-disciplinary team of knowledgeable individuals in a systematic brainstorming effort. The HazOp results are being used as a scoping tool to determine which potential accident sequences must be analyzed in detail in order to demonstrate that the mixer pumps and ancillary equipment in AWF Waste Tank 241-AZ-101 can be safely operated following installation.

This page intentionally left blank.

2.0 SCOPE

The HazOp identifies equipment and facilities shown on configuration drawings and diagrams within the scope of Project W-151 which could contain quantities of hazardous (radiologically hazardous or toxic) materials with a potential to cause significant consequences to the site personnel or the general public. Areas with limited potential to cause consequences outside of the facility boundaries or initiate significant events in other tanks within the tank farms were not included in the scope of the HazOp.

This page intentionally left blank.

3.0 ORGANIZATIONAL RESPONSIBILITIES

The HazOp was performed using personnel from Westinghouse Safety Analysis and Nuclear Engineering, Double-Shell Tanks (DST) Retrieval Construction Projects, and other groups essential to the W-151 Project. Safety Analysis and Nuclear Engineering coordinated the effort by providing methodology, facilitation, recording, and HazOp tables (Attachment 1 of Appendix 3A) and HazOp Report development and editing. DST Retrieval Construction Projects produced the initial draft of the HazOp tables from raw notes. Other groups included and represented in the HazOp effort are TWRS Quality Assurance and TWRS Engineering.

This page intentionally left blank.

4.0 METHODOLOGY

The HazOp documents the effects of deviations from the design intent of the various "process" parameters. Flow diagrams were used to break the system into nodes. Each major piece of equipment involved in the process is a node, and the piping and/or instrument lines connecting the equipment are also nodes. Pertinent process parameters (guide words) such as flow, pressure, level, and temperature are chosen, and a series of questions are asked about each parameter. Each "question" concerns an abnormal condition of the parameter (for example, "no flow"). The HazOp team, based on design knowledge and operational experience, postulates the cause(s) and effects of the abnormal process condition. From this information, a qualitative estimate of the consequences of the abnormal condition is obtained. The estimate is then used as a screening tool to determine the need for further analysis.

The product of the HazOp study is a series of tables (Attachment 1 of Appendix 3A) showing the results. The results are further categorized to include a list of potential abnormal conditions which might cause consequences in the various categories, which is used to prepare a list of accidents to be considered for further analysis.

This page intentionally left blank.

5.0 RESULTS

The summary of results of the HazOp is included in this section.

The results of the HazOp analyses were a number of postulated abnormal events which were ranked with respect to severity and frequency of occurrence. Table 3A-1 of this appendix shows the number of events considered to have potential consequences in each category, for each study node. Note that the number of ranked abnormal events does not have a one-to-one correlation with the node deviations. In some cases, deviations of a parameter associated with one node would cause another deviation of a parameter associated with a second node. (For example, high flow through a line node might cause high level in the destination vessel.) In some cases the cause and consequences of a particular deviation at a node are identical to a deviation at another node. These are cross referenced in the HazOp tables and not generally included in the count as separate ranked abnormal events.

Table 3A-1 of this appendix shows a summary of the consequence severity and probability of occurrence categories for the energy source/hazard potentials shown in the HazOp study tables. Table 3A-2 of this appendix provides a description of the occurrence severity indices and Table 3A-3 of this appendix a description of the indices for frequencies of occurrence. Only those abnormal events having a potential severity consequence of I or II and a probability range $>1.0 \times 10^{-6}$ will be considered for detailed analysis.

The HazOp tables are included in Attachment 1 of this appendix. Abnormal events identified in Table 3A-1 of this appendix as having a frequency $> 1 \times 10^{-6}$/yr and industrial events with risks to hazards commonly accepted in industry are excluded from the events having potential unacceptable safety risk summarized here.

5.1 NODE 1 — INLET TO EXISTING VENTILATION SYSTEM

F3 - S2

1. Potential exposure of onsite individual to airborne radionuclides and toxic substances when filters fail due to tank over-pressure resulting when exhauster fails.

F2 - S1

1. Potential exposure of occupational individual to airborne radionuclides and toxic substances when filters fail due to tank over-pressure resulting when a riser in another tank connected to the AWF ventilation system is opened.

F2 - S1

1. Potential exposure of occupational individual to airborne radionuclides and toxic substances when ventilation ducting fails due to seismic event, high wind, or impact by construction equipment.

F1 - S2

1. Potential exposure of onsite individual to airborne radionuclides and toxic substances when a chemical reaction results in igniting tank head space flammable gases creating pressure that fails filters causing unfiltered release.

F1 - S1

1. Potential exposure of occupational individual to airborne radionuclides and toxic substances when high wind causes reversal of air flow through open riser on tank.

5.2 NODE 2 — INLET TO NEW VENTILATION SYSTEM

F3 - S1

1. Potential exposure of occupational individual to airborne radionuclides and toxic substances when valve in exhaust duct remains closed allowing pressure to build up, exhaust duct valve then opens pressurizing filters causing them to fail, which results in an unfiltered release.

2. Potential exposure of occupational individual to airborne radionuclides and toxic substances when filters fail due to tank over-pressure resulting when exhauster fails.

3. Potential exposure of occupational individual to airborne radionuclides and toxic substances when filters fail due to tank over-pressure resulting when a riser in another tank connected to the AWF ventilation system is opened.

F2 - S2

1. Potential exposure of onsite individual to airborne radionuclides and toxic substances when ignition of tank head space flammable gases and resulting pressure and heat fail filters causing unfiltered release.

F2 - S1

1. Potential exposure of occupational individual to airborne radionuclides and toxic substances when ventilation ducting fails due to seismic event, high wind, or impact by construction equipment.

F1 - S2

1. Potential exposure of onsite individual to airborne radionuclides and toxic substances when a chemical reaction results in igniting tank head space flammable gases and resulting pressure fails filters causing unfiltered release.

F1 - S1

1. Potential exposure of occupational individual to airborne radionuclides and toxic substances when high wind causes reversal of air flow through open riser or collapsed stack on tank.

5.3 NODE 3 — WASTE TANK

F3 - S1

1. Potential exposure of occupational individual to airborne radionuclides and toxic substances when filters fail due to tank over-pressure resulting when exhauster fails.

2. Potential exposure of occupational individual to airborne radionuclides and toxic substances when filters fail due to tank over-pressure resulting when a riser in another tank connected to the AWF ventilation system is opened.

3. Potential exposure of occupational individual to airborne radionuclides and toxic substances when filters fail due to tank over-pressure resulting when a mixer pump is started and mixing action creates a change in the vapor space composition and pressure.

4. Potential exposure of occupational individual to airborne radionuclides and toxic substances when ignition of tank head space flammable gases created by heat input from mixer pump results in pressure and heat that fail filters causing unfiltered release.

F2 - S2

1. Potential exposure of onsite individual to airborne radionuclides and toxic substances when ignition of tank head space flammable gases results in pressure and heat that fail filters causing unfiltered release.

2. Potential exposure of onsite individual to radionuclides and toxic substances when ignition of tank head space flammable gases results in pressure and heat that breach the tank allowing exposure of the soil column to tank contents.

3. Potential exposure of onsite individual to airborne radionuclides and toxic substances and contamination when ignition of tank head space flammable gases result in pressurizing contaminants through piping leading from tank farm pits when subsequent work is performed in the pits.

F2 - S1

1. Potential exposure of occupational individual to airborne radionuclides and toxic substances when filters fail due to tank over-pressure resulting when a mixer pump is started and mixing/chemical action creates a change in the vapor space composition and pressure.

F1 - S2

1. Potential exposure of onsite individual to radionuclides and toxic substances when tank containment is breached and tank contents are leaked to the soil column due to impact by dropped equipment during installation or removal operations.

2. Potential exposure of onsite individual to radionuclides and toxic substances when tank containment is breached and tank contents are leaked to the soil column due to impact by a missile ejected by a mixer pump.

3. Potential exposure of onsite individual to radionuclides and toxic substances when tank containment is breached and tank contents are leaked to the soil column due to erosion by mixer pump action.

4. Potential exposure of onsite individual to airborne radionuclides and toxic substances when filters fail due to tank over-pressure resulting when a mixer pump is started and mixing/chemical action creates a change in the vapor space composition and pressure.

5. Potential exposure of onsite individual to airborne radionuclides and toxic substances when filters fail due to tank over-pressure resulting when a mixer pump is started, rearranging tank material which results in critical mass formation and criticality.

5.4 NODE 4 — OLD EXHAUST VENTILATION SYSTEM

F3 - S2

1. Potential exposure of onsite individual to airborne radionuclides and toxic substances when valve in exhaust duct remains closed, loss of power to exhaust fan or exhaust fan failure allows pressure to build up, then the exhaust duct valve opens pressurizing filters causing them to fail which results in an unfiltered release.

2. Potential exposure of onsite individual to airborne radionuclides and toxic substances when valve in exhaust duct remains closed allowing flammable gases to build up. Ignition of gases creates ventilation system over-pressure causing filters to fail which results in an unfiltered release.

3. Potential exposure of onsite individual to airborne radionuclides and toxic substances when valve in exhaust duct remains closed causing diminished cooling which results in tank heating causing a tank bump. Sudden release of gases creates ventilation system over-pressure causing filters to fail which results in an unfiltered release.

F3 - S1

1. Potential exposure of occupational individual to airborne radionuclides and toxic substances when filters fail due to tank over-pressure resulting when a riser in another tank connected to the AWF ventilation system is opened.

F2 - S2

1. Potential exposure of onsite individual to airborne radionuclides and toxic substances when filters fail due to tank over-pressure resulting when filters plug with particulate.

F1 - S3

1. Potential exposure of offsite individual to airborne radionuclides and toxic substances when ventilation ducting is breached due to high wind/tornado.

F1 - S2

1. Potential exposure of onsite individual to airborne radionuclides and toxic substances when ventilation ducting is breached due to Seismic event.

F1 - S1

1. Potential exposure of occupational individual to airborne radionuclides and toxic substances when filters fail due to tank over-pressure resulting when a riser in another tank connected to the AWF ventilation system is opened.

5.5 NODE 5 — NEW EXHAUST VENTILATION SYSTEM

F3 - S2

1. Potential exposure of onsite individual to airborne radionuclides and toxic substances when valve in exhaust duct remains closed, loss of power to exhaust fan or exhaust fan failure allows pressure to build up, then the exhaust duct valve opens pressurizing filters causing them to fail which results in an unfiltered release.

2. Potential exposure of onsite individual to airborne radionuclides and toxic substances when valve in exhaust duct remains closed allowing flammable gases to build up. Ignition of gases creates ventilation system over- pressure causing filters to fail which results in an unfiltered release.

3. Potential exposure of onsite individual to airborne radionuclides and toxic substances when valve in exhaust duct remains closed causing diminished cooling which results in tank heating causing a tank bump.

Sudden release of gases creates ventilation system over-pressure causing filters to fail which results in an unfiltered release.

F3 - S1

1. Potential exposure of occupational individual to airborne radionuclides and toxic substances when filters fail due to tank over-pressure resulting when fan control allows it to over-speed.

2. Potential exposure of occupational individual to airborne radionuclides and toxic substances when filters fail due to tank over-pressure resulting when a riser in another tank connected to the AWF ventilation system is opened.

F2 - S2

1. Potential exposure of onsite individual to airborne radionuclides and toxic substances when filter fails due to tank over-pressure resulting when filters plug with particulate.

2. Potential exposure of onsite individual to airborne radionuclides and toxic substances when ignition of tank head space flammable gases created by plugged filter results in pressure and heat that fail filters causing unfiltered release.

3. Potential exposure of occupational individual to airborne radionuclides and toxic substances when ventilation ducting fails due to impact by construction equipment.

F1 - S2

1. Potential exposure of onsite individual to airborne radionuclides and toxic substances when ventilation ducting is breached due to seismic event.

2. Potential exposure of onsite individual to airborne radionuclides and toxic substances when gases build in tank due to a filter failure which fails due to particulate restriction, and the loosed filter media plugs the stack. When the force holding the filter media lodged in the stack are overcome by the pressure that has built up in the tank, the media is dislodged and an unfiltered release occurs.

F1 - S1

1. Potential exposure of occupational individual to airborne radionuclides and toxic substances when filters fail due to tank over-pressure resulting when a riser in another tank connected to the AWF ventilation system is opened.

5.6 NODE 6 — MIXING PUMPS

F3 - S1

1. Potential exposure of onsite individual to radionuclides and toxic substances when tank containment is breached and tank contents are leaked to the soil column due to impact by missile ejected by mixer pump.

2. Potential exposure of onsite individual to airborne radionuclides and toxic substances when loss of power to exhaust fan, or exhaust fan failure, allows pressure to build up causing filters to fail which results in an unfiltered release.

5.7 NODE 7 — EQUIPMENT INSTALLATION AND REMOVAL

F3 - S1

1. Potential exposure of onsite individual to direct radiation and/or airborne radionuclides and toxic substances when removing or installing tank equipment.

2. Potential contamination of soil on top of tank resulting from a spill during tank equipment removal.

This page intentionally left blank.

Table 3A5-1. Summary of HazOp Study Consequence Severity and Frequency of Occurrence Indices.

Equipment/system	Severity	Frequency	No. of Events
Inlet to Existing Ventilation System	S2	F3	1

Table 3A5-2. Event Severity Index.

Safety-Class category designation	Description
S3	Potential significant radiological dose consequences or chemical exposure to the offsite receptor.
S2	Potential significant radiological dose consequences or chemical exposure to the onsite co-located worker.
S1	Potential industrial injury, radiological dose consequences or chemical exposure to the facility worker.
S0	No effect outside the facility confinement systems and no safety concerns for the facility worker, the onsite worker, or members of the general public.

Table 3A5-3. Event Frequency Index.

Frequency category designation	Numeric definition	Word definition
F3	$> 10^{-2}$/year	Anticipated
F2	$> 10^{-4}$ to $\leq 10^{-2}$/year	Unlikely
F1	$> 10^{-6}$ to $\leq 10^{-4}$/year	Extremely unlikely
F0	$\leq 10^{-6}$/year	Beyond extremely unlikely

6.0 ACCIDENTS

The purpose of the accident analysis is to demonstrate assurance that the design and operations resulting from Project W-151 can be conducted in a manner that will limit risk to the health and safety of the public and employees and protect the environment. The safety analysis provides the analytical bases for the AWF Tank 241-AZ-101 Waste Retrieval System Safety Requirements. First the facility hazards were identified to determine, to the maximum extent practical, the range of potential accidents or process upsets the facility may experience. Categories of potential accidents were extracted from the hazards assessment and representative scenarios will be developed for each category. Next, dose consequences will be calculated for each scenario. The dose consequences will be compared to the risk acceptance criteria described in WHC-CM-4-46.

6.1 ACCIDENT SELECTION

The HazOp estimates were made for the likelihood of occurrence (Frequency) of each accident shown in the HazOp study tables. There are four Frequency Categories. Also shown are four Severity Categories. These categories were used along with common release mechanisms to group or bin accidents with common attributes. Bin or group numbers are shown on the HazOp study tables.

An accident scenario was developed which bounded all accidents assigned to a bin or group. Six groups or bins were identified. Therefore, six bounding (candidate) accident scenarios were developed. The Bounding candidate accidents are identified in the following section.

6.2 BOUNDING ACCIDENTS

Releases of airborne radionuclides and/or toxic materials that have a potential impact on the onsite and/or offsite individual result from ventilation HEPA filter failure, backflow through open tank risers, leakage via failed vent ducting, and installation or removal of tank equipment. Potential exposure of the soil column to tank contents and potential contamination of the ground water could result from a waste tank leak.

The following accidents are specific to Project W-151 and bound all other accidents resulting from hazards shown in the HazOp study tables.

1. Candidate accident that bounds all accidents listed for Bin 1. Radionuclide release resulting from filter failure due to over-pressurization caused by:

    - Vacuum breaker fault
    - Aerosol generation from chemical reaction
    - Ignition of flammable gases in the dome void space

- Increased aerosol generation due to mixer pump action and heat input
- Plugging of filters with particulate or moisture
- Tank Bump (sudden release of aerosol with the tank liquid volume).

2. Candidate accident that bounds all accidents listed for Bin 2. Radionuclide and toxic material release resulting from opening in top of tank due to reversal of flow caused by:
   - Wind (air flow over open riser draws aerosols from tank)
   - Causes for tank pressurization listed in 1 above while riser is open
   - Tank dome overload resulting in tank dome collapse and breach.
3. Candidate Accident that bounds all accidents listed for Bin 3. Radionuclide and toxic material release resulting from breach in ventilation ducting due to reversal of flow caused by:
   - Seismic event during equipment installation and operation
   - High wind during equipment installation and operation
   - Impact by construction equipment or vehicle.
4. Candidate accident that bounds all accidents listed for Bin 4. Breach of containment which allows tank contents to enter the soil column creating a potential for a pathway to the ground water beneath the tank caused by:
   - Excessive draw down
   - Pressure from flammable gas burn
   - Dropped equipment into tank during installation or removal
   - Missile from pump
   - Erosion during mixer pump operation.

5. Candidate accident that bounds all accidents listed for Bin 5. Radiological and toxicological material release resulting form over-pressure due to Criticality caused by rearrangement of material due to:

   - Mixer pump action during operation or
   - Mixer pump action results after mixer pump shutdown.

   Criticality Safety Evaluation Report WHC-SD-W151-CSA-001, "CSER 96-014 Criticality Safety Of Project W-151, 241-AZ-101 Retrieval System Process Test," will evaluate the criticality safety aspects of the process test. The evaluation extends to the testing and operation of the mixer pumps and does not include the transfer of waste from the tank. The report provides justification that a nuclear criticality is extremely unlikely, if not impossible, in this tank.

6. Radiological and toxicological material release resulting from a seismic event.

Table ATT1-1. Definition of HazOp Table and Hazard Summary Table Terms.

Term	Definition
Accident	An unplanned event or sequence of events that results in undesirable consequences.
Cause	That which produces the effect or consequence of an accident.
Consequence	Effect created by an accident resulting form a hazard condition: the result or effect of a release of hazardous material (radiological or chemical) usually expressed in terms of dose and exposure.
Defense-in-Depth Controls	Subset of all remaining engineering and administrative features identified in the hazards analysis that are not specified as "credited" in the Hazards Summary Table and which have been agreed as appropriate for inclusion in the safety documentation.
Detection	Engineering or administrative requirements that are either already there or that can be introduced to discover or discern a hazard that may lead to an accident
Guide word	A simple word or phrase used to qualify or quantify the design intention and associated parameters in order to discover design deviations or departures resulting in hazards leading to accidents
Hazard	A source of danger with the potential to cause illness, injury, or death to personnel; or damage to a facility or to the environment.
Mitigating Features	Engineering or administrative requirements that prevent or reduce the consequences resulting from an accident
Node	The point or location on a process diagram at which process parameters are investigated for deviations (or departures from design intent)
Parameter	Aspects of a process that describe it physically or in terms of what is happening
Rank	Accident severity and frequency of occurrence standing
Receptor	The individual affected by an accident
Remark	Comment or observation
Risk Bin Number	Obtained from the RISK MATRIX BIN NUMBERS Table and is a function of Consequence and Frequency.
HazOp Table	A detailed listing of the hazards identified with a qualitative evaluation of the consequences
Hazards Summary Table	A summary record of the information obtained during the hazards analysis process.

Table ATT1-3. Ranking Criteria Hazards and Operability Study for Project W-151 Qualitative Accident Severity Levels.

Safety Consequence Category Designators	
Category designation	Description
S3	Potential significant radiological dose consequences or chemical exposure to the offsite receptor.
S2	Potential significant radiological dose consequences or chemical exposure to the on-site co-located worker.
S1	Potential industrial injury, radiological dose consequences or chemical exposure to the facility worker.
S0	No effect outside the facility confinement systems and no safety concerns for the facility worker, the onsite worker, or members of the general public.
Environmental Consequence Category Designators	
E3	Environmental discharges of hazardous material outside the Hanford Site Boundary or to the groundwater.
E2	Reportable environmental discharge of hazardous material within the Hanford Site boundary associated with an S2 Safety Consequence.
E1	Limited environmental discharge of hazardous material outside a facility associated with an S1 Safety Consequence.
E0	No environmental impact.

Table ATT1-4. Ranking Criteria Hazards and Operability Study For Project W-151.

Category designation	Numeric definition	Word definition
F3	$> 10^{-2}$ /year	Anticipated
F2	$> 10^{-4}$ to $\leq 10^{-2}$ /year	Unlikely
F1	$> 10^{-6}$ to $\leq 10^{-4}$ /year	Extremely Unlikely
F0	$\leq 10^{-6}$ /year	Beyond Extremely Unlikely

HAZARDS ANALYSIS SUMMARY

This page intentionally left blank.

Table 3B-1. Hazards Analysis Summary. (6 sheets)

Event category	Postulated event description	Significant causes or energy sources	Receptor	Credited prevention (attributes that lower frequency)	Event frequency		Credited mitigation (attributes that lower consequences)	Consequences		Risk bin number		Defense in depth controls
					Without prevention	With prevention		Without mitigation	With mitigation	Without prevent mitigation	With prevent mitigation	
Event 1 — Radionuclide and toxic release resulting from filter failure												
Internal event caused from within the facility	Release of radionuclides due to filter failure	Ventilation filter failure caused by:	Public	Engineered features: • Backup exhaust train Administrative features: • Tank head space monitoring during mixer pump operation • Controls for opening risers • Controlled startup of mixer pump • Work control procedure • Daily surveillance • Vent system maintenance • Waste compatibility program	F3	F2	Engineered features: • Backup exhaust system • Ventilation system condensers and heater Administrative features: • Ventilation system in operation during mixer pump use • Controlled startup of mixer pump	S2	S1	14	8	
			Co-located worker	Same as for Public			Same as for Public					
		• Vacuum break fault • Chemical reaction • Ignition of flammable gases • Plugged filter • Tank bump	Immediate worker	Same as for Public			Same as for Public					
			Potential for contamination of the environment:									

Table 3B-1. Hazards Analysis Summary. (6 sheets)

Event category	Postulated event description	Significant causes or energy sources	Receptor	Credited prevention (attributes that lower frequency)	Event frequency		Credited mitigation (attributes that lower consequences)	Consequences		Risk bin number		Defense in depth controls
					Without prevention	With prevention		Without mitigation	With mitigation	Without prevent mitigation	With prevent mitigation	
Event 2 — Radionuclide and Toxic aerosol release from tank opening												
Internal event caused from within the facility	Release of radionuclide and toxic aerosols from tank through opening in tank due to reversal of airflow (air is normally drawn into the tank then exhausted via HEPA filters)	• Wind (air) flow over open riser	Public	Engineered features: • HEPA filter differential instruments Administrative features: • Vent system maintenance • Controlled startup of mixer pump • Controls for opening risers • Tank Dome loading controls (equipment and materials) • Ventilation system surveillance • Tank head space monitoring during mixer pump operation	F3	F2	Engineered features: • Ventilation System Administrative features: • Controlled start of mixer pumps	S2	S1	14	8	
		• Chemical reaction resulting in tank pressurization • Vacuum breaker fault • Ignition of flammable gases • Plugged HEPA filters • Tank bump • Tank dome collapse due to overload	Co-located worker	Same as for Public			Same as for Public					
			Immediate worker	Same as for Public			Same as for Public					
			Potential for contamination of the environment:									

Table 3B-1. Hazards Analysis Summary. (6 sheets)

Event category	Postulated event description	Significant causes or energy sources	Receptor	Credited prevention (attributes that lower frequency)	Event frequency		Credited mitigation (attributes that lower consequences)	Consequences		Risk bin number		Defense in depth controls
					Without prevention	With prevention		Without mitigation	With mitigation	Without prevent mitigation	With prevent mitigation	
Event 3 — Radionuclides and Toxic aerosol release from breach in tank ventilation duct												
Internal event caused from within the facility	Radionuclides and toxic aerosols are released through a tank ventilation duct breach	• Seismic event during pump installation	Public	Engineered features: • Ducting designed to withstand designed based earthquake • Ducting designed to withstand high wind Administrative features: • Critical lift procedure for crane • Job controls	F1	F1	Engineered features: • None identified Administrative features: • None identified	S2	S2	9	9	
		• High wind during pump installation	Co-located worker	Same as for Public			Same as for Public					
Natural phenomena, wind, earthquake		• Impact by construction equipment or vehicle	Immediate worker	Same as for Public			Same as for Public					
External event--vehicle impact			Potential for contamination of the environment:									

Table 3B-1. Hazards Analysis Summary. (6 sheets)

Event category	Postulated event description	Significant causes or energy sources	Receptor	Credited prevention (attributes that lower frequency)	Event frequency		Credited mitigation (attributes that lower consequences)	Consequences		Risk bin number		Defense in depth controls
					Without prevention	With prevention		Without mitigation	With mitigation	Without prevent mitigation	With prevent mitigation	
Event 4 — Radionuclides and Toxic material releases from tank												
Internal event caused from within the facility	Radionuclide enter the soil through a breach in the tank containment and enter groundwater	• Excessive draw down of tank level	Public	Engineered features: • Pump strain instruments Administrative features: • Critical lifting procedure • Controlled startup of mixer pump • Operating procedures • Waste Compatibility Program • Preventive maintenance • Surveillances • Pump speed control	F2	F2	Engineered features: • Energy absorption cylinder • Secondary confinement • Screen on pump intake Administrative features: • Controlled startup of mixer pumps	S2	S1	12	B	
		• Pressure resulting from flammable gas burn	Co-located worker	Same as for Public			Same as for Public					
		• Missile from pump	Immediate worker	Same as for Public			Same as for Public					
		• Erosion ring mixer pump operation • Equipment dropped into tank	Potential for contamination of the environment:

Table 3B-1. Hazard and Operability Study - Node 1. (2 sheets)

Project: W-151, Tank 241-AZ-101 Waste Retrieval System Date: 02/13/96					Node: 1		Page: 3A-7
Node Description: Inlet to existing ventilation system. Design Intention: Provide inlet air for tank dome space ventilation system (cooling and confinement of radioactive particulates). In backflow situations, exhaust is unfiltered.							
Parameter/ Guide word	Cause	Consequence	Detection	Mitigating Features	Rank	Bin No.	Remark
Low/No Flow	Over-pressure event in tank (possibly because of a blockage to the exhaust system)	Possible equipment damage and/or loss of valve function (could lead to unfiltered release from breached filter, hydrogen buildup in tank). Unfiltered release, tank heat up.	Dome space pressure instruments and alarms Flow elements in exhaust system	Ventilation system operating while mixer pumps are on or equipment being removed	S0 F3	1	
	Breach of confinement in another location	Depends on breach size (either loss negative pressure or atmospheric release)	Event is probably linked to construction or maintenance activity which will be known (i.e., visual).	Fix the problem (portable exhauster may be needed during construction). Established control for opening risers.	S0 F3	1	
	Exhauster failure	Tank head space pressure causes filters to breach leading to unfiltered release of contaminants to atmosphere.	Flow meters in the exhaust line and dp (differential pressure) instrument and alarms dp across exhaust HEPAs zero	Backup exhaust train	S2 F3	1	
	Icing	High negative pressure in tank if the exhaust fan continues to run Inadequate dome space gas mixing resulting in flammable gas pockets	Dome space pressure instruments and alarms	Work control procedures	S0 F3	1	
	Stack collapsing during wind storm	Same as exhauster failure.	Same as exhauster failure.	Design criteria for stack (wind, seismic, SDC4.1)	S1 F1	1	
	Failure in another tank (i.e., open riser)	Same as breach of confinement (over-pressurization).	Dome space pressure instruments and alarm	Work control and procedures ventilation system operating	S1 F3	1	

Table 3B-1. Hazard and Operability Study - Node 1. (2 sheets)

Project: W-151, Tank 241-AZ-101 Waste Retrieval System Date: 02/13/96					Node: 1		Page: 3A-8
Node Description: Inlet to existing ventilation system. Design Intention: Provide inlet air for tank dome space ventilation system (cooling and confinement of radioactive particulates). In backflow situations, exhaust is unfiltered.							
Parameter/ Guide word	Cause	Consequence	Detection	Mitigating Features	Rank	Bin No.	Remark
High Flow	Vacuum break valve fault (fails open)	Unfiltered inlet	HEPA dp instruments and alarms (low dp on inlet HEPA filter)	Ventilation system operating; may need to increase tank farm ventilation flow rate.	S0 F2	1	Consider additional control for future multiple waste tank mixer pump operation.
	Ducting breach from seismic/high wind/ construction impact	Same as over-pressurization in tank.	Same as over-pressurization in tank.	Work control procedures; ventilation system operating.	S1 F2	1	
Reverse Flow	Wind or tornado	Release of radionuclides and toxic gases through open riser	Dome space pressure instruments and alarms	ventilation system operating Work controls and procedures	S1 F1	1	
More Temperature	Chemical reactions ignite flammable gases Heater faulty	Release of unfiltered radionuclides and toxic gases due to pressure and heat causing filters to fail	Dome space pressure instruments and alarms	Waste compatibility program	S2 F1	1	
Less Temperature	See icing under No Low	Release of radionuclides and toxic gases	Dome space pressure instruments and alarms	Daily surveillances visual	S0 F3	1	

Table 3B-1. Hazard and Operability Study - Node 2. (2 sheets)

Project: W-151, Tank 241-AZ-101 Waste Retrieval System Date: 02/13/96				Node: 2			Page: 3A-9
Node Description: Inlet to new ventilation system.							
Design Intention: Provide inlet air for tank dome space ventilation system (cooling and confinement of radioactive particulates) and provide filtered exhaust in backflow situations (W-030 upgrade).							
Parameter/ Guide word	Cause	Consequence	Detection	Mitigating Features	Rank	Bin No.	Remark
Low/No Flow	Over-pressure event in tank because of a faulty valve to the exhaust system.	Possible equipment damage and/or valve function leads to unfiltered release when valve remains closed allowing pressure buildup, then valve opens allowing pressure to fail filters causing an unfiltered release.	Dome space instruments and alarms Flow Alarm in inlet system	Inlet air filters and Condensers	S1 F3	1	
	Inlet HEPA plugging (water, condensation, debris)	High negative pressure in tank if the exhaust fan continues to run	Visual inspection of filter screens on inlet; HEPA dp indicators and alarms; dome space instruments and alarms	Daily surveillance and maintenance program	S0 F3	1	Differential pressure (dp)
		Inadequate dome space gas mixing resulting in flammable gas pockets	HEPA dp indicators and alarms; dome space pressure instruments and alarms	Daily surveillance and maintenance program	S0 F3	1	
	Breach of confinement in another location	Depends on breach size (either less negative pressure or atmospheric release)	Event is probably linked to construction or maintenance activity which will be known (i.e., visual).	Repair the problem (portable exhauster may be needed during construction). Instituted controls for opening risers.	S0 F3	1	
	Exhauster failure	Over-pressure in the tank causing filter failure and potential atmospheric release	Flow meter in the inlet; pressure dome space instruments and alarms; HEPA dp instruments and alarms	Backup exhaust train; daily surveillance and maintenance program	S1 F3	1	
	Icing due to heater failure	Same as inlet HEPA plugging	visual inspection of filter screens on inlet; dp instruments across inlet HEPAs and alarms	System bypass available (vacuum break); daily surveillance	S0 F3	1	
	Stack collapsing during wind storm	Same as exhauster failure	Same as exhauster failure	Design criteria for stack (wind, seismic, SDC 4.1)	S1 F1	1	
	Damage to inlet due to dropped equipment	Same as icing and HEPA plugging.	Same as icing and HEPA plugging.	Heavy equipment lifting/movement is considered a critical lift and is treated on a case by case basis (NUREG 612); procedures.	S0 F3	3	Only inlet station is above ground.

Table 3B-1. Hazard and Operability Study - Node 2. (2 sheets)

Project: W-151, Tank 241-AZ-101 Waste Retrieval System Date: 02/13/96	Node: 2	Page: 3A-10

Node Description: Inlet to new ventilation system.

Design Intention: Provide inlet air for tank dome space ventilation system (cooling and confinement of radioactive particulates) and provide filtered exhaust in backflow situations (W-030 upgrade).

Parameter/ Guide word	Cause	Consequence	Detection	Mitigating Features	Rank	Bin No.	Remark
Low/No Flow (Continued)	Closed valve in inlet line	Same as inlet HEPA plugging	Same as inlet HEPA plugging.	Daily surveillance and PM	S0 F3	1	preventative maintenance (PM)
	Failure in another tank (i.e., open riser)	Same as breach of confinement and over-pressurizing action.	Same as breach of confinement and over-pressurizing action.	repair problem; work controls; portable exhauster	S1 F3	1	
High Flow	Vacuum break valve fault (fails open)	Unfiltered inlet	HEPA dp instruments and alarms (low dp on inlet HEPA filter)	Ventilation system operating; may need to increase tank farm ventilation flow rate	S0 F2	1	Consider additional control for future multiple waste tank mixer pump operation
	Ducting breach from seismic/high wind/ construction impact	Same as over-pressurization in tank.	Same as over-pressurization in tank	Work control procedures; ventilation system operating	S1 F2	1	
	Inlet HEPA failure	No potential release unless negative tank pressure lost (see reverse flow).	HEPA dp instruments and alarms; dome space pressure instruments and alarms	Maintenance, repair, and daily surveillance	S1 F3	2	
Reverse Flow	Natural draft (wind blowing across inlet with open riser)	Release of radionuclides and toxic gases	Dome space pressure instruments and alarms; inlet flow instruments and alarms	HEPA filters on inlet will filter reverse flow.	S1 F1	2	
	Ignition of flammable gases in the dome space melt inlet HEPAs	Release of unfiltered radionuclides and toxic gases due to heat and pressure which causes filter failure	HEPA dp instruments and alarms; stack flow instruments and alarms	work controls (mixer pump controlled startup)	S2 F2	1	Consider monitoring of gas concentration in tank head space prior to and during mixer pump operation.
More Temperature	Ignition of flammable gases in the dome space melt inlet HEPAs	Release of unfiltered radionuclides and toxic gases due to heat and pressure which causes filter failure	HEPA dp instruments and alarms; stack flow instruments and alarms	work controls (mixer pump controlled startup)	S2 F2	1	Consider monitoring of gas concentration in tank head space prior to and during mixer pump operation.
	Heat from chemical reactions ignite flammable gases. Heater fault ignites flammable gases	Release of radionuclides and toxic gases	HEPA dp instruments and alarms; stack flow instruments and alarms	Waste compatibility program; heater PM; daily surveillance; work controls	S2 F1	1	
Less Temperature	See plugging and icing under "No Flow."	Same as plugging	Visual and dp instruments and alarms	Heater PM and daily surveillance	S0 F3	1	

Table 3B-1. Hazard and Operability Study - Node 3. (5 sheets)

Project: W-151, Tank 241-AZ-101 Waste Retrieval System Date: 02/14/96					Node: 3		Page: 3A-11
Node Description: Waste Tank Design Intention: Encompass tank liquid containment and vapor head space confinement.							
Parameter/ Guide word	**Cause**	**Consequence**	**Detection**	**Mitigating Features**	**Rank**	**BIN NO.**	**Remark**
High Level	Mixer pump seal failure (Bearing water drains to tank faster than normal.)	Increase in tank level	Tank level instruments and alarms	Administrative control on addition of water; daily surveillances; design features (disaster bushings, maximum flow orifice)	S0 F3	See remarks	Not binned because there is no release.
	Loss of spray water control during equipment removal from tank via riser	Increase in tank level	Tank level instruments and alarms	Limited volume (4,500 gal tanker truck)	S0 F3	Same as above.	Same as above.
	Mis-transfer due to mis-routing	Increase in tank level	Tank level instruments and alarms	Operating procedures	S0 F3	Same as above.	Same as Above.
	External flooding	release of tank contents to environment	Visual		S3 F0	Same as above.	External flooding is considered incredible.
	Mixer pump insertion	displacement of tank waste leading to increase in tank level (very small)	Level instruments and alarms	Level will be known prior to pump insertion. Tank surveillance requirements	S0 F3	Same as above.	Mixer pump displacement will be range of 500 gallons.
Low Level	Breach of containment due to equipment drop during installation or removal	Leakage of tank waste to soil column	Tank level instruments and alarms; Primary tank leak detection system (Annulus conductivity probes and continuous air monitor)	Critical lift work procedures and job controls Energy absorption cylinder Secondary containment (Annulus)	S3 F1	4	
	Missile ejection by mixer pump operation punctures primary tank	Leakage of tank waste to annulus	Primary tank leak detection system	Work control (controlled startup); Screened mixer pump intake	S3 F1	4	
	Breach of containment due to tank erosion caused by mixer pump action	Leakage of tank waste to annulus	Primary tank leak detection system	Work control (controlled startup); Screened mixer pump intake			
	Excessive draw down due to inadvertent startup of existing transfer pump	Violation of Low Level Limit (tank structural damage)					

Table 3B-1. Hazard and Operability Study - Node 3. (5 sheets)

Project: W-151, Tank 241-AZ-101 Waste Retrieval System Date: 02/14/96				Node: 3			Page: 3A-12
Node Description: Waste Tank Design Intention: Encompass tank liquid containment and vapor head space confinement.							
Parameter/ Guide word	**Cause**	**Consequence**	**Detection**	**Mitigating Features**	**Rank**	**BIN NO.**	**Remark**
Low Negative Pressure	Energetic explosive events (same as reverse flow and ignition of flammable gas events)	Potential back flow through the inlet station (new) or pits (existing)	Dome space pressure and temperature instruments and alarms	Waste compatibility program Tank head space monitoring during mixer pump operations Work controls	S2 F2	1	
		Backflow of liquid waste to pits resulting in exposure to occupational workers when subsequent work is done in the pits	Pit leak detection instruments and alarms		S2 F2	1	
		Damage to HEPA filters resulting in unfiltered release	HEPA dp instruments and alarms		S2 F2	1	
		Possible impact to tank structure resulting in loss of containment and release to the environment	Dome space pressure instruments and alarms		S2 F2	4	
	Inadequate exhauster operation	Loss of confinement (potential unfiltered release)	Dome space pressure instruments and alarms, HEPA dp instruments and alarms	Proper system balance and maintenance, dp across filter banks, alarms, and shutdown ventilation system Redundant ventilation system	S1 F3	1	Consider backup/standby portable exhauster during operations.
	High volume input (Same as for High Flow in Node 2 vacuum break valve fault.)	Possible wetting of filters if continued long enough	Same as for High Flow in Node 2.	Control of transfer rate; HEPA dp would be an indication of success. Same as for High Flow in Node 2.	S0 F2	1	
	Events at tank or other tanks (opening risers)	Same as inadequate exhauster operation.	Same as inadequate exhauster operation.	Same as inadequate exhauster operation.	S1 F3	1	
	Excess gas release from mixer pump operation	Potential for greater concentrations of toxic substances, flammable gases and radionuclide particles resulting in over-pressure that fails filter causing an unfiltered release.	Stack monitoring instruments and alarms	Controlled startup of mixer pumps	S1 F2	1	
	Mixer pump causes unexpected chemical reaction	Same as for "chemical reactions ignite flammable gases" in Node 2.	Same as for "chemical reactions ignite flammable gases" in Node 2.	Same as for "chemical reactions ignite flammable gases in Node 2.	S2 F1	1	
High Negative Pressure	Same as Node 1 No/Low Flow tank over-pressure event.	Same as Node 1 No/Low Flow tank over-pressure event.	Same as Node 1 No/Low Flow tank over-pressure event.		S0 F3	1	

Table 3B-1. Hazard and Operability Study - Node 3. (5 sheets)

Project: W-151, Tank 241-AZ-101 Waste Retrieval System Date: 02/14/96				Node: 3			Page: 3A-13
Node Description: Waste Tank Design Intention: Encompass tank liquid containment and vapor head space confinement.							
Parameter/ Guide word	**Cause**	**Consequence**	**Detection**	**Mitigating Features**	**Rank**	**BIN NO.**	**Remark**
Vapor Space Composition Change	Mixer pump operation	Increased aerosol loading from heat or splashing results in over-pressurizing filters and an unfiltered release.	HEPA filter dp; monitoring of dome space activity	Controlled startup of mixer pumps	S1 F2	1	
		Potential higher activity in tank dome space	HEPA filter dp and stack monitor instruments and alarms Monitoring of ventilation exhaust during mixer pump operation Portable humidity monitor available	Controlled startup of mixer pumps	S1 F3	1	
		Potential higher concentration of flammable/toxic gases and heat resulting in over-pressure causing filter failure and an unfiltered release	Gas samplers and activity monitors in the exhaust stack Monitoring of dome space concentrations during mixer pump operation	Controlled startup of mixer pumps; operation of ventilation system	S1 F3	1	
	Increase in vapor space as tank level is drawn down.	Stratification of the vapor resulting in a possible buildup of gas concentration due to decreased air sweep ability	Tank level indication	Consider increased ventilation system flow if conditions warrant it.	S0 F1	1	Assumed gas concentration as below 25% of LFL (dropped from OSD-0030 Appendix B).
More Temperature	Tank material rollover	Potential higher concentration of flammable/toxic gases; increased release of toxic gases via the exhaust system	Gas samplers and stack monitor instruments and alarms; vapor space flammable gas monitoring; dome space pressure instruments and alarms	Operation of ventilation system; controlled startup of mixers	S1 F0	1	With the current material composition in this tank rollover is not considered credible. This tank is not on watch list.
		Increased aerosol loading	Gas samplers and activity monitors in the exhaust stack; vapor space flammable gas monitoring; dome space pressure instruments and alarms	Operations of ventilation system; controlled startup of mixers	S1 F0	1	

Table 3B-1. Hazard and Operability Study - Node 3. (5 sheets)

Project: W-151, Tank 241-AZ-101 Waste Retrieval System Date: 02/14/96 | Node: 3 | Page: 3A-14

Node Description: Waste Tank

Design Intention: Encompass tank liquid containment and vapor head space confinement.

Parameter/ Guide word	Cause	Consequence	Detection	Mitigating Features	Rank	BIN NO.	Remark
More Temperature (Continued)	Tank material rollover (Continued)	Higher activity in dome space Gas samplers and activity monitors in the exhaust stack; vapor space flammable gas monitoring; dome space pressure instruments and alarms; operations of ventilation system; controlled startup of mixers S1 F01; excessive HEPA filter loading/airborne material/high activity from dome space failure of HEPA leading to unfiltered release					
			HEPA dp instruments and alarms; stack flow instrument and alarms	HEPA filter performance monitoring; standby exhaust system	S1 F0	1	
	Explosion event	Release of unfiltered radionuclides and toxic gases due to heat and pressure which causes filter failure	HEPA dp instruments and alarms; stack flow instruments and alarms	work controls (mixer pump controlled startup)	S2 F2	1	
	Fire event (deflagration)	See Node 1 More Temperature.			S2 F2	1	
	Increased temperature of the waste due to mixer pump heat input	See tank material rollover.			S1 F3	1	
	Extended low air flow in tank head space	Refer to exhaust/ inlet nodes (Node 4 Low Flow and Node 3 Low Negative Pressure).			SO F3	1	
	Loss of cooling/heat exchanger failure	See Nodes 4 and 5 Less Temperature.				1	
	Chemical reaction	Over-pressurization potential for fire and explosion	Dome space pressure instruments and alarms	Waste compatibility program	S2 F1	1	
		Over temperature of the tank structure (primary and concrete) resulting in tank breach and possible release to soil.	Thermocouples in waste and in tank wall, floor, exhaust stream	Work controls, controlled startup of mixer pumps; waste compatibility program	S2 F2	4	
	Redistribution of layers at the start of mixing	Potential release of flammable and toxic gases and radionuclides and steam causing filter failure and unfiltered release	Dome space pressure instruments and alarms Temp thermocouple indications; gas monitoring	Controlled startups; gas monitoring during mixer pump operation	S1 F3	1	

Table 3B-1. Hazard and Operability Study - Node 3. (5 sheets)

Project: W-151, Tank 241-AZ-101 Waste Retrieval System Date: 02/14/96				Node: 3		Page: 3A-15
Node Description: Waste Tank Design Intention: Encompass tank liquid containment and vapor head space confinement.						
Parameter/ Guide word	**Cause**	**Consequence**	**Detection**	**Mitigating Features**	**Rank**	**BIN NO.**	**Remark**
Composition Change	What if one pump fails during operation?	Would not meet 90% criteria; insufficient mobilization of tank waste	Pump instruments thermocouples, gamma probes	Stop operations (option; install another pump).	S0 F3	See remarks	Not binned because there is no release.
More Viscosity	Excess evaporation	May not be able to mix due to increased viscosity	Increased load on pump will be noted if viscosity increases. Tank level instruments and alarms; Tank level surveillance	Water addition (e.g., condensate recycle)	S0 F1	SAME AS ABOVE.	Significant tank level decreases due to evaporation take three months. Not binned because there is no release.
Criticality	Rearrangement of material due to mixer pump action (and/or subsequent mixer shut down)	Release of steam and gases, aerosols, increased temp., high activity	Tank temperature and dome space pressure instruments and alarms; ventilation system instruments and alarms	Criticality specifications;	S2 F1	5	Critical Safety Report WHC-SD-W151-CSA-001, "CSER 96-014 Criticality Safety of Project W-151, 241-AZ-101 Retrieval, System Process Test," will evaluate the criticality safety aspects of the process test. The evaluation extends to the testing and operation of the mixer pumps only and does not include the transfer of waste from the tank. The report provides justification that a nuclear criticality is extremely unlikely, if not impossible, in this tank.
More Dome Loading	Increased load from newly installed equipment; unauthorized heavy equipment; dropped load; ash, snow and soil loading	Dome collapse; loss of confinement	Visual survey; dome space pressure instruments; stack flow instruments and alarms	Administrative controls (dome load control document)	S2 F2	4	

Table 3B-1. Hazard and Operability Study - Node 4. (3 sheets)

Project: W-151, Tank 241-AZ-101 Waste Retrieval System Date: 02/14/96 Node: 4 Page: 3A-16

Node Description: Old exhaust ventilation system.

Design Intention: Provide a flow path for the ventilation of the tank and flow of contaminated air to the filters.

Parameter/ Guide word	Cause	Consequence	Detection	Mitigating Features	Rank	Bin No.	Remark
No/Low Flow	Blocked valve or damper	Flammable gas buildup in vapor space. Potential for flammable gas burn causing over pressurization of filters leading to unfiltered release. Potential for pressure release failing filters when valve opened resulting to an unfiltered release	Stack flow instruments and alarms	Administrative control of valve lineup/system balancing	S2 F3	1	
			damper position indication	Standby exhaust system; work controls (ventilation system operating during mixer pump operation)	S2 F3	1	
		Diminished cooling in tank leading to potential tank bump which causes over pressurization of filters leading to an unfiltered release.	Exhaust system instruments and alarms	Standby exhaust system; work controls (ventilation system operating during mixer pump EYEPIECE)	S2 F3	1	
		Decreased negative pressure in dome (i.e., loss of in leakage) leading to unfiltered unmonitored release of aerosols or particulate	Dome space pressure instruments and alarms	Standby exhaust system; work controls (ventilation system operating during mixer pump EYEPIECE)	S2 F3	1	
	Loss of power	Same as for blocked valve.	Same as for blocked valve.	PM (Preventive Maintenance); standby power	S2 F3	1	Preventative Maintenance (PM)
	Seismic event	Same as for blocked valve.	Same as for blocked valve.	Design features	S2 F1	1	
	Fan failure	Same as blocked valve.	Same as for blocked valve.	PM; daily surveillances	S2 F3	1	
No/Low Flow (Continued)	Stack blockage	Flammable gases build up and ignite in tank. The burn results in pressure build up which cannot vent due to plugged stack. The tank breaches due to over-pressure releasing contents to soil column. Potential for pressure to dislodge plug. Radionuclides and toxic substances released to atmosphere. Pressurized condition could occur even without flammable gas burn.	Same as for blocked valve	PM; daily surveillances	S3 F1	4	Blockage envisioned to occur from a burst HEPA filter

Table 3B-1. Hazard and Operability Study - Node 4. (3 sheets)

Project: W-151, Tank 241-AZ-101 Waste Retrieval System	Date: 02/14/96	Node: 4		Page: 3A-17

Node Description: Old exhaust ventilation system.

Design Intention: Provide a flow path for the ventilation of the tank and flow of contaminated air to the filters.

Parameter/ Guide word	Cause	Consequence	Detection	Mitigating Features	Rank	Bin No.	Remark
	Exhaust HEPA plugged by aerosols during mixing	HEPA filter failure due to high dp leading to unfiltered release of accumulated material	Flow indication on exhaust stack; HEPA filter dp instrumentation; dome space pressure instruments and alarms	HEPA monitoring and testing; backup HEPA filters in parallel train; standby exhaust system	S2 F2	1	
		Unacceptable concentrations of flammable gases in the dome space due to inadequate air removal	Same as HEPA failure flammable gas monitoring.	Same as HEPA failure.	S2 F2	1	
More Flow	Ductwork breach from external phenomena (seismic event, vehicle impact, tornado)	Unfiltered unmonitored release to the environment	Visual; exhaust stack flow instruments and alarms	Administrative controls; design of exhaust duct to withstand seismic event; low frequency of other events	S2 F1 Seismic S2 F1 Vehicle S2 F0 Tornado	3 3 3	

Table 3B-1. Hazard and Operability Study - Node 4. (3 sheets)

Project: W-151, Tank 241-AZ-101 Waste Retrieval System	Date: 02/14/96	Node: 4		Page: 3A-18

Node Description: Old exhaust ventilation system.

Design Intention: Provide a flow path for the ventilation of the tank and flow of contaminated air to the filters.

Parameter/ Guide word	Cause	Consequence	Detection	Mitigating Features	Rank	Bin No.	Remark
More Flow (Continued)	Open riser	Same as Node 3 Low Negative Pressure.	Same as Node 3 Low Negative Pressure.		S2 F3	1	
Reverse Flow	Pressurization in interconnected tank that temporarily exceeds the exhaust system negative pressure	Same as Low/No Flow.	dome space pressure instruments and alarms	Work controls	S2 F1	1	
		mixing of gas streams forming undesirable products	dome space pressure instruments and alarms	Work controls	S2 F1	1	
More Temperature	See Node 3 More Temperature.						
Less Temperature	Not an issue for this node.						
More Moisture	See Node 3 Vapor Space Composition Change.						

Table 3B-1. Hazard and Operability Study - Node 5. (3 sheets)

Project: W-151, Tank 241-AZ-101 Waste Retrieval System Date: 02/14/96				Node: 5			Page: 3A-19
Node Description: New exhaust ventilation system Design Intention: Provide a flow path for the ventilation of the tank and flow of contaminated air to the filters.							
Parameter/ Guide word	**Cause**	**Consequence**	**Detection**	**Mitigating Features**	**Rank**	**Bin No.**	**Remark**
No/Low Flow	Blocked valve or damper	Flammable or toxic gas buildup in vapor space. Potential for flammable gas burn if ignited causing over pressurization of filter and failure leading to an unfiltered release.	Flow instruments and alarms; damper position indication	Procedural control of valve and system; redundant exhaust system	S2 F3	1	
		Diminished cooling in tank leading to potential tank bump (steam release) which causes over pressurization of filters and failure leading to an unfiltered release.	Exhaust system instruments and alarms	Procedural control of valve and system; redundant exhaust system	S2 F3	1	
		Decreased negative pressure in dome leading to unfiltered unmonitored release of aerosols or particulate	Dome space pressure instruments and alarms	Procedural control of valve and system; redundant exhaust system	S2 F3	1	
	Loss of power	Same as for blocked valve.	Same as for blocked valve.	PM (Preventive Maintenance); back-up power	S2 F3	1	Preventative maintenance (PM)
	Seismic event	Same as for blocked valve.	Same as for blocked valve.	Design features	S2 F1	1	
	Fan failure	Same as for blocked valve.	Same as for blocked valve.	PM	S2 F3	1	
	Stack blockage	Same as for blocked valve.	Same as for blocked valve.	PM, daily surveillances	S2 F1	1	Blockage envisioned to occur from burst HEPA filter.

Table 3B-1. Hazard and Operability Study - Node 5. (3 sheets)

Project: W-151, Tank 241-AZ-101 Waste Retrieval System Date: 02/14/96	Node: 5	Page: 3A-20
Node Description: New exhaust ventilation system Design Intention: Provide a flow path for the ventilation of the tank and flow of contaminated air to the filters.		

Parameter/ Guide word	Cause	Consequence	Detection	Mitigating Features	Rank	Bin No.	Remark
No/Low Flow (Continued)	Exhaust HEPA plugged by aerosols during mixing	HEPA filter failure due to high dp leading to unfiltered release of accumulated material	Stack flow instruments and alarms; HEPA filter dp instruments and alarms; dome pressure instruments and alarms	HEPA Monitoring and testing; backup HEPA filters in parallel train	S2 F2	1	
		Concentrations of flammable gases in the dome space exceed limit due to inadequate air removal. Ignition results in pressurization which causes filter failure and an unfiltered release.	Same as HEPA failure; flammable gas monitoring during mixer pump.	Same as HEPA failure; plus standby exhaust system; controlled start of mixer pumps.	S2 F2	1	
More Flow	Improperly balanced system	Increased negative pressure; breach HEPAs and lead to unfiltered release	Flow instruments and alarms	Control system/monitoring Redundant exhaust system	S0 F3	1	
	Overspeed on fan	Breach HEPAs and lead to unfiltered release	dp on HEPAs, stack monitoring, instruments and alarms	Redundant fan; preventive maintenance; operating procedures	S1 F3	1	
	Ductwork breach from external phenomena (seismic event, excavation)	Unfiltered, unmonitored release (tank pressurization)	Visual; stack flow instruments and alarms	Operational controls; design of exhaust duct to withstand seismic event	S2 F1 seismic S2 F2 excavation.	1 1	(breach between tanks and HEPAs)

Table 3B-1. Hazard and Operability Study - Node 5. (3 sheets)

Project: W-151, Tank 241-AZ-101 Waste Retrieval System Date: 02/14/96							Node: 5	Page: 3A-21
Node Description: New exhaust ventilation system Design Intention: Provide a flow path for the ventilation of the tank and flow of contaminated air to the filters.								
Parameter/ Guide word	Cause	Consequence	Detection	Mitigating Features	Rank	Bin No.	Remark	
More Flow (Continued)	Open risers (harder for system to maintain negative pressure)	Same as for Node 3 Low Negative Pressure.	Same as Node 3 Low Negative Pressure.	Work controls	S1 F3	2		
Reverse Flow	Pressurization in interconnected tank that temporarily exceeds the exhaust system negative pressure	Same as for No/Low Flow, breach HEPAs.	Dome space pressure instruments and alarms in tank dome and in interconnected tank	Controlled startup of mixer pump	S1 F1	1	Consider backflow preventer in tank farm ventilation system.	
More Temperature	See Node 3.							
Less Temperature	Heater shut down	Excessive moisture buildup in filters resulting in failure and potential unfiltered release	HEPA dp instruments and alarms across filters; flow instruments and alarms	Redundant exhaust trains	S1 F3	1		
More Moisture	Same as above. Also, see Node 3 Vapor Space Composition Change					1		

Table 3B-1. Hazard and Operability Study - Node 6. (2 sheets)

Project: W-151, Tank 241-AZ-101 Waste Retrieval System Date: 02/15/96				Node: 6			Page: 3A-22
Node Description: Mixing pumps. Design Intention: Mobilize Sludge.							
Parameter/ Guide word	Cause	Consequence	Detection	Mitigating Features	Rank	Bin No.	Remark
Low Flow	Loss of power and/or motor/VFD (Variable Frequency Drive)	Lack of mixing	Strain gauges; pump instruments (current, rpm); gamma probes	Design features, work controls, PM	S0 F3	Not binned since release.	Variable frequency drive (VFD) Preventative maintenance (PM)
		Potential failure of mission	Same as lack of mixing.	Design features, work controls, PM	S0 F3	See remarks.	Not binned because there is no release.
		Pressurization of tank, if power off long enough, results in filter failure and unfiltered release.	Same as lack of mixing.		S1 F3	1	
	Plugging of screen or pump intake	Catastrophic failure of pump (cavitation)	Pump instruments (current, rpm)	Design features, bowl flush capability	S0 F3	See remarks.	Not binned because there is no release.
	Mechanical failures of pump (catastrophic)	Potential damage of other equipment (instruments, tank, etc.)	Same as lack of mixing.	PM	S1 F3	Same as above.	Not binned because there is no release.
		Potential failure of mission	Same as lack of mixing.	PM	S0 F3	Same as above.	Not binned because there is no release.
		Missile from pump penetrates primary tank	Same as lack of mixing.	Design features, work controls, PM	S1 F3	Same as above.	Not binned because there is no release.
	Seismic event (causing deformation or failure of pump shaft)	Catastrophic failure of pump	Perceptions (e.g., movement of ground visual); pump instruments		S0 F1	6	Tank itself may be damaged in seismic event.

Table 3B-1. Hazard and Operability Study - Node 6. (2 sheets)

Project: W-151, Tank 241-AZ-101 Waste Retrieval System Date: 02/15/96				Node: 6		Page: 3A-23
Node Description: Mixing pumps. Design Intention: Mobilize Sludge.						
Parameter/ Guide word	Cause	Consequence	Detection	Mitigating Features	Rank	Bin No.	Remark
Low Flow (Continued)	Characteristics of the nonconnective layer leading to pump failure or degraded operation	Catastrophic failure of pump	Pump instruments (current, rpm)	Design features	S0 F2	See remarks.	Not binned because there is no release.
	Foreign object in flow stream gets past flow screen	See mechanical failure and/or plugging.		Design features (i.e., screen will stop items which will get stuck in impeller); work controls (controlled startup)	S0 F3	See remarks.	Not binned because there is no release.
High flow	Pump overspeed due to viscosity change	Tank erosion	Strain gages, pump instruments	Control pump speed; shut pump	S0 F2	4	
	Variable Frequency Drive failure (locked in overspeed)	Tank erosion	Strain gages, pump instruments	Shut down pump	S0 F3	4	

Table 3B-1. Hazard and Operability Study - Node 7. (2 sheets)

Project: W-151, Tank 241-AZ-101 Waste Retrieval System Date: 05/15/96					Node: 7		Page: 3A-24
Node Description: Equipment installation and removal. Design Intention: Worker access to tank during equipment installation and removal; open risers to install and remove equipment.							
Parameter/ Guide word	Cause	Consequence	Detection	Mitigating Features	Rank	Bin No.	Remark
High Exposure	Removal of contaminated equipment	Personnel exposure to direct radiation	Dosimetry	Administrative and work controls on installation/ removal activities	S1 F3	See remarks.	Not binned; see section of test discussing work safety.
		Personnel contamination by direct contact	HPT (Health Physics Technician) survey	Health physics controls; decontamination showers/eyewash available	S1 F3	Same as above.	Same as above.
		Environmental contamination	HPT survey soil samples	Plastic sheeting work controls	S1 F3	Same as above.	Same as above.
	Spill from removal of contaminated components	Environmental contamination	HPT survey soil samples	Plastic sheeting work controls	S1 F3	See as above.	Same as above.
		Personnel exposure to airborne radioactive material via re-suspension	HPT survey	Temporary confinement such as greenhouse, wrapping, flexible receiver for equipment removal	S1 F3	Same as above.	Same as above.
	Overflow of waste from tank	See remarks			S2 F0		Not possible to overflow tank because the only additions for this project are with spray water supplied from a 4500 gallon tank truck.
	Reversal of air flow from tank to atmosphere through riser during installation or removal	Personnel exposure to airborne contaminants (toxic gases and radionuclides)	HPT monitoring; dome space pressure and exhaust flow instruments and alarms	Ventilation system operating; work controls	S1 F3	2	

Table 3B-1. Hazard and Operability Study - Node 7. (2 sheets)

Project: W-151, Tank 241-AZ-101 Waste Retrieval System Date: 05/15/96					Node: 7		Page: 3A-25
Node Description: Equipment installation and removal. Design Intention: Worker access to tank during equipment installation and removal; open risers to install and remove equipment.							
Parameter/ Guide word	Cause	Consequence	Detection	Mitigating Features	Rank	Bin No.	Remark
High Pressure Leak	Hose fault	Occupational worker injury	Visual High pressure spray pump instruments	Design features; work controls; distance	S1 F3	See remarks	Requires close proximity to point of discharge. Not binned; see section of text discussing worker safety.
	Pump Fault (catastrophic)	Same as hose fault.	Visual High pressure spray pump instruments	Design Features; work controls; distance	S2 F3	See remarks.	Not binned; see section of text discussing worker safety.
	Relief Valve fault	Same as hose fault.	Visual High pressure spray pump instruments	Design Features; work controls; distance	S2 F3	Same as above.	Same as above.
	Variable Frequency Drive fault (i.e., pump overspeed)	Same as hose fault.	Visual High pressure spray pump instruments	Design Features; work controls; distance	S2 F3	Same as above.	Same as above.
