This ECN updates the TWRS Basis for Interim Operation (BIO),HNF-SD-WM-BIO-001 as Revision 1 based on activities performed to review and update TWRS Authorization Basis per U.S. Department of Energy Order 5480.23. All USQ Evaluations performed since the initial release of the BIO were reviewed and appropriate changes were made to the BIO. Changes made to the BIO were evaluated in the USQ Evaluation TF-98-0896, "TWRS Authorization Basis Annual Update," Rev. 1. Please refer to the USQ Evaluation TF-98-0896 for details.

In addition to the changes made to the BIO based on the annual review discussed above, the following negative USQ Evaluations and RL directions were also incorporated in the Revision 1 of the BIO. (Please refer to the ECN Continuation Sheet [Page 3] for details):

1. USQ Evaluation TF-98-0977, "TWRS Authorization Basis Changes For Cribs," Rev. 0
2. USQ Evaluation TF-98-0224. "Project W320 SAR & Process Control Thermal Analyses," Rev. 0
3. 98-TWR-025, "Contract No. DE-AC06-96RL13200 - Addendum To Safety Evaluation Report (SER) For Project W-320, Tank 241-C-106 Sluicing" (Letter from J.D. Wagoner, RL, to R.D. Hanson, FDH), dated 9/25/98.

This sheet identifies changes made to the BIO based on the negative USQ Screenings/Determination and RL directions listed below. For changes made to the BIO as a result of the annual review, please refer to the USQ Evaluation TF-98-0896:

USQ Screening/Determinations or RL Direction	Summary of Change
USQ Evaluation TF-98-0977, *TWRS Authorization Basis changes for Cribs*, Rev. 0	This USQ Evaluation addresses the cribs in the 200 East and 200 West Areas whose ownership is being transferred to TWRS from the Environmental Restoration (ER) Program. As a result of this change, the following sections in the BIO were updated: Section B2.4.8.1, "Cribs." Figure B2-35, "200 East and 200 West Area Cribs, Ditches and Ponds." Table B2-20, "Cribs, Ditches, and Ponds Currently Owned or Operated By Tank Waste Remediation System."
USQ Evaluation TF-98-0224, *Project W320 SAR & Process Control Thermal Analyses*, Rev. 0	This USQ Evaluation evaluated the release of the updated process control thermal analysis for Project W-320. As a result of this evaluation, the following sections of the BIO Addendum 1, *Tank 241-C-106 Sluicing Safety Analysis*, were updated: Chapter 2.0, "Facility Description": Updated references HNF-SD-W320-ER-004, *Project W-320 SAR and Process Control Thermal Analysism*, 1998, Revision 1, in place of WHC-SD-WM-ER-588, *Tank 241-C-106 Sluicing Evaluation*, 1996, Revision 1. Chapter 3.0, "Accident Analysis": Updated references HNF-SD-W320-ER-004, *Project W-320 SAR and Process Control Thermal Analysis*, 1998, Revision 1, in place of WHC-SD-WM-ER-588, *Tank 241-C-106 Sluicing Evaluation*, 1996, Revision 1, in section 3.4.2.11 and 3.4.2.12. In addition, the total heat load in Tank 241-AY-102 after sluicing was increased by 12,000 Btu/hr based on the revised thermal analysis.

98-TWR-025, *Contract No. DE-AC06-96RL13200 - Addendum To Safety Evaluation Report (SER) For Project W-320, Tank 241-C-Sluicing* (Letter from J.D. Wagoner, RL, to R.D. Hanson, FDH), dated 9/25/98.	This letter is an addendum to the Project W-320 Safety Evaluation Report (SER). The letter provides closure of three prestart findings from the U.S. Department of Energy, Richland Operations Office (RL) Operational Readiness Review for Tank 241-C-106 Sluicing (Project W-320). Per SER, the accident analysis consequences of a liner breach due to steam between the steel liner and concrete shell in Tank 241-C-106 has been revised in BIO Addendum 1, *Tank 241-C-106 Sluicing Safety Analysis*. Specifically, the following sections in Addendum 1 were revised: Table 3.4.2.12-1, "Consequences of a Liner Breach Assuming No Controls": Updated radiological and toxicological consequences per SER. Section 3.5, "References": included SER in the reference list.

Tank Waste Remediation System Basis for Interim Operation

EXECUTIVE SUMMARY

This page intentionally left blank.

EXECUTIVE SUMMARY

This Basis for Interim Operation establishes an improved Authorization Basis for Tank Waste Remediation System facilities and operations required for the storage management of high-level radioactive waste (current and future tank waste). This Basis for Interim Operation documents the basis for the conclusion that authorized Tank Waste Remediation System facility operations can be conducted safely until approval of the Final Safety Analysis Report and associated Technical Safety Requirement document complying with the requirements of DOE 5480.23, *Nuclear Safety Analysis Reports*, and DOE 5480.22, *Technical Safety Requirements*.

This Basis for Interim Operation provides a cohesive, integrated, and systematic interim safety basis. Implementation of the controls established by this Basis for Interim Operation enhances the safe operation of Tank Waste Remediation System facilities. This Basis for Interim Operation also provides a sound basis for conducting effective Unreviewed Safety Question evaluations to ensure continued safe operations.

SCOPE

The Basis for Interim Operation and associated Technical Safety Requirement document applies to the following Tank Waste Remediation System equipment and facilities:

- 177 underground high-level waste tanks including single-shell (149) and double-shell (28) tanks in the 200 East and 200 West Areas
- Catch tanks
- Double-contained receiver tanks
- Waste transfer system
- 2727-W Sodium Storage Facility
- 204-AR Waste Unloading Facility
- 244-AR Vault
- Miscellaneous inactive storage facilities
- 209-E Mixed Waste less than 90-Day *Resource Conservation and Recovery Act of 1976* waste storage pads
- Cribs, ditches, and ponds
- Light duty utility arm
- Push mode sampling
- Cone Penetrometer

- 213-W Dry Waste Compactor Facility
- Vertical storage units within the tank farm boundaries
- Rotary Mode Core Sampling (Flammable Gas Hazards).

Other Tank Waste Remediation System facilities, activities, and projects (e.g., 242-S and 242-T Evaporators; rotary-mode core sampling [excluding flammable gas hazards]) are subject to separate Authorization Basis documents. These separate Authorization Basis documents and future Authorization Basis documents will be incorporated into this Basis for Interim Operation or the subsequent Final Safety Analysis Report as specific changes.

STRUCTURE

This Basis for Interim Operation is organized in the format recommended by DOE-STD-3011-94, *Guidance for Preparation of DOE 5480.22 TSR and DOE 5480.23 (SAR) Implementation Plans*. Chapter 1.0 is an introduction and provides a brief background on Tank Waste Remediation System facilities, mission, and the existing Authorization Basis, including impacts of the Basis for Interim Operation on the current Authorization Basis. Chapter 2.0 and its appendices provide descriptions of Hanford Site characteristics and Tank Waste Remediation System facilities and operations. Relevant operational history of the Hanford Site tank farms is summarized in Chapter 3.0. Chapter 4.0 discusses the safety management programs that provide the administrative framework for the safe operation of Tank Waste Remediation System facilities. The safety analysis that supports this Basis for Interim Operation is described in Chapter 5.0. The safety analysis includes hazard and accident analyses and provides the basis for the interim controls required for protection of the public, onsite workers, facility workers, and the environment. Safety structures, systems, and components and Technical Safety Requirements derived from the safety analysis are summarized in Chapter 6.0. Chapter 7.0 contains a summary of the Basis for Interim Operation conclusions.

Supplemental information specific to the project Authorization Basis is included in the designated addenda. The Basis for Interim Operation addenda are prepared in accordance with format and content guidance of DOE-STD-3009-94, *Preparation Guide for the U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports*. Addendum 1, "Tank 241-C-106 Sluicing Safety Analysis," contains the Basis for Interim Operation specific to the Tank 241-C-106 Waste Retrieval Sluicing System, Project W-320. Addendum 2, "Safety Analysis for the Replacement Cross-Site Transfer System," contains the Basis for Interim Operation specific to the replacement cross-site transfer system, Project W-058. Addendum 3, "702-AZ Ventilation System (241-AZ-702) Safety Analysis" contains the Basis for Interim Operation specific to the 241-AZ-702 ventilation system, Project W-030. Addendum 4 contains the Basis for Interim Operation for the 241-AZ-101 mixer pump test.

SAFETY MANAGEMENT

The TWRS Integrated Safety Management System (ISMS) ensures consistency, formality, and rigor in the development and maintenance of the Tank Waste Remediation System Authorization Basis, safety basis documents, and technical baseline. Implementation of an ISMS is a significant step forward in supporting the U.S. Department of Energy commitment to satisfying Defense Nuclear Facilities Safety Board (1995), *Recommendation 95-2 to the Secretary of Energy*. The ISMS includes safety management programs that ensure protection of the public, workers, and the environment from exposures and releases of radioactive and hazardous materials. Key safety-related activities that comprise these safety management programs range from radiation and hazardous material protection to disciplined conduct of operations.

HAZARD ANALYSIS

The Basis for Interim Operation includes a comprehensive hazard analysis of Tank Waste Remediation System facilities and operations. The hazard identification methods and techniques include the following:

- Review of past Tank Waste Remediation System safety documents
- Review of Tank Waste Remediation System reportable event history (e.g., unusual occurrence reports)
- Review of historical records of similar operations (e.g., Savannah River Site).
- Participation by current and former Tank Waste Remediation System operations and engineering personnel in the hazard analysis effort
- Use of standardized checklists of hazardous materials and energy sources to consider
- Review of Tank Waste Remediation System facilities and operations descriptions
- Facility walkdowns
- Review of existing Tank Waste Remediation System hazard analyses.

Standard industry hazard evaluation techniques (what-if, preliminary hazard analysis, and hazard and operability study) identified over 1,200 hazardous conditions that might affect the public, onsite workers, facility workers, and the environment. For the hazardous conditions, the hazard evaluation identifies their causes and qualitatively estimates their frequency and consequences.

The hazard analysis selected 29 representative accidents for further quantitative accident analysis based on the release attributes and causes of the identified hazardous conditions (Table ES-1). The supplemental project hazard analyses are presented in the designated addenda to the Basis for Interim Operation. The hazard analysis for the Waste Retrieval Sluicing

System identified 18 representative accidents for further analysis. The hazard analysis for the replacement cross-site transfer system identified 6 representative accidents for further analysis. The hazard analysis for the 241-AZ-702 ventilation system identified several accidents that required re-analysis to account for the 241-AZ-702 ventilation system. The hazard analysis for the 241-AZ-101 mixer pump test is presented in Addendum 4.

Those accidents that may significantly affect the public and onsite workers were selected for detailed analysis using the following criteria: accidents that bound those of lesser but similar potential consequences; accidents that represent the highest risk; and other accidents, although not necessarily bounding, that present some unique or important phenomenological challenge to safety.

Controls for protection of the public and onsite workers are based on the results of both the hazard and accident analyses. Additional controls required to protect the facility worker and the environment are based primarily on the qualitative hazard analysis.

HAZARD CLASSIFICATION

A hazard classification of Tank Waste Remediation System facilities and operations has been performed in accordance with DOE-STD-1027-92, *Hazard Categorization and Accident Analysis Techniques for Compliance with DOE Order 5480.23, Nuclear Safety Analysis Reports*. The hazard classification for all of the double-shell tanks (including aging waste facility tanks), single-shell tanks, and associated waste transfer systems is Hazard Category 2. The associated waste transfer systems include the 204-AR Waste Unloading Facility and the 244-AR Vault. The Hazard Category 2 classification is based on comparing the radioactive material thresholds listed in DOE-STD-1027-92 with estimated waste tank inventories.

ACCIDENT ANALYSIS

The Basis for Interim Operation summarizes the quantitative analysis of 29 representative accidents. The accident analysis considers radiological and toxicological exposure to the public and onsite workers. In the accident analysis, conservative assumptions are used to account for uncertainties and unknowns, simplify analysis, and reduce control complexity. Conservatism is included with the following elements of the accident analyses:

- Accident frequency estimates
- Radiological and toxicological source term estimates
- Accident scenarios
- Estimates of physical conditions and parameters.

The results of the supplemental representative accidents identified for projects and their associated consequences and control requirements are contained in the designated addenda. The results of the representative

accidents identified for the Waste Retrieval Sluicing System and their associated consequences and control requirements are contained in Addendum 1. The results of the representative accident analysis identified for the replacement cross-site transfer system and their associated consequences and control requirements are contained in Addendum 2 and Table 6-1. The results of the representative accident analyses identified for the 702-AZ ventilation system and their associated consequences and control requirements are contained in Addendum 3 and Table 6-1. The results of the representative accident analysis identified for the 241-AZ-101 mixer pump test and their associated consequences and control requirements are contained in Addendum 4 and Table 6-1.

Accidents Below Risk Guidelines with No Controls

Analysis determined that five of the accidents do not pose significant risks (the risks were below the risk guidelines) with no controls. These accidents, whose preventive or mitigative controls are addressed as Defense-in-Depth, are as follows:

- Tank failure due to vacuum or degradation
- Evaporator dump
- Mixing of incompatible waste—toxic vapor generation
- Unplanned excavation or drilling in crib, ditch, or pond
- Aboveground structure failure.

Accidents Below Risk Guidelines With Selected Controls

Analysis determined that another twelve accidents do not pose significant risks with the application of controls (i.e., the risks are below the risk guidelines). For these accidents, application of controls ensures operations can be conducted safely. Additional Defense-in-Depth controls that serve to further reduce the risks from these accidents were also identified. The accidents are as follows:

- Nuclear criticality
- Mixing of incompatible waste—tank pressurization
- High-efficiency particulate air filter failure—exposure to high temperature
- Waste transport vehicle accident
- Caustic spray leak
- Unfiltered release
- Subsurface leak resulting in pool

- Leak from railcar or tank trailer
- Surface leak resulting in pool
- Subsurface leak remaining subsurface
- Sodium fire
- Steam intrusion from interfacing systems.

Accidents Prevented with Selected Controls

The following five accidents are prevented by implementing controls. For each accident, the hazardous condition results directly from activities required for safe waste storage or is inherent to waste storage. With controls implemented, these accidents are "extremely unlikely" or "beyond extremely unlikely." It is judged that the controls selected ensure safe operation.

- **In-tank Fuel Fire/Deflagration**—Vehicles used in the tank farm could impact risers and cause fuel to enter a tank and burn. Prohibiting vehicles from entering the tank farm is not practical because many operations such as sampling and maintenance activities require the use of vehicles. Further, to complete these tasks, bringing these vehicles into close proximity with tank risers is often necessary, precluding the use of physical barricades around risers within tank farm boundaries. Preventive controls reduce the occurrence of vehicle fuel system failures (e.g., provide protection for the vehicle fuel system, limit speed within the tank farms). Outside of the tank farm perimeter fencing, the use of physical barriers will be implemented to restrict vehicle access to aboveground structures that can direct liquids into waste tanks. Only vehicles with protected fuel systems are allowed within the barrier. These controls allow for vehicle access to continue safely. Additionally, Defense-in-Depth measures such as the use of spotters further reduce risks.

- **Fire in Contaminated Area**—Fire in a valve pit, pump pit, or diversion box (i.e., contaminated area) could be caused by vehicle fuel entering the contaminated area and igniting. Preventive controls protect vehicle fuel systems, and physical barriers outside the tank farm boundaries limit vehicle access. These controls allow for vehicle access to continue safely. Additional risk reduction is provided by Defense-in-Depth measures such as fire prevention measures and vegetation control.

- **Tank Failure Due to Excessive Loads**—Dropping a heavy load onto the tank could cause an airborne release of waste material from the tank. Prohibiting lifting of heavy loads in the tank farm is not practical because these lifts are associated with essential safety upgrades and required maintenance activities. Compliance with DOE-RL-92-36, *Hanford Site Hoisting and Rigging Manual*, is required to assure critical lifts are analyzed and controlled. A restriction

of lift height is also imposed. These preventive controls reduce the likelihood of a heavy load drop that could penetrate the tank. These controls therefore provide reasonable assurance that crane operations in the tank farms can continue safely.

Consideration should be given to the following items to further reduce risk:

- Implementing a comprehensive inspection program for double-shell tanks (including Aging Waste Facility tanks), single-shell tanks, double-contained receiver tanks, catch tanks, and waste transfer piping to identify areas that require preventive maintenance or that have a high likelihood of failure

- Accelerating the interim stabilization of single-shell tank farms will reduce significantly the need for heavy load lifting, thereby reducing the time at risk.

- **Spray Leak from Underground Waste Transfer Lines**—A spray leak or leak resulting in a pool could result if an active waste transfer line is impacted by excavation activities. Facility upgrades and maintenance require excavation activities in the 200 East and 200 West Areas, but excavation controls effectively prevent the postulated accident. Excavation controls include requirements for an excavation permit, exclusion of waste transfers in transfer lines located near ongoing excavations, and aboveground labeling of waste transfer lines outside of the tank farm fences.

- **Tank Bump**—Extreme conditions could cause an extended outage of the active ventilation system in the tank, which cause the temperature in the tank to increase. If the temperature reaches the waste saturation temperature, a tank bump could occur. Preventive controls include temperature monitoring (to alert operators so necessary actions can be taken to prevent waste from reaching the saturation temperature) and transfer controls (to ensure that the end state does not produce uncontrollable conditions). Defense-in-Depth controls are also identified. These preventive measures provide assurance that operations can continue safely.

  Consideration should be given to the following items to further reduce risk:

  - Retrieval of waste from Tank 241-C-106 to address the most significant single-shell tank with high heat waste

  - Acceleration of the retrieval of other single-shell tanks where an analysis of the tank heat load indicates the tank contents could approach the saturation temperature in the absence of active ventilation.

Natural Phenomena

The following three natural phenomena are initiators of accidents. These events are analyzed within the context of other accidents presented in this Basis for Interim Operation:

- **High Wind**—High wind is a potential initiator of tank failure due to excessive loads (i.e., crane boom collapse caused by high wind) and aboveground structure failure (i.e., high winds causing a flexible receiver containment bag to swing and tear or puncture). Controls to prevent operations in high winds effectively prevent the conditions that could lead to these accidents.

- **Lightning**—Lightning is a potential initiator for an organic solvent fire, organic salt-nitrate reaction, and flammable gas deflagration. Controls place restrictions on tank farm activities when there is lightning activity within 80 km (50 mi).

  Consideration should be given to the following items to further reduce risk:

  - Completion of the upgrades to provide grounding, bonding, and air terminals to reduce the possibility of lightning-initiated ignition

  - Installation of additional lightning protection systems (e.g., catenary network) for waste tanks that pose significant long-term risks caused by lightning-initiated accidents.

- **Seismic**—A seismic event is a potential initiator for several of the representative accidents. Seismic-initiated leaks resulting in a spray or pool and seismic initiated flammable gas deflagration have the potential for the most severe consequences. Controls for spray leaks and leaks resulting in pools may not be effective following a seismic event. Emergency response planning is identified to control the risk of these accidents following a seismic event. (Seismic-induced flammable gas deflagration is discussed later in this Executive Summary.)

  Consideration should be given to the following items to further reduce risk.

  - Provide a seismic monitor notification and alarm capability in the 200 Areas to alert personnel in case of a seismic event so emergency actions can be initiated as quickly as possible.

  - Provide an automatic shut down of waste transfer pumps following a seismic event.

  - Perform a comprehensive seismic vulnerability study that considers the process operating history of the tank farm facilities to provide recommendations that address identified vulnerabilities.

Accidents Above Risk Guidelines with Existing Available Controls

Four postulated accidents and the seismically induced flammable gas accident exceed the risk guidelines used in this analysis even with existing and available controls. Two accidents are slightly above the risk guidelines and two are significantly above the risk guidelines. Although the risk guidelines are exceeded, it is concluded that the interim risk from these postulated accidents is acceptable for the following reasons.

- The risks are inherent to the characteristics of the stored waste or result from operations required to ensure safe waste storage.
- All existing controls that are available to prevent or mitigate the postulated accidents are implemented.
- The estimates of accident frequency and the calculations of the accident consequences are conservative.

Continued efforts to reduce the risk of these accidents are, however, required. For each accident, additional studies or controls are identified that should be considered to further understand or reduce risk. Efforts that should be considered to remove or reduce the conservatism in the accident analysis methodology to allow a better understanding of the risk are listed later in this Executive Summary.

Accidents Slightly Above Risk Guidelines with Existing Available Controls

The following two accidents with existing and available controls are provided special treatment because the calculated accident results slightly exceed risk guidelines:

- **Organic Solvent Fire**—This accident could result from a fire in the waste tank that burns organic solvent present in the tank. For some analyzed cases, the onsite radiological and toxicological consequences could be higher than the risk guidelines even with controls. A sufficiently energetic heat source, such as lightning, vehicle fuel fire, or hot slag from flame cutting, could cause the organic solvent to ignite and cause the release. Restrictions on tank farm activities when lightning activity is within 80 km (50 mi) reduces the possibility of lightning-initiated ignition. Vehicle access controls and fuel system protection reduce the potential for ignition from a vehicle accident. Ignition controls on flame cutting prevent this ignition source. These actions provide reasonable assurance that operations can be conducted safely.

  Consideration should be given to the following items to further reduce risk:

  - Completion of the upgrades to provide grounding, bonding, and air terminals to reduce the possibility of lightning-initiated ignition

- Completion of the tank vapor space sampling program for all tanks to predict the presence of significant quantities of organic solvents

- Reduction in the organic solvent inventory in tanks.

- **Spray Leak in Structures or from Overground Transfer Lines**—This accident could result from a waste transfer line leak that occurs as a very fine spray. Even with controls, the onsite radiological consequences continue to pose a risk to workers. Completely halting waste transfers is not possible without stopping volume reduction activities and interim stabilization activities. These activities facilitate significant long-term safety improvement initiatives. Controls have been identified for mitigation and prevention (e.g., covers on potential spray locations, isolation and verification of transfer routes to prevent mistransfers, configuration controls). The implemented controls provide assurance that operations can be conducted safely.

  Consideration should be given to the following items to further reduce risk.

  - Spray leaks are currently modeled conservatively because of large uncertainties in the phenomena of leak size, orientation, crack plugging, aerosol loading, and deposition. Crack plugging by solids carried in the waste could be investigated with some simple experiments. This would potentially limit the duration of the spray leak and significantly reduce the inventory released. More detailed computer modeling of the generation, agglomeration, deposition, and leakage of aerosols from an enclosed pit or compartment would likely reduce the dose from the mitigated spray leaks (from pits and compartments).

  - Installation and operation of high-efficiency particulate air filter ventilation systems on process pits, diversion boxes, vault pits, and cleanout boxes; and installing and operating radiation monitors in process pits, diversion boxes, vault pits, and cleanout boxes to detect waste leaks.

Accidents Significantly Above Risk Guidelines with Existing Available Controls

The following two accidents and the seismically induced flammable gas accident are given special treatment because the calculated mitigated results significantly exceed risk guidelines with existing and available controls.

- **Flammable Gas Deflagrations**—Appendix E, "Flammable Gas/Slurry Growth Unreviewed Safety Question: Justification for Continued Operation for the Tank Farms at the Hanford Site," addresses the flammable gas deflagration accident. The Justification for Continued Operation

provides the basis for the required operational restrictions and controls that are incorporated into this Basis for Interim Operation.

Consideration should be given to the following items to further reduce the risk of flammable gas deflagrations.

- **Ventilation Upgrades**-Making modifications to allow direct measurement of the flow rate through each individual actively ventilated tank would provide better assurance that flammable gases are not accumulating as a result of continuous releases. Double-contained receiver tank design modifications to provide an inlet flow path to each tank and to allow measurement of the flow rate through each double-contained receiver tank would provide assurance that flammable gases are not accumulating in double-contained receiver tanks.

- **Monitoring Upgrades**-Adding monitors (e.g., flammable gas, level) with alarms to tanks (a) which either exhibit gas release, level change, or other parameters that would be valuable in better defining the hazard, or (b) where intrusive work is planned, would allow detection of changes in parameters such as flammable gas concentrations.

- **Ignition Controls**-Verifying that tank ventilation systems, instrumentation, and equipment for intrusive activities meet industry standard (e.g., National Fire Protection Association, American Petroleum Institute) requirements for hazardous location equipment would eliminate potential hazards. Upgrade equipment that does not meet these requirements or justify that the design is equivalent to the industry standard requirements.

- **Other Controls**-Installation and operation of mixer pumps in tanks with the potential for gas release events would reduce the time at risk for these large releases by converting the releases into manageable continuous releases. Provisions of a sample port on the ventilation inlet duct would facilitate sampling on loss of ventilation.

In addition consideration should be given to continuing research on flammable gas generation and retention phenomena in tank waste.

- **Organic Salt-Nitrate Reaction**-This accident could result from an ignition of dry, solid organic salt waste. The offsite and onsite radiological and toxicological consequences could pose significant risk. Three dependent criteria exist which are important to understanding the risk posed by organic-nitrate waste. In the order of importance they are the total organic carbon in percent, the moisture level in the waste in percent, and energetics required to initiate or propagate in J/g (measured by calorimetry). If a tank waste can be shown, with the appropriate confidence levels, to contain total organic carbon levels below an established limit, moisture and energetics are not important. Ignition and propagation are not possible if tank waste is shown to contain adequate moisture

even if the total organic carbon levels are greater than established limits. Moisture eliminates ignition and propagation. Energetics are still being evaluated to determine if a limit can be established, below which propagation cannot occur, even if adverse total organic carbon and/or moisture levels exist. Tanks are identified as either safe (insufficient total organic carbon), conditionally safe (moisture above criteria), or unsafe (based on total organic carbon and moisture measurement and analysis). For all of the tank waste sample data collected thus far, no waste measurements have exceeded the conditionally safe criteria. Less than 10 tanks fall into the conditionally safe category because of fuel content. On the basis of sample tank analyses and process information, none of the unsampled tanks is expected to contain average total organic carbon concentrations above the fuel criterion. The Tank Waste Remediation System program continues testing with surrogate and actual waste samples to determine if the conditions assumed in the analysis are possible. Tank characterization is prioritized to sample tanks scheduled for interim stabilization and tanks with the highest reaction potential.

Controls are required to reduce the frequency of the accident. To protect against the organic salt-nitrate reaction hazard, high moisture conditions are maintained in the waste, if possible, and medium strength (>10 J) ignitors are prevented from contacting the waste.

Consideration should be given to the following items to further reduce risk:

- Augmenting the characterization and testing to address the actual chemical compositions making up total organic carbon would reduce conservatisms in modeling reaction energetics
- Investigating the efficiency of removing soluble organic species that could cause propagating reactions by salt well pumping or washing with sodium hydroxide solution
- Installing and operating a tank spray system in tanks with high organic concentrations to ensure adequate moisture in the waste
- Completing the upgrades to provide grounding, bonding, and air terminals to reduce the possibility of lightning-initiated accidents.

- **Natural Phenomena - Seismic**-A seismic event can cause a flammable gas release event in a tank and ignition of the flammable gas. Emergency response planning is required to minimize the post-seismic risk.

Consideration should be given to the following items to further reduce the risk of seismically induced flammable gas deflagrations:

- Provide a seismic monitor notification and alarm capability in the 200 Areas to alert personnel in case of a seismic event so emergency actions can be initiated as quickly as possible.

- Eliminate or mitigate gas release events by accelerating tank waste retrieval.

General Accident Analysis Conservatism

A number of areas exist in the accident analysis methodology where conservatism could be removed if additional work were performed. These include conservatism in the physical models (e.g., spray release model), conservatism in the modeling of tank waste phenomena (e.g., quantity and rate of hydrogen release), and conservatism in radiological and toxicological consequence modeling. Considerations for addressing the first two conservatisms are identified for the specific postulated accidents.

Consideration should be given to the following items to reduce the known conservatism in accident consequence modeling.

Source Term-The radioactive inventory estimates for the high-level waste tanks are currently divided into three groups of tanks: double-shell tanks, Aging Waste Facility tanks, and single-shell tanks, with the isotopic inventories represented by the maximum sample value within the group. Except for the Aging Waste Facility tanks, this is a recognized conservatism necessary because sampling and analysis data presently cannot provide discrete source terms for all individual tanks with adequate statistical confidence to support a safety basis. With more complete data of the high-level waste tank inventory, the double-shell tanks and single-shell tanks could be parceled into more groups with only a few tanks having to be represented by the current conservative inventory estimates. Orders of magnitude reductions could be achieved for some double-shell tanks and some single-shell tanks. It is important that little reduction in the inventory estimates is achievable for some tanks because the sample data represents the actual tank contents.

Toxicological Methodology-The current toxicological exposure methodology is based on a sum-of-fractions which represents the best approach currently available. Potential risk reductions could be achieved by developing a method which, while still conservative, does not rely on a simple sum of exposure concentrations divided by the respective concentration limits. Additional risk reductions could also be achieved by revising the toxic risk guidelines, which are based on routine occupational exposures at the lowest limits, to less conservative limits.

Atmospheric Dispersion Modeling-The accident analysis modeling of atmospheric dispersion neglects agglomeration and deposition of particulate material. The radioactive components and some of the toxicological components are carried by aerosols. More detailed computer

modeling of the agglomeration and deposition of the combustion aerosols could reduce the consequences of several accidents (e.g., organic salt-nitrate reaction, organic solvent).

Emergency Response Actions-Calculating radiological and toxicological exposures to the maximum offsite and onsite individuals takes no credit for emergency response actions (evacuation, sheltering) or personnel self-evacuations based on observed or sensed conditions. If further assessment of postulated accidents identifies means of detecting the event and if a demonstrated ability to take emergency response actions can be shown, the exposure times to the maximum offsite and onsite individual may be reduced. Accident detection could require classification of additional safety structures, systems, and components; new Technical Safety Requirements; or consideration for adding new monitoring systems.

CONTROLS

The hazard and accident analyses were used to select safety structures, systems, and components, Technical Safety Requirements, and other Defense-in-Depth and environmental controls according to a disciplined methodology and process using established control decision criteria. The implemented controls maintain facilities and operations within a safe envelope and provide protection for the public, onsite workers, facility workers, and the environment. The safety, environmental, and operational requirements were optimized to enable the selection of an integrated set of effective controls that accomplish the following:

1. Reduce risk to the public and onsite and facility workers
2. Be effectively implemented in a timely fashion
3. Provide Defense-in-Depth.

The selected controls primarily use existing safety structures, systems, and components with limited exceptions for design additions or modifications that can be rapidly implemented. Although most of the Technical Safety Requirement controls are implemented in existing procedures, there are a number of new or revised controls. For example, new waste transfer controls require extension of the transfer route beyond the previous two-valve isolation to all physically connected systems.

Although the safety structures, systems, and components and Technical Safety Requirement controls were derived primarily from the analysis of the representative accidents, all hazard conditions were analyzed to ensure protection was provided by the controls selected. This is ensured by identifying the applicable controls for each hazardous condition identified for Tank Waste Remediation System facilities and operations.

Hazardous conditions with significant environmental consequences are identified in the hazard analysis. For many of these hazardous conditions, the controls identified to protect the public, onsite worker, and facility

worker also provide protection for the environment. When controls selected to protect the public, onsite worker, and facility worker do not adequately protect the environment, additional required controls are identified.

Chapter 6.0 of the Basis for Interim Operation describes implementation of controls in Technical Safety Requirements or health and safety plans. The control descriptions in Chapter 6.0 and in the Technical Safety Requirements identify safety function, operability requirements, and surveillance requirements.

The controls derived from the hazard and accident analyses for protection of the public, onsite worker, facility worker, and the environment provide the full suite of interim controls necessary to maintain operations within an acceptable level of risk.

DEFENSE-IN-DEPTH

Engineered features and administrative programs and procedures that act to further prevent or mitigate accident risk beyond the safety structures, systems, and components and Technical Safety Requirement controls are identified as Defense-in-Depth controls. Defense-in-Depth controls that provide for significant risk reduction were elevated to safety structures, systems, and components or Technical Safety Requirement controls. Although Defense-in-Depth items are not controlled as safety structures, systems, and components or Technical Safety Requirement controls, they add to overall safety and are governed by configuration control procedures. Identification in the Defense-in-Depth controls increases the awareness of the contribution these features make to safety.

CONCLUSIONS

In summary, this Basis for Interim Operation reaches the following conclusions.

- The accidents analyzed to date confirm known vulnerabilities.
- The selected safety structures, systems, and components and controls (Technical Safety Requirements, health and safety plans, and implementing procedures) provide prevention and mitigation measures to address these vulnerabilities.
- The analyses show that these measures provide reasonable assurance that continued Tank Waste Remediation System facility operations can be conducted safely.
- Several postulated accidents are shown to be significantly above the risk guidelines based on conservative bounding analyses. Existing and available controls are selected to provide immediate, near-term protection while options for additional measures to further reduce risk are evaluated.

Collectively, these conclusions find that the Tank Waste Remediation System facilities can be operated safely following the requirements of this Basis for Interim Operation until the Basis for Interim Operation is replaced by a fully compliant Final Safety Analysis Report. Continuing safety analysis for the Final Safety Analysis Report will further improve understanding of the risk of Tank Waste Remediation System facilities and operation and refine the interim controls established by this Basis for Interim Operation. Action on considerations identified in the Basis for Interim Operation to further reduce risk is also required to address the long-term risk associated with continued storage management.

The project-specific supplemental conclusions are included in the designated addenda to the Basis for Interim Operation. The conclusion of Addendum 1 to the Basis for Interim Operation is that the Waste Retrieval Sluicing System activities can be conducted safely following implementation of the controls and requirements identified in Addendum 1. The conclusion of Addendum 2 to the Basis for Interim Operation is that the replacement cross-site transfer system can be operated safely following implementation of the controls and requirements identified in Addendum 2 and Table 6-1. The conclusion of Addendum 3 to the Basis for Interim Operation is that the 241-AZ-702 ventilation system can be operated safely following implementation of the controls and requirements identified in Addendum 3 and Table 6-1. The conclusions of Addendum 4 to the Basis for Interim Operation is that the 241-AZ-101 mixer pump test can be conducted safely following implementation of controls and requirements identified in Addendum 4 and Table 6-1.

1.0 INTRODUCTION

This Basis for Interim Operation (BIO) document, with its companion Technical Safety Requirements (TSR) document (HNF-SD-WM-TSR-006, *Tank Waste Remediation System Technical Safety Requirements)*, provides the basis for interim operation of the Hanford Site Tank Waste Remediation System (TWRS). The BIO will remain in effect until replaced by the TWRS Final Safety Analysis Report and the revised TSR document, which are currently being prepared in accordance with the requirements of U.S. Department of Energy (DOE) orders DOE 5480.23, *Nuclear Safety Analysis Reports*, and DOE 5480.22, *Technical Safety Requirements*. The overall strategy for preparing the BIO is based on DOE-STD-3011-94, *Guidance for Preparation of DOE 5480.22 (TSR) and DOE 5480.23 (SAR) Implementation Plans*.

The objective of this BIO is to provide an improved interim Authorization Basis that enhances safe operation of the Hanford Site TWRS facilities by providing an improved basis for interim operation and operational controls. This BIO provides a cohesive, integrated interim Authorization Basis that supersedes numerous safety documents, thus minimizing inconsistencies and the potential for error and confusion. The details of how the BIO was developed are in Appendix A, "Basis for Interim Operation Development Process."

This BIO applies to the following TWRS equipment and facilities:

- 177 underground high-level waste (HLW) tanks including single-shell (149) and double-shell (28) tanks in the 200 East and 200 West Areas
- Catch tanks
- Double-contained receiver tanks
- Waste transfer system
- 2727-W Sodium Storage Facility
- 204-AR Waste Unloading Facility
- 244-AR Vault
- Miscellaneous inactive storage facilities
- 209-E Mixed Waste less than 90-Day *Resource Conservation and Recovery Act of 1976* waste storage pads
- Cribs, ditches and ponds
- Push mode sampling
- Light duty utility arm
- Cone Penetrometer

- Rotary Mode Core Sampling (Flammable Gas Hazards)
- 213-W Dry Waste Compactor Facility
- Vertical storage units within the tank farm boundaries

See Appendix B, "Facility and Process Description," for details about these facilities.

The BIO analyzed the 242-S and 242-T Evaporators only for flammable gas hazards, as documented in Appendix E, "Flammable Gas/Slurry Growth Unreviewed Safety Question: Justification for Continued Operation for the Tank Farms at the Hanford Site." Appendix E provides the Justification for Continued Operation for the flammable gas hazard and includes controls applying to 242-S and 242-T. The applicable controls are not included in the TSRs and must be implemented prior to the initiation of intrusive activities or waste disturbing activities. All other hazards that apply to the 242-S and 242-T Evaporators are outside the scope of the BIO.

1.1 FACILITY MISSION

The TWRS mission, as described in HNF-SD-WM-MAR-008, *TWRS Mission Analysis Report*, is divided into two phases. Phase 1 retrieval and disposal activities will continue to safely store TWRS remaining tank wastes, demonstrate the capability to retrieve waste from DSTs and SSTs, immobilize and dispose of the low-activity waste (LAW) and immobilize and store the HLW from the DSTs, and safely store retrieved SST waste in the DSTs until Phase 2 commences. Phase 2 retrieval and disposal efforts will (1) continue to safely store TWRS tank waste until removal; (2) completely remove tank wastes, process the cesium and strontium capsules, immobilize LAW and HLW, dispose of the LAW, and provide the interim storage and subsequent transfer of immobilized HLW to the national geologic repository; (3) close the tank farms and clean up, decontaminate, and decommission the unneeded facilities; and (4) maintain long-term surveillance of the LAW disposal facilities. The BIO establishes an improved Authorization Basis for selected facilities and activities of the tank waste management function of the TWRS mission analysis. These activities include the storage, characterization, and transfer of tank wastes in a manner that complies with environmental regulations and minimizes public and worker risk.

1.2 FACILITY BACKGROUND

Between 1944 and 1980, Hanford Site production operations generated large amounts of solid and liquid radioactive mixed waste. Chemical processing of irradiated uranium fuels generated alkaline slurries containing heavy metals, organic solvents, inorganic salts, uranium, plutonium, and mixed fission products. While cooling water, condensates, and other low-level wastes from processing operations were discharged to the ground, high-level wastes were placed in large underground tanks for temporary storage. The first 149 tanks were constructed between 1943 and 1964. These tanks formed a total of 12 farms consisting of 4 to 18 tanks in each farm. Location of these farms is divided between the 200 East and 200 West Areas. The original tank design

comprises a single, reinforced-concrete shell and dome with mild carbon steel lining the bottom and walls. The capacity of these single-shell tanks ranges from approximately 208,000 to 3.79 million L (55,000 to 1 million gal). Between 1968 and 1986, 28 double-shell tanks were built in 6 tank farms with 2 to 8 tanks in each farm. Five of these tank farms are located in the 200 East Area, and one is located in the 200 West Area. Each of the double-shell tanks comprises a carbon-steel primary tank and a carbon-steel secondary tank in a protective reinforced-concrete shell. The capacity of these double-shell tanks is approximately 3.79 million L (1 million gal) each.

The ancillary systems, facilities, and equipment that support operations performed in the tank farms (both single-shell and double-shell tank farms) include underground and aboveground waste transfer pipelines, valves, diversion boxes, jumper connectors, waste transfer pumps, double-contained receiver tanks, catch tanks, process pits, the 204-AR Waste Unloading Facility, and the 244-AR Vault. Other ancillary systems include miscellaneous storage facilities that are now inactive.

1.3 DESCRIPTION OF AUTHORIZATION BASIS

Portions of the previously existing TWRS Authorization Basis, as defined in Chapter 6.0, "Operational Controls" from WHC-SD-WM-ISB-001, *Hanford Site Tank Farm Facilities Interim Safety Basis*, are superseded by the BIO and its associated TSR document. The list of TWRS Authorization Basis documents is maintained in the TWRS Unreviewed Safety Question (USQ) procedure (HNF-IP-0842, "TWRS Administration," Vol. IV, Section 5.4, "Unreviewed Safety Questions").

The principal TWRS Authorization Basis documents are the BIO and the TSR document. Other Authorization Basis documents include U.S. Department of Energy, Richland Operations Office (RL) letters that approved the use of contractor-controlled documents as part of the Authorization Basis, RL letters that provide Authorization Basis controls, and Safety Evaluation Reports.

During initial implementation of the BIO and the TSRs, each document and individual control from the previous Authorization Basis was compared to the BIO and the TSR to determine whether its content, basis, and applicability were addressed in the new documents (HNF-SD-WM-RPT-303, *Authorization Basis Requirements Comparison Report)*. The results of this comparison were used to define the new Authorization Basis.

1.3.1 Open Unreviewed Safety Questions

There are presently three open USQs applicable to TWRS. They concern the following issues:

- Condensed-phase organic nitrate reactions
- Flammable gas and slurry growth
- Waste surface level change in Tank 241-SY-101.

The condensed-phase organic nitrate reaction has been declared a USQ. Results of an analysis are documented in Chapter 5.0, "Safety Analysis" and address the condensed-phase organic nitrate reactions USQ issues.

The original USQ on Tank 241-SY-101 for flammable gas and slurry growth has been closed (Kinzer 1996, *Closure of Hanford Tank 241-SY-101 Flammable Gas Unreviewed Safety Question [USQ]*). LA-UR-92-3196, *A Safety Assessment for Proposed Mixing Pump Operations to Mitigate Episodic Gas Releases in Tank 241-SY-101*, provides the basis for the Tank 241-SY-101 mixer pump operation which allowed this USQ to be closed. The justification for continued operation prepared to support the USQ for flammable gas and slurry growth for all other tanks containing flammable gas has been approved by DOE and is included as Appendix E.

A USQ has been declared related to the unexplained level growth in Tank 241-SY-101. The waste surface level in the tank has risen and does not respond to the mixer pump operation. This situation was not evaluated in LA-UR-92-3196. DOE declared this USQ on February 26, 1998 (Kinzer, 1998, *Declaration of an Unreviewed Safety Question (USQ) Related to Waste Surface Level Changes in Tank 241-SY-101*). Single-Shell Tanks Standing Order 98-15 has been issued to ensure that routine operations continue to maintain the facility in a safe condition.

The details of the technical issues addressed by these USQs are provided in Chapter 3.0, "Relevant Operational History" and the controls from these USQs are described in Chapter 5.0, "Safety Analysis."

1.3.2 Authorization Basis Documents Annual Update

DOE 5480.23, Section 9.c requires an annual update to applicable Authorization Basis documents. The annual update is a mechanism for revising the Authorization Basis to incorporate previously approved changes, changes to the facility configuration, non-technical editorial changes, and other changes that do not require DOE approval. Annual updates must reflect all changes implemented up to six months prior to the submission of the update to DOE. The annual update must include, as a minimum, USQs that have been approved by DOE, amendments to the TSRs, and materials submitted to DOE in support of the noted changes.

WRSS	Waste Retrieval Sluicing System

2.0 FACILITY DESCRIPTION

The Tank Waste Remediation System (TWRS) facilities are located throughout the 200 East, 200 West, and 600 Areas on the Hanford Site.

A description of site characteristics necessary for understanding the TWRS and Hanford Site environs is included as Appendix C of this Basis for Interim Operation document. A description of TWRS facilities and operations is included as Appendix B, "Facility and Process Description." Supplemental project-specific facility descriptions are included in the designated addenda. A description of the Waste Retrieval Sluicing System (WRSS) is provided in Addendum 1, "Tank 241-C-106 Sluicing Safety Analysis." A description of the replacement cross-site transfer system is provided in Addendum 2, "Safety Analysis for the Replacement Cross-Site Transfer System." A description of the 702-AZ ventilation system is provided in Addendum 3, "702-AZ Ventilation System (241-AZ-702) Safety Analysis." A description of the modification to Tank 241-AZ-101 to perform the mixer pump test is provided in Addendum 4.

2.1 STRUCTURES, SYSTEMS, AND COMPONENTS IMPORTANT TO SAFETY

The controls selected for each accident are described in Chapter 5.0, "Safety Analysis," and summarized in Chapter 6, "Operational Controls." The selection process follows the structures, systems, and components (SSCs) classification methodology described in WHC-CM-4-46[1], *Safety Analysis Manual*, and Dunford (1996), *Tank Waste Remediation System Final Safety Analysis Report Selection of Safety Structures, Systems, and Components; and Technical Safety Requirements*. Section 5.4.1 "Control Decision Criteria," provides an additional description of the control decision criteria used to classify SSCs.

SSCs important to safety are classified as either Safety-Class or Safety-Significant; all other SSCs are considered to be general services. Safety-Class SSCs prevent or mitigate releases to the public that would otherwise exceed the offsite radiological risk guidelines or prevent accidental nuclear criticality. Those items that support the safety function of Safety-Class SSCs are considered as Safety-Class.

DOE-STD-1027-92, *Hazard Categorization and Accident Analysis Techniques for Compliance with DOE Order 5480.23, Nuclear Safety Analysis Reports*, states that the requirements of 29 CFR 1910.119, "Process Safety Management of Highly Hazardous Chemicals," apply when analyses of chemical hazards show the potential for significant offsite consequences. The TWRS hazard and accident analyses have identified no SSCs required solely to prevent or mitigate the release of toxic chemicals to the offsite public.

---

[1]Refer to Appendix F, "Site-wide Controlled Manual Cross Reference Table," of the BIO for cross-walk between Site-wide controlled manuals (e.g., WHC-CM-X-XX) superseded by Fluor Daniel Hanford, Inc., Procedures (e.g., HNF-PRO-XXX).

Safety-Significant SSCs prevent or mitigate releases of radiological materials to onsite workers and toxic chemicals to the offsite public and onsite workers. Barriers judged to substantially contribute to Defense-in-Depth, independent of quantitative analysis, are designated Safety-Significant SSCs. Safety-Significant SSCs are also selected to protect the facility worker from serious injury caused by hazards, exclusive of standard industrial hazards. Those items that support the safety function of a Safety-Significant SSC are also considered as Safety-Significant. SSCs that serve more than one safety function are classified for the higher function (e.g., a fan with a Safety-Class cooling function and Safety-Significant ventilation function is classified as Safety-Class).

The classification of SSCs is often at the system level. The Design Authority[2] determines the components required to perform the system function including supporting SSCs in developing the safety equipment list (Appendix A, "Basis for Interim Operation Development Process"). The SSCs must meet as a minimum the design and functional requirements used in the accident analysis. The safety function for the designated SSCs is described in this chapter.

Double-shell tanks (DSTs) (including Aging Waste Facility [AWF] tanks), single-shell tanks (SSTs), and their associated waste transfer systems[3] are not included in the list of Safety-Class or Safety-Significant SSCs in this chapter. The classification of these passive design features as Safety-Class, Safety-Significant, or General Service will be provided in the TWRS Final Safety Analysis Report.

2.1.1 Safety-Class Structures, Systems, and Components

Following is a summary of SSCs that perform a Safety-Class function. For more details on the identification of Safety-Class SSCs, refer to Chapter 5.0. Supplemental SSCs specific to the construction projects are included in the designated addenda. Addendum 1 includes a description of the supplemental SSCs for WRSS. Addendum 2 includes a description of the supplemental SSCs for the replacement cross-site transfer system. Addendum 3 includes a description of the supplemental SSCs for the 702-AZ ventilation system. Addendum 4 includes a description of the Supplemental SSCs for the 241-AZ-101 mixer pump test.

2.1.1.1 Transfer System Covers. The safety function of transfer system covers (for process pits, diversion boxes, vault pits, and cleanout boxes), credited in the spray leak in structures or from overground waste transfer lines accident analysis, is to provide a physical barrier to knock down spray and limit release of aerosols to the atmosphere in case of a release during a transfer.

---

[2]The design authority function is assigned to qualified personnel within the TWRS engineering organization.

[3]Double-contained receiver tanks, catch tanks, process pits, diversion boxes, vault pits, cleanout boxes, and transfer lines.

The diversion boxes, vault pits, and cleanout boxes are described in Appendix B. The process pits for DSTs, SSTs, and other storage tanks are described in Appendix B. The discussion applies to all waste transfer systems including DST and SST transfer systems in the 200 East and 200 West Areas, the original cross-site transfer system, and the processing plant transfer systems (lines from the Plutonium Uranium Extraction Plant, B Plant, T Plant, 222-S Laboratory, U Plant, the Plutonium Finishing Plant, and the 204-AR Waste Unloading Facility).

Potential sites of spray leaks include piping and jumpers in the process pits, diversion boxes, vault pits, and cleanout boxes of DSTs (including AWF tanks) and SSTs; encasement risers; raw water supply system components; SST overground waste transfer lines; and 204-AR Waste Unloading Facility.

2.1.1.2 Pressure Switch Interlock(s) or Alarm to Waste Transfer Pumps (Raw Water and Other Water Service Supply Lines). The safety function of the pressure switch interlocks to waste transfer pumps, credited in the spray leak in structures or from overground waste transfer lines and surface leak resulting in pool accident analyses, is to prevent backflow of waste into interconnecting systems. The pressure switch interlocks to waste transfer pumps are described in Appendix B.

2.1.1.3 Stack Continuous Air Monitor and Interlock to Exhaust Fan on 204-AR Waste Unloading Facility. The safety function of the stack continuous air monitor and interlock to exhaust fan, credited in the spray leak in structures or from overground waste transfer lines accident analysis, is to detect radioactivity caused by failure of a high-efficiency particulate air (HEPA) filter and the shut-off of the exhaust fan at the 204-AR Waste Unloading Facility. The stack continuous air monitor and interlock to exhaust fan are described in Appendix B.

2.1.1.4 Overground Waste Transfer Line Concrete Shielding System. The safety function of the overground waste transfer line concrete shielding system, credited in the spray leak in structures or from overground waste transfer lines and surface leak resulting in pool accident analyses, is to protect the overground waste transfer line from external events. The overground waste transfer line concrete shielding (protection) system is described in Appendix B.

2.1.1.5 Transfer Leak Detection System. The safety function of the transfer leak detection system, credited in the surface leak resulting in pool accident analysis, is to detect waste accumulation in the pits and the transfer pump auto stop or alarm function.

The transfer leak detectors are described in Appendix B. The discussion applies to waste transfer-associated structures (process pits, diversion boxes, vault pits, and cleanout boxes).

2.1.1.6 Overground Waste Transfer Line Encasements and Connections. The safety function of the overground waste transfer line encasements and connections, credited in the surface leak resulting in pool and spray leak in structures or overground waste transfer lines accident analyses, is to confine waste leaked from the primary pipe (barrier). The overground waste transfer line encasements and connections are described in Appendix B.

2.1.1.7 Primary Tank Leak Detection for Double-Shell Tanks. The safety function of the annulus leak detector in a DST, credited in the surface leak resulting in pool and flammable gas deflagration accident analyses, is to detect waste accumulation in the DST annulus. Annulus leak detection for DSTs is described in Appendix B.

2.1.1.8 Mixer Pump on Tank 241-SY-101. The safety function of the mixer pump in Tank 241-SY-101, credited in the flammable gas deflagration accident, is to release flammable gases trapped in the waste by mixing the waste. The mixer pump in Tank 241-SY-101 is described in Appendix B.

2.1.1.9 Level Monitors on Tank 241-SY-101. The safety function of the level monitors on Tank 241-SY-101, credited in the flammable gas deflagration accident, is to provide an indication of tank waste level, which directs the operation of the mixer pump. The level monitoring system for DSTs is described in Appendix B.

2.1.1.10 Hydrogen Monitor on Tank 241-SY-101. The safety function of the hydrogen monitor on Tank 241-SY-101, credited in the flammable gas deflagration accident, is to indicate and alarm for hydrogen gas concentration in the vapor space and to activate an interlock to stop mixer pump operation if hydrogen concentration reaches 0.75% (7,500 ppm) by volume, thereby preventing operation of the pump during a gas release event. The standard hydrogen monitoring system is described in Appendix B.

2.1.1.11 Pressure Monitor on Tank 241-SY-101. The safety function of the pressure monitor on Tank 241-SY-101, credited in the flammable gas deflagration accident, is to indicate that the ventilation system is operating, ensuring that hydrogen concentration is minimized during mixer pump operation. The pressure monitoring system for DSTs is described in Appendix B.

2.1.1.12 Ventilation Flowmeter on Tank 241-SY-101. The safety function of the ventilation flowmeter on Tank 241-SY-101, credited in the flammable gas deflagration accident, is to indicate the ventilation flow rate and to provide alarm capability to ensure that the mixer pump operation is stopped if ventilation flow is too high or too low. Primary tank ventilation systems are described in Appendix B.

2.1.1.13 Ammonia Detection System on Tank 241-SY-101. The safety function of the ammonia detection system on Tank 241-SY-101, credited in the flammable gas deflagration accident, is to detect the ammonia in the tank headspace/exhaust gas and alarm on the Data Acquisition Control System when a high level of ammonia exists. The ammonia detection system on Tank 241-SY-101 is described in Appendix B.

2.1.1.14 Temperature Monitors on Tank 241-SY-101. The safety function of the temperature monitors on Tank 241-SY-101, credited in the flammable gas deflagration accident, is to indicate the temperature of the tank waste and alarm if the temperature reaches a preset limit. The temperature monitoring system for DSTs is described in Appendix B.

2.1.1.15 Ventilation System on DSTs. The safety function of the ventilation system on DSTs, credited in the flammable gas deflagration accident, is to provide sufficient ventilation into the headspace of the tank to maintain flammable gas concentration below 25% of the lower flammability limit. The ventilation system for DSTs is described in Appendix B.

2.1.1.16 Active Ventilation System on SSTs. The safety function of the active ventilation system on SSTs, credited in the flammable gas deflagration accident, is to provide sufficient ventilation into the headspace of the tank to maintain flammable gas concentration below 25% of the lower flammability limit. The active ventilation system for SSTs is described in Appendix B.

2.1.1.17 Waste Level Dip Tube Air Flow Indicator in Double-Contained Receiver Tanks. The safety function of the waste level dip tube air flow indicator in double-contained receiver tanks (DCRTs), credited in the flammable gas deflagration accident, is to provide sufficient ventilation into headspace of the tank to maintain flammable gas concentration below 25% of the lower flammability limit. Where the level dip tubes are used for ventilation, the safety function is to provide inlet air flow to the DCRTs. The waste level dip tube air flow indicator for DCRTs is described in Appendix B. This discussion applies to the following DCRTs: 244-A, 244-BX, 244-CR, 244-S, 244-TX, 244-U.

2.1.1.18 Dip Tube Air Flow Indicator on 244-AR Vault (TK-002). The safety function of the dip tube air flow indicator on 244-AR Vault (TK-002), credited in the flammable gas deflagration accident, is to provide sufficient ventilation into the headspace of the tank to maintain flammable gas concentration below 25% of the lower flammability limit. The ventilation system for the 244-AR Vault (TK-002) is described in Appendix B.

2.1.1.19 Waste Transfer Pipe Encasements. The safety function of the pipe encasements, credited in the subsurface leak resulting in pool accident, is to ensure that a leak in the primary waste transfer system piping is directed to a waste transfer-associated structure. Pipe encasements are described in Appendix B.

2.1.1.20 Stack Continuous Air Monitor and Interlock to Exhaust Fan on All Actively Ventilated Tanks. The safety function of the stack continuous air monitor and interlock to exhaust fan, credited in the spray leak in structure or from overground waste transfer line accident analysis, is to detect radioactivity caused by a failure of a HEPA filter and to shut off the exhaust fan for all actively ventilated tanks. The stack continuous air monitor and interlock to exhaust fan is described in Appendix B.

2.1.1.21 Passive Ventilation System on SSTs. The safety function of the passive ventilation system on SSTs, credited in the flammable gas deflagration accident, is to provide sufficient ventilation into headspace of the tank to maintain flammable gas concentration below 25% of the lower flammability limit. The passive ventilation system for SSTs is described in Appendix B.

2.1.1.22 Supplemental Covers. The safety function of supplemental covers, required for the spray leak accident, is to contain liquid spraying from a covered process pit. The accident will then be bounded by the surface leak

resulting in pool analysis (HNF-2296, *Justification for Continued Operation of Transfer Lines Having Structures With Less Volume Than the 241-A-A Valve Pit).* Supplemental covers are described in Appendix B.

2.1.2 Safety-Significant Structures, Systems, and Components

The following is a summary of SSCs that perform a Safety-Significant function. For more details on the identification of Safety-Significant SSCs, refer to Chapter 5.0. Supplemental SSCs specific to the project authorization bases are included in the designated addenda. Addendum 4 includes a description of the supplemental SSCs for the 241-AZ-101 mixer pump test.

2.1.2.1 High-Efficiency Particulate Air Filters in Double-Contained Receiver Tanks 244-A, 244-S, and 244-TX. The safety function of the HEPA filters, credited in the mixing of incompatible material-tank pressurization accident analysis, is to remove airborne particulates in the effluent from DCRTs. The HEPA filters in the DCRTs are described in Appendix B.

2.1.2.2 Continuous Air Monitor Interlock. The safety function of the continuous air monitor interlock on the ventilation system of DSTs (including AWF tanks) and SSTs (active ventilation only), credited in the HEPA filter failure-exposure to high temperature or pressure accident analysis, is to detect radioactivity and to close the ventilation systems for DSTs (including AWF tanks), and SSTs (active ventilation only). The continuous air monitor interlock on the ventilation systems of DSTs (including AWF tanks) and SSTs (active ventilation only) is described in Appendix B.

2.1.2.3 Raw Water or Service Water System Backflow Preventers. The safety function of backflow preventers, credited in the spray leak in structures or from overground waste transfer lines accident analysis, is to prevent the backflow of waste into raw water or service water systems. The raw water and service water system backflow preventers are described in Appendix B.

2.1.2.4 204-AR Waste Unloading Facility Building. The safety function of the building at the 204-AR Waste Unloading Facility, credited in the spray leak in structures or from overground waste transfer lines accident analysis, is to knock down/confine spray within the facility from the potential releases from leaks. The building at the 204-AR Waste Unloading Facility is described in Appendix B.

2.1.2.5 Temperature Monitoring System. The safety function of the temperature monitors, credited in the tank bump accident analysis and also for protection from a postulated "chemical runaway" accident, is to provide temperature monitoring for DSTs (including AWF tanks) and the following SSTs: 241-C-106, 241-SX-103, 241-SX-107–112, and 241-SX-114. The temperature monitoring systems for DSTs (including AWF tanks) and SSTs are described in Appendix B.

2.1.2.6 Tank Level Monitors. The safety function of level monitors, credited in subsurface leak resulting in pool, surface leak resulting in pool, and

subsurface leak remaining subsurface accident analyses, is to indicate the waste level in the tank to support material balance calculations during waste transfers.

The waste tank level monitors are described in Appendix B. The discussion applies to waste transfers through single-walled direct-buried lines, concrete-encased lines, and pipe-in-pipe encased lines; waste storage tanks (DCRTS, DSTs [including AWF tanks], SSTs, catch tanks, and miscellaneous inactive storage facilities); the 244-AR Vault; the 204-AR Waste Unloading Facility; and waste transfer-associated structures (process pits, diversion boxes, vault pits, cleanout boxes).

2.1.2.7 Salt Well Flow Totalizer. The safety function of salt well flow totalizer, credited in the subsurface leak resulting in pool, surface leak resulting in pool, and subsurface leak remaining subsurface accident analyses, is to indicate the total quantity of liquid pumped to support material balance calculations during waste transfers.

The salt well flow totalizer is described in Appendix B. The discussion applies to waste transfers through overground waste transfer lines, single-walled direct-buried lines, and pipe-in-pipe encased lines involving DCRTs, DSTs (including AWF tanks), SSTs, and waste transfer-associated structures (process pits, diversion boxes, vault pits, cleanout boxes).

2.1.2.8 Transfer System Covers. The safety function of transfer system covers, credited in the surface leak resulting in pool accident analysis, is to limit release of aerosols generated by splatter inside the pit and limit shine and skyshine dose to the onsite receptor.

The discussion applies to waste transfer-associated structures (process pits, diversion boxes, vault pits, cleanout boxes). The diversion boxes, vault pits, and cleanout boxes are described in Appendix B. The process pits for DSTs, SSTs, and other storage tanks are described in Appendix B.

2.1.2.9 Waste Tank Level Monitors. The safety function of level monitors, credited in the tank bump accident analysis, is to indicate the waste level in the tank in support of implementing the tank temperature control. The waste tank level monitors are described in Appendix B.

The discussion applies to all DSTs and AWF tanks.

2.1.2.10 Waste Transfer Pipe Encasements. The safety function of waste transfer pipe encasements, credited in the subsurface leak remaining subsurface accident analysis, is to ensure that a leak in the primary waste transfer system piping is directed to a waste transfer-associated structure.

The waste transfer pipe encasements are described in Appendix B. The discussion applies to waste transfer system piping (concrete-encased lines and pipe-in-pipe encased lines).

2.1.2.11 Transfer Leak Detection Systems. The safety function of the transfer leak detection systems, credited in the subsurface leak remaining subsurface accident analysis, is to detect a potential waste accumulation in

the transfer-associated structures (e.g., process pits, diversion boxes, valve pits, cleanout boxes) and/or transfer piping encasement during a transfer and to alert the operator.

The transfer leak detection systems are described in Appendix B. The discussion applies to waste transfer piping (concrete-encased lines and pipe-in-pipe encased lines) and transfer associated structures (process pits, diversion boxes, vault pits, and cleanout boxes).

2.1.2.12 2727-W Sodium Storage Facility. The safety function of the 2727-W Sodium Storage Facility, credited in the sodium fire analysis, is to provide a physical barrier to the potential release from high winds and vehicle crashes. The 2727-W Sodium Storage Facility is described in Appendix B.

2.1.2.13 Service Water Flow Totalizers. The safety function of the service water flow totalizers, credited in surface leak resulting in pool accident analysis, is to monitor flow of service water. The service water flow totalizer is described in Appendix B.

3.0 RELEVANT OPERATIONAL HISTORY

This chapter discusses significant abnormal occurrences and associated compensatory measures published for the Tank Waste Remediation System (TWRS) operational history. Also discussed are the processes for resolving findings from operational readiness reviews, inspections, and audits; internal and external assessments; open Unreviewed Safety Questions (USQs) and their closure status; and open safety issues.

The hazard analysis activity summarized in Section 5.2, "Hazard Analysis" included a review of documented occurrence reports for TWRS (200 Area tank farms and affiliated facilities). The intent of the review was to identify a comprehensive set of hazards and potential accident causes to be used in the hazard analysis activity. This review involved comparing the nature of the occurrences with the potential causes or accidents identified by the hazard analysis and verifying that those occurrences are not material to the hazard analysis results. Review of the occurrences was also used to assist in determining qualitative frequencies for some of the hazardous conditions in the TWRS hazard and operability study (HazOp) and preliminary hazard analysis (PHA).

3.1 SIGNIFICANT ABNORMAL OCCURRENCES

The occurrence reporting and processing system, described in Section 4.16, "Occurrence Reporting," was established in 1990 to track unusual occurrence reports, off-normal events, and critiques. This system implements the reporting requirements of DOE 5000.3B, *Occurrence Reporting and Processing of Operations Information*[1].

One thousand-ninety occurrence reports and off-normal events from January 1972 to May 1998 were reviewed to determine the degree of significance and qualitative frequencies. These occurrence reports and off-normal events were compared with the hazardous conditions identified in TWRS HazOp and PHA. Two databases were created to track occurrences and off-normal events. For events that occurred before 1990, the database consists of unusual occurrence reports produced by previous Hanford Site Contractors, including the following: Atlantic Richfield Hanford Company (January 1972 through June 1977); Rockwell Hanford Company (June 1977 through June 1987); and Westinghouse Hanford Company (June 1987 through December 1989). Copies of tank farm-associated unusual event reports, critiques, and event fact sheets for the years 1986 through 1990 were reviewed and included in the database as appropriate. The Occurrence Reporting and Processing System (ORPS) database was obtained electronically for the years 1990 to May 1998. This database includes all unusual occurrence reports, off-normal events, and critiques generated by the Westinghouse Hanford Company and PHMC. Minor skin contaminations or reports of minor spread of contamination (specks or

[1]Although DOE Order 5000.3B has been rescinded, the contractor is obligated by the existing contract to meet the requirements stated in that order.

contamination spread to clothing) from tank farms or associated facilities were not included in the database developed to support the TWRS hazard analysis. This information is addressed separately by the Radiation Protection Program.

The criteria in DOE O 232.1, *Occurrence Reporting and Processing of Operations Information*, define what will be reported and the significance categories. The criteria for determining significance or severity of events include impacts on personnel safety, health protection, the environment, public exposure, nuclear safety limits, and emergency preparedness.

None of the tank farm occurrences met the criteria for significant consequences, serious consequences, or very serious consequences. The criteria used for this evaluation are discussed in WHC-SD-WM-CN-036, *Review of Tank Farm Occurrences According to Safety Significant Criteria*.

The hazard identification and evaluation process reviewed the occurrence reports to identify both hazardous conditions and frequency of occurrences. By reviewing existing safety documents and hazard analyses, operating history before 1972 was also considered in the hazards analysis process. The review is documented in Appendix D, "Hazard Analysis Results Report."

3.2 CHANGES TO STRUCTURES, SYSTEMS, AND COMPONENTS IMPORTANT TO SAFETY

TWRS equipment upgrades are initiated for different reasons, including changes in plant conditions, changes in operating or process requirements, identified hazards, self-evaluations, and event-related corrective actions.

Several changes and additions have been made to the safety structures, systems, and components at TWRS since the BIO was implemented. These changes have been incorporated in Appendix B, "Facility and Process Description." Project-specific facility descriptions are included in the BIO addenda.

3.3 SAFETY-RELATED FINDINGS FROM OPERATIONAL READINESS REVIEWS AND INSPECTIONS/AUDITS

The Corrective Action Management System implemented in WHC-CM-1-4[2], *Corrective Action Management Manual*, is used to ensure adverse conditions are identified, tracked, and resolved. The Corrective Action Management System uses a graded approach in performing evaluations and analyses, including root cause analyses, trend analysis, and lessons learned evaluations. The required tracking method for adverse condition status is the Hanford Action and Tracking System. The Hanford Action and Tracking System is a U.S. Department of Energy, Richland Operations Office (RL)-approved sitewide database used

[2]Refer to Appendix F, "Site-wide Controlled Manual Cross Reference Table," of the BIO for cross-walk between Site-wide controlled manuals (e.g., WHC-CM-X-XX) superseded by Fluor Daniel Hanford, Inc., Procedures (e.g., HNF-PRO-XXX).

within TWRS to enter, track, and report the status of conditions, deficiencies, and associated actions identified by internal and external assessments (WHC-SD-GN-CSUD-30013, *HATS Users Guide*).

The Hanford Action Tracking System is being phased out and will be replaced by the Deficiency Tracking System. The Deficiency Tracking System was initiated in November 1997. Project Hanford Procedure HNF-PRO-653, *Deficiency Tracking System*, implements requirements for processing and tracking deficiencies identified by or requiring action by personnel performing work under the Project Hanford Management Contract (PHMC).

3.3.1 Tank Farm Operations and Facilities Assessments by U.S. Department of Energy

3.3.1.1 East Tank Farm Operations Assessment. An operations assessment of the tank farms in the 200 East Area was conducted by RL in July 1995 (Sidpara 1995). The assessment identified six concerns. Only one (Concern 2) remains open as of May 1, 1998. The planned completion date for Concern 2 is September 30, 1998.

- Concern 2: "Shift routines at the Computer Automated Surveillance System (CASS) station are informal. CASS operators do not ensure that alarm status and facility configuration are communicated between the CASS station and the cognizant tank farm shift managers."

3.3.1.2 Tank Farm Operations and Facilities Assessment. An assessment of the tank farm operations and facilities was conducted by U.S. Department of Energy (DOE) and RL in April 1996 (McClusky 1996a). The assessment identified two findings. As of May 1, 1998, no open items remain for TWRS.

3.3.1.3 Special Assessment of 241-A-701 Air Compressor Upgrade Project. A special assessment of the 241-A-701 Air Compressor Upgrade Project at the 200 East Area Tank Farms was conducted by RL in August 1996 following a "near-miss" incident at the 241-A-701 Building (Kinzer 1996a). Several significant deficiencies were identified that led to the near miss incident, including improper acceptance and turnover of systems, improper configuration management control, incorrect labeling of equipment, improper lockout/tagout practices, and inadequate safety and quality oversight. The assessment identified six findings and two observations. A Corrective Action Plan was issued. As of May 1, 1998, no open items remain for TWRS.

3.3.1.4 Tank Farm Operations Secretarial Safety Initiatives Closure Assessment. An assessment was conducted by RL in August 1996 as a result of the special assessment performed on the 241-A-701 Air Compressor Upgrade Project at the 200 East Area Tank Farms (Kinzer 1996b). The results of the assessment concluded that four Secretarial Safety Initiative action items (1d,

5a, 5e, 5f) related to Tank Farm Operations were considered complete, and two action items (4a and 4b) were considered incomplete. As of May 1, 1998, Action Item 4a remains open.

- Safety Initiative 4: Infrastructure Upgrades

  Action Item 4a: Upgrade alarm panels in 7 tank farms by March 1995.

3.3.1.5 Tank Waste Remediation System Characterization Vapor Project Assessment. An assessment of the TWRS Characterization Vapor Project was conducted by RL in November 1996 (McClusky 1996b). The assessment described a number of deficiencies in the project deliverables. RL requested that the contractor provide a path forward and implementation dates by December 6, 1996, for the following issues:

- Current applicable TWRS permits (primarily the Rotary Mode Core Sampling permit) need to be reevaluated and renegotiated to include risk-cost-benefit considerations.
- The Vapor Project needs a clear technical basis. This includes a valid approved and signed Quality Assurance Project Plan, Data Quality Objectives(s), and Sampling and Analysis Plan(s).
- A plan is required which clearly outlines a reliable and comprehensive sampling and analysis process.

The path forward should include a detailed plan and schedule that indicate to RL and the Washington State Department of Ecology how the Vapor Project plans to proceed in a reasonably safe, environmentally sound, and cost-effective manner while striving for continuous improvement. Four corrective actions remain open and one remains on schedule (Umek 1997).

3.3.1.6 Management Assessment of Tank Waste Remediation System Basis for Interim Operation Implementation. A Management Assessment of TWRS BIO implementation was conducted by RL in September 1997 (Wagoner 1997). The objective was to verify that RL and the PHMC team had achieved the necessary state of readiness to implement the BIO. An Integrated Transition Plan was jointly prepared by the RL Management Assessment team and the PHMC team. The intent of the plan was to ensure an orderly disposition of the findings by the PHMC Readiness Assessment team, the RL Tier II and Tier III reviews, and the open items remaining from the Directed Changes issued through the BIO Safety Evaluation Report Amendment (TWRS-RT-SER-02, Amendment-1, MA Volume II, *Safety Evaluation Report Amendment to TWRS-RT-SER-02, Revision 1, Reconciliation and Consolidation of Tank Waste Remediation System Authorization Basis Controls*). A total of 131 transition items and conditions were compiled from the findings. The Integrated Transitional List of Items and Conditions is a living document under RL configuration management and will continue to be updated as the open items are closed.

3.3.1.7 RL TWRS Tank Operations Division Evaluations. The RL TWRS Tank Operations Division conducts periodic evaluations (assessments and surveillances) of TWRS facilities and the results are documented in TWRS Monthly Reports. The most recent evaluation was conducted by the RL TWRS Tank

Operations Division in April 1998 (Kinzer 1998a). The evaluation, which identified nine findings and 16 observations, consisted of two assessments of Single Shell Tanks (formerly known as 200 West Tank Farms facility), Double Shell Tanks (formerly known as 200 East Tank Farms facility), and Characterization Project. One of the assessments was a partial conduct of operations assessment, and consisted of eight surveillances. The other assessment covered Project W-030 (Aging Waste Facility ventilation upgrade project) turnover in the Double Shell Tanks. No significant deficiencies were identified during the partial conduct of operations assessment. The Lock and Tag Program for Single Shell Tanks was found to be well run and administered and in compliance with DOE orders, Occupational Safety and Health Administration standards, the sitewide program, and the contractor's program. The TWRS labeling upgrade program was found to have made significant progress under very difficult field conditions. Two significant issues were identified during the Project W-030 turnover assessment as follows:

- Project W-030 exceptions for system startup were overdue with no clear path for closeout, or the contractor closed out exceptions that were accepted in an inadequate condition.
- Procedures were not adequate to support initial system startup and shutdown.

As of May 1, 1998, all corrective actions remain open.

3.3.2 Independent Oversight Evaluations

3.3.2.1 Tiger Team Assessment. An independent oversight evaluation of environmental, safety, and health programs at the Hanford Site determined that improvement is needed in the following programs (DOE 1996 and Wagoner 1996a):

- Radiological Control
- Conduct of Operations/Procedural Rigor
- Requirements Management/Authorization Basis
- Monitoring/Assessments/Management Field Presence
- Corrective Action Program
- Subcontractor Safety
- Occupational Medicine/Medical Surveillance Programs.

The Fluor Daniel Hanford, Inc. (FDH) response to these deficiencies targets the broad categories of findings, linked to the systemic problems, from a management perspective rather than responding to detailed findings. The FDH Office of Environment, Safety, and Health (ES&H) was established to manage and integrate ES&H activities on a sitewide basis, with eight departments (each with specific defined roles). Quarterly reports indicate the status of the various deficiencies and overall progress towards their improvement. Several of the deficiencies described above are directly linked

to Performance Agreements. Significant programmatic improvements have been made, enabling closure of some Performance Agreements. Others remain open as of May 1, 1998.

3.3.2.2 Defense Nuclear Facilities Safety Board Independent Oversight. The Defense Nuclear Facilities Safety Board (Board) is an independent organization within the executive branch chartered with the responsibility of providing recommendations and advice to the President and the Secretary of Energy regarding public health and safety issues at DOE defense nuclear facilities, including TWRS. The most significant and challenging safety issues being tracked by the Board are reflected in the Board recommendations that remain open. Significant, ongoing Board-related activities at TWRS facilities are summarized below.

3.3.2.2.1 Integrated Safety Management System Implementation. During 1997 the Board focused on implementation of the Integrated Safety Management System (ISMS) at TWRS, which is a high-priority facility for implementation of ISMS programs. Implementation of Board Recommendation 95-2, "Integrated Safety Management," is central to DOE's nuclear safety management and the Board's approach to safety oversight. The objective of Recommendation 95-2 is to systematically integrate safety into management and work practices at all levels so that missions are accomplished while protecting the public, workers, and the environment. The status of ISMS implementation at TWRS will continue to be a primary focus by the Board.

3.3.2.2.2 Configuration Management. In 1996, the Board observed instances of configuration management problems at TWRS facilities and new construction projects (e.g., 241-A-701 Building "near-miss" event, Tank 241-AZ-102 ventilation system loss, flammable gas sample truck modification, Project W-320 delay) which raised concerns about the existing documentation and knowledge basis for the configuration of systems and equipment. Deficiencies observed include inadequate as-built drawings used by maintenance and operations personnel, inadequate labeling of equipment, and lack of update of maintenance and operating procedures. Following the 241-701-A near-miss event, tank farms reconstituted its labeling and drawing upgrade program into a project organization. The project has strong DOE and contractor management support, is focused, and involves the appropriate standards and workers. The Board continues to monitor configuration problems at TWRS closely.

3.3.2.2.3 Operational Readiness Reviews. Project W-030 (Aging Waste Facility [AWF] ventilation upgrade project) installed a new ventilation system for the AWF tanks. The new system is an improvement over the previous system, and provides an increased margin of safety in the tank farms. During the contractor and DOE readiness reviews, several significant pre-start findings adverse to the safe operation of the system were identified. Deficiencies were observed in the adherence to the appropriate requirements and intent of DOE 425.1[3], *Startup and Restart of Nuclear Facilities*, and DOE-STD-3006-95,

[3] DOE 425.1 is not part of the PHMC. Therefore, PHMC is obligated to comply with RLID 5480.31, *Startup and Restart of Facilities Operational Readiness Review and Readiness Assessments.*

Planning and Conduct of Operational Readiness Reviews. The Board will continue to monitor this area to ensure that the intent of the orders is met.

3.3.2.2.4 Systems Engineering. There has been progress within TWRS to implement Board Recommendation 92-4, "Systems Engineering." However, the systems engineering process is not institutionalized to the point where it is clearly directed, proceduralized, implemented, and repeatable. Additional efforts are in progress to demonstrate the institutionalization of systems engineering for TWRS to satisfy the objective of Recommendation 92-4.

3.3.2.2.5 Waste Characterization. The PHMC has developed a revised list of high-priority tanks to be sampled and analyzed as part of the Board Recommendation 93-5, "Characterization," Implementation Plan. The new list increases the priority for tanks of interest to the organic and flammable gas safety programs. Characterization is also being conducted in support of disposal system design, in accordance with Recommendation 93-5. Some designs may be driven by waste characterization results. The Board continues to monitor activities supporting implementation of Recommendation 93-5 to ensure potential impacts to the TWRS program are systematically investigated and resolved.

3.3.2.3 Review of the Federal Management of Tank Waste Remediation System. An independent review of the federal management of the TWRS program, commissioned by the RL Manager, was conducted by a team of nine DOE employees and contractors in January 1998 (Rudzinski 1998). The areas reviewed included (1) nuclear safety program management, (2) vadose zone contamination project management, and (3) general management and working environment of the TWRS program. Although the review was focused on management concerns, the team conducted some limited technical reviews to better understand the broader management issues. The team made four findings based on its review:

1. Current TWRS management processes for addressing safety and technical issues lack sufficient rigor to consistently detect, manage, and resolve problems before they become major issues for the program. This lack of rigor is evident throughout several aspects of TWRS nuclear safety management processes.

2. Processes for reviewing and resolving technical and safety comments are weak and have failed to address significant issues in several cases.

3. External credibility issues continue with the vadose zone program. Past management of the program (1980s through present) has contributed substantially to these problems.

4. Management problems identified in previous self-assessments persist.

The team recommended that RL and TWRS take the following actions:

1. Develop and implement corrective actions to address the team's findings within established deadlines.

2. Increase the rigor of safety authorization documentation and the USQ process.

3. Implement a more open and disciplined internal and external comment resolution process.

4. Accelerate current site efforts to develop a process to resolve differences of professional opinion and pilot test the process before implementing it broadly.

5. Fully integrate the vadose zone, groundwater, and Hanford Tank Initiative programs. Establish clear goals for the use of data among the programs and institute expert panel review of methodologies, modeling plans, and interpretations of results.

6. Improve communication of project and policy decisions to the staff and public. This will require the TWRS program to share information more openly and earlier than it has traditionally done.

7. Develop and implement a corrective action plan to address unresolved management problems from this report and previous studies.

Closure of the team recommendations (corrective actions) for RL and TWRS will be monitored by DOE management.

3.3.2.4 Review of Recent Unusual Occurrences and the Process for Verification of Implementation of the Basis for Interim Operation for Tank Waste Remediation System. An independent review of the BIO implementation process was conducted by DOE in February 1998, as the result of four incidents at TWRS that were classified as Unusual Occurrences (Rice 1998). The independent review concluded the following:

1. No systematic breakdown in the process for inclusion of revised Authorization Basis safety requirements existed.

2. The BIO implementation affidavit process, which identified needed changes to management and control documents, was not rigorously applied.

3. Additional verification activities, such as directed self-assessments and Quality Assurance checks of selected activities, are needed to ensure that all TSRs are implemented.

Corrective Actions in response to the report were issued (Rice 1998). The USQ process is highly proceduralized and institutionalized at TWRS. This USQ process, or a fundamentally equivalent process, will continue to be used to ensure the necessary and sufficient implementation of the Authorization Basis documents and requirements. Prior to validation activities involving the use of affidavits, the expectations will be re-emphasized. The recommendation to perform additional verification activities to ensure all TSRs are implemented was incorporated into the Contractor Readiness Assessment of the Replacement Cross-Site Transfer System (Project W-058), completed April 5, 1998, and will be included in all future activities.

3.3.3 Internal Assessments

3.3.3.1 Tank Farms Authorization Basis Assessment. The tank farms Authorization Basis was assessed and the results documented in an internal memo (Propson 1996). The assessment noted a serious lack of rigor in applying the USQ process and therefore issued an associated notice of noncompliance report under 10 CFR 830.120, "Quality Assurance Requirements." This report was subsequently transmitted to DOE-Headquarters (Newland 1996). In response to this report, a root cause analysis was performed (Truax 1996). From the root cause, nine associated findings were corrected. Implementing the corrective actions improved configuration management, procedures, and USQ programs. Three remaining open findings are as follows:

- Maintenance procedures and calibration data sheets that are indicated as safety related have no clear link to Authorization Basis requirements.
- The Compliance Implementation Plan is not a controlled document. The corrective action is to convert the Compliance Implementation Plan to a controlled document. This finding has no safety impact.
- The definition of "operability" as defined by DOE 5480.22, *Technical Safety Requirements*, and the Interim Operational Safety Requirements has not been fully implemented as required (intended) by the Interim Operational Safety Requirements. This finding has been corrected by issuing the BIO Technical Safety Requirements.

3.3.3.2 Westinghouse Hanford Company Quality Assurance Program and Implementation Plan - 10 CFR 830.120. Another assessment documented in WHC-SP-1131, *Westinghouse Hanford Company Quality Assurance Program and Implementation Plan, Implementation of Title 10 Code of Federal Regulations Part 830.120*, identified five action items. One of these action items is completed; those remaining open are as follows (WHC-SP-1131):

- **Generate As-Builts for Construction Projects**—This action was completed by December 1996. There is no compensatory action because no new large-scale construction projects are imminent.
- **Revise "As-Builts" to Denote Upgrades and Maintenance**—This action will be completed by September 2000. Compensatory actions are as follows:
  - The contractor will continue to use the existing Field Verification program (i.e., walkdown of systems to verify field and project-initiated work). The Field Verification program provides accurate drawings of TWRS facilities.
  - A new drawing program has been initiated that effectively establishes the "as-built" status for some systems. As an additional compensatory action, the labeling program provides labels for components and input for the master equipment list, and develops system drawings.

- **Track the Condition and Age of Materials and Equipment**—This action is completed. Implementation of loop calibration is currently focused on system loops associated with the Authorization Basis. The implementation of loop calibration on the remaining loop systems will be based on their importance to safety, quality, environment, and Conduct of Operations.

- **Specify Design Basis for Existing Facilities**—This action will be completed by September 2005. Compensatory actions are as follows:

  - Additional field verification steps are taken during the planning stages of maintenance and operations activities to ensure worker and public safety.

  - Facilities of hazard category 3 and above must pass the contractor Readiness Review process per DOE 5480.31 before they are operated.

3.3.3.3 Westinghouse Hanford Company Facility Evaluation Board Assessment - August 1996. The Westinghouse Hanford Company Facility Evaluation Board conducted its first performance-based assessment of the 200 West Tank Farms facility (now known as Single Shell Tanks) in August 1996 (Wicks 1996). The Facility Evaluation Board conducted the assessment in the areas of Facility Organization and Administration; Operations; Radiological Controls; Engineering; Maintenance; Environment, Safety and Health, & Quality Assurance; and Training and Support. The Facility Evaluation Board evaluated the overall facility performance as "Below Expectations." A grade of "Below Expectations" means standards of performance were minimal and need to be raised. The minimum requirements are generally met in most areas. Performance and programmatic improvements were needed in many areas. Several significant strengths were observed at West Tank Farms, which included a desire to make reengineering work, the willingness to discover and apply new processes, and the drive toward continuous improvement.

The West Tank Farms, however, did have three significant areas of weakness. As of May 1, 1998, all deficiencies are closed. The core issues included the following:

- Radiological Controls

- Correction of Known Deficiencies

- Handling of Hazardous Materials and Dangerous Waste.

3.3.3.4 Fluor Daniel Hanford, Inc. Facility Evaluation Board Assessment - December 1997. The FDH Facility Evaluation Board conducted its first performance-based assessment of the 200 East Tank Farms facility (now known as Double Shell Tanks) and Characterization Project in April 1997 (Grier 1997). The Facility Evaluation Board conducted the assessment in the areas of Facility Organization and Administration; Operations; Radiological Controls; Engineering; Maintenance; Occupational Safety and Health; Training; Emergency Preparedness; Environmental Compliance; and Quality Assurance. The Facility Evaluation Board evaluated the overall performance as "Level 3 (Meets Minimum Requirements)." Level 3 means standards of performance are acceptable. The

minimum requirements are met. Management expectations are generally not satisfied. Performance and programmatic improvements are needed in some areas. Several noteworthy practices were identified during the assessment. Included are the TWRS Facility Excellence Program, East Tank Farms Contamination Water-Borne Capture Coating Procedure, TWRS Vision Training Development Software Program, and Characterization Project Drill Simulation Techniques.

Three core issues were identified by the Facility Evaluation Board during the assessment. The issues reflect deficiencies observed in more than one assessment area. These core issues include the following:

- Procedural Compliance
- Radiological Control Practices
- Corrective Action Management.

A Corrective Action Plan for identified deficiencies was accepted by FDH TWRS Project. As of May 1, 1998, all radiological control deficiencies are closed. Closure of other deficiencies remains in progress.

3.3.3.5 FDH Facility Evaluation Board Assessment - March 1998. The Fluor Daniel Hanford, Inc. Facility Evaluation Board conducted its second performance-based assessment of the Single Shell Tanks organization in November 1997 (Grier 1998a). The Facility Evaluation Board conducted the assessment in the areas of Facility Organization and Administration; Operations; Radiological Controls; Engineering; Maintenance; Occupational Safety and Health; Training; Emergency Preparedness; Environmental Protection and Waste Management; and Quality Assurance. The Facility Evaluation Board evaluated the overall performance as "Level 3 (Meets Minimum Requirements)." Level 3 means standards of performance are acceptable. The minimum requirements are met. Management expectations are generally not satisfied. Performance and programmatic improvements are needed in some areas. The trend of performance is improving from the first assessment conducted in August 1996. Several noteworthy practices and positive observations were identified by the Facility Evaluation Board during the assessment. Two core issues were identified as follows:

- Requirements Management
- Corrective Action Management.

A Corrective Action Plan for identified deficiencies was accepted by FDH TWRS Project. As of May 1, 1998, closure of identified deficiencies remains in progress.

3.4 SUMMARY OF OPEN UNREVIEWED SAFETY QUESTIONS AND SAFETY ISSUES

Open USQs and safety issues are discussed in this section.

3.4.1 Open Unreviewed Safety Questions

Three open USQs exist within TWRS and are discussed in the following sections. These open USQs are tracked and closed through the USQ process (HNF-IP-0842, *TWRS Administration*). The compensatory measures and controls implemented for interim operation are discussed in Chapter 5.0, "Safety Analysis."

3.4.1.1 Flammable Gas and Slurry Growth Unreviewed Safety Question. Three mechanisms (radiolysis of water, thermal production, and corrosion) work simultaneously to produce flammable gases (principally hydrogen, ammonia, and methane) in the site's stored, high-level nuclear waste. Radiolysis of water generates hydrogen and ammonia if the waste contains nitrate or nitrite ions. Thermal production (from chemical reactions) involving radiolytic degradation products of some of the original organic chemicals stored in the tanks generates methane, nitrous oxide, hydrogen, and ammonia. Corrosion of a waste tank's steel lining also generates hydrogen.

Originally, "slurry growth," the phenomena of gases being trapped within the slurry and beneath the crust of the waste, was thought to cause the accumulation of flammable gas. Reviews of vapor space flammability in Tank 241-SY-101 identified that the gas under the waste crust is potentially flammable because nitrous oxide and hydrogen can create flammable mixtures, (which is considered an "Unreviewed Safety Question" [Daugherty 1990]).

Because Tank 241-SY-101 could potentially accumulate flammable gas in its dome space, it was placed on a flammable gas "watch list." A flammable gas mixture in a tank, along with an ignition source, could lead to a deflagration or burning. In turn, this could cause a release of radioactive waste to the environment. In May 1990, the flammable gas USQ was declared (Lawrence 1990).

Since 1990, considerable information has been obtained from tank samples, monitoring data, laboratory experiments, and theoretical modeling and analysis. This information has increased the understanding of flammable gas and slurry growth phenomena. In addition, a mixer pump was installed in Tank 241-SY-101 in July 1993 to gradually release gas, thereby avoiding concentration buildup to flammable levels.

The original USQ on Tank 241-SY-101 was recently closed (Kinzer 1996c). The administrative controls (Wagoner 1996b) on the mixer pump required for closure of this USQ are described in Chapter 5.0.

Another USQ evaluation, USQ Tracking No. TF-96-0433, "Expansion of Flammable Gas and Slurry Growth," identified the following TWRS facilities as potentially having flammable gases: double-contained receiver tanks, double-

shell tanks (including AWF tanks), and single-shell tanks; TWRS-managed inactive miscellaneous underground storage tanks; catch tanks; the 204-AR Waste Unloading Facility; and the 244-AR Vault.

Clarification of the Flammable Gas and Slurry Growth USQ (USQ Tracking No. TF-96-0433) is presented in Appendix E, "Flammable Gas/Slurry Growth Unreviewed Safety Question: Justification for Continued Operation for the Tank Farms at the Hanford Site." The allowed activities and required controls of this justification for continued operation are described in Appendix E.

3.4.1.2 Condensed-Phase Organic Nitrate Reactions Unreviewed Safety Questions. Previous evaluations of the organic salt-nitrate hazard reviewed the bulk heating scenario that caused a disaster in the commonwealth of independent states, formally the Union of Soviet Socialist Republics. This scenario involved a waste tank with a high-radionuclide heat load that was allowed to dry out; the waste self-heated to ignition temperature and exploded.

Comparison of organic waste tanks at the Hanford Site with this scenario concluded that the scenario is not credible because (1) average temperatures in organic tank waste are kept well below the bulk ignition temperature of 230 °C (446 °F), and (2) the waste has ample moisture to prevent ignition from such point sources as lightning, fuel spill or fire, or welding sparks.

However, new information from WHC-SD-WM-SARR-033, *Preliminary Safety Criteria for Organic Watch List Tanks at the Hanford Site*, indicates that it may be possible to ignite dry surface organic waste with similar point sources of heat (e.g., lightning, fuel spill or fire, welding spark) if interstitial water is more than 0.3 m (1 ft) subsurface. Surrogate tests show that point sources can ignite reactive, dry organic waste with an organic carbon of >4.5 wt% and a moisture of <20 wt%.

In May 1996, the contractor declared the condensed-phase organic nitrate reactions USQ (USQ Tracking No. TF-95-0096, "Condensed-Phase Organic Nitrate Reactions"); RL accepted the USQ (Wagoner 1996c). From the USQ evaluation, the following conclusions were made:

- All double-shell tanks are judged to currently have sufficient moisture in the waste to make them conditionally safe from condensed-phase organic nitrate reactions, regardless of the total organic carbon level.
- Double-contained receiver tanks hold only liquid waste for short periods and are thus safe from condensed-phase organic nitrate reactions.
- Two tanks (241-C-201 and 241-C-202) are currently identified as Organic Tanks.
- Two tanks (241-AX-102 and 241-C-204) are identified as Potential-Organic Tanks.

- Miscellaneous underground storage tanks (also known as miscellaneous inactive storage facilities) and the single-shell tanks are still being evaluated.

The allowed activities and required controls for the TWRS facilities are described in Chapter 5.0. The contingency actions for the safe operation of other tanks and inactive miscellaneous underground storage tanks are also described in Chapter 5.0.

3.4.1.3 Waste Surface Level Increase in Tank 241-SY-101. Tank 241-SY-101 has exhibited periodic waste level fluctuations after the initial waste was added to the tank. The fluctuations are associated with the generation, retention, and spontaneous release of large quantities of flammable gas. An increase in the amount of retained gas causes the level to increase, while a release of gas causes the level to drop. The surface level in Tank 241-SY-101 has been used as an indirect measure of retained gas inventory, and therefore as an indicator of the flammable gas hazard associated with the tank. A mixer pump was installed in the tank in 1993 to mitigate the pattern of gas retention and spontaneous release. Before the installation of the mixer pump in 241-SY-101, episodic gas releases occurred at intervals of 3 to 6 months. The releases occurred when the waste level was above 1046.5 cm (412 in.). The waste level was 1031.2 cm (406 in.) when the mixer pump was installed. The waste level decreased to less than 1016 cm (400 in.) after a few months of operation, where it remained through 1996 (Hatch 1998).

Between January and October 1997, the waste surface level increased to approximately 1016 cm (400 in.) as measured by the level indicating device in riser 1C. The rate of level increase is approximately 0.025 to 0.05 cm/day (0.01 to 0.02 in./day) compared with a rate of 0.2 to 0.25 cm/day (0.08 to 0.10 in./day) before the mixer pump was installed. However, the level increase was not expected because of the regular pump operations. The location of the layers of waste in the tank has not changed. Data from the two thermocouple trees installed in the tank indicate that the liquid waste remains below the crust (with a thickness of approximately 127 cm [50 in.]) and above the settled solids layer (with a thickness of approximately 30.5 cm [12 in.]). Data on the tank ventilation (both in the headspace and in the annulus) indicate that its performance has not been degraded over the course of the year. No degradation in the pump performance has been observed either, as indicated by pump motor current, pump rotating speed, volute and nozzle discharge pressure, and oil temperature rate of increase. The waste temperature readings indicate that waste flow is penetrating to the radius of the thermocouple trees, when the jets are directed at the thermocouple trees. These data are consistent with previous behavior. Gas releases following pump operation are also within established norms (Hatch 1998).

The Test Review Group has the option to consider aggressive pump operations when the waste level in Tank 241-SY-101 reaches 1014.7 cm (399.5 in.) (WHC-SD-WM-PLN-081, *Mixer Pump Long Term Operations Plan for Tank 241-SY-101*). As a result, the Test Review Group directed that the number of pump runs be increased from three to four per week, starting October 27, 1997. The increased number of pump runs did not slow the increase in surface level. In fact, it appeared that the level continued to increase with increased pump operation. On December 9, 1997, the Test Review Group directed that the pump operation return to three runs per week (Hatch 1998).

The TWRS Plant Review Committee declared that the unexplained level increase in Tank 241-SY-101 constituted a "discovery" on December 27, 1997. As a result, occurrence report RL-PHMC-TANKFARM-1997-0106, *Potential Inadequacy in the Authorization Basis for Tank 241-SY-101*, was issued. Also, USQ Screening/Determination TF-97-0975, "Waste Surface Level Change in Tank 241-SY-101," was declared by the contractor to document the findings. Single Shell Tanks Standing Order 98-15, "Operations in Tank 241-SY-101," was generated to impose new controls to ensure the safety of the waste in the tank.

The USQ TF-97-0975 and Standing Order 98-15 were transmitted to RL on February 20, 1998 (Hatch 1998). RL concurred with the contractor on February 26, 1998, that the unexplained waste level change in Tank 241-SY-101 represents an USQ (Kinzer 1998b). RL issued direction on the proposed new controls as contained in Single Shell Tanks Standing Order 98-15, on March 5, 1998 (Wagoner 1998). At this time, the following restrictions on mixer pump operations are in effect:

1. Prior to each pump operation, the Shift Manager shall verify that all Tank 241-SY-101 riser 17B and 17C multiple instrument tree operational thermocouples are indicating less than 125 °F, as observed on either Tank Monitor and Control System (TMACS) or Data Acquisition and Control System (DACS) outputs. If any of the 17B or 17C multiple instrument tree operational thermocouples exceed 125 °F, the Shift Manager shall obtain written guidance from the Test Review Group prior to performing pump operations.

2. Mixer pump operation shall continue in accordance with the Los Alamos National Laboratory (LANL) Safety Assessment (LA-UR-92-3196, *A Safety Assessment for Proposed Pump Mixing Operations to Mitigate Episodic Gas Releases in Tank 241-SY-101: Hanford Site, Richland, Washington*) and the long term operating plan. However, changes to pump operations required at 1021 cm (402 in.) as measured by the 1C ENRAF no longer apply.

3. The Test Review Group shall review tank data at least monthly and issue the Shift Manager authorization to continue pump operations.

3.4.2 Safety Issues

On November 5, 1990, the U.S. Congress enacted Public Law 101-510 *National Defense Authorization Act for Fiscal Year 1991*. Section 3137 of the law, "Safety Measures for Waste Tanks at Hanford Nuclear Reservation," addresses safety issues concerning the handling of high-level nuclear waste in storage tanks at the Hanford Site. In response to this law, the Secretary of Energy reported to the U.S. Congress in June 1991 (DOE 1991) regarding (1) actions being taken to promote safety in the "watch list" tanks; (2) the timetable for resolving waste tank safety issues; and (3) procedures for handling the radioactive waste in Hanford Site waste tanks. A more detailed report (DOE 1992) followed and provided safety issue descriptions, technical bases, alternatives, and an action plan for each safety issue identified in WHC-EP-0422, *A Plan to Implement Remediation of Waste Tank Safety Issues at the Hanford Site*.

Further review by the DOE High-Level Waste Tanks Task Force, in 1992, identified additional safety issues and a new category called "system deficiencies." The High-Level Waste Tanks Task Force report (DOE 1992) identified a total of 30 safety issues and system deficiencies to be addressed at the Hanford Site, Savannah River, Idaho Falls National Engineering Laboratory, and West Valley facilities. Of the 30 issues and deficiencies identified, 28 issues and deficiencies applied to the Hanford Site.

The safety issues were prioritized in three categories, according to the potential for an accident to occur. Priority 1 comprises four issues that include most of the necessary conditions that could lead to exposing an onsite worker to an uncontrolled release of radioactive waste. Priority 2 comprises eight issues that include some of the necessary conditions that could lead to an uncontrolled release of radioactive waste under extreme assumptions. Priority 3 comprises seven issues that include the necessary conditions that could lead to future release of radioactive waste. This "future" release is assumed to occur during the 5 to 30 years of intermediate storage of high-level waste before waste removal, treatment, and vitrification. System deficiencies are additional areas affecting tank farm operations that need improvement. Where practical, TWRS goals include resolving the safety issues by leaving the waste in the tank until it is removed for final disposal. This approach minimizes cost and radiation exposure to personnel. If necessary, resolving safety issues by removing the waste from a tank for treatment or storage elsewhere is recommended. When complete, the TWRS program will resolve the safety issues for the Hanford Site waste tanks. Safety issues for TWRS are summarized by priority level in Table 3-1. Table 3-2 identifies system deficiencies.

For more information on the safety issues and system deficiencies, refer to WHC-EP-0600, *Status Report on Resolution of Waste Tank Safety Issues at the Hanford Site*. Also provided in WHC-EP-0600 are the status of the resolution of each safety issue and system deficiency, summaries of the completed actions and actions being taken to promote tank safety, and timetables for resolving safety issues and system deficiencies.

Table 3-1. Safety Issues for the Tank Waste Remediation System.

Safety issue description	Priority
High flammable gas concentrations	1
Potentially explosive mixtures of ferrocyanides[1]	1
Potential for runaway organic-nitrate reactions	1
Water additions needed to cool single-shell tank	1
Potential for nuclear criticality in high-level waste tanks[2]	2
Inadequate single-shell tank leak detection	2
Storage of high-level waste in tanks that have leaked	2
Inability of waste tanks and ancillary equipment to withstand a design basis earthquake	2
Single-shell tank emergency pumping capability inadequate	2
Tank vapor release	2
Inadequate response time to a leaking double-shell tank	2
Storage of high-level waste in tanks with no secondary containment	2
Insufficient tank storage capacity to handle waste resulting from resolution of existing safety issues	3
Cracked tank farm ventilation header	3
Insufficient hydroxide concentration in tanks	3
Inadequate sealing of single-shell tanks to prevent intrusions that could leak contamination out of tank	3
Inadequacies in waste transfer line leak detection	3
Excessive unfiltered airflow passages into tanks	3
Uncharacterized corrosion of high-level waste tanks	3

NOTES:

[1]This issue is resolved based on WHC-SD-WM-SARR-038, Assessment of the Potential for Ferrocyanide Propagating Reaction Accidents and Contract Number DE-AC06-96RL13200; Approval to Revise the Interim Safety Basis to Remove Ferrocyanide Tanks from the Watch List (Wagoner 1996d).

[2]U.S. Department of Energy, Richland Operations Office review team has recently (September 1996) recommended closing the criticality safety issue (Tayloe 1996).

Table 3-2. System Deficiencies for the Tank Waste Remediation System.

Insufficient tank contents characterization
Inadequate safety documentation
Deficient maintenance and upgrade of facilities
Deficient instrumentation upgrades in single-shell and double-shell tanks
Extended tank safety operating life
Conduct of operations deficient
Lack of plant-essential drawings
Questionable transfer-line-concrete-encasement integrity
Leak detection in double-shell tanks

4.0 SAFETY MANAGEMENT

The objective of the Integrated Safety Management System (ISMS) is to facilitate *SAFE WORK*. The Tank Waste Remediation System (TWRS) organization is committed to performing work safely and efficiently and in a manner that ensures the protection of the public, the workers, and the environment. The overall management of safety functions and activities is an integral part of the TWRS Mission. This is accomplished through the effective integration of safety management into all facets of work planning and execution.

The ISMS establishes a single, defined environment, safety and health (ES&H) management system that integrates requirements into work planning and execution and identifies a set of requirements that reflects U.S. Department of Energy's (DOE) commitment to a "standards based" safety program and the safety concepts reflected by these requirements.

Improvements in the TWRS Authorization Basis and the implementation of an ISMS within TWRS are a significant step toward the implementation of Defense Nuclear Facilities Safety Board (DNFSB) Recommendation 95-2, concerning integrated safety management.

Key safety management programs included in this chapter provide the administrative framework for the safe operation of TWRS facilities.

TWRS is committed to safety management programs that ensure the following:

- Safe storage of radioactive and hazardous materials
- Protection of facility workers from exposure to radioactive and hazardous materials and industrial hazards
- Protection of the public and environment from releases of radioactive and hazardous materials.

The safety management programs comprise safety-related activities that range from radiation and hazardous material protection to disciplined conduct of operations. Developing and maintaining the Authorization Basis documents and associated safety basis documents are essential to safety management. TWRS has implemented improvements in the Authorization Basis process to improve safety that include both organizational changes (Section 4.1 "Organizational Structure and Management Responsibilities") and configuration control changes (Section 4.15 "Configuration Management").

Another important part of the TWRS safety management is provided by HNF-SD-WM-HSP-002, *Tank Farms Health and Safety Plan*, which addresses routine operations performed at the tank farms, establishes procedures, and provides general guidelines to minimize health and safety risks to the facility workers and other onsite workers. In addition to the Technical Safety Requirements, HNF-SD-WM-HSP-002 includes measures to protect some of the safety controls identified during the safety analysis process.

For the set of representative accidents analyzed in Chapter 5.0, "Safety Analyses," Defense-in-Depth systems and components; Safety-Significant structures, systems, and components (SSCs); and Safety-Class SSCs are identified. Their safety functions and other appropriate comments are captured in the tables which follow each analysis, and the basic criteria and programmatic requirements for each are summarized below. The discipline imposed by these criteria and requirements goes beyond merely supporting the assumptions identified in the analysis; it is an integral part of the Defense-in-Depth philosophy.

Defense-in-Depth systems and components are protected by the following disciplines.

- Configuration Control/Configuration Management. Engineering drawings and other design media are controlled per approved procedures. Facility configuration underlying the documented safety basis is not changed without implementing and completing the Unreviewed Safety Question process described in Section 4.17, "Unreviewed Safety Questions", and the process for changing plant design provides a controlled and auditable interface with that Unreviewed Safety Question process. Design changes affecting the human-machine interface receive special attention and a graded approach for approval of all engineering documents is followed. In addition, purchasing processes for spare parts and other materials needed for work activities are controlled by approved procedures.

- Work Control. Facility work is not performed without proper authorization. Section 4.9, "Work Control," describes approved work control processes which are followed for all modifications to the physical plant and all preventive and corrective maintenance to the plant equipment.

- Conduct of Operations. To achieve and sustain safe operations, a comprehensive program of management oversight and assessment covering operations, surveillance and maintenance practices, feedback of operational experience, and overall effectiveness of management controls has been established and is being maintained per Section 4.8, "Conduct of Operations." The implementing requirements and programs for TWRS are described in HNF-IP-0842, *TWRS Administration*.

- Quality Assurance. Appropriate quality assurance processes and procedures per Section 4.12, "Quality Assurance," are followed. Appropriate levels of quality control involvement in equipment maintenance, plant modifications, and other quality-affecting work activities are exercised.

- Training and Procedures. Per Sections 4.11, "Training and Procedures," and 4.18, "Human Factors," the preparation, approval, validation, and use of written procedures to guide operations, testing, surveillance, and maintenance activities are required. A competent operating staff is well trained in the use of all operations, testing, surveillance, and maintenance procedures.

Safety-Significant and Safety-Class SSCs are protected by the following disciplines. In addition to the following, all basic criteria and programmatic requirements for Defense-in-Depth systems and components apply:

- A change to a safety SSC is only possible after careful consideration of the reasons which support why the SSC was originally identified as a safety SSC.
- A Safety Equipment List has been created and maintained to clearly identify each component part of a safety SSC which performs, or directly supports the performance of, the identified safety function. The Safety Equipment List is contained in HNF-SD-WM-SEL-040, *TWRS Facility Safety Equipment List*.
- Enhanced inspection, testing, and maintenance programs are implemented to provide a high degree of assurance that all Safety-Significant and Safety-Class SSCs perform their safety functions when required.

The safety management programs, applicable requirements, and implementing documents that support TWRS operations are briefly described in the rest of this chapter. These programs are not independent of each other. Often one program is implemented through the application of the other programs (e.g., conduct of operations is implemented through work control, procedures, and training). Thus, the implementation of all these programs ensures the protection of the public, workers, and the environment.

NOTE: The following sections refer to the site-wide controlled manuals, however, most of the manuals (e.g., WHC-CM-X-XX) have been superseded by the Fluor Daniel Hanford, Inc. (FDH), procedures (e.g., HNF-PRO-XXX). A cross-reference table has been provided in Appendix F, "Site Wide Controlled Manual Cross Reference Table," to guide the reader in locating the current FDH procedure(s). As part of implementation of the BIO controls, the references to the controlled manuals will be updated as appropriate to reflect the current FDH procedures.

4.1 ORGANIZATIONAL STRUCTURE AND MANAGEMENT RESPONSIBILITIES

The contractor's organizational structure provides for the clear identification of roles and responsibilities, especially as they relate to safe operation of the facilities. The organizational structure provides for the following:

- Identification and control of the requirements related to each safety management program (Section 4.2 "Standards/Requirements Identification Document")
- Identification of the responsibility for implementing those requirements through contractor documents such as policies and procedures

- Identification of the responsibility for implementing contractor policies and procedures.

For Authorization Basis development and control, the above responsibilities are implemented through HNF-IP-0842, Volume 4. The following sections of this chapter provide roles and responsibilities for the safety management programs.

4.2 STANDARDS/REQUIREMENTS IDENTIFICATION DOCUMENT

The U.S. Department of Energy (DOE) approved, WHC-SD-MP-SRID-001, *High Level Waste Storage Tank Farms/242-A Evaporator Standards/Requirements Identification Document*, is a concise compilation of facility-specific federal, state, and local laws; regulations; permit conditions; industry consensus codes; standards; and good business practices. The applicable environmental safety and health and safeguards and security functional areas are also identified.

WHC-SD-MP-SRID-001 is currently being implemented. Implementation is verified through reviews (assessments, audits, and surveillance) conducted by internal oversight organizations.

4.3 CRITICALITY PROTECTION

The purpose of criticality protection is to ensure that sufficient controls are in place to reduce the likelihood of inadvertent nuclear criticality excursions.

The TWRS Criticality Protection Program, which addresses the following general aspects, follows DOE 5480.24[1], *Nuclear Criticality Safety*; industry standards; company safety policy; and accepted safety practices:

- Nuclear criticality safety administration
- Nuclear criticality safety control principles
- Criticality safety training
- Nuclear criticality safety control documents
- Criticality safety plans and procedures
- Criticality emergencies and limit violations.

[1]Although DOE Orders 5000.3B, 5480.7A, 5480.10, and 5480.24 have been rescinded the contractor is obligated by the existing contract to meet the requirements stated in those orders.

Supplementing the general aspects are the following specific elements of the criticality safety program:

- Parameter controls are established for waste transfer into the tank farms to meet double contingency requirements for the prevention of a criticality accident
- Parameter controls are documented and independently verified.

Criticality protection at TWRS facilities is implemented through WHC-CM-4-29[2], *Nuclear Criticality Safety Manual*, and Technical Safety Requirement Administrative Control (AC) 5.7, "Nuclear Criticality Safety."

4.4 RADIOLOGICAL PROTECTION

The TWRS radiological protection program for TWRS facilities provides for the protection of the worker during normal operations and implements specific safety controls identified in Chapter 5.0. The worker protection program comprises the following elements:

- As Low as Reasonably Achievable (ALARA) goals
- Radiation worker training
- Radiation exposure control
- Radiological monitoring
- General employee radiation training.

Radiological protection activities at the Hanford Site implement the requirements of 10 CFR 835, "Occupational Radiation Protection," as directed by the HSRCM-1, *Hanford Site Radiological Control Manual*.

The Tank Waste Operations organization administers the Radiological Protection Program for TWRS. This project also establishes radiological protection standards and procedures; provides independent review and evaluation of the program; conducts radiological and dosimetry support; develops and implements training; and coordinates the ALARA Program.

4.5 HAZARDOUS MATERIAL PROTECTION

The Hanford Site Industrial Hygiene Program is designed to protect all workers from hazardous exposures to physical, chemical, and biological agents. The program provides the basis for an effective industrial hygiene program

---

[2]Refer to Appendix F, "Site-wide Controlled Manual Cross Reference Table," of the BIO for cross-walk between Site-wide controlled manuals (e.g., WHC-CM-X-XX) superseded by Fluor Daniel Hanford, Inc. (FDH), procedures (e.g., HNF-PRO-XXX).

that preserves worker health and well being following DOE 5480.4, *Environmental Protection, Safety, and Health Protection Standards*, and DOE 5480.10[1], *Contractor Industrial Hygiene Program*. These DOE orders implement 29 CFR 1910, "Occupational Safety and Health Standards," and 29 CFR 1926, "Safety and Health Regulations for Construction." Current procedures are documented in WHC-CM-1-11[2], *Industrial Hygiene Manual*, and WHC-CM-4-40[2], *Industrial Hygiene Manual*. The Industrial Hygiene Program is implemented by Tank Waste Operations.

Contractor procedures provide for the identification and evaluation of existing and potential health hazards; the implementation of control measures; the periodic monitoring to ensure the maintenance of satisfactory conditions; and the conduct of employee training.

4.6 RADIOACTIVE AND HAZARDOUS MATERIAL WASTE MANAGEMENT

TWRS stores and processes wastes in a manner that ensures that releases of radioactive and hazardous materials to the environment are maintained within regulatory limits and exposure of workers and the public to radioactive and hazardous materials is minimized.

Criteria for confinement, safe handling, and disposal of solid, liquid, and gaseous waste are provided in WHC-CM-7-5[2], *Environmental Compliance*, which identifies the requirements of the DOE 5400 series orders, with emphasis on DOE 5400.5, *Radiation Protection of the Public and the Environment*.

Contractor procedures, which meet the requirements of DOE 5820.2A, *Radioactive Waste Management*, establish requirements for TWRS facility waste acceptance programs. These waste acceptance requirements ensure that all waste has been properly identified and characterized before being shipped. Each hazardous and radioactive waste generator that delivers waste to TWRS facilities is required to comply with TWRS waste acceptance program requirements.

TWRS radioactive and hazardous waste management is implemented through the following:

- *Dangerous Waste Portion of the Resource Conservation and Recovery Act Permit for the Treatment, Storage, and Disposal of Dangerous Waste* (Ecology 1995a)
- *Hanford Federal Facility Agreement and Consent Order* (Ecology et al. 1996)
- WHC-CM-7-5[2], *Environmental Compliance* (1996)
- WHC-EP-0063, *Hanford Site Solid Waste Acceptance Criteria* (1993)
- WHC-EP-0479, *Facility Effluent Monitoring Plan for the Tank Farm Facility* (1995)

- HNF-EP-0496, *Project Hanford Management Contract Pollution Prevention Program Implementation Plan* (1996)
- WHC-EP-0846, *Waste Specification System* (1995)
- WHC-SD-WM-EV-090, *Tank Farms Transition Projects Waste Minimization/Pollution Prevention Plan* (1996)

TWRS environmental protection relies heavily on compliance with federal and state requirements and working with the regulatory community and stakeholders.

The TWRS organizational infrastructure includes a multi-level, independent oversight program. This independent oversight program is designed to verify federal, state, and local environmental laws and regulations and DOE requirements are addressed adequately in the TWRS management policies and that TWRS operations are conducted in compliance with those policies. Assessment activities are performed in accordance with written guidance and criteria to verify that applicable elements of the environmental protection program have been developed and implemented effectively.

4.7 TESTING, SURVEILLANCE, AND MAINTENANCE

Initial testing, in-service surveillance, and maintenance programs at TWRS ensure the integrity and operability of safety structures, systems, and components (SSCs).

The initial testing program encompasses all safety SSCs, and requires the development of testing procedures and the review, evaluation, and approval of test results. Testing programs within the initial testing program are specified as quality assurance requirements in WHC-CM-4-2[2], *Quality Assurance Manual*.

In-service surveillance and inspections at TWRS are conducted on the basis of DOE 4330.4B, *Maintenance Management Program*. Program requirements include periodic inspections to ensure that proper conditions, cleanliness, and housekeeping are maintained to support safe and reliable facility operations.

Surveillance requirements have been established for Safety-Class and Safety-Significant SSCs. These requirements provide assurance that the necessary quality of SSCs is maintained and that the Limiting Conditions for Operation are being met.

The TWRS maintenance program meets the requirements of DOE 4330.4B. Compliance with this order is documented in WHC-SP-0850, *Maintenance Implementation Plan for Waste Tank Maintenance and Production Management*. Major maintenance programs include the following:

- Preventive maintenance
- Spare parts control

- Maintenance history
- Corrective maintenance
- Maintenance training
- Measuring and test equipment.

Requirements for the maintenance program reflect the relative importance of facility SSCs in protecting the public, workers, and the environment.

4.8 CONDUCT OF OPERATIONS

Conduct of operations requirements at TWRS are based on DOE 5480.19, *Conduct of Operations Requirements for DOE Facilities*. Contractor procedures provide detailed requirements for procedures, communications, training, shift operations, and facility operations. The implementing requirements and programs for TWRS are described in HNF-IP-0842.

4.9 WORK CONTROL

All work activities at TWRS are controlled through a formal work control program and design configuration management program. The work control program ensures the following:

- The work scope is fully defined
- The hazards associated with the work are identified and evaluated
- Sufficient controls, based on the hazards, are identified and implemented to ensure that the work can be performed safely
- The work is executed safely and the completed work is verified.

Management of work activities within TWRS is defined in WHC-CM-1-8[2], *Work Management*.

4.10 FIRE PROTECTION PROGRAM

The contractor's fire protection program, established to meet the requirements of DOE 5480.7A[1], *Fire Protection*, ensures the following conditions are met.

- No threats to the public health or welfare will result from a fire.
- No undue fire hazards exist for site personnel.

The program uses fire detection and extinguishing systems and equipment, administrative controls, procedures, and trained personnel to meet the requirements of DOE 5480.7A[1]. Three principles are followed to prevent and mitigate the consequences of potential fires:

1. Control of ignition sources and combustible and flammable materials
2. Prompt detection and suppression of fires through a combination of installed fire protection systems and a professional firefighting organization
3. Employee training.

The TWRS fire protection program is implemented through WHC-CM-4-41[2], *Fire Protection Program Manual*.

4.11 TRAINING AND PROCEDURES

The training program for TWRS described in HNF-IP-0842 addresses the requirements of DOE 5480.18B, *Nuclear Facility Training Accreditation Program*, and DOE 5480.20A, *Personnel Selection, Qualification, and Training, Requirements at DOE Nuclear Facilities*.

The purpose of the training program is to provide training to help workers safely and effectively perform their work assignments. The training program ensures the following:

- Programs are established to identify training needs and requirements, to define qualification criteria, and to document employee participation in required training.
- Workers acquire the knowledge and skills required to perform assigned duties.
- Training conducted adheres to cost-effective business practices; meets job and organizational needs; and fulfills requirements of applicable DOE directives, regulations, and contractor policies and procedures.
- Training activities are integrated to ensure that site resources are used effectively to contain costs; to promote excellence in job performance; and to support uniformity of training analysis, design, development, implementation, and evaluation.
- Training activities are managed by division training managers who ensure compliance with the training program policy.

The contractor uses approved procedures, appropriate to the tasks to be performed, to ensure maintenance and operation of all facilities are accomplished in a disciplined manner. DOE and the contractor are focusing on the following efforts to make procedures more usable and effective:

- Increasing the technical correctness of procedures

- Providing appropriate support capabilities to ensure timely processing and distribution of procedures
- Increasing user compliance
- Promoting procedures as key management controls that ensure the safe and efficient operation of TWRS facilities.

The procedures define requirements for management approval of all activities within TWRS to maintain the safety envelope.

4.12 QUALITY ASSURANCE

Requirements for systematically implementing a quality assurance program, specified in 10 CFR 830.120, "Quality Assurance" and DOE 5700.6C, *Quality Assurance*, are established in HNF-MP-599, *Project Hanford Quality Assurance Program Description* and WHC-CM-4-2[2].

Activities affecting quality, safety, or reliability of TWRS operations, products, and services are performed following documented and approved procedures appropriate for the task. The TWRS procedure manuals are used to ensure that quality assurance requirements are systematically implemented. Procedures are provided in the contractor's quality assurance program for the following functions and processes:

- Design control
- Procurement control
- Control of instructions, procedures, and drawings
- Document control
- Control of purchased items and services
- Identification and control of items
- Control of processes
- Inspection and test control
- Control of measuring and test equipment
- Packaging, handling, shipping, and storage control
- Inspection, test, and operating status control
- Control of nonconforming items and activities
- Software control

- Control of stop-work and corrective actions
- Control of personnel training and certification
- Control of records
- Control of audits.

4.13 EMERGENCY PREPAREDNESS

The TWRS Emergency Preparedness Program establishes planning, procedures, and training programs to effectively prepare for, respond to, and manage emergencies and incidents affecting the health and safety of the worker and the public. The emergency management program implements the DOE 5500 series orders.

The TWRS Emergency Plan includes descriptions of the following:

- Response organizations, authorities, responsibilities, and relationship with the technical support center and emergency operations facility established for emergency response
- Actions to be taken with state and local agencies for responses to events that involve the potential for a release of radiological materials
- Emergency classification system and associated emergency action levels
- Notification processes and the communications systems
- Methods, systems, and equipment available for assessing the actual or potential emergency conditions
- Protective actions required to provide maximum protection to workers and the public
- Medical resources available to assist in the event of an emergency
- Technical assessment and mitigation of facility emergency conditions
- Requirements for providing information to the public, offsite authorities, and local media
- Emergency facilities and equipment available to support emergency operations
- Staffing and training needs of the emergency response organization
- Drills and exercise required to develop, maintain, and test the response capabilities of the emergency response organization.

TWRS emergency preparedness program is implemented through the following procedures.

- WHC-IP-0263-TF, *Tank Farms Building Emergency Plan* (1994)
- WHC-IP-0971, *Tank Waste Remediation System (TWRS) Emergency Preparedness Program Plan* (1997).

4.14 DECONTAMINATION AND DECOMMISSIONING

A formal decontamination and decommissioning (D&D) plan has not been prepared for the TWRS. The TWRS Final Safety Analysis Report, however, will contain limited discussions of D&D considerations. Detailed plans will be prepared as required to support final D&D of TWRS.

Cleanup methods will be selected for TWRS facilities on the basis of the disposition method deemed appropriate for the waste in those facilities. Facilities that are identified as treatment, storage, and disposal units will be closed according to the requirements of the *Regulations for Implementing Procedural Provisions of the National Environmental Policy Act* (Ecology 1995b).

The design of the original TWRS facilities contained no specific criteria to facilitate D&D. The TWRS facilities were, however, engineered with features to contain leaked waste products and to minimize the spread of contamination (e.g., nonporous tank walls and coatings in pits and buildings that can be decontaminated). Representative design features that benefit D&D are as follows:

- Double-shell tank
- Encased piping
- Valve pits
- High-efficiency particulate air filters.

Operational considerations necessary for compliance with HSRCM-1 and WHC-CM-7-5[2] help maintain the spread of contamination to ALARA. Representative operational features that benefit D&D are as follows:

- Leakage monitoring
- Interim stabilization.

4.15 CONFIGURATION MANAGEMENT

WHC-SD-WM-CM-013, *TWRS Configuration Management Program Plan*, defines the requirements and responsibilities for the execution of the TWRS configuration management program.

The TWRS configuration management program provides for the identification and control of physical, functional, and operational requirements of configuration-controlled SSCs, including TSR design features, and Defense-in-Depth SSCs. TWRS has developed a hierarchy of contractor-generated documents that identifies all requirements for configuration-controlled SSCs as technical baseline documents. A subset of the technical baseline documents that establish the requirements for safety SSCs, including Defense-in-Depth SSCs, are identified as safety basis documents. Within the safety basis documents are those documents that require DOE approval. This subset is identified as the Authorization Basis documents. Authorization Basis documents also include DOE-prepared documents.

The responsibilities and requirements for the control of all TWRS technical baseline documents are provided in HNF-IP-0842. These requirements include maintaining a listing of all technical baseline documents, a listing of all safety basis documents, and a listing of all Authorization Basis documents. Additionally, the requirements and responsibilities for revision control of all technical baseline documents (including Defense-in-Depth items) are identified in HNF-IP-0842. The revision control process ensures all proposed changes are properly reviewed and approved before authorization. Impacts to the Authorization Basis are identified through the Unreviewed Safety Question (USQ) process (Section 4.17).

4.16 OCCURRENCE REPORTING

The occurrence reporting and processing system is designed to bring to the attention of management and DOE officials events, conditions, or concerns that have or may have safety, health, quality assurance, security, operational, or environmental implications. WHC-CM-1-5[2], *Standard Operating Practices*, establishes (1) a consistent process on a sitewide basis for the identification of events, conditions, and concerns; (2) the protocol for reporting incidents; and (3) the guidelines for the appropriate follow-up activities (including corrective action determination and implementation). TWRS occurrence reporting program is based on the requirements of DOE 5000.3B[1] (superseded by DOE O 232.1), *Occurrence Reporting and Processing of Operations Information*.

4.17 UNREVIEWED SAFETY QUESTIONS

The concept of USQs, as presented in DOE 5480.21, *Unreviewed Safety Questions*, allows contractors to make physical and procedural changes and to conduct tests and experiments without prior approval from DOE. These changes must neither explicitly nor implicitly affect the Authorization Basis of the facility.

When Authorization Basis documents are revised, they are subjected to the USQ process, unless such changes are directed or otherwise approved by the U.S. Department of Energy, Richland Operations Office. The TWRS plant review committee is responsible for resolving issues concerning the identification of USQs and other safety matters relating to TWRS. The plant review committee is also the interpretive authority of the Technical Safety Requirements.

The TWRS USQ process is implemented through HNF-IP-0842.

4.18 HUMAN FACTORS

The application of human factors is graded on project risk, complexity, and level of involvement of the operator at the facility. Although, TWRS does not have a formal human factors program, human factors are addressed at various organizational levels within TWRS. The Design Authority and Nuclear Safety and Licensing organizations are responsible for ensuring human factors are included as an explicit consideration in the modification of TWRS facilities, systems, or equipment that may affect safety.

Operation of the TWRS facility is the responsibility of the Tank Waste Operations organization. Several organizations provide support and expertise on topics such as industrial safety, industrial hygiene, hazardous material and radiological control, maintenance, procedures, and training. These groups assist the line manager in addressing human factors issues in the following ways:

- **Safety and Quality Support**—Ensure that the operational environment (e.g., noise, lighting, industrial hazards) in which tasks must be performed permit the safe and reliable performance of the expected tasks.
- **Procedures Organization**—Ensure that human performance (i.e., ability to perform task as described in procedure) is addressed, during the preparation and writing of the procedure.
- **Training Organization**—Ensure consideration of human factors in training programs by developing needs analysis, job analysis, or task analysis (e.g., lessons learned) to determine operational requirements and needed skills based operational tasks and current skill levels.

Additionally, the training and procedures organizations work together to identify training requirements for new operations.

5.3.2.5-1	Consequences of a Steam Intrusion from Interfacing Systems	5.3.2.5-4
5.3.2.5-2	Technical Safety Requirement Controls for Steam Intrusion from Interfacing Systems	5.3.2.5-4
5.3.2.5-3	Defense-In-Depth Controls For Steam Intrusion from Interfacing Systems	5.3.2.5-5
5.3.2.6-1	Consequences of a Leak from a Railcar/Tank Trailer	5.3.2.6-5
5.3.2.6-2	Technical Safety Requirement Controls for Potential Railcar/Tank Trailer Leaks at the 204-AR Waste Unloading Facility	5.3.2.6-5
5.3.2.6-3	Defense-in-Depth Controls for Potential Railcar and Tank Trailer Leaks at the 204-AR Waste Unloading Facility	5.3.2.6-6
5.3.2.7-1	Consequences of a Subsurface Leak Remaining Subsurface	5.3.2.7-4
5.3.2.7-2	Items Determined to be Safety-Significant by Extrapolating the Subsurface Leak Remaining Subsurface Accident Scenario to Other Applicable Tank Farm Transfer Equipment and Locations	5.3.2.7-4
5.3.2.7-3	Technical Safety Requirement Controls for Subsurface Leaks Remaining Subsurface	5.3.2.7-5
5.3.2.7-4	Defense-in-Depth Controls that Provide Defense-in-Depth for Potential Subsurface Leak Remaining Subsurface	5.3.2.7-6
5.3.2.8-1	Radioactive Isotopes and Inventory Assumed Present in Crib 216-Z-20	5.3.2.8-4
5.3.2.8-2	The Toxicological Constituents and Concentrations Assumed Present in Crib 216-Z-20	5.3.2.8-4
5.3.2.8-3	Consequences of Unplanned Excavations or Drilling in Cribs, Ditches, and Ponds	5.3.2.8-5

LIST OF TABLES (cont)

5.3.2.8-4 Controls That Provide Defense-in-Depth For Potential Unplanned Excavations or Drilling in Cribs, Ditches, and Ponds 5.3.2.8-5

5.3.2.9-1 Consequences of a Caustic Spray Leak Assuming No Controls 5.3.2.9-4

5.3.2.9-2 Technical Safety Requirement Controls for Caustic Spray Leaks 5.3.2.9-4

5.3.2.9-3 Defense-in-Depth Controls for Caustic Spray Leaks . . . 5.3.2.9-5

5.3.2.10-1 Summary of Consequences and Frequencies for a Sodium Fire without Controls 5.3.2.10-4

5.3.2.10-2 Safety Structures, Systems, and Components for Sodium Fire 5.3.2.10-5

5.3.2.10-3 Defense-in-Depth Controls for Sodium Fire 5.3.2.10-5

5.3.2.11-1 Defense-in-Depth Controls for Chemical Reaction in Double-Contained Receiver Tank 5.3.2.11-3

5.3.2.12-1 Summary of Consequences and Frequencies for Mixing of Incompatible Waste—Tank Pressurization without Controls 5.3.2.12-3

5.3.2.12-2 Summary of Consequences and Frequencies for Mixing of Incompatible Waste—Tank Pressurization with Controls 5.3.2.12-3

5.3.2.12-3 Technical Safety Requirement Controls for Mixing of Incompatible Materials—Tank Pressurization 5.3.2.12-4

5.3.2.12-4 Safety Structures, Systems, and Components for Mixing of Incompatible Materials—Tank Pressurization 5.3.2.12-4

5.3.2.12-5 Defense-in-Depth Controls for Mixing of Incompatible Waste—Tank Pressurization 5.3.2.12-4

5.3.2.13-1 Consequences of a Load Drop Assuming No Controls . . 5.3.2.13-6

5.3.2.13-2 Technical Safety Requirement Controls for Load Drops 5.3.2.13-7

5.3.2.13-3 Defense-in-Depth Controls for Load Drops 5.3.2.13-9

5.3.2.14-1 Results Assuming No Controls Accident Scenario for Flammable Gas Deflagrations 5.3.2.14-10

LIST OF TABLES (cont)

5.3.2.14-2 Safety Systems, Structures, and Components for Flammable Gas Deflagrations 5.3.2.14-11

5.3.2.14-3 Technical Safety Requirement Controls for Flammable Gas Deflagrations 5.3.2.14-13

5.3.2.15-1 Organic Solvent Fire Accident Scenarios Applicable to Different Types of Tanks 5.3.2.15-11

5.3.2.15-2 Onsite Consequences of Organic Solvent Fire Scenarios Assuming No Controls and a Frequency of "Unlikely" 5.3.2.15-12

5.3.2.15-3 Offsite Consequences of Organic Solvent Accident Scenarios Assuming No Controls and a Frequency of "Unlikely" 5.3.2.15-13

5.3.2.15-4 Summary of Accident Frequencies for Organic Solvent Fires Assuming No Controls 5.3.2.15-14

5.3.2.15-5 Technical Safety Requirement Controls for Organic Solvent Fires 5.3.2.15-15

5.3.2.15-6 Organic Solvent Fire Topography 5.3.2.15-16

5.3.2.15-7 Defense-in-Depth Controls for Toxic Vapor Nitrate Fires. 5.3.2.15-21

5.3.2.16-1 Unmitigated Consequences of Vehicle Fuel Pool Fire . . 5.3.2.16-7

5.3.2.16-2 Technical Safety Requirement Controls for Vehicle Fuel Fire/Deflagration 5.3.2.16-7

5.3.2.16-3 Defense-in-Depth Controls of Vehicle Fuel Fire/Deflagration 5.3.2.16-8

5.3.2.17-1 Organic-Nitrate Waste Grouping 5.3.2.17-12

5.3.2.17-2 Summary of Organic-Nitrate Condensed Phase Ignition Source Evaluation 5.3.2.17-13

5.3.2.17-3 Radiological and Toxicological Consequences for 25 m^3 Organic-Nitrate Combustion Accident (No controls in place - accident is "unlikely") 5.3.2.17-14

5.3.2.17-4 Radiological and Toxicological Consequences for 25 m^3 Organic-Nitrate Combustion Accident (Controls in place - Accident is "extremely unlikely") 5.3.2.17-14

LIST OF TABLES (cont)

5.3.2.17-5 Technical Safety Requirement Controls for Organic-Nitrate Condensed-Phase Combustion Accidents 5.3.2.17-15

5.3.2.17-6 Defense-in-Depth Controls for Organic-Salt Nitrate Reactions 5.3.2.17-18

5.3.2.17-7 Safety Structures, Systems, and Components for Organic Salt-Nitrate Reaction 5.3.2.17-19

5.3.2.18-1 Consequences of Surface Leak Resulting in Pool Assuming No Controls 5.3.2.18-7

5.3.2.18-2 Consequences of Surface Leak Resulting in Pool Assuming Controls 5.3.2.18-7

5.3.2.18-3 Safety Structures, Systems, and Components for Surface Leak Resulting in Pool 5.3.2.18-8

5.3.2.18-4 Technical Safety Requirement Controls for Surface Leak Resulting in Pool 5.3.2.18-10

5.3.2.18-5 Defense-in-Depth Controls for Surface Leak Resulting in Pool 5.3.2.18-13

5.3.2.19-1 Consequences of a Subsurface Leak Resulting in Pool Assuming No Controls 5.3.2.19-6

5.3.2.19-2 Consequences of a Subsurface Leak Resulting in Pool Assuming Controls 5.3.2.19-6

5.3.2.19-3 Safety Structures, Systems, and Components for Subsurface Leak Resulting in Pool 5.3.2.19-7

5.3.2.19-4 Technical Safety Requirement Controls for Subsurface Leak Resulting in Pool 5.3.2.19-7

5.3.2.19-5 Defense-in-Depth Controls for Subsurface Leak Resulting in Pool 5.3.2.19-8

5.3.2.20-1 Summary of Consequences and Frequencies without Controls 5.3.2.20-6

5.3.2.20-2 Summary of Consequences and Frequencies with Controls 5.3.2.20-6

5.3.2.20-3 Safety Structures, Systems, and Components for Spray Leaks 5.3.2.20-7

5.3.2.20-4 Technical Safety Requirement Controls for Spray Leaks 5.3.2.20-9

LIST OF TABLES (cont)

5.3.2.20-5 Defense-in-Depth Controls for Transfer System Spray Leaks 5.3.2.20-11

5.3.2.21-1 Technical Safety Requirement Controls for Spray Leak and Surface Pools from Underground Waste Transfer Lines 5.3.2.21-3

5.3.2.21-2 Defense-in-Depth Controls for Spray Leak and Surface Pools from Underground Waste Transfer Lines . . 5.3.2.21-4

5.3.2.22-1 Consequences of a Tank Bump Assuming No Controls . . . 5.3.2.22-5

5.3.2.22-2 Safety Structures, Systems, and Components for Tank Bumps 5.3.2.22-5

5.3.2.22-3 Technical Safety Requirement Controls for Tank Bumps 5.3.2.22-6

5.3.2.22-4 Defense-in-Depth Controls for Tank Bumps 5.3.2.22-7

5.3.2.23.1-1 Estimates of Peak Wind Gusts and Frequencies of Occurrence at the Hanford Site 5.3.2.23-16

5.3.2.23.1-2 Consequences of Flexible Receiver Bag Failure . . . 5.3.2.23-16

5.3.2.23.1-3 Technical Safety Requirement Controls for High Winds 5.3.2.23-16

5.3.2.23.1-4 Defense-in-Depth Controls for High Wind 5.3.2.23-17

5.3.2.23.2-1 Technical Safety Requirement Controls for Lightning as an Accident Initiator 5.3.2.23-17

5.3.2.23.2-2 Defense-in-Depth Controls for Lightning as an Accident Initiator 5.3.2.23-18

5.3.2.23.3-1 Technical Safety Requirement Controls for Seismic Event 5.3.2.23-18

5.4-1 Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences . . 5.4-7

5.4-2 Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency 5.4-114

5.4-3 Safety Structures, Systems, and Components and Technical Safety Requirements for Potentially Severe (E3 and E2) Environmental Consequences 5.4-161

CHAPTER 5.0
SAFETY ANALYSIS

CONTENTS

5.0 SAFETY ANALYSIS 5.0-1
5.1 HAZARD CLASSIFICATION 5.1-1
5.1.1 References 5.1-1
5.2 HAZARD ANALYSIS 5.2-1
5.2.1 Methodology 5.2-1
5.2.1.1 Hazard Identification 5.2-2
5.2.1.2 Hazard Evaluation 5.2-2
5.2.1.3 Accident Selection 5.2-3
5.2.1.4 Controls Identification 5.2-5
5.2.2 Hazard Analysis Results 5.2-6
5.2.2.1 Hazard Identification 5.2-6
5.2.2.2 Hazard Evaluation 5.2-7
5.2.3 References 5.2-9
5.3 ACCIDENT ANALYSIS 5.3.1-1
5.3.1 Methodology 5.3.1-1
5.3.1.1 Radiological Consequence Calculation Methodology 5.3.1-1
5.3.1.2 Toxicological Consequence Calculation Methodology 5.3.1-4
5.3.1.3 Basis for Estimating Accident Frequency 5.3.1-5
5.3.1.4 References 5.3.1-5
5.3.2 Accident Analysis Scenarios 5.3.2-1
5.3.2.1 Nuclear Criticality 5.3.2.1-1
5.3.2.2 HEPA Filter Failure - Exposure to High Temperature or Pressure 5.3.2.2-1
5.3.2.3 Fire In Contaminated Area. 5.3.2.3-1
5.3.2.4 Evaporator Dump 5.3.2.4-1
5.3.2.5 Steam Intrusion From Interfacing Systems . . . 5.3.2.5-1
5.3.2.6 Leak from Railcar/Tank Trailer 5.3.2.6-1
5.3.2.7 Subsurface Leak Remaining Subsurface 5.3.2.7-1
5.3.2.8 Unplanned Excavation/Drilling in Crib/Ditch/Pond 5.3.2.8-1
5.3.2.9 Caustic Spray Leak 5.3.2.9-1
5.3.2.10 Sodium Fire 5.3.2.10-1
5.3.2.11 Mixing of Incompatible Material - Toxic Vapor Generation 5.3.2.11-1
5.3.2.12 Mixing of Incompatible Material - Tank Pressurization 5.3.2.12-1
5.3.2.13 Tank Failure Due to Excessive Loads 5.3.2.13-1
5.3.2.14 Flammable Gas Deflagrations 5.3.2.14-1
5.3.2.15 Organic Solvent Fire 5.3.2.15-1
5.3.2.16 In-Tank Fuel Fire/Deflagration 5.3.2.16-1
5.3.2.17 Organic Salt-Nitrate Reaction 5.3.2.17-1
5.3.2.18 Surface Leak Resulting in Pool 5.3.2.18-1
5.3.2.19 Subsurface Leak Resulting in Pool 5.3.2.19-1
5.3.2.20 Spray Leak in Structure or From Overground Waste Transfer Line 5.3.2.20-1

CONTENTS (cont)

5.3.2.21 Spray Leak from Underground Waste Transfer Lines 5.3.2.21-1
5.3.2.22 Tank Bump 5.3.2.22-1
5.3.2.23 Natural Phenomena 5.3.2.23-1
5.3.2.23.1 High Wind 5.3.2.23-1
5.3.2.23.2 Lightning 5.3.2.23-7
5.3.2.23.3 Seismic Events 5.3.2.23-11
5.4 ENGINEERED AND ADMINISTRATIVE CONTROLS 5.4-1
5.4.1 Control Decision Criteria 5.4-1
5.4.2 Public and Onsite Worker Protection 5.4-4
5.4.3 Facility Worker Protection 5.4-4

5.4.5 References 5.4-5

LIST OF FIGURES

5.3.2.1-1 Perspective of Hanford Site Waste Tank Subcritical Limits–Plutonium Critical Mass Versus Concentration (Spherical Geometry) 5.3.2.1-9

LIST OF TABLES

5.1-1 Hazard Category for Tank Waste Remediation System Facilities . . 5.1-3

5.2-1 Frequency Categories for Tank Waste Remediation System Facilities 5.2-11

5.2-2 Consequence Categories for Tank Waste Remediation System Facilities 5.2-11

5.2-3 Applicable Hazard Evaluations for Tank Waste Remediation System Facilities 5.2-13

5.2-4 Natural Phenomena, External Events, and Common Cause Hazards for Tank Waste Remediation System Facilities 5.2-42

5.2-5 Representative Accidents Analyzed and Cross-Reference to Basis for Interim Operation Accident Analysis Sections . . . 5.2-43

5.3.1-1 Representative Accidents Analyzed and Cross-Reference to Basis for Interim Operation Accident Analysis Sections 5.3.1-7

5.3.1-2 Radiological Risk Guidelines 5.3.1-8

5.3.1-3 Toxicological Risk Guidelines 5.3.1-8

5.3.1-4 In-Tank Concentrations of the 11 Radionuclides Chosen for Inclusion in Accident Analysis 5.3.1-9

5.3.1-5 Unit Liter Doses for Tank Farm Composites 5.3.1-9

5.3.1-6 Composite Concentrations for the 24 Analytes at the Tank Waste Remediation System Tank Farms 5.3.1-10

5.3.1-7 Worst-Case and Maximum Steady-State Headspace Gas Composite Concentrations in the Tank Waste Remediation System 5.3.1-11

5.3.1-8 Sum-of-Fraction of Risk Guidelines for a Unit Release of Chemicals and Gases 5.3.1-12

5.3.2.1-1 H to Pu Atom Ratios 5.3.2.1-10

5.3.2.1-2 Subcritical Ratios 5.3.2.1-10

LIST OF TABLES (cont)

5.3.2.1-3 Radiological Consequences for Waste Tank Criticality . . 5.3.2.1-10

5.3.2.1-4 Summary of Toxicological Consequences for Nuclear Criticality Accident Scenarios 5.3.2.1-11

5.3.2.1-5 Technical Safety Requirement Controls for Nuclear Criticality Accident Scenario 5.3.2.1-11

5.3.2.2-1 Consequences and Frequencies Assuming No Controls for High-Efficiency Particulate Air Filter Failure-Exposure to High Temperature 5.3.2.2-9

5.3.2.2-2 Consequences and Frequencies Assuming Controls for High-Efficiency Particulate Air Filter Failure-Exposure to High Temperature 5.3.2.2-10

5.3.2.2-3 Safety Structures, Systems, and Components for High-Efficiency Particulate Air Filter Failure—Exposure to High Temperature 5.3.2.2-11

5.3.2.2-4 Technical Safety Requirement Controls for High-Efficiency Particulate Air Filter Failure—Exposure to High Temperature 5.3.2.2-11

5.3.2.2-5 Defense-in-Depth Controls for High-Efficiency Particulate Air Filter Failure—Exposure to High Temperature 5.3.2.2-12

5.3.2.2-6 Total Radiological Dose Consequences Assuming No Controls for a High-Efficiency Particulate Air Filter Failure—Exposure to High Pressure from a Pressurized High-Efficiency Particulate Air Release Event and a Continuous, Unfiltered Release 5.3.2.2-13

5.3.2.2-7 Total Toxicological Exposure Consequences (Sum-of-Fractions) Assuming No Controls from High-Efficiency Particulate Air Filter Failure-Exposure to High Pressure and a Continuous, Unfiltered Release for an Accident Frequency of "Anticipated" 5.3.2.2-14

5.3.2.3-1 Consequences of a Fire in Contaminated Area Assuming No Controls. 5.3.2.3-4

5.3.2.3-2 Technical Safety Requirement Controls for Fire in Contaminated Area 5.3.2.3-4

5.3.2.3-3 Defense-in-Depth Controls for Potential Fire in Contaminated Area 5.3.2.3-5

5.3.2.4-1 Consequences of an Evaporator 242-A Dump to Tank 241-AW-102 . . . . . 5.3.2.4-4

LIST OF TABLES (cont)

5.3.2.4-2 Defense-in-Depth Controls for Evaporator 242-A Dump to Tank 241-AW-102 . . . . . 5.3.2.4-4

5.3.2.5-1 Consequences of a Steam Intrusion from Interfacing Systems 5.3.2.5-4

5.3.2.5-2 Technical Safety Requirement Controls for Steam Intrusion from Interfacing Systems 5.3.2.5-4

5.3.2.5-3 Defense-in-Depth Controls For Steam Intrusion from Interfacing Systems 5.3.2.5-5

5.3.2.6-1 Consequences of a Leak from a Railcar/Tank Trailer . . . 5.3.2.6-5

5.3.2.6-2 Technical Safety Requirement Controls for Potential Railcar/Tank Trailer Leaks at the 204-AR Waste Unloading Facility 5.3.2.6-5

5.3.2.6-3 Defense-in-Depth Controls for Potential Railcar and Tank Trailer Leaks at the 204-AR Waste Unloading Facility. 5.3.2.6-6

5.3.2.7-1 Consequences of a Subsurface Leak Remaining Subsurface 5.3.2.7-4

5.3.2.7-2 Items Determined to be Safety-Significant by Extrapolating the Subsurface Leak Remaining Subsurface Accident Scenario to Other Applicable Tank Farm Transfer Equipment and Locations 5.3.2.7-4

5.3.2.7-3 Technical Safety Requirement Controls for Subsurface Leaks Remaining Subsurface 5.3.2.7-5

5.3.2.7-4 Defense-in-Depth Controls that Provide Defense-in-Depth for Potential Subsurface Leak Remaining Subsurface 5.3.2.7-6

5.3.2.8-1 Radioactive Isotopes and Inventory Assumed Present in Crib 216-Z-20 . . . . . 5.3.2.8-4

5.3.2.8-2 The Toxicological Constituents and Concentrations Assumed Present in Crib 216-Z-20 . . . . . 5.3.2.8-4

5.3.2.8-3 Consequences of Unplanned Excavations or Drilling in Cribs, Ditches, and Ponds 5.3.2.8-5

5.3.2.8-4 Controls That Provide Defense-in-Depth For Potential Unplanned Excavations or Drilling in Cribs, Ditches, and Ponds 5.3.2.8-5

LIST OF TABLES (cont)

5.3.2.9-1 Consequences of a Caustic Spray Leak Assuming No Controls 5.3.2.9-4

5.3.2.9-2 Technical Safety Requirement Controls for Caustic Spray Leaks 5.3.2.9-4

5.3.2.9-3 Defense-in-Depth Controls for Caustic Spray Leaks . . . 5.3.2.9-5

5.3.2.10-1 Summary of Consequences and Frequencies for a Sodium Fire without Controls 5.3.2.10-4

5.3.2.10-2 Safety Structures, Systems, and Components for Sodium Fire 5.3.2.10-5

5.3.2.10-3 Defense-in-Depth Controls for Sodium Fire 5.3.2.10-5

5.3.2.11-1 Defense-in-Depth Controls for Chemical Reaction in Double-Contained Receiver Tank 5.3.2.11-3

5.3.2.12-1 Summary of Consequences and Frequencies for Mixing of Incompatible Waste—Tank Pressurization without Controls 5.3.2.12-3

5.3.2.12-2 Summary of Consequences and Frequencies for Mixing of Incompatible Waste—Tank Pressurization with Controls 5.3.2.12-3

5.3.2.12-3 Technical Safety Requirement Controls for Mixing of Incompatible Materials—Tank Pressurization 5.3.2.12-4

5.3.2.12-4 Safety Structures, Systems, and Components for Mixing of Incompatible Materials—Tank Pressurization 5.3.2.12-4

5.3.2.12-5 Defense-in-Depth Controls for Mixing of Incompatible Waste—Tank Pressurization 5.3.2.12-4

5.3.2.13-1 Consequences of a Load Drop Assuming No Controls . . . 5.3.2.13-6

5.3.2.13-2 Technical Safety Requirement Controls for Load Drops 5.3.2.13-7

5.3.2.13-3 Defense-in-Depth Controls for Load Drops 5.3.2.13-9

5.3.2.14-1 Results Assuming No Controls Accident Scenario for Flammable Gas Deflagrations 5.3.2.14-10

5.3.2.14-2 Safety Systems, Structures, and Components for Flammable Gas Deflagrations 5.3.2.14-11

5.3.2.14-3 Technical Safety Requirement Controls for Flammable Gas Deflagrations 5.3.2.14-13

LIST OF TABLES (cont)

5.3.2.15-1 Organic Solvent Fire Accident Scenarios Applicable to Different Types of Tanks 5.3.2.15-11

5.3.2.15-2 Onsite Consequences of Organic Solvent Fire Scenarios Assuming No Controls and a Frequency of "Unlikely" 5.3.2.15-12

5.3.2.15-3 Offsite Consequences of Organic Solvent Fire Scenarios Assuming No Controls and a Frequency of "Unlikely" 5.3.2.15-13

5.3.5.15-4 Summary of Accident Frequencies for Organic Solvent Fires Assuming No Controls 5.3.2.15-14

5.3.2.15-5 Technical Safety Requirement Controls for Organic Solvent Fires 5.3.2.15-15

5.3.2.15-6 Organic Solvent Fire Topography 5.3.2.15-16

5.3.2.15-7 Defense-in-Depth Controls for Toxic Vapor Nitrate Fires. 5.3.2.15-21

5.3.2.16-1 Unmitigated Consequences of Vehicle Fuel Pool Fire . . 5.3.2.16-7

5.3.2.16-2 Technical Safety Requirement Controls for Vehicle Fuel Fire/Deflagration 5.3.2.16-7

5.3.2.16-3 Defense-in-Depth Controls of Vehicle Fuel Fire/Deflagration 5.3.2.16-8

5.3.2.17-1 Organic-Nitrate Waste Grouping 5.3.2.17-12

5.3.2.17-2 Summary of Organic-Nitrate Condensed Phase Ignition Source Evaluation 5.3.2.17-13

5.3.2.17-3 Radiological and Toxicological Consequences for 25 m^3 Organic-Nitrate Combustion Accident (No controls in place - accident is "unlikely") 5.3.2.17-14

5.3.2.17-4 Radiological and Toxicological Consequences for 25 m^3 Organic-Nitrate Combustion Accident (Controls in place - Accident is "extremely unlikely") 5.3.2.17-14

5.3.2.17-5 Technical Safety Requirement Controls for Organic-Nitrate Condensed-Phase Combustion Accidents 5.3.2.17-15

5.3.2.17-6 Defense-in-Depth Controls for Organic-Salt Nitrate Reactions 5.3.2.17-18

LIST OF TABLES (cont)

5.3.2.17-7 Safety Structures, Systems, and Components for Organic Salt-Nitrate Reaction. 5.3.2.17-19

5.3.2.18-1 Consequences of Surface Leak Resulting in Pool Assuming No Controls 5.3.2.18-7

5.3.2.18-2 Consequences of Surface Leak Resulting in Pool Assuming Controls 5.3.2.18-7

5.3.2.18-3 Safety Structures, Systems, and Components for Surface Leak Resulting in Pool 5.3.2.18-8

5.3.2.18-4 Technical Safety Requirement Controls for Surface Leak Resulting in Pool 5.3.2.18-10

5.3.2.18-5 Defense-in-Depth Controls for Surface Leak Resulting in Pool 5.3.2.18-13

5.3.2.19-1 Consequences of a Subsurface Leak Resulting in Pool Assuming No Controls 5.3.2.19-6

5.3.2.19-2 Consequences of a Subsurface Leak Resulting in Pool Assuming Controls 5.3.2.19-6

5.3.2.19-3 Safety Structures, Systems, and Components for Subsurface Leak Resulting in Pool 5.3.2.19-7

5.3.2.19-4 Technical Safety Requirement Controls for Subsurface Leak Resulting in Pool 5.3.2.19-7

5.3.2.19-5 Defense-in-Depth Controls for Subsurface Leak Resulting in Pool 5.3.2.19-8

5.3.2.20-1 Summary of Consequences and Frequencies without Controls 5.3.2.20-6

5.3.2.20-2 Summary of Consequences and Frequencies with Controls 5.3.2.20-6

LIST OF TERMS

AC	Administrative Control
ADF	aerosol depletion factor
AWF	Aging Waste Facility
BIO	Basis for Interim Operation
Bq	becquerel
CAM	continuous air monitor
Ci	curie
COB	cleanout box
CPS	criticality prevention specification
CSER	criticality safety evaluation report
DCRT	double-contained receiver tank
DST	double-shell tank
EDTA	ethylenediaminetetraacetic acid
ERPG	Emergency Response Planning Guide
FSAR	Final Safety Analysis Report
HazOp	hazard and operability study
HEME	high-efficiency mist eliminator
HEPA	high-efficiency particulate air (filter)
HEDTA	hydroxyethylethylenediaminetriacetic acid
HMP	Hazardous Material Protection
HS	headspace
GRE	gas release event
JCO	Justification for Continued Operation
LCO	Limiting Condition for Operation
LFL	lower flammability limit
n/a	not applicable
NTA	nitrilotriacetic acid
MAR	material at risk
MISF	miscellaneous interim storage facility
mSv	millisievert
OGT	overground transfer
PEL	permissible exposure limit
PFP	Plutonium Finishing Plant
PHA	preliminary hazards analysis
psig	pounds per square inch gauge
RCRA	*Resource Conservation and Recovery Act of 1976*
RMCS	rotary mode core sampling
SC	Safety-Class
SS	Safety-Significant
SOF	sum-of-fractions
SSC	structure, system, and component
SST	single-shell tank
TBP	tributyl phosphate
TOC	total organic carbon
TSR	Technical Safety Requirement
TWA	time-weighted average
TWRS	Tank Waste Remediation System
USQ	Unreviewed Safety Question
WF	weight factor
WRSS	Waste Retrieval Sluicing System

5.0 SAFETY ANALYSIS

The safety analysis of the Tank Waste Remediation System (TWRS) facilities and operations that support this Basis for Interim Operation (BIO) is described in this chapter. The safety analysis includes hazard and accident analyses, and provides the basis for the interim controls required for protection of the public, onsite workers, facility workers, and the environment.

The safety analysis for this TWRS BIO exceeds the minimum requirements established in DOE-STD-3011-94, *Guidance for Preparation of DOE 5480.22 (TSR) and DOE 5480.23 (SAR) Implementation Plans*. The DOE-STD-3011-94 requirements are surpassed because much of the hazard and accident analyses being performed for the TWRS Final Safety Analysis Report (FSAR) were available and used in establishing this interim safety basis. The hazard and accident analyses that are continuing for the FSAR development will build on the BIO safety analysis. Revisions to the BIO safety analysis and the derived interim controls are expected in the FSAR due to the continuing hazard and accident analyses and associated work on technical issues such as flammable gas and organic salt-nitrate reactions. The FSAR will also provide more extensive and comprehensive discussions of the hazard and accident analysis methodology and results and of the derivation of controls.

The hazard classification of TWRS facilities, performed in accordance with DOE 5480.23, *Nuclear Safety Analysis Reports*, and DOE-STD-1027-92, *Hazard Categorization and Accident Analysis Techniques for Compliance with DOE Order 5480.23, Nuclear Safety Analysis Reports*, is provided in Section 5.1, "Hazard Classification." Section 5.2, "Hazard Analysis," and Section 5.3, "Accident Analysis," describe the analysis methodology and the results of the hazard and accident analyses of TWRS facilities and operations, respectively. Controls that protect the public, onsite workers, facility workers, and the environment from the hazardous conditions identified for TWRS facilities and operations are presented in Section 5.4, "Engineered and Administrative Controls." Section 5.4 also discusses the criteria used for making control decisions.

The interim controls derived from the hazard and accident analyses in this chapter include the following:

- Safety-Class and Safety-Significant structures, systems, and components (SSCs) and Technical Safety Requirements (TSRs)
- Controls providing Defense-in-Depth
- Controls specifically for environmental protection.

Safety SSCs and TSRs required for the protection of the public, onsite workers, and facility workers are based on the qualitative hazard analysis and the quantitative accident analysis (Sections 5.2, 5.3, and 5.4). Controls that provide Defense-in-Depth are identified for the analyzed representative accidents in Section 5.3. Defense-in-Depth controls are existing engineered features or administrative programs or procedures that may further reduce the risk of an accident, but are not essential requirements like safety SSC and

TSR controls. In addition to safety SSCs, TSRs, and Defense-in-Depth controls identified for protection of the public, onsite workers, and facility workers, controls specifically for the protection of the environment are discussed in Section 5.2.2.2.3, "Environmental Protection," and Section 5.4.

The TWRS BIO safety analysis and the interim controls derived from the safety analysis address and encompass the following open TWRS Unreviewed Safety Questions (USQs).

- **Flammable Gas and Slurry Growth USQ**—The BIO safety analysis and interim controls incorporate Appendix E, "Flammable Gas/Slurry Growth Unreviewed Safety Question: Justification for Continued Operation for the Tank Farm at the Hanford Site." The controls on the Tank 241-SY-101 mixer pump required in closure of the original flammable gas USQ are also included in the BIO interim controls (Kinzer 1996, *Closure of Hanford Tank 241-SY-101 Flammable Gas Unreviewed Safety Question (USQ)*; and Wagoner 1996b, *RL Approval of Engineering Change Notice (ECN) 169389 to Interim Operational Safety Requirements*) (Section 5.3.2.14, "Flammable Gas Deflagrations").

- **Condensed-Phase Organic Nitrate Reaction USQ**—The BIO safety analysis and the interim controls that provide the Authorization Basis for the Condensed-Phase Organic Nitrate Reaction USQ (Wagoner 1996a, *Recommendation for Declaring an Unreviewed Safety Question (USQ) Regarding Condensed-Phase Organic Nitrate Reactions*) are included in the BIO (Section 5.3.2.17, "Organic Salt-Nitrate Reaction"). (Note: There will be no separate justification for continued operation [JCO] for the Condensed-Phase Organic Nitrate Reaction USQ.)

- **Soil Density Discrepancy in AP Tank Farm USQ**—The BIO safety analysis and interim controls incorporate the Authorization Basis established by the approved JCO for the Soil Density Discrepancy Discovery in AP Tank Farm USQ (Lee 1994, *Request for Approval-Justification for Continued Operations-Dome Loading*; and Wagoner 1995, *Justification for Continued Operation, Tank Farm Dome Loading*), and the open safety issue on high heat related to Tank 241-C-106 (Section 5.3.2.13, "Tank Failure Due to Excessive Loads").

BIO Addendum 1, "Tank 241-C-106 Sluicing Safety Analysis" and the associated TSR changes close the USQ Tracking Number TF-95-0105, *Project W-320, C-106 Sluicing and Waste Retrieval for Storage in AY-102.* BIO Addendum 2, "Replacement Cross-Site Transfer System Safety Analysis" and associated TSR changes close the USQ Tracking Number TF-96-1007, *Replacement Cross-Site Transfer System Tie-Ins at 244 A-Lift Station and 241-SY Valve Pits.* BIO Addendum 3, "702-AZ Ventilation System (241-AZ-702) Safety Analysis" and associated TSR changes close the USQ Tracking Number TF-93-0055, *Tank Farm Ventilation Upgrade, Project W-030.* BIO Addendum 4 and associated TSR changes close USQ Tracking Number TF-94-0266, *Mixer Pump Process Test for Waste in 241-AZ-101, Aging Waste Double-Shell Tank (W-151).*

5.1 HAZARD CLASSIFICATION

DOE 5480.23, *Nuclear Safety Analysis Reports*, requires the hazard classification of nuclear facilities and operations. Guidelines for hazard classification that meet the requirements of DOE 5480.23 are provided in DOE-STD-1027-92, *Hazard Categorization and Accident Analysis Techniques for Compliance with DOE Order 5480.23, Nuclear Safety Analysis Reports*. DOE-STD-1027-92 classifies a facility as either Hazard Category 1, 2, or 3 depending on the quantities of radioactive material in the facility. Hazard Category 2 and 3 facilities contain quantities of radioactive material in excess of the threshold values in Table A.1 of DOE-STD-1027-92. Hazard Category 1 facilities are limited to Category A reactors and facilities designated by the Program Secretarial Officer. A facility that does not exceed the DOE-STD-1027-92 Hazard Category 3 threshold for radioactive material but possesses some amount of radioactive material is considered a Radiological Facility.

A hazard classification of TWRS facilities and operations performed in accordance with DOE-STD-1027-92 determined that all the single-shell tanks, double-shell tanks, Aging Waste Facility tanks, and associated waste transfer systems are Hazard Category 2 facilities. The associated waste transfer systems include the 204-AR Waste Unloading Facility and the 244-AR Vault. The Hazard Category classifications for projects are based on supplemental project hazard analysis and are contained in the designated addenda. The Hazard Category 2 classification is based on estimated waste inventories for single-shell tanks, double-shell tanks, and Aging Waste Facility tanks (Dunford 1996, *Tank Waste Remediation System Final Safety Analysis Report Project Plan Comment Response; Risk Based Approach*) that exceed the Hazard Category 2 threshold in DOE-STD-1027-92.

Applying the DOE-STD-1027-92 concept of facility segmentation, there are a number of TWRS facilities that are independent segments where the radioactive and hazardous material in one segment cannot interact with the radioactive and hazardous material in other segments. These independent segments are the vertical storage units; 209-E Storage Area; 2727-W Sodium Storage Facility; 213-W Compactor Building; cribs, ditches, and ponds; and miscellaneous inactive storage facilities. The hazard classification of these facilities is provided in Table 5.1-1 based on their estimated radioactive material inventory.

Table 5.1-1. Hazard Category for Tank Waste Remediation System Facilities.

TWRS facility	Function	Independent segment	Hazard category
Double-shell tanks (including Aging Waste Facility tanks), and associated waste* transfer systems	Storage and transfer of high-level radioactive waste	No	2
Single-shell tanks and associated waste* transfer systems	Storage and transfer of high-level radioactive waste	No	2
204-AR Waste Unloading Facility	Transfer of dilute waste to TWRS from other Hanford Site facilities	No	2
244-AR Vault	Lag storage and transfer of plutonium uranium extraction (PUREX) waste to TWRS	No	2
Vertical storage units	Storage of contaminated tank equipment	Yes	3
209-E Storage Area	Temporary storage of RCRA and low-level mixed waste before disposal	Yes	3
2727-W Sodium Storage Facility	Sodium metal storage	Yes	Radiological facility
213-W Compactor Building	Contaminated instrument repair	Yes	3
Cribs, ditches, and ponds	Capture of wastewater and effluent discharge	Yes	3
Miscellaneous inactive storage facilities	Storage of various materials ranging from tank waste to diesel fuel to sewage	Yes	2
Tank 241-C-106 Waste Retrieval Sluicing System (WRSS), Project W-320	Retrieval of waste from Tank 241-C-106 and transfer to Tank 241-AY-102 using sluicing techniques	No	2

*Double-contained receiver tanks, catch tanks, process pits, diversion boxes, vault pits, cleanout boxes, and transfer lines.

5.2 HAZARD ANALYSIS

Presented in this section are the methodology (Section 5.2.1, "Methodology") and results (Section 5.2.2, "Hazard Analysis Results") of the hazard analysis conducted for the Tank Waste Remediation System (TWRS) facilities and operations. Supplemental hazard analysis for the Waste Retrieval Sluicing System (WRSS) is contained in Addendum 1. Supplemental hazard analysis for the replacement cross-site transfer system is contained in Addendum 2. Supplemental hazard analysis for the 702-AZ ventilation system is contained in Addendum 3. The events considered in the hazard analysis are internal, external, and natural phenomena events that can affect the public, onsite workers, facility workers, or the environment through the uncontrolled release of radioactive or hazardous materials. Sabotage and terrorism are not included.

The hazard analysis addressed both inactive and active facilities. Inactive facilities were addressed as follows:

- Facilities classified as miscellaneous inactive storage facilities including inactive miscellaneous underground storage tanks and other inactive underground and aboveground storage facilities were analyzed.
- Interfaces with inactive facilities outside the scope of the TWRS BIO that had a physical connection to TWRS systems, including the inactive evaporators (242-S and 242-T), were analyzed.
- Inactive facilities within the scope of the TWRS BIO, including the 244-AR Vault, were analyzed.
- Abandoned or inactive portions of TWRS systems physically connected to active TWRS facilities were included in the analysis of the facility to which they were connected.

The results of the hazard analysis for inactive facilities were used with the results for active facilities to select candidate accidents for analysis and identify controls.

5.2.1 Methodology

The methodology used to perform the hazard analysis is presented in this section. The hazard analysis is a systematic and predominantly qualitative evaluation of the spectrum of risks to the public, onsite workers, facility workers, and the environment. Following is a discussion of the activities performed in the hazard analysis.

5.2.1.1 Hazard Identification. The hazard analysis includes identification of the hazards associated with each facility identified in the scope of this BIO. Hazards are defined as radioactive or hazardous material, referred to as material at risk (MAR), and as the energy sources that could contribute to the uncontrolled release of the MAR. The hazard identification methods and techniques include the following:

- Review of past TWRS safety documents
- Review of TWRS reportable event history (e.g., unusual occurrence reports)
- Review of historical records of similar operations (e.g., Savannah River Site)
- Participation by current and former TWRS operations and engineering personnel in the hazard analysis effort
- Use of standardized checklists of hazardous materials and energy sources to consider
- Review of TWRS facilities and operations descriptions
- Facility walkdowns
- Review of existing TWRS hazard analyses.

The hazard identification activity included a review of occurrence reports for TWRS (200 Area tank farms and affiliated facilities). These reports were examined to assure that a comprehensive set of hazards and potential accident causes were addressed by the hazard analysis activity. Comprehensiveness was assured by comparing the nature of the occurrences with potential causes or accidents identified by the hazard analysis and verifying that those occurrences not covered were not material to the hazard analysis results. Review of the occurrences also was used to assist in determining frequencies for some of the hazardous conditions in the TWRS hazard and operability study and preliminary hazards analysis.

5.2.1.2 Hazard Evaluation. The hazard evaluation is a structured and systematic examination using standard industry (AIChE, 1992, *Guidelines for Hazard Evaluation Procedures*) hazard evaluation techniques. The hazard evaluation team comprises cognizant TWRS operations and engineering personnel, safety analysts familiar with TWRS, and technical experts in specialty areas.

Hazard evaluations representative of all TWRS facilities are performed. Representative hazard evaluations are chosen on the basis of selection criteria designed to ensure comprehensive coverage of all TWRS facilities and their design and operation variations. Specific hazard evaluations are chosen to address the following:

- Material at risk
- Unique phenomenology (e.g., high heat, flammable gas, organics)

- Unique configuration variations (e.g., interface with the evaporators, active ventilation systems, passive ventilation systems, double-shell tanks, single-shell tanks)
- TWRS operations (e.g., waste transfers, in-tank activities, waste sampling)
- Unique facilities (e.g., 204-AR Waste Unloading Facility, 2727-W Sodium Storage Facility)
- Unique operations (e.g., Tank 241-C-106 WRSS as evaluated in Addendum 1).

The hazard evaluation technique selected for each representative hazard evaluation depends on the nature of the TWRS facility or operation being analyzed. The hazard evaluation techniques used are hazard and operability study, preliminary hazards analysis, and "What-If" analysis. These hazard evaluation techniques and where they were applied are discussed in Appendix D, "Hazard Analysis Results Report."

For each technique, the hazard evaluation identifies hazardous conditions (i.e., accidents) related to the facility, MAR, and energy sources. For each hazardous condition, the following information is developed:

- Hazardous condition description
- Cause
- Frequency
- Consequence.

The causes of hazardous conditions include internal events, external events, and natural phenomena events. Single and multiple failures (equipment and human errors) are considered as well as common cause failures. Both human errors of commission and omission (i.e., human reliability) are identified as potential causes or contributors to hazardous conditions.

The frequency assessments for the hazardous conditions are presented in occurrences per TWRS year and are assigned to a frequency category. A description of the frequency categories is provided in Table 5.2-1.

The consequence category assessments address potential impacts on the health and safety of the public and workers, and on the environment. A description of the consequence categories is provided in Table 5.2-2. The more severe consequence categories include the less severe consequence categories. For example, a hazardous condition assessed as having onsite consequences (S2) also is considered to have facility worker consequences (S1).

5.2.1.3 Accident Selection. The hazardous conditions identified by the hazard evaluation process are used to select representative accidents for more detailed quantitative analysis. The general selection criteria used are consistent with guidance in DOE-STD-3009-94, *Preparation Guide for*

U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports: "The range of accident scenarios analyzed in a safety analysis report should be such that a complete set of bounding conditions to define the envelope of accident conditions to which the operation could be subjected are evaluated and documented."

The concept of selecting representative accidents from all the hazardous conditions identified is based on evaluating frequency and consequences for a representative accident, developing controls to mitigate or prevent the accident, and applying those controls to the entire set of accidents (i.e., hazardous conditions) covered by the representative accidents.

Representative accidents are selected on the basis of the following criteria: accidents that bound those of lesser but similar potential consequences; accidents that represent the highest risk; and accidents, although not necessarily bounding, that present some unique challenge to safety. The selection process comprises six steps.

1. **Initial Screening**—All hazardous conditions not assessed as S3 (offsite consequences) or S2 (onsite consequences) are dropped from the accident selection process. The S1 and S0 hazardous conditions are addressed on the basis of the qualitative hazard analysis results only.

2. **Assignment of Accident Release Attributes**—Each hazardous condition (i.e., accident) is described with accident release attributes related to uncontrolled release of the MAR. This process ensures that each release condition is represented by at least one accident.

   The release attributes for hazardous material are as follows:

   - Initial energy available to release the hazardous material
   - Initial release location
   - Initial form of the release.

   Initial conditions are used for these assignments because it is possible (and sometimes likely) that other conditions may evolve during the accident progression. For example, a release may begin as a pool of liquid on the ground and become airborne as wind blows over the pool. The progression of the accident is thoroughly examined in the accident analysis.

   The attributes related to energy level have three designations: high, moderate, and low. A high energy level (A) is assigned to energetic events such as explosions, fires, and criticality. A moderate energy level (B) is assigned to events such as liquid spray from pressurized lines, splash or airborne particles caused by hardware being dropped into a material, or airborne particles from a ventilation system that is breached when the fans are running. A low energy level (C) includes events such as leaks from nonpressurized liquid containers and releases from passive ventilation systems.

The attributes related to the initial release location have three designations: (1) atmospheric, (2) ground surface, and (3) subsurface. In some cases, the accident may result in release to more than one location. An accident resulting in significant portions of materials being released to more than one location is assigned the location attribute associated with the most severe consequence.

The attributes related to the initial form of the release have three designations: (a) vapor, gas, or aerosol; (b) liquid or slurry; and (c) solid or sludge. Again, in some cases, the accident may result in release of more than one form of material and thus be assigned the attribute associated with the most severe consequence.

3. **Creation of Accident Release Bins**—Once the release attributes are assigned to each hazardous condition (accident), accidents with common release attributes are collected to form accident release categories or bins.

4. **Sorting of Hazardous Conditions by Cause**—The hazardous conditions within each accident release bin are next grouped by cause. This includes grouping by common accident phenomena (e.g., fire, criticality). Examination of the various causes supports selection of a representative set of accidents from each release attribute bin.

5. **Selection of Representative Accidents from Each Accident Release Bin**—Within each accident release bin, the most severe accident in terms of consequence, and the highest risk accident (considering both frequency and consequences) are selected. One accident may represent both cases.

6. **Selection of Unique Accidents**—For each release attribute bin, if the accidents selected in step 5 do not represent each cause or important challenge to safety within the bin, additional accidents are selected. This process supports the development of controls for accidents with similar consequences, but different causes.

The results of this process are documented in Appendix D. The representative accidents selected by this process bound the consequences of all the hazardous conditions within their respective bins. The representative accidents are quantitatively analyzed in the accident analysis (Section 5.3).

5.2.1.4 Controls Identification. The hazard analysis results, together with the accident analysis results, are used to identify Safety-Class and Safety-Significant structures, systems, and components (SSCs), Technical Safety Requirements (TSRs), and other controls that provide Defense-in-Depth or environmental protection. Controls for protection of the public and onsite workers are based on the results of both the hazard analysis and the accident analysis. Additional controls required to protect the facility worker or the environment are based primarily on the qualitative hazard analysis.

The safety SSCs, TSRs, and other controls are identified by the following process.

1. For each analyzed representative accident, a necessary and sufficient set of controls is identified for protection of the public and onsite worker. This includes identifying any significant contributors to Defense-in-Depth.

2. A determination of whether the selected controls acceptably prevent or mitigate all the hazardous conditions represented by the analyzed representative accident at all the facilities where the hazardous conditions exist is made. If necessary, additional controls are identified for the hazardous conditions and facilities being evaluated.

3. All the controls chosen to protect the public and onsite worker are reviewed to determine whether any significant facility worker or environmental hazardous conditions remain uncontrolled. If necessary, additional controls are identified.

Details of the methodology and process for identification of controls are contained in Appendix D and Dunford 1996, *Tank Waste Remediation System Final Safety Analysis Report Selection of Safety Structures, Systems, and Components; and Technical Safety Requirements*. Criteria used for control decisions are presented in Section 5.4.1, "Control Decision Criteria."

5.2.2 Hazard Analysis Results

5.2.2.1 Hazard Identification. Results of the hazard identification activities are presented in the following sections. Supplemental hazard identification information for projects is contained in the designated addenda, as applicable. The results of the hazard identification for WRSS are contained in Addendum 1. The results of the hazard identification for the replacement cross-site transfer system are contained in Addendum 2. The results of the hazard identification for the 702-AZ ventilation system are contained in Addendum 3.

5.2.2.1.1 Material at Risk. TWRS facilities containing MAR are listed based on the facility description in Appendix B, "Facility and Process Description." The facilities evaluated are identified in Table 5.2-3. Facility-specific information on the MAR used during the hazard evaluations is documented in WHC-SD-WM-TI-759, *Hazard Evaluations for the Tank Waste Remediation System Final Safety Analysis Report*, and in Appendix D. Refer to Section 5.3 of this report for information on the MAR used for the accident analyses.

Hazardous materials were identified in TWRS that are not included in the MAR list. These materials, such as residual quantities of low-level wastes and laboratory quantities of chemicals, are controlled by standard practices (Section 5.2.2.2.2, "Facility Worker Protection").

5.2.2.1.2 Energy Sources. The next step in the hazard identification process is the identification of the energy sources that could contribute to the uncontrolled release of the MAR. The energy sources for TWRS facilities were identified using an energy source checklist. The checklist allowed documentation of the energy sources present at the facilities and the unique phenomena occurring in the tanks.

The checklist applied to TWRS facilities was developed from the Management Oversight Risk Tree list (DOE-76-45/4 SSDC-4, *MORT User's Manual*) with other energy sources included that were specific to the TWRS facilities being analyzed.

The energy source checklist analysis included the following unique phenomena occurring in the tanks:

- High heat
- Flammable gas (hydrogen, methane, ammonia)
- Organics.

The identified energy sources present at each facility are documented in WHC-SD-WM-HIE-007, *Tank Waste Remediation System FSAR Hazard Identification/Facility Configuration Verification Report*.

5.2.2.1.3 Natural Phenomena, External Events, and Common-Cause Hazards. Other hazards were identified during the hazard evaluation through "What-If" analyses. The three types of hazards analyzed were natural phenomena, external events, and common cause.

Natural phenomena events are those events caused by weather and geological events that could affect one or more facilities or locations resulting in potentially hazardous conditions. For this "What-If" analysis, a list of potential natural phenomena was developed, the frequency of the event was estimated, and the resulting consequences were determined qualitatively.

External events are those potential initiators of hazardous conditions that come from outside the facility or operation. For this "What-If" analysis, a list of external events was developed, the frequency of the event was estimated, and the resulting consequences determined qualitatively.

A common cause is an initiator with potential impacts on more than one location. For this "What-If" evaluation, a list of potential common-cause events was developed, the frequency of the event was estimated, and the resulting consequences were determined qualitatively.

The natural phenomena, external events, and common-cause hazardous conditions that were analyzed during the "What-If" analyses are identified in Table 5.2-4.

5.2.2.2 Hazard Evaluation. The results of the TWRS hazard evaluations are documented in WHC-SD-WM-TI-759. Supplemental hazard evaluations for projects are included in the designated addenda, as applicable. Hazard evaluations for WRSS are contained in Addendum 1. Hazard evaluations for the replacement

cross-site transfer system are contained in Addendum 2. Hazard evaluations for the 702-AZ ventilation system is contained in Addendum 3. Each hazard evaluation was assigned a hazard evaluation identifier. For each facility, the applicable hazard evaluation identifier is included in Table 5.2-3. The hazard evaluation activity determined a set of hazardous conditions and their causes that could result in the uncontrolled release of hazardous material.

The identification of causes was based on the hazard identification results, reviews of the systems, historical event data, and other sources (e.g., existing safety documentation) including discussions with experienced facility personnel. Typical causes of the postulated hazardous conditions include equipment failures, operational errors, abnormal operating conditions, and environmental conditions. The causes of a postulated hazardous condition were identified to support a qualitative frequency evaluation.

Each hazardous condition was assigned a hazardous condition identification number. The alpha-numeric identifier for each hazardous condition permits tracing the condition to the specific item in the applicable hazard and operability study, preliminary hazard analysis, or what-if evaluation. The description of each hazardous event, its cause, frequency category, consequence category, and hazardous condition and identification number (ID) are included in Appendix D.

5.2.2.2.1 Accident Selection. Representative accidents were selected using the methodology described in Section 5.2.1.3, "Accident Selection." The representative accidents that bound the consequences of all S2 (onsite) and S3 (offsite) hazardous conditions are listed in Table 5.2-5 along with the corresponding section in this BIO that contains the quantitative accident analysis results. The complete process is documented in Appendix D. Section 5.3 contains the methodology and results of the analysis of the representative accidents listed in Table 5.2-5.

5.2.2.2.2 Facility Worker Protection. The TWRS hazard analysis process identified potential hazardous conditions that would effect the facility worker. These hazardous conditions are divided into three categories: uncontrolled releases of radioactive or hazardous material, operational radiation and hazardous material protection concerns, and occupational safety concerns.

Protection Against Uncontrolled Releases—Anticipated hazardous conditions affecting the facility worker were reviewed to determine if the safety SSC and TSR controls developed for the analyzed accidents applied to these hazardous conditions. If the safety SSCs and TSRs did not sufficiently control the hazard, the hazardous conditions were reviewed to determine if a potential existed for serious injury or death to the facility worker. For those hazardous conditions, Safety-Significant SSCs and TSRs were identified.

The list of anticipated hazardous conditions affecting the facility worker and the safety SSCs and TSRs applicable to each hazardous condition is given in Section 5.4.

Operational Radiological and Hazardous Material Protection—A number of potential facility worker radiological and hazardous material exposure concerns expected during operation were identified in the hazard evaluation.

Although identification of potential facility worker radiation exposure and hazardous material concerns was not the specific focus of the hazard evaluations, the exposure concerns were recorded in Appendix D and have been sent to the Radiation Protection Program and Hazardous Material Protection Program to ensure that appropriate safeguards are in place to mitigate or prevent the event. The Radiation Protection Program and Hazardous Material Protection Program are summarized in Chapter 4.0, "Safety Management" of this chapter.

Occupational Safety—The hazard evaluation identified a number of potential facility worker occupational safety concerns. Although identification of potential facility worker occupational safety concerns was not the specific focus of the hazard evaluations, the exposure concerns were recorded in Appendix D and have been sent to the Industrial Health and Safety Program to ensure that appropriate safeguards are in place to mitigate or prevent the event.

5.2.2.2.3 Environmental Protection. The hazard analysis identified hazardous conditions with significant environmental (E3 or E2) consequences. For most of these hazardous conditions, the controls identified to protect the public, onsite worker, and facility worker also provide for protection of the environment. A listing of the hazardous conditions with significant environmental consequences (E3 and E2) and applicable safety SSCs and TSRs is provided in Section 5.4. Additional controls required specifically to provide protection for the environment are also discussed in Section 5.4.

Table 5.2-1. Frequency Categories for Tank Waste Remediation System Facilities.

F3 ($>10^{-2}$)	**Anticipated events:** Frequency greater than once in 100 operating years
F2 (10^{-4} to 10^{-2})	**Unlikely:** Frequency between once in 10,000 years and once in 100 operating years
F1 (10^{-6} to 10^{-4})	**Extremely unlikely:** Frequency between once in 1 million years and once in 10,000 operating years
F0 ($<10^{-6}$)	**Beyond extremely unlikely:** Frequency of less than once in a million operating years

Table 5.2-2. Consequence Categories for Tank Waste Remediation System Facilities.

Category	Definition
S3	Significant radiological or chemical exposure to the public
S2	Significant radiological or chemical exposure to onsite worker
S1	Significant radiation or chemical exposure to facility worker
S0	No significant effect outside facility systems. No consequences for facility workers, onsite workers, or public
E3	Offsite discharge or discharge to groundwater
E2	Significant discharge onsite
E1	Localized discharge of hazardous material
E0	No significant environmental consequence

Tank 241-AN-107	HazOp	107AN
Tank 241-AW-102	HazOp	102AW
Tank 241-S-102	HazOp	102S
Tank 241-SX-114	HazOp	114SX
Cross-site (XS) transfer (Tank 241-SY-102) (selected portions of Project W-058)	HazOp	XS, W058
209-E Storage Area (includes less than 90-Day Storage Pad)	PHA (Preliminary Hazard Analysis)	90D
213 Compactor	PHA	213W
244-AR Vault	PHA	244AR-PH
2727-W Building	PHA	2727W
Cleanout boxes	PHA	COB
Cone Penetrometer[1]	PHA	CP
Cribs, ditches, and ponds	PHA	CDP
Light Duty Utility Arm[1]	PHA	LDUA
MISF - Inactive miscellaneous underground storage tank (plus other inactive facilities)	PHA	Identifier ends in - I, e.g., CRN-05-I
Siphoning	PHA	TSF*
Tank operations (Tank 241-AZ-102)	PHA	BND, CVR, CRN, DCN, FR, GRN, ITK, RAD, RSR, SFF, VEH*
Tank operations (Tank 241-BX-109)	PHA	BND, CVR, CRN, DCN, FR, GRN, ITK, RAD, RSR, SFF, VEH*
Tank operations (Tank 241-SY-101)	PHA	BND, CVR, CRN, DCN, FR, GRN, ITK, RAD, RSR, SFF, VEH*
Vertical storage units	PHA	VSU
Common cause failure	"What If" (What If Analysis)	CCF
External events	"What If"	EE
Natural phenomena	"What If"	NP

*Abbreviation List for Tank Farm Activities:

BND - Bonding
CDP - Cribs, ditches, and ponds
CVR - Cover Block Installation and Removal
CRN - Crane Operations
DCN - Decontamination
FR - Flex Receivers
GRN - Greenhouse or Confinement Construction and Removal
ITK - In-Tank Equipment Installation, Operation and Removal
RAD - Radiological Monitoring and Surveys
RSR - Riser Access (and possible asbestos removal)
SFF - Sniffing (gas monitoring)
TSF - Tank Farm Waste Transfer Syphoning Events
VEH - Vehicle Operations

The above key relates the type of representative analysis performed to the TWRS facilities listed below.

		241-SX TANK FARM	
241-SX-101	Single-shell tank, flammable gas, active ventilation	HAZOP: AW-102, C-106, S-102, SX-114, SY-102, 242-T, Overground Transfers PHA: AZ-102/BX-109/SY-101/ITK WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF,I-242T,OGT
241-SX-102	Single-shell tank, flammable gas, active ventilation	HAZOP: AW-102, C-106, S-102, SX-114, SY-102, 242-T, Overground Transfers PHA: AZ-102/BX-109/SY-101/ITK WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF,I-242T,OGT
241-SX-103	Single-shell tank, flammable gas, organics, active ventilation	HAZOP: AW-102, C-106, S-102, SX-114, SY-102, 242-T, Overground Transfers PHA: AZ-102/BX-109/SY-101/ITK WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF,I-242T,OGT
241-SX-104	Single-shell tank, flammable gas, active ventilation	HAZOP: AW-102, C-106, S-102, SX-114, SY-102, 242-T, Overground Transfers PHA: AZ-102/BX-109/SY-101/ITK WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF,I-242T,OGT
241-SX-105	Single-shell tank, flammable gas, active ventilation	HAZOP: AW-102, C-106, S-102, SX-114, SY-102, 242-T, Overground Transfers PHA: AZ-102/BX-109/SY-101/ITK WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF,I-242T,OGT
241-SX-106	Single-shell tank, flammable gas, organics, active ventilation	HAZOP: AW-102, C-106, S-102, SX-114, SY-102, 242-T, Overground Transfers PHA: AZ-102/BX-109/SY-101/ITK WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF,I-242T,OGT
241-SX-107	Single-shell tank, high heat load, active ventilation	HAZOP: AW-102, C-106, S-102, SX-114, SY-102, 242-T, Overground Transfers PHA: AZ-102/BX-109/SY-101/ITK WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF,I-242T,OGT

Table 5.2-3. Applicable Hazard Evaluations for Tank Waste Remediation System Facilities. (30 sheets)

241-SX-108	Single-shell tank, high heat load, active ventilation	HAZOP: AW-102, C-106, S-102, SX-114, SY-102, 242-T, Overground Transfers PHA: AZ-102/BX-109/SY-101/ITK WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF,I-242T,OGT
241-SX-109	Single-shell tank, high heat load, active ventilation	HAZOP: AW-102, C-106, S-102, SX-114, SY-102, 242-T, Overground Transfers PHA: AZ-102/BX-109/SY-101/ITK WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF,I-242T,OGT
241-SX-110	Single-shell tank, high heat load, active ventilation	HAZOP: AW-102, C-106, S-102, SX-114, SY-102, 242-T, Overground Transfers PHA: AZ-102/BX-109/SY-101/ITK WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF,I-242T,OGT
241-SX-111	Single-shell tank, high heat load, active ventilation	HAZOP: AW-102, C-106, S-102, SX-114, SY-102, 242-T, Overground Transfers PHA: AZ-102/BX-109/SY-101/ITK WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF,I-242T,OGT
241-SX-112	Single-shell tank, high heat load, active ventilation	HAZOP: AW-102, C-106, S-102, SX-114, SY-102, 242-T, Overground Transfers PHA: AZ-102/BX-109/SY-101/ITK WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF,I-242T,OGT
241-SX-113	Single-shell tank	HAZOP: AW-102, C-106, S-102, SX-114, SY-102, 242-T, Overground Transfers PHA: AZ-102/BX-109/SY-101/ITK WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF,I-242T,OGT
241-SX-114	Single-shell tank, dry crust, high heat load, active ventilation	HAZOP: AW-102, C-106, S-102, SX-114, SY-102, 242-T, Overground Transfers PHA: AZ-102/BX-109/SY-101/ITK WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF,I-242T,OGT
241-SX-115	Single-shell tank	HAZOP: AW-102, C-106, S-102, SX-114, SY-102, 242-T, Overground Transfers PHA: AZ-102/BX-109/SY-101/ITK WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF,I-242T,OGT
241-SX-151	Diversion box	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
241-SX-152	Diversion box	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
241-SX-A	Valve pit	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
241-SX-B	Valve pit	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR

Table 5.2-3. Applicable Hazard Evaluations for Tank Waste Remediation System Facilities. (30 sheets)

241-U-151	Diversion box	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
241-U-152	Diversion box	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
241-U-153	Diversion box	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
241-U-154	Diversion box	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
241-U-201	Single-shell tank	HAZOP: AW-102, C-106, S-102, SX-114, SY-102, 242-T, Overground Transfers PHA: AZ-102/BX-109/SY-101/ITK WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF,I-242T,OGT
241-U-202	Single-shell tank	HAZOP: AW-102, C-106, S-102, SX-114, SY-102, 242-T, Overground Transfers PHA: AZ-102/BX-109/SY-101/ITK WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF,I-242T,OGT
241-U-203	Single-shell tank, organics	HAZOP: AW-102, C-106, S-102, SX-114, SY-102, 242-T, Overground Transfers PHA: AZ-102/BX-109/SY-101/ITK WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF,I-242T,OGT
241-U-204	Single-shell tank, organics	HAZOP: AW-102, C-106, S-102, SX-114, SY-102, 242-T, Overground Transfers PHA: AZ-102/BX-109/SY-101/ITK WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF,I-242T,OGT
241-U-252	Diversion box	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
241-U-3018	Catch tank	HAZOP: AW-102, C-106, S-102, SX-114, SY-102 PHA: AZ-102/BX-109/SY-101 WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF
241-UR-151	Diversion box	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR

Table 5.2-3. Applicable Hazard Evaluations for Tank Waste Remediation System Facilities. (30 sheets)

241-UR-152	Diversion box	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
241-UR-153	Diversion box	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
241-UR-154	Diversion box	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
241-UX-154	Diversion box	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
241-UX-302A	Catch tank	HAZOP: AW-102, C-106, S-102, SX-114, SY-102 PHA: AZ-102/BX-109/SY-101 WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF
DCRTs, CATCH TANKS, CATCH STATIONS, AND LIFT STATIONS			
244-A	DCRT catch station	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
244-BX	DCRT catch station	HAZOP: AW-102, C-106, S-102, SX-114, SY-102 PHA: AZ-102/BX-109/SY-101 WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF
244-CR	DCRT catch station	HAZOP: AW-102, C-106, S-102, SX-114, SY-102 PHA: AZ-102/BX-109/SY-101 WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF
244-S	DCRT catch station	HAZOP: AW-102, C-106, S-102, SX-114, SY-102 PHA: AZ-102/BX-109/SY-101 WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF
244-TX	DCRT catch station	HAZOP: AW-102, C-106, S-102, SX-114, SY-102 PHA: AZ-102/BX-109/SY-101 WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF
244-U	DCRT catch station	HAZOP: AW-102, C-106, S-102, SX-114, SY-102 PHA: AZ-102/BX-109/SY-101 WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF
MISCELLANEOUS DIVERSION BOXES, CAISSONS, VENT STATIONS			
241-AR-151	Diversion box	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR

Table 5.2-3. Applicable Hazard Evaluations for Tank Waste Remediation System Facilities. (30 sheets)

241-CR-151	Diversion box	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
241-CR-152	Diversion box	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
241-CR-153	Diversion box	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
241-ER-151	Diversion box	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
241-ER-152	Diversion box	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
241-ER-153	Diversion box	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
241-ER-311	Catch tank	HAZOP: AW-102, C-106, S-102, SX-114, SY-102 PHA: AZ-102/BX-109/SY-101 WHAT IF: CCF, EE	102AW, 106C, 102S, 114SX, XS, BND, CRN, ITK, RAD, VEH, EE, CCF
241-EW-151	Vent station	HAZOP: XS	XS
241-F-505	Diverter caisson	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
241-F-562	Valve pit	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
		MISCELLANEOUS FACILITIES	
Located in each tank farm	Caisson	HAZOP: AW-102, SY-102	102AW, XS
Located in each tank farm	Catch tank pit	HAZOP: AW-102, SY-102	102AW, XS
Located in each tank farm	Cleanout box	PHA: COB	COB

Table 5.2-3. Applicable Hazard Evaluations for Tank Waste Remediation System Facilities. (30 sheets)

Located in each tank farm	Diversion box	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
Located in each tank farm	Diverter station	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
Located in each tank farm	Flush pit	HAZOP: AW-102, SY-102	102AW, XS
Located in each tank farm	Leak detection pit	HAZOP: AW-102, SY-102	102AW, XS
Located in each tank farm	Pump pit	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
Located in each tank farm	Service pit	HAZOP: AW-102, SY-102	102AW, XS
Located in each tank farm	Sluice transfer box	PHA: COB	COB
Located in each tank farm	Valve pit	HAZOP: 222-S, 242-A, 242-S, 242-T, AW-102, C-106, S-102, SX-114, SY-102, B Plant, T Plant, U Plant, PFP, PUREX, Overground Transfers PHA: AZ-102/BX-109/SY-101	I-222S, I-242A, I-242S, I-242T, 102AW, 106C, 102S, 114SX, W058, XS, I-BPLANT, I-UPLANT, I-TPLANT, I-PFP, I-PUREX, OGT, CVR
Located in various tank farms	Vertical Storage units	PHA: VSU	VSU
Located in various tank farms	MISF - Miscellaneous inactive storage facilities (includes inactive underground storage facilities and other inactive facilities)	PHA: MISF	-I (Identifier ends in -I, e.g., CRN-05-I)
Overground Transfer Line	Portable Overground Transfer Line	HAZOP: Overground Transfers	OGT
PFP Pond	Pond	PHA: CDP	CDP
Vertical Storage Units	12" - 20' in depth	PHA: VSU	VSU
209-E	less than 90-day storage pad	PHA: 209E	90D
216-Z-20	Crib	PHA: CDP	CDP
216-Z-21	Pond	PHA: CDP	CDP
241-AR-204	Railcar/truck receiving facility	HAZOP: 204AR	204AR
241-AR-244	Vault	HAZOP: 244AR PHA: 244AR	244AR, 244AR-PH
2727-W	Sodium storage bldg	PHA: 2727W	2727W

U Satellite Accumulation Area	Satellite Accumulation Area	PHA: 209E	90D

[1]These devices are used on an as-needed basis throughout TWRS, therefore, the hazard analyses are applicable to the anticipated uses and not on a specific facility or tank.

Table 5.2-4. Natural Phenomena, External Events, and Common Cause Hazards for Tank Waste Remediation System Facilities.

Natural phenomena[a]	External events[b]	Common cause[b]
Lightning	Aircraft crashes	Loss of electrical power
Tornadoes	Range fires	Loss of water supply
High winds	Dam collapse	Loss of steam supply
Earthquakes	Onsite and offsite transportation accidents	Loss of fuel supply
Ashfall	Water/steam main breaks	Loss of air supply
Eruption of molten lava	Excavation	Disabled or unavailable staff
Severe dust storms or dust devils		Poor quality materials
Accumulation of heavy snow		Aging effects
Severe hail storms		Chemical phenomena

[a]Natural phenomena are also considered as potential common cause hazards.

[b]Human error is a contributor to many external and common cause events. Consideration of this contributor occurs as an integral part of the Preliminary Hazards Analysis (PHA) and What-if process.

Table 5.2-5. Representative Accidents Analyzed and Cross-Reference to Basis for Interim Operation Accident Analysis Sections.*

Analyzed Accidents	Section
Nuclear Criticality	5.3.2.1
In-Tank Fuel Fire/Deflagration	5.3.2.16
Mixing of Incompatible Material - Tank Pressurization	5.3.2.12
Flammable Gas Deflagrations	5.3.2.14
HEPA Filter Failure - Exposure to High Temperature or Pressure	5.3.2.2
Fire in Contaminated Area	5.3.2.3
Waste Transport Vehicle Accident	5.3.2.23
Organic Solvent Fire	5.3.2.15
Organic Salt-Nitrate Reaction	5.3.2.17
Natural Phenomena - High Wind	5.3.2.23
Natural Phenomena - Lightning	5.3.2.23
Tank Failure Due to Excessive Loads	5.3.2.13
Tank Failure Due to Vacuum or Degradation	5.3.2.13
Natural Phenomena - Seismic	5.3.2.23
Spray Leak in Structure or from Overground Waste Transfer Lines	5.3.2.20
Spray Leak from Underground Waste Transfer Lines	5.3.2.21
Caustic Spray Leak	5.3.2.9
Tank Bump	5.3.2.22
Unfiltered Release	5.3.2.2
Subsurface Leak Resulting in Pool	5.3.2.19
Evaporator Dump	5.3.2.4

5.3 ACCIDENT ANALYSIS

This section describes the accident analysis methodology (Section 5.3.1, "Methodology") and summarizes the accident analysis results (Section 5.3.2, "Accident Analysis Scenarios"). Table 5.3-1 is a list of the representative accidents selected for further quantitative analysis and the sections where the corresponding accident results are summarized.

5.3.1 Methodology

This section summarizes the general calculation methods for quantifying the radiological and toxicological consequences of postulated accidents (Section 5.3.1.1, "Radiological Consequence Calculation Methodology" and 5.3.1.2, "Toxicological Consequence Calculation Methodology," respectively). Consequence calculation methods specific to individual accidents are described in the calculation note(s) for corresponding accidents. Section 5.3.1.3, "Basis for Estimating Accident Frequency," explains the basis used in estimating the frequency category for postulated accidents with and without controls.

Accident consequences are combined with the accident frequency and compared to the risk guidelines shown in Tables 5.3.1-2 and 5.3.1-3. For comparison with the risk guidelines, the radiological and toxicological consequences of accidents must be calculated at the location of the maximum onsite and the maximum offsite individual. The maximum onsite and offsite individuals are defined in WHC-CM-4-46[1], *Nonreactor Facility Safety Analysis Manual*, as follows.

- **Maximum Onsite Individual**—The hypothetical onsite receptor located at the distance (at least 100 m [330 ft] or at the facility boundary) and in the direction from the point of release at which the maximum dose occurs. This receptor represents the onsite worker for the purpose of reporting the consequences of postulated accidents.

- **Maximum Offsite Individual**—The hypothetical receptor located at or beyond the Hanford Site boundary location at the distance and in the direction from the point of release at which the maximum dose occurs. This receptor represents the public for the purpose of reporting the consequences of postulated accidents.

For Tank Waste Remediation System (TWRS) facility accidents, the maximum onsite individual is located at 100 m (330 ft) when radioactive or hazardous material is released at ground level. A ground-level release is assumed for all the TWRS facility accidents analyzed.

---

[1]Refer to Appendix F, "Sitewide Controlled Manual Cross-Reference Table," of the BIO for cross-walk between sitewide controlled manuals (e.g., WHC-CM-X-XX) superseded by Fluor Daniel Hanford, Inc., procedures (e.g., HNF-PRO-XX).

Based on Hanford Site meteorology, the maximum offsite individual for TWRS facility accidents is located on the Hanford Site boundary at 8,760 m (5.44 mi) to the north (near side of Columbia River).

5.3.1.1 Radiological Consequence Calculation Methodology. The ORIGEN2 computer program (ORNL-5621, *ORIGEN2-A - A Revised and Updated Version of the Oak Ridge Isotope Generation and Depletion Code*) was used to identify the presence of radionuclides in TWRS tank waste. Use of the program revealed the presence of more than 150 radionuclides. The following seven radionuclides contribute approximately 99% of the inhalation dose: ^{90}Sr, ^{90}Y, ^{137}Cs, ^{239}Pu, ^{238}Pu, ^{241}Pu, and ^{241}Am. Two additional radionuclides, ^{237}Np and ^{244}Cm, were added based on process knowledge; and two additional radionuclides, ^{60}Co and ^{154}Eu, were added to account for external exposure considerations.

The in-tank concentrations of the 11 radionuclides chosen for inclusion in accident analyses are given in Table 5.3.1-4. A detailed discussion of the development of the radionuclide inventory is presented in WHC-SD-WM-SARR-037, *Development of Radiological Concentrations and Unit Liter Doses for Tank Waste Remediation System Final Safety Analysis Report Radiological Consequence Calculations.*

Two potential radiological exposure pathways, internal (committed effective dose equivalent) and external (effective dose equivalent), are associated with releases of radioactive materials. The total effective dose equivalent calculated for an individual is equal to the sum of the dose contributions from the two exposure pathways.

- **Internal Exposure Pathway**—Internal exposure pathways include inhalation and ingestion. The inhalation pathway is the major internal exposure pathway for TWRS facility accidents. Exposure by means of the inhalation pathway occurs (1) when an accident results in a release of airborne radioactive material transported by wind and inhaled by the maximum onsite and offsite individuals, or (2) when radioactive materials that have been deposited on the ground become suspended and are subsequently inhaled. The dose contribution from inhalation of resuspended materials is orders of magnitude less than that from inhalation of airborne radioactive materials during plume passage. Because the dose contribution of inhalation of resuspended materials is minor, the resuspension dose is not included in consequence calculations for the maximum onsite individual. However, the resuspension dose is included in consequence calculations for the maximum offsite individual as an inherent part of the ingestion dose calculations.

  Exposure by means of the ingestion pathway can occur when radioactive material that has been deposited offsite is ingested by any of the following methods:

  - Eating crops on which radioactive materials have deposited
  - Eating crops grown in, or animals raised on, contaminated soil
  - Drinking contaminated water.

  Depending on the type of tank waste involved, the dose contribution from the ingestion of contaminated food during a 24-hour period can

account for up to 20% of the total effective dose equivalent. Therefore, the dose contribution from the ingestion of contaminated foods for 24 hours has been included in offsite consequence calculations. The 24-hour exposure duration is based on the premise that the maximum offsite individual can be notified and appropriate corrective action can be taken within 24 hours of the start of the accident (DOE/RL-94-02, *Hanford Emergency Response Plan*).

- **External Exposure Pathway**—External exposure pathways include submersion, ground shine, and direct exposure from a concentrated radioactive source, such as a pool formed from a spill of liquid radioactive material.

  Submersion refers to the external dose received by a person located in the plume of airborne radioactive material during plume passage. For the radionuclides present in tank waste, the submersion dose is orders of magnitude less than the inhalation dose. Because the contribution of submersion dose is minor, the submersion dose is not included in consequence calculations.

  Ground shine refers to the external dose received by a person standing on ground contaminated by radioactive materials deposited during plume passage. The ground shine dose is orders of magnitude less than the inhalation dose; and, therefore, it is not included in consequence calculations for the maximum onsite individual. The ground shine dose is included in consequence calculations for the maximum offsite individual as an inherent part of the ingestion dose calculation.

  The dose contribution to the maximum onsite individual from the direct exposure pathway can be significant for accident scenarios that result in surface pools of radioactive waste. For these accidents, the direct exposure dose to the maximum onsite individual is calculated and included in the consequence calculations.

Because the risk guidelines in Tables 5.3.1-2 and 5.3.1-3 apply to only doses resulting from direct exposure to the passing plume (i.e., inhalation and submersion), the comparison with doses from a postulated accident that include the dose from the above internal and external exposure pathways is conservative.

5.3.1.1.1 Dose Calculation Methods. For unmitigated accident analyses, dose calculations for the maximum onsite individual conservatively assume that the individual remains at a distance of 100 m (330 ft) for 12 hours. The 12-hour duration is chosen as it is the normal work shift in terms of hours worked for tank farm operating personnel. Dose calculations for the maximum offsite individual assume that the individual remains at the worst-case distance and direction for 24 hours. The 24-hour duration is based on the premise that the maximum offsite individual can be notified and appropriate corrective action (e.g., sheltering, evacuation) can be taken within 24 hours of the start of the accident. Mitigated accident analyses may use a different exposure time based on a demonstrated ability to detect the accident and protect the receptor (emergency response).

The airborne source term is the amount of airborne radioactive material generated by the accident that is available for transport to the maximum onsite and offsite individuals. The airborne source term was calculated by multiplying conservatively estimated material at risk by factors affecting the release (e.g., damage ratio, airborne release fraction, respirable fraction, leak path factor). Conservative values of release factors specific to the accident scenario are selected from tank farm data or sources such as DOE-HDBK-3010-94, *Airborne Release Fractions/Rates and Respirable Fractions for Nonreactor Nuclear Facilities*. Given the airborne source term, the doses are calculated according to the methodology in WHC-SD-WM-SARR-016, *Tank Waste Compositions and Atmospheric Dispersion Coefficients*, and WHC-SD-WM-SARR-037. In this methodology, doses are calculated using unit liter doses. The unit liter dose is the dose from inhalation or ingestion of one liter of tank material. Unit liter doses are calculated for single-shell tank solids and liquids, double-shell tank solids and liquids (including Aging Waste Facility solids and liquids), and an all-liquids and all-solids composite. The unit liter doses are based on the maximum sample data for each isotope in each composite. The unit liter doses are given in Table 5.3.1-5, and the details of the dose derivation are given in WHC-SD-WM-SARR-016.

5.3.1.2 Toxicological Consequence Calculation Methodology. The chemical composition of tank farm wastes has been determined based on an evaluation of available tank waste characterization data. The composite concentrations for the 24 analytes of concern are presented in Table 5.3.1-6. A detailed discussion of the development of the chemical inventory is presented in WHC-SD-WM-SARR-011, *Toxic Chemical Considerations for Tank Farm Releases*.

Tank headspace contains gases released from the waste caused by continuing chemical reactions and vapor pressure changes. Worst-case and maximum steady-state headspace gas composite concentrations are presented in Table 5.3.1-7. The organic concentrations are identical for the two composites and are based on Tank 241-C-103 data. For the worst-case composite, the ammonia and nitrous oxide concentrations are based on Tank 241-SY-101 slurry release data. For the maximum steady-state composite, the ammonia and nitrous oxide concentrations were conservatively selected based on headspace sample data. The sample data indicates a peak steady-state ammonia concentration of 1,140 ppm and nitrous oxide concentration of 701 ppm. A concentration of 2,000 ppm for ammonia and 1,400 ppm for nitrous oxide is assumed for this analysis.

The toxicological source terms resulting from tank farm accidents comprise liquid and solid particulates and gases. Evaluation of the effects of chemical exposure is based on the airborne pathway only, because the toxicological risk guidelines are based on the chemical concentration at the location of the maximum onsite and offsite individuals. External exposure to the skin and eyes was considered in the development of the risk guidelines for corrosives and irritants.

5.3.1.2.1 Exposure Calculation Methods. Toxicological consequence calculations are performed to determine the peak 15-min average

concentration[2] for the maximum onsite and offsite individual over the duration of the release for all chemicals where the toxic effect is immediate (i.e., concentration-dependent). If it is known that the toxic effects of a chemical are not concentration-dependent, but depend on the total quantity of chemical taken up by the body (i.e., dose-dependent), then the peak 1-h concentration may be used. The calculated toxic chemical concentration is compared with *Emergency Response Planning Guidelines* (AIHA 1988) or alternative equivalent guidelines (Table 5.3.1-3). The Emergency Response Planning Guidelines are based on exposures of up to 1 h and are the best existing values for evaluation of acute exposure to toxic chemicals.

Equations used to calculate peak concentrations of individual chemicals are presented in WHC-SD-WM-SARR-011. The peak concentrations were used to calculate sum-of-fraction values. Table 5.3.1-8 contains the sum-of-fractions of risk guidelines for a unit release of chemicals and gases. A detailed discussion of the derivation of sum-of-fractions values is presented in WHC-SD-WM-SARR-011.

5.3.1.3 Basis for Estimating Accident Frequency. The original frequency category (Table 5.2-1) for the representative accident without controls is qualitatively estimated during the hazard evaluation. The accident frequency category without controls is reconfirmed based on review of the postulated accident scenario. The frequency of the accident scenario with selected controls is determined assuming that the safety structures, systems, and components perform their safety function and that the Technical Safety Requirements (HNF-SD-WM-TSR-006, *Tank Waste Remediation System Technical Safety Requirements*) are followed. For preventive controls, the postulated accident may be prevented or the frequency of the accident reduced with the same consequences. For mitigative controls, the accident frequency remains unchanged, but the accident consequences are reduced. Estimated frequencies are the annual frequency of the representative accident at TWRS facilities (i.e., all tank farms).

The assumption that safety structures, systems, and components perform their safety function is reasonable because the reliability of structures, systems, and components was an important control decision criteria. Additionally, several controls are typically selected to reduce the risk of the postulated accident. The failure of structures, systems, and components and Technical Safety Requirement controls will be considered in the TWRS Final Safety Analysis Report in the assessment of beyond design basis accidents.

Table 5.3.1-8. Sum-of-Fraction of Risk Guidelines for a Unit Release of Chemicals and Gases. (2 sheets)

Tank waste type (units of sum-of-fractions follow tank waste type)	Maximum individual	Accident frequency, 1/yr		
		10^{-2} - 1	10^{-4} - 10^{-2}	10^{-6} - 10^{-4}
Gas Release - Maximum Sample Composite Note this data should be used only when the accident scenario does not involve a slurry gas release. Otherwise use the above sum-of-fractions.				
Continuous (s/m^3)	Onsite	2.6 E+00	3.3 E-01	7.1 E-02
Continuous (s/m^3)	Offsite	2.3 E-03	2.3 E-03	2.8 E-04
Puff (m^{-3})	Onsite	7.9 E-01	9.9 E-02	2.1 E-02
Puff (m^{-3})	Offsite	9.3 E-06	9.2 E-06	1.1 E-06
50% NaOH releases				
Continuous (s/L)	Onsite	1.3 E+04	1.0 E+03	2.6 E+02
Continuous (s/L)	Offsite	1.1 E+01	1.1 E+01	8.6 E-01
Puff (L^{-1})	Onsite	3.8 E+03	3.0 E+02	7.5 E+01
Puff (L^{-1})	Offsite	4.3 E-02	4.3 E-02	3.5 E-03
All-liquids and all-solids continuous release				
All liquids (s/L)	Onsite	1.0 E+04	7.5 E+02	2.1 E+02
All Liquids (s/L)	Offsite	8.4 E+00	8.4 E+00	6.2 E-01
All solids (s/L)	Onsite	5.1 E+04	2.3 E+04	1.2 E+03
All solids (s/L)	Offsite	2.5 E+02	4.2 E+01	1.9 E+01
All-liquids or all-solids puff release				
All liquids (L^{-1})	Onsite	2.9 E+03	2.2 E+02	6.0 E+01
All liquids (L^{-1})	Offsite	3.4 E-02	3.4 E-02	2.5 E-03
All solids (L^{-1})	Onsite	1.5 E+04	6.6 E+03	3.6 E+02
All solids (L^{-1})	Offsite	1.0 E+00	1.7 E-01	7.6 E-02

Note (1): The Aging Waste Facility tanks are grouped with the other double-shell tanks for the toxicological analysis.
DST = double-shell tank
SST = single-shell tank

Note (2): Use of the information in this table relative to WRSS is presented in Addendum 1.

*The sum-of-fractions is multiplied by the release rate for continuous release and release amount for a puff releases. Release rates for continuous releases are in units of liters per second for liquids and solids, and units of cubic meters per second for gases. Puff release quantities are in units of liters for solids and liquids and units of cubic meters for gases.

5.3.2 Accident Analysis Scenarios

This section analyzes representative accidents as selected in the TWRS facilities hazard analysis. Supplemental accident analyses specific to the projects are included in the designated addenda. The accident analysis for WRSS operations is presented in Addendum 1. The accident analysis for the replacement cross-site transfer system is presented in Addendum 2. The accident analysis for the 702-AZ ventilation system is presented in Addendum 3. The accident analysis for the 241-AZ-101 mixer pump test is presented in Addendum 4. The purpose of the accident analysis is to quantify the accident frequency and consequences of scenarios and to identify the associated necessary and sufficient set of controls that ensure tank farm operations can be conducted without undue risk to onsite workers or the public. The results of the analyses are also used in the selection of controls to protect facility workers and the environment.

Background information is presented for each accident under the headings "Purpose of Analysis" and "Analysis Strategy." This is followed by an analysis assuming the absence of controls and, if required, an analysis assuming controls. The controls may be engineered (i.e., safety SSCs) or administrative (i.e., Technical Safety Requirements [TSRs]). An important control decision criteria for the selection of controls is comparison of the accident frequency and consequences to the risk guidelines (Section 5.4.1). In addition to safety SSCs and TSR controls, engineered features and administrative controls that provide Defense-in-Depth are also identified.

Key assumptions are presented for each accident. These assumptions are those used in the analyses that are a function of the facility configuration, condition, or operational practices that, if changed, could invalidate the analysis results. They represent a subset of the complete set of assumptions made in the analysis as documented in referenced calculation note documents. The key assumptions are specifically identified to assist unreviewed safety question reviewers in evaluations of facility and procedural changes.

In addition to the safety SSCs and TSR controls identified for each representative accident in the following sections, there are two controls implicit to multiple accidents. First is a prohibition of transfer, exclusive of flushing, into single-shell tanks. This is another key element of the TSR Administrative Control on Transfer Controls. The second control involves safety functions assumed in the accident analyses of the single-shell tanks, double-shell tanks, Aging Waste Facility tanks, and their associated waste transfer Systems.[1] The classification of these passive design features as Safety-Class, Safety-Significant, or general services will be provided in the TWRS Final Safety Analysis Report.

Analysis Addressing State Highway 240 Transient Populations. An analysis of the potential consequences to transient individuals on State Highway 240 from four bounding postulated accidents at TWRS facilities was also performed to support the development of emergency response plans for TWRS (HNF-SD-TWR-TI-002, *Analysis of Consequences at State Route 240 from*

[1]Double-contained receiver tanks, catch tanks, process pits, diversion boxes, vault pits, cleanout boxes, and transfer lines.

Postulated Accidents at Tank Waste Remediation System Facilities to Support Development of Emergency Response Plans). State Highway 240 is a two-lane highway that runs through the Hanford Site and passes near TWRS facilities. For each postulated accident (a spray leak, a flammable gas deflagration in a double-shell tank, a flammable gas deflagration in a single-shell tank, and an organic salt-nitrate reaction), the radiological and toxicological consequences at State Highway 240 were calculated. The analyzed accident scenarios included safety structures, systems, and components and TSRs that prevent or mitigate the event. The accident analysis methodology described previously in Section 5.3.1 was used. Toxicological exposure analyses were also performed using the EPIcode.[2] The calculated radiological doses and toxicological exposures were compared with established emergency response guidelines for taking or recommending protective actions. The results of the analysis showed the following:

- For the maximum hypothetical receptor on State Highway 240, the radiological protective action guide of 0.01 Sv (1 rem) committed dose is exceeded for the postulated single-shell tank flammable gas deflagration (0.013 Sv [1.3 rem]) and the organic salt-nitrate reaction (0.17 Sv [17 rem]). The calculated organic salt-nitrate reaction dose is very conservative to encompass uncertainties and unknowns in waste characterization and accident phenomenology.

- The toxicological exposures calculated by the EPIcode for the maximum hypothetical receptor on State Highway 240 are below the toxicological emergency response planning guideline (ERPG-2) for all peak analytes (e.g., ammonia, sodium hydroxide, mercury).

In accordance with DOE/RL-94-02, *Hanford Emergency Response Plan*, an accident (emergency event) whose potential consequences exceeds 0.01 Sv (1 rem) committed dose or ERPG-2 guidelines at State Highway 240 is a Site Area Emergency because the consequences at the facility boundary (100 m [328 ft]) would also exceed these limits. When a Site Area Emergency for a 200 Area facility is declared, a preplanned action is for the Hanford Patrol Operations Center to contact the Washington State Patrol to request closure of State Highway 240 from the Yakima Barricade (north end) to the intersection of State Highway 240, Horn Road, and Route 10 (south end).

Additional protective action decisions in response to Hanford Site emergency events affecting State Highway 240 are the responsibility of the state and counties. The results of the safety analysis for this BIO will be evaluated by the Hanford Site emergency preparedness organization, the existing emergency planning hazards assessment will be revised as necessary, and the postulated results compared to existing emergency plans and procedures. Upon completion of the hazards assessment and comparison to existing emergency planning documents, the results will be communicated to the state of Washington and to Benton, Franklin, or Grant County emergency management agencies, as appropriate. Preplanned protective actions will be developed in concert with the U.S. Department of Energy, Richland Operations Office and the state and counties.

Control Strategy for Potential Misrouting of Waste Transfers. Misrouting of waste transfers is a potential cause for the following postulated accidents analyzed in the following subsections.

- Subsurface Leak Remaining Subsurface (Section 5.3.2.7)
- Surface Leak Resulting in Pool (Section 5.3.2.18)
- Subsurface Leak Resulting in Pool (Section 5.3.2.19)
- Spray Leak in Structure or From Overground Waste Transfer Lines (Section 5.3.2.20)

The selected safety structure, system, and component and TSR controls provide three levels of defense to prevent or mitigate the risk of these accidents caused by waste transfer misrouting.

The first level of defense requires that the controls selected to prevent or mitigate leaks from waste transfer systems (e.g., Transfer System Covers and Entry Doors, transfer system leak detection systems, periodic ground-level radiation surveys of single-walled direct-buried/bermed lines) are operable or implemented for the "physically connected" topography of the waste transfer. The physically connected topography refers to piping, structures, and tanks and their associated instrumentation as follows:

1. Physically connected piping is any piping which is part of or connected to the transfer route. Piping need not be considered connected to the transfer route if it is physically disconnected by a removal of piping (i.e., air gap) or isolated with a blind flange/process blank. (Note: Closed valves do <u>not</u> physically disconnect piping.)

   The East/West cross-site transfer line is considered physically connected piping only when cross-site waste transfers are in progress. The East/West cross-site transfer line is the piping between 241-UX-154 diversion box and 241-ER-151 diversion box.

   An operable service water pressure detection system is considered to physically disconnect piping on either side of the detection system.

2. Physically connected structures are those structures through which physically connected piping runs, or those structures which could be subject to leakage from physically connected piping.

3. Physically connected tanks are those tanks connected to the transfer route, those tanks connected to the physically connected piping, and those tanks designed to receive leakage from physically connected piping through a drain path.

This first level of defense ensures that, should a mistransfer occur because of a leaking or misaligned isolation valve, controls are operable/implemented, at the point where the waste could be misrouted, to detect and/or mitigate the consequences of a potential waste leak (i.e. spray, pool, underground plume). For example, the transfer system leak detection

systems must be operable in all physically connected structures (i.e., process pits, diversion boxes, vault pits, and cleanout boxes) during the waste transfer.

The second level of defense is the selection of additional controls for identifying waste transfer leaks or misroutings. These controls are the TSRs for periodic material balances and periodic monitoring of interconnected tanks during waste transfers. Upon indication of a significant material balance discrepancy or unexpected tank level rise, the waste transfer would be shutdown to limit the potential quantity of waste leaked or misrouted.

The third level of defense is controls that prevent waste transfer misrouting. These TSR controls included the following.

- Wherever practical, isolation of piping connected to the planned waste transfer path with two closed valves in series.
- Independent verification of the planned waste transfer route.
- Waste transfer system and jumper configuration control.
- Waste transfer system operations by approved procedures.

These controls reduce the likelihood of misrouting during planned waste transfers.

In summary, the selected safety structure, system, and component and TSR controls and their required application during waste transfers provide diversity and multiple levels of defense. The controls minimize the likelihood of a waste transfer misrouting and ensure that, should a waste leak occur as a result of a misrouting, mitigative safety structures, systems, and components or TSR controls are in place to reduce the accident consequences.

5.3.2.1 Nuclear Criticality.

Purpose of Analysis: WHC-SD-WM-TI-725, *Tank Farm Nuclear Criticality Review*, evaluated the possibility of a nuclear criticality occurring in tank farm facilities. Considering current plutonium inventories and operating conditions within the scope of this BIO, the discussion concluded that a nuclear criticality accident was not credible in Hanford Site double-contained receiver tanks (DCRTs), double-shell tanks (DSTs), and single-shell tanks (SSTs). The discussion then presented an analysis of a hypothetical criticality accident resulting from the transfer of new plutonium inventory into the tank farms. Based on information in WHC-SD-WM-TI-725, the analysis of this BIO will (1) analyze the possibility of a nuclear criticality occurring in tank farm facilities, and (2) quantify the consequences of the hypothetical criticality incident resulting from the transfer of plutonium to the tank farms.

Analysis Strategy. Many factors were studied to establish a technical basis for safe subcritical storage of wastes in DCRTs, DSTs, and SSTs. These factors included (1) the neutronics of the waste tank system, (2) chemical and physical phenomena, including fluid dynamics factors related to initial deposition of wastes in the tanks; aging of the wastes, and (3) the behavior of the wastes under established operating conditions. In addition to the technical basis described in WHC-SD-WM-TI-725, a detailed discussion of potential tank neutronics is defined in WHC-SD-SQA-CSA-507, *CSER 96-010: Criticality Parameters for Tank Waste Evaluation*. Evaluation of the phenomenology and fluid dynamics is documented in WHC-SD-WM-TI-757, *Fluid Dynamic Particulate Segregation, Chemical Processes, and Natural Ore Analog Discussions that Relate to the Potential for Criticality in Hanford Tanks*.

Collectively, the DSTs and SSTs contain an estimated 500 to 1,000 kg (1,100 to 2,200 lb) of plutonium. Analyses of tank waste samples show that the plutonium content of the waste is primarily associated with the sludge phase. The maximum measured plutonium concentration in a sludge phase is about 0.35 g/L (a single data point for Tank 241-SY-102 gave a concentration of 0.7 g/L).

A conservative waste model was developed for comparing the margin between the plutonium concentration in these samples with the concentration necessary for a criticality. In this model, conservative refers to the neutronic characteristics of the waste. Chemical components of waste with a greater ability to absorb neutrons are assumed to be present at lower than expected concentrations. Chemical components with a greater ability to scatter neutrons are assumed to be present at greater than expected concentrations. The result of these two assumptions is a model in which the concentration of plutonium needed to go critical is minimized. Based on this model, the minimum plutonium concentration needed for criticality is 2.6 g Pu/L in an infinite system. In a finite system, the concentration of plutonium required for criticality is shown in Figure 5.3.2.1-1. As an example, assume the plutonium concentration is 4 g/L. At this concentration, a sphere 3.7 m (12 ft) in diameter or a corresponding total of 106 kg (233 lb) of plutonium is necessary to go critical.

Based on the preceding discussion, the highest sample data points (0.35 and 0.7 g Pu/L) are factors of 7 and 4 respectively below the subcritical concentration limit of 2.6 g Pu/L for an infinite system. Because the waste tanks are not an infinite system, the margin to a criticality is even greater. In most of the DSTs and SSTs, the plutonium concentration in the sludge phase is more than 100 times less than 2.6 g Pu/L. This situation reflects the deliberate controls exercised throughout operation of fuel reprocessing and purification facilities to minimize the plutonium concentration in waste streams.

The model is also based on optimum moderation. Table 5.3.2.1-1 provides the H to Pu values used, where H is the moderator.

The presence of more water than that shown in Table 5.3.2.1-1 means that the system is overmoderated. Overmoderated systems require more plutonium to go critical than the optimum amount shown in the middle column of Table 5.3.2.1-1.

Figure 5.3.2.1-1 is a summary graphic representation of the degree of conservatism that has been included in the criticality safety analysis of the Hanford Site tank wastes. The figure shows the relationship among current tank conditions, historical operating limits, and subcritical limits as a function of mass and plutonium concentration. The "optimized conservative waste model" subcritical limit represents conservatively modeled waste conditions. The "average waste composition" represents subcritical limits for a waste composition representing an average composition of 19 elements from 28 actual tank samples. All cases are calculated assuming a high degree of conservatism (using a spherical geometry). Figure 5.3.2.1-1 shows that even using conditions that are most favorable to criticality, the tank contents are highly subcritical.

In addition to neutronics, the chemical makeup of the waste precludes criticalities based on the controlled plutonium concentration in the process waste streams discharged to the tank farms and the neutron absorber content. A review was performed of the waste streams from the plutonium separation and purification, fuel reprocessing and uranium recovery, plants to the tank farms. The review focused on the plutonium concentration and the chemical constituents of these waste streams. The chemical processes reviewed were:

- Bismuth phosphate process (B Plant and T Plant)
- Reduction-oxidation process (S Plant)
- Metal recovery process (U Plant)
- Plutonium uranium extraction process (PUREX Facility)
- Various processes at the Plutonium Finishing Plant (PFP).

These processes routinely discharged waste to the tank farms. To avoid corrosion of the mild steel of associated tanks, all waste streams were made alkaline before transfer. Historical sample files for these streams show typical plutonium concentrations of less than 0.003 g Pu/L.

Additionally, each waste stream contained either iron, uranium, manganese, aluminum, or zirconium. All of these elements are neutron absorbers. If absorbers are present in sufficiently high concentrations, a criticality is impossible. The subcritical ratio is the ratio of the concentration of the element to the concentration of plutonium above which a criticality can not occur, regardless of the plutonium concentration. The waste streams exceeded at least one of these ratios. Some waste streams contained sufficient chemicals to exceed more than one of the subcritical ratios. The subcritical ratios are given in Table 5.3.2.1-2.

The plutonium in the waste streams from the processing plants exists in the waste tanks in one of the following forms:

- **Adsorbed onto iron or aluminum oxyhydroxides**—The process of making the waste alkaline results in the rapid formation of precipitates of these metals. Iron and aluminum precipitates (as oxyhydroxides) adsorb plutonium from the waste because the plutonium forms precipitates more slowly. The adsorbed plutonium is chemically attached to the metal precipitate. Because both are good neutron absorbers, a criticality would require larger plutonium concentrations than calculated by the model.

- **As an ion within a crystal lattice (solid solution)**—A different co-precipitation mechanism is solid solution formation. In this case, a plutonium ion can replace another metal's ion within a crystalline lattice. Because of the size of the plutonium ion, this can only occur in zirconium-, lanthanum-, or bismuth-bearing waste. Zirconium is a poor absorber of neutrons. However, if present in sufficient quantity (zirconium/plutonium mass ratio of greater than 4,000), a criticality is not possible. This chemical form is only found in a limited number of tanks.

- **In a floc with other oxyhydroxides**—Flocculation of particles can result in plutonium being effectively bonded with other solids. In this form, greater concentrations of plutonium are required for criticality than are calculated by the conservative waste model.

- **Dissolved in liquid**—Experimental and theoretical work documented in WHC-SD-WM-TI-757 shows that the concentration of plutonium in the waste tank liquids cannot exceed 0.2 g Pu/L. The peak concentration occurs in fresh solutions that have high carbonate concentrations. It was also shown by experiment that aging reduces the concentration in tank liquids by an order of magnitude or more.

- **As plutonium oxyhydroxide precipitate**—If pure hydrous plutonium oxide formed as a crystalline precipitate when acidic wastes were made alkaline, the plutonium oxide particles would be expected to agglomerate or mix with neutron absorbers. For nuclear criticality to occur for either of the latter cases, large plutonium particles, tens of micrometers in size and free of neutron absorbers, must be created and then concentrated by hydraulic force. All literature data, as well as calculations for modeling hydraulic operations such as salt well pumping, air lift circulators, and transfer pumps,

indicate that concentration and separation of such plutonium-bearing particles are not plausible.

Because the plutonium in the waste exists in the forms described, higher concentrations of plutonium than predicted by the conservative waste model are needed to achieve criticality.

In summary, the following factors have been analyzed and demonstrate that a criticality in the tank farms is not possible with the existing inventory of plutonium and chemistry in the tanks.

- A conservative waste model was developed. For the inventories in the tanks, a minimum concentration of at least 2.6 g/L plutonium was shown to be needed for a criticality. This compares to maximum sample concentrations of 0.35 and 0.7 g/L plutonium taken from the tanks.

- Optimum moderation was assumed in the conservative waste model. The wastes contain more water than the optimum condition, and therefore greater concentrations than predicted by the model would be required.

- Wastes from the plutonium processing plants were chemically treated to make them alkaline before they were discharged from the plants. Historical sample results from the plants show maximum concentrations of 0.003 g/L Pu.

- Each of the processing plant waste streams contained either iron, uranium, manganese, aluminum, or zirconium. The waste streams exceed the subcritical ratio for at least one of these elements based on flowsheet composition. Some waste streams contained sufficient chemicals to exceed more than one of the subcritical ratios. This would require concentrations greater than those predicted by the model to achieve criticality.

- Plutonium will undergo at most only minor redistribution as a result of tank farm operations within the scope of this BIO and normal storage.

- The peak concentration of plutonium in waste tank liquids is less than the concentration required for criticality caused by solubility constraints.

- Plutonium in the sludges is either adsorbed onto, agglomerated with, or in the vicinity of solids that have varying capabilities of absorbing neutrons. For certain mass ratios of one of these solids of plutonium, a criticality is impossible. For other solids and ratios, the concentration of plutonium within a given volume must be greater for a criticality to occur than that predicted by the conservative waste model.

- Tank farm operations and activities that redistribute plutonium do so into slab geometry, not spherical geometry. As a result, larger quantities of plutonium are required to go critical.

No credible scenario has been identified leading to a criticality in a DCRT, DST, or SST according to the existing inventory of plutonium that is in the tank farms. For information purposes, the following analysis quantifies the consequences of a criticality event initiated by the hypothetical transfer of a large volume of new waste containing a high plutonium concentration.

5.3.2.1.1 Accident Scenario Assuming No Controls.

Sequence of Events. For the scenario assuming no controls, it is assumed that 500 L of solution with a concentration of 10 g Pu/L is transferred from the PFP to tank farms. The concentration and quantity is based on an estimate of the quantity of plutonium that could conceivably be transferred from PFP providing that multiple failures occurred. Transfers of a higher plutonium concentration would be overly conservative. Lower plutonium concentrations would require too large of a volume and too great of a quantity of plutonium for a criticality to occur. A concentration of 10 g Pu/L could constitute a critical sphere with reasonable diameter and quantity of plutonium.

The PFP is the only plant that stores plutonium and makes associated transfers to tank farms. It is assumed, notwithstanding the inordinate number of failures required, that a solution containing thousands of grams of plutonium accumulates in PFP waste receiver Tank D-8 through repeated and undetected sequential process upsets to a previously empty tank. If the tank is not originally empty or other waste is dumped into the tank between the process upsets, the waste would be diluted causing a decrease in the Pu concentration. The contents of Tank D-8 are then transferred to Tank D-5. Both tanks have a diameter of oyer 3 m and require over 18 kg of Pu to achieve an areal density of 2580 g Pu/m^2, the minimum for a criticality. Because the waste transfer contains only 5 kg of Pu, there is no criticality in either Tank D-8 or Tank D-5 for this size transfer. The contents of Tank D-5 are routed to a previously empty 244-TX DCRT. The transferred waste will not go critical in 244-TX DCRT because this tank has an even larger surface area than Tank D-5. When the Plutonium Finishing Plant waste is transferred to the DST, the waste is postulated to form a compact spherical shape in the existing waste. The radius of this sphere is assumed to increase until a critical volume is reached.

If a criticality is postulated (an incredible event), there would be a fission burst followed by a rapid shutdown. The shutdown is effected as a consequence of fission energy release that results in thermal expansion, density reduction from the formation of very small bubbles, and fissile dilution through mixing from convective currents with expulsion of part of the critical mass. Early in the burst, the small bubbles are formed. As the burst continues, the amount of dissolved gas increases, supporting the formation and expansion of larger bubbles. As the burst terminates, there is a sudden internal pressure relief resulting in rapid steam production and release of dissolved gases. The gases and steam, along with the fission gas and a fraction of the waste, are carried into the headspace of the tank. The increase in the pressure in the headspace is relieved by venting a fraction of the headspace through high-efficiency particulate air filters. The high-efficiency particulate air filters are not ruptured. The pressure of the steam also causes the critical volume to expand and disperse. The tank is large compared with the critical volume and the expansion results in dilution

of the fissile-bearing volume. The associated turbulence and dilution should perturb the fissile bearing volume sufficiently that reassembly into a new critical mass is not reasonable. The DST criticality is therefore modeled as a single burst.

Because the critical volume for a 10 g Pu/L solution has been calculated to be 300 L (WHC-SD-SQA-CSA-507) with a radius of 41.5 cm, the transfer of 500 L is potentially enough to reach a critical condition. At the fill rate of 4.7 L/s, it takes 63 seconds to reach this condition.

Based on the similarity of the postulated DST criticality with the calculations performed by Hetrick 1993, *Computer Models for Predicting the Effects of Criticality Accidents in Solutions*, it is assumed that 89 MJ of energy (equivalent to 2.8 x 10^{18} fissions) is released in the DST criticality with inertial pressures of about 0.6 MPa. Most of the 89 MJ (Hetrick 1993) of fission energy goes into heating the liquid within the critical volume. The temperature of the fissile bearing volume is increased from the power burst until the saturation temperature is reached and steam is generated. About 75% of 89 MJ is needed to raise the liquid temperature from a DST liquid temperature of 48 °C to boiling. This leaves 25% (or 22 MJ) available to create steam. A volume of 15.4 m^3 of steam is produced, raising the pressure in the headspace of a full DST by about 0.0015 Mpa (6 in. of H_2O).

The dose consequences result from the release of radioactive noble gases, iodine, and aerosolized plutonium and tank waste. Of the fission products resulting from the postulated criticality, 100% of the noble gases and 25% of the iodine are assumed to be released to the headspace and then to the environment. The release of particulate fission products is negligible. The high-efficiency particulate air filters are not ruptured by the pressure transient, so the only path out of the tank for the particulates is through unfiltered vent paths, such as around the cracks between cover blocks.

The sequence of events given at the beginning of this section highlights that numerous failures, both human and equipment, would be required to transfer 5 kg of plutonium to the tank farms from the PFP. The frequency is judged to be "beyond extremely unlikely."

Results Summary. The following tables present the onsite and offsite radiological and toxicological consequences for the criticality accident. Supporting calculations are documented in WHC-SD-WM-CN-047, *Calculation Notes That Support Accident Scenario and Consequence For Determination of a Waste Tank Criticality.*

Implications of Results. The radiological doses and toxicological exposures of a criticality assuming no controls are compared with the offsite and onsite risk guidelines in Tables 5.3.2.1-3 and 5.3.2.1-4. Although the accident is considered to have a frequency "beyond extremely unlikely" range (less than 10^{-6}), both the onsite and offsite radiological doses are shown to be acceptable for an accident in the "extremely unlikely" range (frequency of 10^{-6} to 10^{-4} per year). The toxicological sum-of-fractions are well below one, and are shown to be acceptable for an accident in the "extremely unlikely" range, for both onsite and offsite receptors.

5.3.2.1.2 Scenario Assuming Controls. An accident scenario assuming accident controls was not developed as a criticality is not credible.

5.3.2.1.3 Key Assumptions. Key assumptions relating to the frequency and consequences of a criticality accident are presented below.

Important to Frequency.

1. Five hundred to 1,000 kg (1,100 to 2,200 lb) of plutonium were sent to the tank farms. Future waste additions will not significantly increase this total.

2. The plutonium is scattered in all of the tanks.

3. Non-aged (i.e., fresh) plutonium containing liquids with high carbonate (>1M) concentrations do not exist in the tanks and will not be transferred into the tanks.

4. The existing wastes are alkaline and future additions will be alkaline. As a result most of the Pu is in solid form along with the important neutron absorbers and the attractors of plutonium (i.e., chemicals that result in attachment of plutonium because of adsorption, solid solution, flocculation, and attraction of metals by hydroxides).

5. Only mechanical movement and separation of plutonium occurs within the tanks. No chemical separations occur.

5.3.2.1.4 Controls. The controls described in this section apply to DCRTs, DSTs, and SSTs.

Safety Structures, Systems, and Components. A criticality is not credible. The consequences of the hypothetical criticality presented were within guidelines for an extremely unlikely event. Therefore, no Safety-Class or Safety-Significant structures, systems, and components are required.

Technical Safety Requirement Controls. Table 5.3.2.1-5 presents Technical Safety Requirement controls that protect some of the key assumptions.

In general, limits are provided on concentration, alkalinity, and neutron absorbers. Tank farms receive wastes from some facilities which may contain very low concentrations of plutonium (e.g., B Plant, 222-S Laboratory, and 340 Facility which collects laboratory wastes in the 300 Area). Shipments from the 340 Facility from mid-1994 to mid-1996, for example, contained plutonium in amounts ranging from a few hundredths of 1 g up to 3 g in liquid batches ranging from a few thousand gallons up to about 10,000 gallons. The facility typically may make a half dozen such shipments per year.

For wastes containing less than 0.001 g Pu/L, neutron absorbers are not necessary and are not required. The maximum expected concentration of dissolved plutonium range from about 0.002 to 0.2 g/L, depending on the hydroxide and carbonate concentrations in the waste solution (Yamaguchi et al. 1994, *Effects of Complexation on Solubility of Pu(IV) in*

Aqueous Carbonate System). Generally, the more carbonate that is present, the more plutonium can be dissolved in this range. By maintaining plutonium concentration in incoming waste streams below the solubility range given, the plutonium will not precipitate unless the solution were intentionally made strongly alkaline (e.g., 2M). The lower the concentration of plutonium, the more difficult it is to precipitate. Even if the plutonium were to precipitate, the total amount of these shipments is small and would not result in a criticality concern.

Defense-in-Depth. No structures, systems, and components or administrative controls have been identified that provide Defense-in-Depth.

5.3.2.2 HEPA Filter Failure - Exposure to High Temperature or Pressure. Passive or active high-efficiency particulate air (HEPA)-filtered ventilation is maintained across single-shell tanks (SSTs) and double-shell waste tanks (DSTs), double-contained receiver tanks (DCRTs), the 204-AR Waste Unloading Facility, the 244-AR Vault, the W-213 Dry Waste Compactor Facility, and 7 of 12 catch tanks (listed in Table 5.3.2.2-1). A description of these ventilation systems and facilities is provided in Appendix B.

In the following two sections, potential releases of radioactive and hazardous materials resulting from HEPA filter failures are evaluated. Section 5.3.2.2.1 presents an accident analysis of HEPA filter failure caused by exposure to high temperatures. Section 5.3.2.2.2 presents a nonmechanistic consequence analysis of HEPA filter failure caused by exposure to high pressure.

5.3.2.2.1 HEPA Filter Failure - Exposure to High Temperature.

Purpose of Analysis: High temperatures associated with an external fire (occurring in close proximity to a HEPA filter system) or the failure of an in-line heater (present in some HEPA filter systems) could degrade the ventilation system filters. If the integrity of the filters were compromised, the inventory on the filters could be released, followed by an unfiltered release from the tank vapor space.

Analysis Strategy: The hazard analysis identified two potential hazardous conditions associated with HEPA filter systems. The first is a fire associated with a ventilation system that releases the inventory on the filters and results in an unfiltered pathway. The second is an unfiltered release resulting from seal failure, a defective or deteriorated HEPA filter, or improper installation of a HEPA filter. The analysis strategy is to produce a bounding estimate for all failures of HEPA filters caused by exposure to high temperatures. Because of the additional release associated with the filter inventory, the fire scenario was analyzed as bounding.

Accident Scenario Assuming No Controls

Sequence of Events. A generic accident scenario was developed that applies to each HEPA filter system configuration associated with the Tank Waste Remediation System facilities identified in Section 5.3.2.2, "HEPA Filter Failure - Exposure to High Temperature or Pressure." The postulated scenario assumes that a fire occurs in or around a ventilation system, the heat from the fire degrades the filters, a fraction of the inventory of tank waste accumulated on prefilters (if present) and HEPA filters is released, and an unfiltered release pathway is established. For actively ventilated systems, the exhaust fans continue to run. Releases from the unfiltered pathway are assumed to continue for up to one year. In addition, heat from the fire releases a fraction of the inventory of tank waste accumulated on ventilation system ductwork. The amount of accumulated material is assumed equal to the loading on one stage of HEPA filtration.

The total consequences of this event are calculated by adding the consequences due to the amount of respirable material released during the HEPA filter failure and the amount of respirable material released during the

subsequent continuous, unfiltered release following the filter failure. Consequences resulting from the unfiltered release pathway were calculated for 12 hours (onsite receptor), 24 hours (offsite receptor), and one year (onsite and offsite receptors). For the one year unfiltered release to the onsite receptor, the dose is adjusted by an occupancy factor of 0.286 to account for the actual time spent at work.

The consequences created as a result of the annual unfiltered release were calculated because the ventilation systems operate continuously such that the release duration is essentially infinite in the absence of controls. This is in contrast to other potential accidents that have a finite duration. The consequences as a result of the annual unfiltered release show the sensitivity of the analysis to assumptions regarding release duration and were used in conjunction with the 12- and 24-hour consequences to select the necessary and sufficient set of controls.

The event frequency for this overtemperature accident scenario is "anticipated" ($> 10^{-2}$ to $\leq 10^{0}$) based on the initiating event frequency for either a heater failure or an external fire. Heaters in the ventilation system have failed in the past resulting in high temperatures in the exhaust air and some degradation of the filters has been observed. The failure of the heater to shut-off could create an overtemperature situation and cause the failure of the filters in the ventilation system. An external fire around the ventilation system would likely cause a filter degradation, as analyzed here. This event frequency is consistent with the analysis presented in Section 5.3.2.3, "Fire in Contaminated Area," that evaluates the consequences of a fire in a contaminated area.

Results Summary. The onsite and offsite radiological and toxicological consequences for the scenario assuming no controls are presented in Table 5.3.2.2-1. The associated calculations are documented in WHC-SD-WM-CN-062, *HEPA Filter Failure by Fire or Heater Overtemperature and Subsequent Unfiltered Release* and HNF-SD-WM-CN-099, *Radiological and Toxicological Analyses of Tank 241-AY-102 and Tank 241-C-106 Ventilation Systems*.

Implications of Results. The onsite and offsite consequences for SSTs with passive ventilation, DCRTs, 204-AR Waste Unloading Facility, 244-AR Vault, the W-213 Dry Waste Compactor Facility, and the catch tanks are below the risk guidelines. Accordingly, no controls are required for these systems.

The offsite consequences for SSTs with active ventilation and DSTs (including AWF tanks) are below the risk guidelines. However, the onsite consequence values for DSTs (including AWF tanks) and for SSTs with active ventilation are above the risk guidelines. Therefore, controls are required for these systems.

Note that all toxicological consequence values (both onsite and offsite) shown in Table 5.3.2.2-1 are below risk guidelines.

Accident Scenario Assuming Controls

Sequence of Events. A continuous air monitor (CAM) interlock that detects increased radiation levels in the exhaust air and shuts off the ventilation system is selected to mitigate the consequences of a HEPA filter failure from high temperature. This control is applicable to DSTs (including AWF tanks) and actively ventilated SSTs.

Similar to the accident assuming no controls, a fire is postulated to occur in or around the ventilation system. Heat from the fire degrades the filters; a fraction of the inventory of tank waste accumulated on prefilters (if present), HEPA filters, and ductwork is released; and an unfiltered release pathway is created. Because of the CAM interlock system, however, the ventilation system shuts off within 10 minutes, thereby terminating the unfiltered release.

The event frequencies assuming controls are the same as the frequencies assuming no controls because the CAM interlock system has no effect on frequency.

Results Summary. The onsite and offsite radiological consequences for the scenario assuming controls are presented in Table 5.3.2.2-2. No toxicological consequences for the scenario assuming controls were calculated as the toxicological guidelines were met for the scenario assuming no controls. The associated calculations are documented in WHC-SD-WM-CN-062 and HNF-SD-WM-CN-099.

Implications of Results. The onsite consequences for SSTs with active ventilation and DSTs (including AWF tanks) are below the risk guidelines.

Key Accident Scenario Assumptions. Key assumptions related to the derivation of the accident frequency and calculation of the accident consequences as documented in WHC-SD-WM-CN-062 and HNF-SD-WM-CN-099 are summarized in the following paragraphs.

Important to Accident Frequency. No assumptions related to the facility design or operation have been made in the analysis that are important in relation to the accident frequency.

Important to Accident Consequences. The following assumptions are important to the calculation of accident consequences for a HEPA filter failure because of fire:

- Ventilation system configuration is as described in Appendix B
- Filter dimensions are as described in WHC-SD-WM-CN-062 and HNF-SD-WM-CN-099
- SST active ventilation flow rate is 3,300 L/s (7,000 cfm)
- SST passive ventilation flow rate is 0.68 L/s (1.4 cfm)
- DST active ventilation flow rate is 550 L/s (1,170 cfm)

- AWF tank active ventilation flow rate is 1,890 L/s (4,000 cfm)
- DCRT active ventilation flow rate is 1,980 L/s (4,200 cfm). This value is based on the ventilation flow rate associated with the 244-CR Vault. This is conservatively high from the standpoint of representing the balance of the DCRTs because they are bounded by a ventilation capacity of 94.4 L/s (200 cfm)
- 204-AR Waste Unloading Facility active ventilation flow rate is 940 L/s (2,000 cfm)
- 244-AR Vault active ventilation flow rate is 7,080 L/s (15,000 cfm)
- W-213 Dry Waste Compactor Facility active ventilation flow rate is 940 L/s (2,000 cfm)
- Catch tanks have inlet HEPA filters only
- Contact dose rate measured on individual prefilter and HEPA filter housings is less than or equal to 2 mSv/h (200 mrem/h). This dose rate was used to calculate the quantity of waste material accumulated on filters based on the radionuclide content. This quantity of waste also defines the toxicological source term.
- The filter media making up the HEPA filters is made of fiberglass (or other non-combustible material). There is no paper (or other highly combustible) filter media used in the Tank Farm ventilation systems HEPA filters.
- Contact dose rate measurements are performed at the location defined in WHC-SD-WM-CN-033, *MICROSHIELD Dose Rate Calculations for HEPA Filters and Prefilters* for all ventilation systems identified in this section except the 296-P-16 ventilation system which is used in the 241-C Tank Farm, the 296-S-15 ventilation system which is used in the 241-SX Tank Farm, and the 702-A ventilation system which is used in the 241-AY and 241-AZ Tank Farms. Specific analyses of the 296-P-16, 296-S-15, and the 702-A ventilation systems are provided in HNF-SD-WM-CN-099.
- CAM interlock will detect and shut off active DST (including AWF tanks) and SST ventilation within 10 minutes
- The products of combustion will not cause the CAM interlock to malfunction or result in delayed operation
- An unfiltered release from the W-213 Dry Waste Compactor Facility or catch tanks was not calculated because these facilities do not routinely contain a significant airborne source term.
- The analysis results bound the consequences associated with a release from any inlet HEPA filters that may be present on DSTs.

Controls

Safety Structures, Systems, and Components. CAM interlocks on the ventilation systems are designated Safety-Significant structures, systems, and components for this accident as shown in Table 5.3.2.2-3.

Technical Safety Requirement Controls. There are Technical Safety Requirement controls on HEPA filters and CAM interlocks as shown in Table 5.3.2.2-4.

Defense-in-Depth. Table 5.3.2.2-5 shows the Defense-in-Depth controls for this accident.

5.3.2.2.2 HEPA Filter Failure - Exposure to High Pressure.

Purpose of Analysis: A pressure differential of 2.5 kPa (0.36 lb/in^2 [10 in. water gauge]) can fail HEPA filters. Upon failure, the inventory on the filters could be released, followed by an unfiltered release from the tank vapor space. The purpose of this analysis is to provide a common set of reference values to be used in analyzing potential accidents that could raise tank pressures to greater than 2.5 kPa. These accidents include the following: steam intrusions (Section 5.3.2.5), flammable gas deflagrations (Section 5.3.2.14), organic salt-nitrate reactions (Section 5.3.2.17), organic solvent fire (Section 5.3.2.15), tank bump (Section 5.3.2.22), and in-tank fuel fire/deflagrations (Section 5.3.2.16).

Analysis Strategy: The analysis strategy is to perform a bounding, representative consequence analysis of a HEPA filter failure caused by high pressure to provide a common set of reference values for the accidents identified in the Purpose of Analysis.

Accident Scenario Assuming No Controls

Sequence of Events. An overpressurization event is postulated to occur within a waste tank, all prefilters and HEPA filters in the ventilation system fail because of the pressure increase, a fraction of the inventory of tank waste accumulated on the filters plus the ventilation system ductwork is released, and an unfiltered release pathway is established.

Doses calculated for the HEPA filter overpressurization accident are not related to an event frequency nor compared with guideline limits. This is because the potential accidents that can generate high pressures identified earlier differ in frequency and guideline limits for radiological consequences as a function of event frequency. The section describing the specific accident scenario (see Purpose of Analysis) will provide such information. Toxicological exposure consequences are calculated by using a frequency-dependent sum-of-fractions methodology. This analysis presents sum-of-fractions values for the anticipated frequency category.

Results Summary. Tables 5.3.2.2-6 and 5.3.2.2-7 present the onsite and offsite radiological and toxicological consequence values for releases from failed HEPA filters because of an overpressurization event. These values combine the consequences associated with the release from the filters because

of overpressurization with the unfiltered release consequences calculated for a HEPA fire as in Section 5.3.2.2.1. The associated supporting calculations are documented in WHC-SD-WM-CN-062, WHC-SD-WM-CN-063, *Releases From Failed HEPA Filter Due to an Overpressurization Event*, and HNF-SD-WM-CN-099 for the 296-P-16 ventilation system that is used in the 241-C Tank Farm, the 296-S-15 ventilation system which is used in the 241-SX Tank Farm, and the 702-A ventilation system that is used in the 241-AY and 241-AZ Tank Farms.

Implications of Results. The consequences are used in the scenarios identified in purpose of analysis.

Accident Scenario Assuming Controls. Controls are selected on an accident-specific basis; thus, appropriate controls are described in the applicable sections discussing the accidents identified in the Purpose of Analysis.

Key Accident Scenario Assumptions

Important to Accident Frequency. No assumptions have been made in the analysis that are important in relation to the accident frequency.

Important to Accident Consequences. The assumptions important to the calculation of accident consequences are the same as those for a HEPA failure from high temperatures, except that the CAM interlock and combustion product assumptions do not apply.

Controls. The controls established to mitigate the risk associated with HEPA filter failure caused by high pressure are discussed in this section. The applicability of these controls is specified in the associated tables.

Representative accident scenario:

- **Safety Structures, Systems, and Components**—The safety structures, systems, and components are defined according to the specific accident scenario. Thus, appropriate safety structures, systems, and components are described in the applicable sections discussing the accidents identified in the purpose of analysis.

- **Technical Safety Requirement Controls**—Technical Safety Requirement controls are developed for specific accident scenarios. Thus, appropriate controls are described in the applicable sections discussing the accidents identified in the purpose of analysis. A Technical Safety Requirement control is established for HEPA filter loading (Table 5.3.2.2-4).

  - 2 mSv/h (200 mrem/h) material loading on filter arrays.

- **Defense-in-Depth**—Additional controls that provide Defense-in-Depth apply according to the specific accident scenario. Thus, appropriate Defense-in-Depth controls are described in the applicable sections discussing the accidents identified in the purpose of analysis.

[a] To convert Sv to rem, multiply by 100.
[b] 12-hour unfiltered release.
[c] 24-hour unfiltered release.
[d] Annual unfiltered release.
[e] Catch tanks do not have dedicated active ventilation systems. Two catch tanks have shared ventilation systems. The 241-A-417 and 241-AX-152 are connected to the 702-A ventilation system via a ventilation line. The ventilation systems for the following catch tanks and DCRTs consist of a breather filter similar to the breather filer assemblies on SSTs: 241-A-350, 241-A-417, 241-EW-151, 241-S-304, 241-AZ-151, 241-AZ-154. The following catch tanks have no HEPA filtration systems: 241-A-302-A, 241-TX-302-C, 241-U-301-B, 241-UX-302-A, and 241-ER-311.
[f] The bounding consequences shown here are for the 296-S-15 ventilation system used in the 241-SX Tank Farm. See the HEPA filter dose contribution results and additional discussion documented in Attachments 5 and 7 of HNF-SD-WM-CN-099, 1998, Radiological and Toxicological Analyses of Tank 241-AY-102 and Tank 241-C-106 Ventilation Systems, Rev. 1, Fluor Daniel Northwest, Inc., Richland, Washington.
[g] See Attachments 5 and 7 of HNF-SD-WM-CN-099 for the HEPA filter dose contribution results for this ventilation system (i.e., 702-A).

AWF = Aging Waste Facility.
DCRT = double-contained receiver tank.
DST = double-shell tank.
ERPG = Emergency Response Planning Guideline.
HEPA = high-efficiency particulate air (filter).
PEL = permissible exposure limit.
Sv = sievert.
SOF = sum-of-fractions.
SST = single-shell tank.
TWA = time-weighted average.

Table 5.3.2.2-2. Consequences and Frequencies Assuming Controls for High-Efficiency Particulate Air Filter Failure-Exposure to High Temperature.

[a] To convert Sv to rem, multiply by 100.
[b] An analysis assuming controls was not performed because the unmitigated consequence were well within the guidelines.
[c] There is no effect on frequency from the controls.
[d] The bounding consequences shown here are for the 296-S-15 ventilation system used in the 241-SX Tank Farm. See Attachment 5 of HND-SD-WM-CN-099, 1998, Radiological and Toxicological Analyses of Tank 241-AY-102 and Tank 241-C-106 Ventilation Systems, Rev. 1A, Fluor Daniel Northwest, Inc., Richland, Washington for the HEPA filter dose contribution results and additional discussion.
[e] See Attachment 5 of HNF-SD-WM-CN-099 for the HEPA filter dose contribution results for this ventilation system (i.e., 702-A).

AWF = Aging Waste Facility.
DST = double-shell tank.
HEPA = high-efficiency particulate air (filter).
Sv = sievert.
SOF = sum-of-fractions.
SST = single-shell tank.

Table 5.3.2.2-3. Safety Structures, Systems, and Components for High-Efficiency Particulate Air Filter Failure—Exposure to High Temperature.

Structures, systems, or components	Safety classification	Safety function	Comments
Continuous air monitor-interlock on ventilation system	Safety-Significant	Prevent the unfiltered release from occurring for more than 10 minutes	Applies to single-shell tanks with active ventilation and double-shell tanks (including Aging Waste Facility tanks)

HEPA = high-efficiency particulate air (filter).

Table 5.3.2.2-4. Technical Safety Requirement Controls for High-Efficiency Particulate Air Filter Failure—Exposure to High Temperature.

Control	Safety function	Comments
CAM interlock on ventilation system	Detect the high radioactivity and shut off ventilation within 10 minutes. This prevents the potential unfiltered release from occurring for more than 10 minutes	Applies to single-shell tanks (with active ventilation only) and the primary tank ventilation system on double-shell tanks (including Aging Waste Facility tanks)
HEPA Filter Control Program with the following key elements: 1. Periodic radiation survey to monitor HEPA filter loading 2. HEPA filter replacement per change-out criteria, i.e., $\leq$ 2 mSv/h (200 mrem/h)	Reduce consequences from a possible HEPA filter failure by limiting the inventory available	Applies to all HEPA filters and prefilters in the ventilation system

CAM = continuous air monitor.
HEPA = high-efficiency particulate air (filter).
mSv = millisievert

Table 5.3.2.2-5. Defense-in-Depth Controls for High-Efficiency Particulate Air Filter Failure—Exposure to High Temperature.

Control	Function	Remarks
Low Delta P interlock across the HEPA filters on the ventilation system	Shut off the ventilation system to prevent unfiltered release	None
High Delta P alarm on the ventilation system	Direct the operator to shut off the ventilation system because of excessive loading on the filters	Workers trained in responding properly to all alarms
Annual aerosol testing of filters on the ventilation system	Ensure the operability of the filters on the ventilation system	Workers trained in testing the filters
Record sampler	Provide quantitative release amounts reported to state. A higher than normal amount would indicate that an unfiltered release is occurring	Record samplers tested periodically
Interlock/alarm on heater over temperature	Prevent the failure of the ventilation system	Interlock/alarms tested periodically
Periodic surveillance of HEPA Delta P and continuous air monitor	Ensure the operability of the filtration monitoring system	None
HEPA filter replacement typically performed at 1 mSv/h (100 mrem/h)	Limit inventory available for release and limit dose rate to workers in the vicinity of the filters	None

HEPA = high-efficiency particulate air (filter).
mSv = millisievert
*Defense-in-Depth controls shown here apply only to the SSTs with active ventilation and the primary tank ventilation system on DSTs (including AWF tanks).

5.3.2.3 Fire In Contaminated Area.

Purpose of Analysis: Within the TWRS facilities, there are numerous contaminated areas that could release hazardous material should a fire occur. Many of these contaminated areas are associated with the waste transfer system, and some parts of the system, including valve pits, pump pits, and diversion boxes, are routinely accessed.

Analysis Strategy: The hazard analysis performed for the tank farms identified several potential causes for a fire in a contaminated area. Some of these causes were human error in positioning a crane load, pump motor electrical failure, range fire, and a vehicle being driven over a pit cover that ruptures the fuel tank. The fuel tank failure was selected for analysis because it maximizes the energy available for the dispersion of hazardous material.

5.3.2.3.1 Accident Scenario Assuming No Controls.

Sequence of Events. In a fire in contaminated area scenario, an operator is assumed to position a crane close enough to a valve pit that the fuel tank of the crane or nearby support vehicle hits the pit curb, rupturing the tank and spilling fuel into the open pit. An ignition source is assumed present, and the fuel in the pit catches fire. Convection from the fire sweeps the hazardous material out of the pit into the atmosphere where it is transported away from the accident location by atmospheric dispersion phenomena. A valve pit was chosen for this accident scenario because it is larger than the other types of pits and has a drain arrangement that may hold significant quantities of residual waste.

The fire is assumed to last for less than 2 hours. To calculate radiological dose consequences, an acute dispersion coefficient is used, and toxicological exposure consequences are analyzed assuming the total amount of respirable material is released over a period of 15 minutes. These assumptions ensure that both the radiological and toxicological exposure consequences are calculated conservatively.

A frequency of "anticipated" was qualitatively assigned to this unmitigated accident scenario. Investigation showed that the frequency of such an event occurring based on one location and one vehicle would be approximately 9.0×10^{-7} per year ("beyond extremely unlikely"). The frequency analysis was based on the number of miles per hour traveled by a single crane or support vehicle near a single pit, as well as U.S. Department of Transportation statistics involving vehicle-related fires. However, the overall frequency of an event within the TWRS complex (multiple vehicles and locations) is estimated to be much higher (i.e., "anticipated").

Results Summary. Table 5.3.2.3-1 contains a summary of radiological and toxicological consequence values for the fire in a contaminated area accident scenario. The associated calculations are documented in WHC-SD-WM-CN-056, *Fire in a Contaminated Area.*

Implications of Results. The radiological consequences to the onsite receptor for the accident scenario assuming no controls exceed the onsite risk guidelines for an accident frequency in the "anticipated" category. The offsite radiological consequences, however, are well within the risk guidelines. Note that the onsite radiological guidelines are exceeded regardless of the frequency category. Thus, controls are necessary.

The toxicological exposure consequences to an offsite receptor are well within the risk guidelines, but consequences to an onsite receptor are slightly over the risk guidelines.

5.3.2.3.2 Accident Scenario Assuming Controls. As a result of the analysis described in Section 5.3.2.3.1, "Accident Scenario Assuming No Controls," Technical Safety Requirement controls are proposed to prevent the fire in the contaminated area from occurring. These controls, discussed in Section 5.3.2.3.4, "Controls," comprise two key elements of the Tank Farms Ignition Control Program. Because the selected controls are preventive, no consequences were calculated.

5.3.2.3.3 Key Accident Scenario Assumptions.

Important to Accident Frequency. No assumptions related to the facility design or operation have been made in the analysis that are important in relation to the accident frequency.

Important to Accident Consequences. The following assumptions are important to the calculation of accident consequences for a fire in a contaminated area assuming no controls:

- The material at risk is the quantity of residual contamination present in a valve pit before the accident commences assuming a drain in the floor of the pit protrudes 25.4 mm (1 in.) above the floor. Drains are known to be at this level to provide a detectable liquid surface for a leak detector element; thus, this is a reasonable and conservative assumption. The floor slopes from the pit walls to the drain, and the pit is calculated to contain dried residue resulting from 42.0 L (11.1 gal) of material.

- The source term is made up of 67 vol% aging waste facility liquids and 33 vol% aging waste facility solids. Because this is a bounding source term for all possible waste transfers, this assumption is considered conservative.

5.3.2.3.4 Controls. The following controls are applicable for operations and activities involving waste transfer-associated structures and vehicles/cranes.

Safety Structures, Systems, and Components. No safety structures, systems, and components are required.

Technical Safety Requirement Controls. To protect the onsite workers, an ignition control program shall be established with the elements discussed in Table 5.3.2.3-2.

Defense-in-Depth. Additional controls that provide Defense-in-Depth are shown in Table 5.3.2.3-3.

mSv = millisievert.
TWA = time-weighted average.

Table 5.3.2.3-2. Technical Safety Requirement Controls for Fire in Contaminated Area.

Control	Safety function	Comment
Ignition Control Program with the following key elements: 1. Vehicle access within the tank farms shall be limited to vehicles whose fuel systems are protected from damage caused by potential collisions with tank structures 2. Physical barriers shall restrict vehicle access to those above-ground structures outside of tank farm boundaries that can direct liquids into waste tanks. Only vehicles with protected fuel systems shall be allowed within barriers 3. Speed limit controls Emergency Preparedness with the following key element: - Response procedures for fire in contaminated area	Prevent vehicle fuel system damage in the event of collisions with tank structures within the tank farms. Outside the tank farms where vehicle access can not be controlled, prevent vehicle access to tank structures Mitigate the consequences of a fire in contaminated area	None

Table 5.3.2.3-3. Defense-in-Depth Controls for Potential Fire in Contaminated Area.

Control	Safety function	Comment
Fire Protection Program	Fire prevention	Program contains a number of provisions that would prevent fires in a pit from causes other than ruptured fuel tanks
Radiation Protection Program	Facility workers will use masks when working in areas with the potential for airborne contamination	Provides protection for facility workers that would be closest to the accident location
Contamination Control Program	Survey and cleanup of areas with loose surface contamination	For the scenario analyzed, would reduce the concentration and quantity of contamination in the valve pit
Vehicle positioning spotters	Spotters provide additional level of control in positioning cranes/vehicles	Reduces probability of analyzed accident
Tank Farm fences	Provide line of demarcation within which Ignition Control Program key elements related to vehicle fuel systems must be met	Fence gates are typically closed and locked
Vegetation Control Program	Prevent range fires from impacting Tank Farm facilities	None

5.3.2.4 Evaporator Dump.

Purpose of Analysis: During a loss of electrical power, the 242-A Evaporator is engineered to dump its contents to feed Tank 241-AW-102. This evaporator dump event is the limiting case for a sudden uncontrolled drain of hot evaporator waste to a waste tank. An evaporator dump pressurizes the tank vapor space and releases aerosolized waste to the environment. This analysis develops the scenario for the evaporator dump accident and provides estimates of the potential consequences.

Analysis Strategy: The hazard analysis performed for the tank farms identified an evaporator dump as a potential mechanism for the uncontrolled release of contamination caused by pressurization of Tank 241-AW-102. This section (1) identifies the sequence of events of an evaporator dump scenario, (2) quantifies the postulated material at risk for an evaporator dump scenario assuming no controls, (3) determines the quantity of tank waste anticipated to be released to the environment, and (4) provides an estimate of the radiological and toxicological consequences of the release.

A mathematical model (WHC-SD-WM-CN-060, *Calculation Notes that Support Accident Scenario and Consequence Determination of the Evaporator Dump*) was developed to track the pressure, temperature, aerosol concentration, and exhaust flow from the vapor space of Tank 241-AW-102 during an evaporator dump. The total amount of tank waste released to the environment is the integral of the product of the exhaust flow and aerosol concentration for the duration of the accident.

5.3.2.4.1 Accident Scenario Assuming No Controls.

Sequence of Events. For the evaporator dump scenario assuming no controls, a loss of electricity to both the 242-A Evaporator and the 241-AW Tank Farm is postulated. The 242-A Evaporator, as engineered, discharges the vessel contents to double-shell Tank 241-AW-102. The thermally hot evaporator content mixes as it is dumped into the relatively cooler feed tank waste while spreading across the surface of the existing tank waste. The hot waste spreads across the surface of the existing waste with a layer depth of 0.6-m (2-ft) and a temperature of 55.8 °C (132.5 °F) (the average of the evaporator waste and tank waste temperatures). The 0.6-m (2-ft) layer and 55.8 °C (132.5 °F) temperature are considered conservative. The falling evaporator waste will actually mix, and be cooled by, the double-shell tank waste at some depth below the waste surface as opposed to forming a hot pool that spreads over the surface of the double-shell tank waste and directly heats the vapor space.

The vapor space gas heats as energy is transferred from the waste surface to the vapor space. At the same time, the vapor space volume decreases as the waste level in the tank increases with the addition of evaporator waste. The decrease in vapor space volume and simultaneous increase in vapor space temperature causes an increase in the tank vapor space pressure. The pressure is relieved by some of the vapor space gas venting through both filtered and unfiltered pathways. The ventilation system for Tank 241-AW-102 is assumed to fail as a result of the loss of power.

The tank vapor space pressure reaches a maximum of approximately 2,200 Pa (9 in. W.G.) within the first 12 minutes and then returns to near atmospheric pressure. This pressure does not challenge the structural integrity of the high-efficiency particulate air filters. A small amount of venting continues for two hours as the vapor space gas continues to be heated by the dumped evaporator waste. The consequences for the evaporator dump accident scenario assuming no controls were calculated from the venting (with no filtration) of a portion of the vapor space volume along with its aerosol loading.

Based on three unusual occurrence reports related to evaporator dumps this accident scenario is qualitatively assigned a frequency category of "anticipated."

Results Summary. Table 5.3.2.4-1 summarizes the radiological and toxicological consequence values for the evaporator dump accident scenario. The supporting calculations are documented in WHC-SD-WM-CN-060.

Implications of Results. The unmitigated radiological and toxicological consequences for both the offsite and onsite receptors of the evaporator dump accident scenario are significantly below the risk guidelines. Consequently, no safety structures, systems, and components or Technical Safety Requirement controls are required. Defense-in-Depth controls are identified in Section 5.3.2.4.4, "Controls."

5.3.2.4.2 Accident Scenario Assuming Controls. Analysis of a mitigated evaporator dump accident scenario was not performed because both the onsite and offsite unmitigated radiological and toxicological consequences are below risk guidelines.

5.3.2.4.3 Key Accident Scenario Assumptions.

Important to Accident Frequency. No assumptions have been made in the evaporator dump scenario analysis that are related to the facility design or operation and that are important to the accident frequency.

Important to Accident Consequences. The following assumptions are important to calculation of the evaporator dump accident consequences:

- A maximum volume of 98,421 L (26,000 gal) is dumped through a dump line 10-in. in diameter (WHC-SD-WM-SAR-023, *242-A Evaporator/ Crystallizer Safety Analysis Report*).
- The double-shell tank waste temperature is assumed to be 18 °C (65 °F) with a vapor space temperature of 13 °C (55 °F). The maximum allowable temperature for the evaporator vessel is 93 °C (200 °F) (WHC-SD-WM-SAR-023). The assumed and maximum allowable temperatures give the greatest temperature differential between the vapor space and the evaporator waste to maximize (1) the heat transfer to the vapor space and (2) the vapor space pressure increase resulting from the higher waste temperature.
- WHC-SD-WM-SAR-023 has an Administrative Control that defines the bounding radionuclide inventory for the evaporator waste. The evaporator unit liter dose, 7.7×10^{3}, is based on the

WHC-SD-WM-SAR-023 inventory limit. The toxicological composition of the waste was assumed to be equivalent to double-shell tank liquids.

- No credit is taken for high-efficiency particulate air filters. The maximum differential pressure allowable on the high-efficiency particulate air filter is 2,491 Pa (10 in. W.G.). As long as the tank vapor space pressure remains below 2,491 Pa (10 in. W.G.), the high-efficiency particulate air filter differential pressure maximum is not challenged.

5.3.2.4.4 Controls.

Safety Structures, Systems, and Components. No safety structures, systems, and components are required.

Technical Safety Requirement Controls. No Technical Safety Requirement controls are required.

Defense-in-Depth. Controls that provide Defense-in-Depth for an evaporator dump accident are shown in Table 5.3.2.4-2.

5.3.2.5 Steam Intrusion From Interfacing Systems.

Purpose of Analysis: The purpose of this analysis is to evaluate the risks associated with the use of steam jets for transferring waste into the tank farms. Steam jets are used to transfer waste from some process and laboratory facilities within 200 East and 200 West Areas to the tank farms. These facilities include the Plutonium Finishing Plant, 222-S Laboratory, 242-A Evaporator, PUREX, and T Plant. Additionally, although currently inactive, the 244-AR Vault (a Tank Waste Remediation System facility) is considered as a potential point of steam access to the tank farms. Historically, steam was used by the 244-AR Vault to transfer waste to the tank farms, and the lines have not been physically blanked off.

Failure to shut off a steam jet following a waste transfer has the potential to pressurize the tank headspace of the tank receiving waste and result in a release of tank headspace aerosols through unfiltered pathways (cracks in cover blocks or capped risers, or ruptured high-efficiency particulate air (HEPA) filters.

Analysis Strategy: Both double-contained receiver tanks (DCRTs) and double-shell tanks (DSTs) may receive waste transfers via steam jets. A DST was selected for analysis because it has a potentially larger headspace than a DCRT, which would allow for more particulates in a release and would result in greater consequences.

5.3.2.5.1 Accident Scenario Assuming No Controls.

Sequence of Events. In the steam intrusion from interfacing systems scenario, a liquid waste transfer to a DST is initiated from a process facility using a steam jet as the motive force to move the liquid. After the waste has been transferred, the steam jet is not shut off and pure steam is routed to the headspace of the receiving tank. This may occur as a result of operator error or equipment failure. It is assumed that 724 kPa (90 psig) saturated steam is exhausted into the headspace of a partially full DST at a flow rate of 1,090 kg/h (2,400 lbm/h). Higher flow rates and pressures may be possible, but would only pressurize the headspace faster than in the scenario analyzed resulting in the same cumulative dose. The active ventilation system is assumed to shut off because this maximizes the peak tank pressure. Note that if tank ventilation is operating, a sufficiently high pressure could still be reached to result in filter failure.

Steam is assumed to be supplied until the headspace is saturated with steam. The headspace pressure increases to the point where the HEPA filters in the ventilation system fail, thereby creating an unfiltered pathway for the release of the contaminated headspace contents. Additionally, analysis of the tank conditions when the steam in the tank headspace is condensing shows that equalization to atmospheric pressure is easily achievable and will not create an excessive vacuum.

On the basis of the operational history of the tank farms, the scenario assuming no controls is assigned a frequency of "anticipated" (10^{-2} to 10^{0} per year). Although the occurrence reporting database does not include any entries for steam intrusions, prior operational history has shown that events

similar to those in the described scenario have occurred and are still possible today (because steam jets are still used for transferring waste). The frequency of this accident will diminish as the use of steam jets from process facilities is further limited by ongoing and future deactivation activities.

Results Summary. Table 5.3.2.5-1 contains a summary of radiological and toxicological consequence values for the steam intrusion from interfacing systems. Associated calculations are documented in WHC-SD-WM-CN-044, *Calculation Notes That Support Accident Scenario and Consequence Development for the Steam Intrusion From Interfacing Systems Accident.*

Implications of Results. The radiological and toxicological consequence values shown in Table 5.3.2.5-1 are within the risk guidelines; therefore, no structures, systems, and components have been designated Safety-Class or Safety-Significant. Although the unmitigated consequences do not exceed the risk guidelines, a control is necessary to protect analysis assumptions related to the HEPA filter loading. In addition, controls have been identified that provide Defense-in-Depth (Section 5.3.2.5.4, "Controls").

5.3.2.5.2 Accident Scenario Assuming Controls. Because the analyzed accident scenario assuming no controls resulted in radiological consequences below the risk guidelines, no accident scenario assuming controls was developed.

5.3.2.5.3 Key Accident Scenario Assumptions.

Important to Accident Frequency. No assumptions related to the facility design or operation have been made in the analysis that are important in relation to the accident frequency.

Important to Accident Consequences. The following assumptions are important to the calculation of accident consequences for a steam intrusion from interfacing systems:

- To conservatively calculate the source term, the entire volume of contaminated air that was initially present in the headspace (V_{HS} = 3.11 x 10^3 m^3 [1.10 x 10^5 ft^3] of air) is assumed to be vented directly to the atmosphere without being filtered. This is the volume associated with a DST that is approximately half full. Less headspace volume will result in less respirable particulate material available to be released. Doubling the volume of available headspace to be vented would still result in radiological dose consequences below the risk guidelines.

  Additionally, because the tank headspace could be pressurized to a point that would rupture contaminated HEPA filters present in the shutdown ventilation system, the filter material is added to the total released. The values for HEPA filter release amounts (including prefilters and ductwork accumulation) are taken from calculation note, WHC-SD-WM-CN-054, *Waste Tank Ventilation System Waste Material Accumulations.* The amount released (based on a HEPA filter inventory of DST liquids) is 9.79 x 10^{-4} L (2.59 x 10^{-4} gal).

- It is assumed that the airborne source term material both entrained in the headspace and present on the HEPA filters is made up of DST liquids. DST liquids were considered appropriate because DST liquids bound the source term for aging waste facility liquids. Additionally, the use of this source term is consistent with calculations performed in determining the amount of respirable material released from the HEPA filter failure just discussed.

Note that numerous assumptions were made in developing the source of the pressurization in the headspace. These included the pressure and flow rate of the incoming steam, the initial tank headspace temperature, and lack of active ventilation. Because these variables only contribute to the pressurization of the headspace (and not to the consequences) controls to protect analysis assumptions for these variables are not required.

5.3.2.5.4 Controls.

The following controls are applicable for operations and activities at all locations that may receive steam jet waste transfers, including: waste storage tanks (DCRTs, DSTs, including Aging Waste Facility tanks; and catch tanks), waste transfer piping (concrete-encased lines, and pipe-in-pipe-encased lines); and waste transfer-associated structures (process pits, diversion boxes, vault pits, cleanout boxes).

Safety Structures, Systems, and Components. No safety structures, systems, and components are required.

Technical Safety Requirement Controls. Because the unmitigated accident scenario involved the release of HEPA filter contents (including prefilters and ductwork accumulation) as a result of the pressurization, a control has been developed to ensure that HEPA filter loadings do not exceed the values assumed in this analysis. A brief summary of the proposed control is included in Table 5.3.2.5-2.

Defense-in-Depth. Additional controls that provide Defense-in-Depth are shown in Table 5.3.2.5-3.

Control	Safety function	Comment
HEPA Filter Control Program with the following key elements: 1. Periodic radiation survey to monitor HEPA filter loading 2. HEPA filter replacement per change-out criteria, i.e., ≤ 2 mSv/h (200 mrem/h)	Reduce consequences from a possible HEPA filter failure by limiting the inventory available	None

HEPA = high-efficiency particulate air (filter)
mSv = millisievert

Table 5.3.2.5-3. Defense-in-Depth Controls For Steam Intrusion from Interfacing Systems.

Control	Function	Remarks
Tank pressurization alarms	Alarms would notify operations personnel that the tank is being pressurized	Alarm may allow time for shutdown of transfer operation and evacuation of tank farm
Transfer line temperature interlock in place for transfers from PFP	Interlock shuts down transfer operation from PFP at a temperature of < 93.3 °C (≤ 200 °F)	Interlock would prevent accident from occurring
Operating ventilation system (with stack) during steam jet transfers	Operating ventilation system will remove heat and mass from the headspace (meaning it will take longer to pressurize)	Operation allows associated alarms to be active
HEPA filter differential pressure alarms	Alarms notify operations of saturated filter situation	Possibly allows time to shut down steam jet transfer operation
Sending tank level alarms to alert operator	Alarm notifies operator to shut off steam jet when the transfer tank is empty (or at desired level)	Alarms may preclude accident from occurring
Operating procedures	May advise operator of possible hazards associated with the steam jet operation	Outlines proper steps to be taken to prevent accident situation
Operator training	May advise operator of possible hazards associated with the steam jet operation	Outlines proper steps to be taken to prevent accident situation
Emergency Response Plans and Procedures	Reduce the consequences to facility workers and onsite personnel	Outlines proper steps to be taken to evacuate area and mitigate the consequences to personnel
HEPA filter replacement typically performed at 1 mSv/h (100 mrem/h)	Limits inventory available for release and limits dose rate to workers in the vicinity of the filters	None

HEPA = high-efficiency particulate air (filter)
mSv = millisievert
PFP = Plutonium Finishing Plant

5.3.2.6 Leak from Railcar/Tank Trailer.

Purpose of Analysis: The 204-AR Waste Unloading Facility receives shipments of liquid radioactive waste for direct transfer to the tank farms. The liquid radioactive waste is generated at facilities not directly connected by piping to the tank farms (e.g., T Plant, 222-S Laboratory, and 340 Facility) and transported by railcar or tank trailer to 204-AR Waste Unloading Facility. At the 204-AR Waste Unloading Facility, the waste is pumped directly from the railcar or tank trailer to a double-shell tank. The Tank Waste Remediation System facilities hazard analysis performed for the unloading facility identified potential hazardous conditions involving the accidental release of liquid radioactive waste from a railcar or tank trailer.

Analysis Strategy: Large liquid releases were postulated to occur both outside and inside the 204-AR Waste Unloading Facility from accidents caused by railcar derailment, railcar or tank trailer collisions, and corrosion or other degradation mechanisms causing railcar or tank trailer leak or failure.

A railcar accident that causes the release of the entire railcar contents to the ground outside the 204-AR Waste Unloading Facility is the bounding representative accident. This accident is considered bounding for several reasons. The total radionuclide inventory allowed in a railcar is higher than a tank trailer based on (1) the shipping requirements for the railcar (WHC-SD-RE-SAP-013, *Safety Analysis Report for Packaging, Railroad Liquid Waste Tank Cars*) and tank trailer (WHC-SD-TP-SEP-011, *Safety Evaluation for Packaging for the 222-S Laboratory Cargo Tank*), and (2) the capacity of the railcar, 75,700 L (20,000 gal), and tank trailer, 18,925 L (5,000 gal). Additionally, a release outside the 204-AR Waste Unloading Facility results in higher consequences because leaks inside the facility must first fill and overflow both the catch tank and pit, which have a combined capacity of 17,030 L (4,500 gal). A fire associated with the liquid waste release was not postulated because the waste is not flammable and is thermally stable.

5.3.2.6.1 Accident Scenario Assuming No Controls.

Sequence of Events. The railcar accident scenario that assumes no controls involves a railcar breach as the railcar is about to enter the 204-AR Waste Unloading Facility. The railcar is derailed, overturned, and breached, and the entire liquid waste contents of the railcar are released. The liquid is assumed to spill from a height of 1.0 m (3.3 ft), splash upon impact with the ground, and form a pool before being absorbed into the soil.

The material at risk assumed to be spilled from the railcar was calculated on the basis of the maximum railcar radionuclide content allowed by WHC-SD-RE-SAP-013. Waste generators that ship by railcar are required to calculate the maximum shipment volume on the basis of the waste radionuclide concentration to ensure compliance with the shipment limits in WHC-SD-RE-SAP-013. That is, for waste with high concentrations of radionuclides, a lower volume of waste is allowed in the railcar. To calculate accident consequences, the railcar material at risk must be equated to waste in a single-shell tank, a double-shell tank, or an aging

waste facility tank. As such, the maximum allowed railcar radionuclide inventory per WHC-SD-RE-SAP-013 is equal to 2,123 L (561 gal) of double-shell tank liquids (WHC-SD-WM-CN-003, *Calculation Notes That Support Accident Scenario and Consequence Development for the Leak from a Railcar/Tank Trailer at the 204-AR Waste Unloading Facility*).

The toxicological composition of the waste delivered to the 204-AR Waste Unloading Facility is not considered in the railcar or the tank trailer safety assessments (WHC-SD-RE-SAP-013 and WHC-SD-TP-SEP-011). Therefore, to evaluate the toxicological consequences of the railcar accident scenario, the waste was conservatively assumed to be equivalent to the chemical composition of double-shell tank liquids. A review of the chemical constituents of wastes that are sent to the 204-AR Waste Unloading Facility indicated that this assumption is reasonable.

An annual frequency of "unlikely" (10^{-4} to 10^{-2} per year) was qualitatively assigned to the railcar accident scenario. National and Hanford Site-specific railroad accident statistics and calculations performed in WHC-SD-RE-SAP-013 and in WHC-SD-WM-CN-021, *204-AR Facility Rail Accident Analysis*, indicate that the frequency of railcar accidents resulting in large spills is less than 1×10^{-4} per year. Therefore, the "unlikely" frequency category is considered appropriate and conservative for the railcar accident scenario.

Results Summary. Table 5.3.2.6-1 contains a summary of the radiological and toxicological consequence values for the leak from a railcar/tank trailer. Associated calculations are documented in WHC-SD-WM-CN-003.

Implications of Results. The radiological dose and toxicological exposure consequence values shown in Table 5.3.2.6-1 are within the risk guidelines; therefore, no structures, systems, and components have been designated Safety-Class or Safety-Significant. A control is necessary, however, to protect the analysis assumption that waste transported to the 204-AR Waste Unloading Facility meets the shipping requirements.

5.3.2.6.2 Accident Scenario Assuming Controls. Because the analyzed railcar accident scenario assuming no controls resulted in radiological dose and toxicological exposure consequences that were below the risk guidelines, no accident scenario assuming controls was developed.

5.3.2.6.3 Key Accident Scenario Assumptions.

Important to Accident Frequency. No assumptions related to the facility design or operation have been made in the railcar accident analysis that are important to the accident frequency.

Important to Accident Consequences. The following assumptions are important to the calculation of accident consequences.

- The material at risk assumed to be spilled was calculated on the basis of the maximum railcar radionuclide content allowed by WHC-SD-RE-SAP-013.
- The waste received at the 204-AR Waste Unloading Facility is not flammable and is thermally stable.

5.3.2.6.4 Controls.

The following controls are applicable for operations and activities at the 204-AR Waste Unloading Facility.

Safety Structures, Systems, and Components. No safety structures, systems, and components are required.

Technical Safety Requirement Controls. A Technical Safety Requirement control is required to protect the analysis assumption that the waste shipment transported to the 204-AR Waste Unloading Facility via railcar complies with WHC-SD-RE-SAP-013 requirements, particularly that the shipment meets the limit on total railcar radionuclide content and that the waste is not flammable and is thermally stable. Similar requirements in the control must ensure that waste shipments made by tank trailer are in accordance with criteria established by WHC-SD-TP-SEP-011, and in accordance with 49 CFR 173.403, "Definitions;" 173.425, "Transport Requirements for Low Specific Activity (LSA) Radioactive Materials"; and 173.435, "Table of A_1 and A_2 Values for Radionuclides." A brief summary of the proposed control is provided in Table 5.3.2.6-2.

Defense-in-Depth. Additional controls that provide Defense-in-Depth for a railcar/tank trailer leak at the 204-AR Waste Unloading Facility are shown in Table 5.3.2.6-3.

SARP = safety analysis report for packaging.

Table 5.3.2.6-3. Defense-in-Depth Controls for Potential Railcar and Tank Trailer Leaks at the 204-AR Waste Unloading Facility.

Control	Function	Remarks
Operator training	Prevent railcar derailments or tank trailer accidents caused by operator error	The train is operated by a Hanford Site-experienced train crew observing commercial standards for train operations The semi trucks that transport the tank trailers are operated by Hanford Site-trained workers. Drivers possess the proper class of commercial driver's license to safely operate the vehicle
Railroad inspection and maintenance	Prevent railcar derailments caused by poor track conditions	The Hanford Site railroad system is inspected and maintained on a preventive maintenance schedule consistent with commercial standards The track inside the 204-AR Waste Unloading Facility unloading canyon is not normally inspected, unless requested. Because this track is set in concrete, adjustments are not normally required
Railcar and tank trailer design	Prevent leaks or spills of waste	All connections to the railcar and tank truck are located on the top of the tanks, minimizing spills and leaks There are no valves or connections located on the railcar or tank trailer that would make a damaging leak possible
Operating procedures	Prevent leaks or spills of waste	Approved plant operating procedures that preclude failures assumed in the development of the accident frequency (e.g., train speed controls, facility doors being open during waste shipment delivery) are in place
Catch tank	Collect and contain waste spilled in the facility	The catch tank and its associated pit have a combined holding capacity of approximately 17,030 L (4,500 gal)
HEPA-filtered exhaust system	Mitigate the consequences of accidents resulting in airborne radioactivity	The 204-AR Waste Unloading Facility ventilation system provides two-stage HEPA filtration for unloading canyon effluents. An interlock shuts down the exhaust fan upon high-differential pressure or high radiation
Leak detection instrumentation	Detect leaks during waste transfer operations	Leak detection instrumentation in the catch tank pit and level detection in the catch tank alert operators of off-normal conditions
Continuous air monitors	Detect airborne radioactivity	Continuous air monitors in the unloading canyon alert operators to increased radiation levels from leaks
Emergency response plans and procedures	Mitigate the consequences of leaks or spills	Emergency response plans and procedures are in place to respond to and mitigate the consequences of spills inside and outside the facility

HEPA = high-efficiency particulate air (filter).

5.3.2.7 Subsurface Leak Remaining Subsurface.

Purpose of Analysis: The purpose of this analysis is to evaluate the risks associated with a potential leak of waste to the soil that remains subsurface. A network of interconnected transfer equipment is used to transfer liquid waste in the tank farms. This network comprises encased pipelines (with some single-walled lines still in use); valve pits; pump pits; and direct-buried, double-contained catch tanks. Although most transfer activities involve the double-shell tanks, many transfer operations involve removal of supernatant and interstitial liquids from the single-shell tanks (SSTs).

Analysis Strategy: The hazard analysis performed for the tank farms identified causes that could result in a subsurface leak that remains subsurface. Some of the causes considered included waste leaks from a cracked or broken pump, valve, and related transfer pits, single-walled and encased-line leaks during waste transfers (caused by corrosion, structural fatigue, or other factors) or waste transfers from processing facilities to either double-contained receiver tanks or diversion boxes. Also considered were the structural failures of double-contained receiver tanks, double-shell tanks, or SSTs and associated containments.

Leaks developing during waste transfers through single-walled, direct-buried transfer piping maximize the radiological dose consequences from associated low-energy subsurface leaks. This unmitigated scenario is considered bounding because a leak in the transfer pipe will go directly into the soil (i.e., no encasement) and because the transfer line is direct-buried at 1 m (3.3 ft) (i.e., minimal soil shielding).

5.3.2.7.1 Accident Scenario Assuming No Controls.

Sequence of Events. Assuming no controls, it is postulated that waste is transferred through a single-walled, direct-buried pipe at a maximum flow rate of approximately 379 L/min (100 gal/min) for 24 hours. A leak develops in the transfer pipe and releases 5% of the total volume transferred within 24 hours (i.e., 27,250 L [7,200 gal]). The leak volume of 5% and the assumed maximum flow rate are based on engineering judgment. The leaked waste was assumed to create a subsurface plume and not a surface pool, thereby increasing the likelihood that the condition would remain undetectable to the facility worker. Larger leak volumes resulting from higher flow rates or leak rates may create a surface pool, which is analyzed separately (Section 5.3.2.19).

The subsurface plume is assumed to be 15.24 cm (6 in.) below the soil surface. A soil cover of 15.24 cm (6 in.) was assumed because lesser soil cover would likely be detected. Greater soil cover would provide more shielding from the source and, therefore, reduce the direct, sky shine, and bremsstrahlung radiation dose consequences. No inhalation dose is considered because the surface soil is not wetted (i.e., no resuspension of waste particles).

While it is difficult to predict the shape of the contaminated underground soil plume that would be created as a result of the transfer line leak, it is necessary to fashion the contaminated soil volume into a common geometric shape for dose rate analysis. The following three volumetric shapes

are considered in this analysis as representative of the shape of the contaminated soil volume may occupy: (1) a horizontal cylinder (leaked waste preferentially moves along the transfer line), (2) a vertical cylinder (leaked waste expands in a vertical cylindrical shape), and (3) a sphere (leaked waste moves in all directions from a central point).

The total radiological dose to the onsite receptor from this accident scenario consists of the direct (line-of-sight), skyshine, and associated bremsstrahlung radiation components for a period of 12 hours.

This accident scenario was qualitatively assigned a frequency of "anticipated" (10^{-2} to 10^{0}/year). The frequency was based on the tank farms operational history and the condition of associated transfer lines. The occurrence reporting database has documented previous related pipe failures.

Results Summary. Table 5.3.2.7-1 contains the onsite radiological consequence value for the subsurface leak remaining subsurface. There are no offsite radiological or toxicological exposure consequences to onsite or offsite receptors from this accident scenario. However, a facility worker could be exposed to a radiological hazard. Associated calculations are documented in WHC-SD-WM-CN-004, *Calculation Notes That Support Accident Scenario and Consequence Development for the Subsurface Leak Remaining Subsurface Accident*.

Implications of Results. The onsite radiological dose consequence value shown in Table 5.3.2.7-1 is within the risk guidelines, therefore, no structures, systems, and components have been designated Safety-Class or Safety-Significant for protection of onsite and offsite receptors.

Controls including safety structures, systems, and components have been designated for the protection of the facility worker.

5.3.2.7.2 Accident Scenario Assuming Controls. No accident scenario assuming controls was postulated because the radiological and toxicological consequences for the "no controls" scenario were below the risk guidelines.

5.3.2.7.3 Key Accident Scenario Assumptions.

Important to Accident Frequency. No assumptions regarding facility design or operation and important to accident frequency have been made in the analysis.

Important to Accident Consequences. The following assumptions are important to the calculation of accident consequences:

- The centerline of the single-walled buried transfer pipeline is located 1.0 m (3.3 ft) subsurface.
- The source term used in this scenario is made up of 67 vol% SST liquids and 33 vol% SST solids. This is a reasonably conservative source term because only SST liquids and solids are transferred through single-walled buried transfer pipes. Although the dose rate

would be higher using either double-shell tank or aging waste facility tank wastes, the analysis using SST waste adequately demonstrates the need for controls.

- The density of the soil is assumed to be 1.6 g/cm^3. This value is consistent with calculations and models used in WHC-SD-WM-SARR-016, *Tank Waste Compositions and Atmospheric Dispersion Coefficients for use in Safety Analysis Consequence Assessments*. Higher density soils can be found on the Hanford Site, however, the density assumed here is considered representative and will provide conservative radiological consequence results.

- The soil porosity (void fraction) is assumed to be 0.40. These pores/voids are where the leaked waste resides. A soil with a lower porosity (i.e., 0.30) was also investigated in the analysis of this accident scenario. It was found that developing the consequences with a lower void fraction would not result in conservative dose consequences since the volume of contaminated soil would be larger and therefore provide more self-shielding.

5.3.2.7.4 Controls. The following controls are applicable for operations and activities at all locations that may receive waste transfers, including: waste storage tanks (double-contained receiver tanks, double-shell tanks [including Aging Waste Facility tanks], SSTs, catch tanks, and miscellaneous inactive storage facilities), waste transfer piping (single-walled direct buried or bermed lines, concrete encased lines, and pipe-in-pipe encased lines); and waste transfer-associated structures (process pits, diversion boxes, vault pits, cleanout boxes). See Section 5.3.2 for additional discussion of how the selected controls prevent or mitigate hazardous conditions and accidents caused by waste transfer misrouting.

Safety Structures, Systems, and Components. As a result of extrapolating controls to the other tank farm transfer equipment and locations where this type of accident is credible, the structures in Table 5.3.2.7-2 have been designated as Safety-Significant for protection of the facility worker.

Technical Safety Requirement Controls. A Transfer Control Program is required to mitigate the consequences to the facility worker. Table 5.3.2.7-3 provides details associated with this control.

Defense-in-Depth. Controls that provide Defense-in-Depth are shown in Table 5.3.2.7-4.

Control	Safety Function	Comments
Transfer control program with the following key elements: 1. Periodic balances during transfers 2. Radiation surveillance: direct-buried line surveillance during waste transfer operations (once per 12 h for salt well pumping, once per 30 min for submersible pumping) 3. Configuration management of transfer routes 4. Independent verification of transfer routings 5. Pipe labeling program: aboveground labeling of direct-buried (single-walled) piping systems 6. Double valve isolation on interconnected lines 7. Monitor interconnected tanks for level increase	Prevents/mitigates significant facility worker hazard	None
Transfer leak detection systems	Detects leak in primary transfer line	None
Transfer pump administrative lock controls	Eliminates motive force for unplanned transfers	None

Table 5.3.2.7-4. Defense-in-Depth Controls that Provide Defense-in-Depth for Potential Subsurface Leak Remaining Subsurface.

Control	Function	Remarks
Pressure/Leak Testing of Transfer Route Before Material Transfer	Provide a greater level of assurance of transfer line integrity before actual transfer of waste	None
Operator Training	Operations of facilities are performed by Hanford Site experienced crews with specific training in these activities	None
Operating Procedures	Operations are performed to approved plant operating procedures	None
Emergency Response Plan/ Procedures	Plans and procedures are in place to respond to emergency conditions	None

5.3.2.8 Unplanned Excavation/Drilling in Crib/Ditch/Pond.

Purpose of Analysis: Liquid radiological and toxicological contaminated wastes produced by Hanford Site facilities and operations have been disposed of in various Tank Waste Remediation System cribs, ditches, or ponds located in the 200 East and 200 West Areas. As a result of past waste disposal practices, these Tank Waste Remediation System facilities contain large quantities of contaminated soils. The contaminated soils in cribs, ditches, and ponds normally do not present a hazard because the contaminated soils are buried under a large overburden of uncontaminated soils. An inadvertent excavation, such as a planned excavation that is performed in the wrong location, or a drilling activity in a crib, ditch, or pond, could expose receptors to radioactive or toxicological hazards.

Analysis Strategy: From an evaluation of the recorded radiological inventories for ditch 216-U-14 and cribs 216-U-16, 216-U-17, and 216-Z-20, crib 216-Z-20 was identified as having the largest concentration of radioactive contamination (WHC-SD-WM-CN-053, *Excavations in Hanford Ponds, Cribs, or Ditches*). Therefore, to assess the potential unmitigated consequences of an inadvertent excavation in a crib, ditch, or pond, an unmitigated accident scenario was developed for crib 216-Z-20. Table 5.3.2.8-1 lists the main dose contributors and associated concentrations of the radiological inventory for crib 216-Z-20. Similarly, Table 5.3.2.8-2 lists the toxicological constituents and concentrations assumed present in the soils of crib 216-Z-20.

5.3.2.8.1 Accident Scenario Assuming No Controls.

Sequence of Events. In the unmitigated accident analysis, the crib was postulated to be excavated with a backhoe at a rate of one bucket of contaminated soil every 2 minutes for a period of 12 hours. This rate would result in approximately 120 m^3 (4,238 ft^3) of soil being excavated. All the excavated material was conservatively assumed to come from the crib; and no credit was taken for the overlying uncontaminated soil that must be excavated to reach the contaminated soils. Because actual excavation operations are not likely to be performed continuously for 12 hours (1 work shift), this assumption is conservative.

The total amount of respirable material released during the unplanned excavation events was calculated by adding the fractions released during the excavation (i.e., falling from the backhoe bucket) and the subsequent resuspension of contaminated soils by the wind during and following the excavation.

As shown in Table 5.3.2.8-2, the concentrations of the toxicological constituents are in the parts per million to parts per billion range. Airborne concentrations of these chemicals resulting from excavation would be at most in the parts per billion range to the onsite receptor. Given this, toxicological exposure consequences to both the onsite and offsite receptor are considered negligible and are not quantified in this analysis.

The operational history of the tank farms was considered when a frequency of "anticipated" (10^{-2} to 10^{0} per year) was qualitatively assigned to the accident scenario assuming no controls. Numerous entries in the occurrence reporting database demonstrate that planned excavation operations have been performed in unintended areas. Some of these events have resulted in unexpected and uncontrolled personnel exposure from transfer lines and other subsurface equipment. Planned excavations both by machine (i.e., backhoe) and by hand have occurred in unintended areas.

Results Summary. Table 5.3.2.8-3 contains a summary of the radiological consequence values for an unplanned excavations or drilling in a crib, ditch, or pond. Toxicological exposure consequences to both the onsite and offsite receptor are considered negligible and are not quantified in this analysis.

The radiological dose consequences presented in Table 5.3.2.8-3 were calculated based on a unit dose per cubic meter of contaminated crib soil. The concentration of the radiological inventory in the contaminated crib soil was assumed representative of the excavated material. The associated calculations are documented in WHC-SD-WM-CN-053.

Implications of Results. The radiological dose consequence values shown in Table 5.3.2.8-3 are within the risk guidelines, therefore, no safety structures, systems, and components or Technical Safety Requirements are required. However, controls that provide Defense-in-Depth are shown in Table 5.3.2.8-4.

5.3.2.8.2 Accident Scenario Assuming Controls. Because the analyzed accident scenario assuming no controls resulted in radiological dose and toxicological exposure consequences that were below the risk guidelines, no accident scenario assuming controls was developed.

5.3.2.8.3 Key Accident Scenario Assumptions.

Important to Accident Frequency. No assumptions related to the facility design or operation have been made in the analysis that are important in relation to the accident frequency.

Important to Accident Consequences. The following assumption is important to the calculation of accident consequences:

- For the isotopes important to dose in the contaminated crib soil, the radiological concentration per cubic meter is bounded by the values shown in Table 5.3.2.8-1.

5.3.2.8.4 Controls.

Safety Structures, Systems, and Components. No safety structures, systems, and components are required.

Technical Safety Requirement Controls. No Technical Safety Requirement controls are required.

Defense-in-Depth. Controls that provide Defense-in-Depth are shown in Table 5.3.2.8-4.

5.3.2.9 Caustic Spray Leak.

Purpose of Analysis: Sodium hydroxide is used to adjust the concentration of hydroxide (OH^-) ions in the waste tank contents to minimize corrosion. A pressurized spray leak of caustic solution during a transfer to a waste tank could disperse a significant amount of respirable sodium hydroxide particles. These particles could cause potentially significant onsite consequences. Therefore, this analysis will (1) estimate the maximum NaOH air concentrations at the onsite and Site boundary receptor locations and (2) assess the resultant safety implications.

Analysis Strategy: This analysis bounds the consequences associated with the bulk storage of cold chemicals at the tank farm facilities. Bounding is accomplished by estimating the maximum consequences to onsite 100 m (328 ft) and Site boundary receptors from inhalation of NaOH as a corrosive/irritant aerosol. No radioactive materials are associated with this event.

5.3.2.9.1 Accident Scenario Assuming No Controls.

Sequence of Events. Sodium hydroxide is either (1) procured from an offsite vendor and transported in 15,140-L (4,000-gal) tanker trucks to the tank farms or (2) mixed on Site. The caustic solution may be as strong as 19 M (50 wt%). The solution may be transferred into a given tank by a mixer pump or directly through an available riser.

The initiating event is assumed to be a crack in a circumferential weld at a flange or fitting in the transfer piping. The crack width is assumed to produce the maximum respirable release rate with a maximum length equal to one pipe diameter (inside). The release continues until an operator stops the transfer and depressurizes the system.

The lightest piping suitable for transferring NaOH solution is 1-in. Schedule 10 commercial steel pipe with a wall thickness of 2.77 mm (0.109 in.). The largest pipe or hose considered is 51-mm (2-in.) cross-linked polyethylene hose with a wall thickness of 10 mm (25/64 in.). The maximum pressure the system can be subjected to is 862 kPa (125 psig). The highest temperature at which the tank truck is loaded is 49 °C (120 °F). It is assumed that the concentration of the solution could range from 5 to 50% NaOH. The postulated maximum release rate corresponds to a crack with a minimum depth equal to the lightest (Schedule 10) pipe wall thickness of 2.77 mm (0.109 in.) and a maximum length equal to one pipe diameter, i.e., 25 mm (1 in.). The width of the crack was optimized to produce the highest respirable particle fraction using the SPRAY Code (WHC-SD-GN-SWD-20007, *A Model for Predicting Respirable Releases from Pressurized Leaks*).

Particles less than about 10 μm tend to remain suspended in the air for long distances, whereas particles larger than 10 μm released from a non-elevated source tend to fall out within the first 50 to 100 m (164 to 328 ft) of travel. The size of the liquid particles will decrease in transit by evaporation of the liquid component. Ultimately, only a smaller particle of the solid material previously in liquid solution will remain. Therefore, the small particle fraction of the spray release, a function of solution

concentration and crack width, was determined by using the initial diameter of a solution particle (with the given solid fraction) that will shrink to 10 μm by evaporation. The leak rate and atomization efficiency increases with decreasing viscosity, and hence with increasing temperature. Therefore, the high end of the temperature range for this liquid (50 °C [122 °F]) was assumed.

A parametric study was performed using the SPRAY Code to determine the worst-case solution concentration within the expected range of 5 to 50% NaOH. The worst-case small particle release rate was calculated over a range of NaOH concentrations. These calculations accounted for variation in viscosity and density with concentration. Results of the calculations indicated that a 12% solution was optimal regarding small particle generation. For this case, the unevaporated particle size range was less than or equal to 20.3 μm and the respirable NaOH release rate was 1.68 g/s. Standard roughness and flow parameters for steel pipe were assumed. For the cases where critical flow developed in the crack, friction factors for laminar flow were assumed for conservatism.

The caustic spray leak scenario has been assigned a frequency of occurrence in the "anticipated" range (10^{-2} to 10^{0}/yr). This frequency category was assigned because only a single failure (e.g., crack in pipe, weld failure, loose piping connection) is required for the event to occur. The associated risk guidelines for onsite and Site boundary receptors are Emergency Response Planning Guideline (ERPG)-1 and permissible exposure limit-time-weighted average, respectively. Both criteria are 2 mg/m^3 for NaOH (WHC-SD-WM-SARR-011, *Toxic Chemical Considerations for Tank Farm Releases*).

Results Summary. The onsite and Site boundary air concentrations of small particle NaOH are shown in Table 5.3.2.9-1. The associated calculations are contained in WHC-SD-WM-CN-065, *Consequence Analysis of a NaOH Solution Spray Release During Addition to Waste Tank*.

Implications of Results. The sum-of-fractions at the Site boundary is far less than the toxicological risk criterion of 1. The criterion is exceeded at the onsite receptor location. Technical Safety Requirement controls are required to protect the onsite receptor.

5.3.2.9.2 Accident Scenario Assuming Controls. Since the liquid being transferred is relatively cool (< 50 °C) and is at relatively low pressure ($\leq$ 125 psig), standard 4 mil polyethylene (or similar material) sleeving or wrap was determined to have ample strength to contain the spray. The sleeving/wrap would not be expected to be pressure tight, however, and the solution would still leak out, producing a minor local cleanup problem, but there would be no significant aerosol release. The aerosol release rate for the mitigated spray was estimated by calculating how much mist generated inside the plastic sleeving could be displaced out of the sleeving by the solution leaking out of the pipe. The maximum total solution leak rate, which occurs at a solution concentration of 50%, and a maximum transient air loading of 1 g/m^3, would force 7.18 x 10^{-5} g/s of solution or 3.59 x 10^{-2} mg/s of NaOH, out of the sleeving in the form of a respirable aerosol. The resulting

receptor concentrations were found to be 1.22 x 10^{-3} mg/m^3 and 1.02 x 10^{-6} mg/m^3 for the onsite and Site boundary receptors, respectively. Both concentrations are negligible compared to the risk guidelines of 2 mg/m^3 for both receptors. Refer to WHC-SD-WM-CN-065 for calculations.

5.3.2.9.3 Key Accident Scenario Assumptions.

Important to Accident Frequency. No key assumptions are associated with the accident frequency.

Important to Accident Consequence. The following assumptions are important to the accident consequences.

- These results are for standard Schedule 10 steel pipe. Use of a thinner wall pipe such as Schedule 5 (wall thickness 1.65 mm, or 0.065 in.) would increase the maximum receptor concentrations and sum-of-fractions by about 30% because of the smaller crack depth and decreased friction losses.
- System pressure was assumed to be limited to 862 kPa (125 psi).

5.3.2.9.4 Controls.

Safety Structures, Systems, and Components. No safety structures, systems, and components are required.

Technical Safety Requirement Controls. The Technical Safety Requirement controls selected for caustic spray leaks are listed in Table 5.3.2.9-2. For each control, the safety function is described and additional comments are provided as appropriate.

Defense-in-Depth. Defense-in-Depth controls for the caustic spray leak accident analysis are provided in Table 5.3.2.9-3.

5.3.2.10 Sodium Fire.

Purpose of Analysis: The 2727-W Sodium Storage Facility is a pre-engineered steel building that contains five horizontally mounted stainless steel tanks that are filled with solid sodium. Two of the tanks are full, one is half full, and the remaining two contain only residual heels (Teynor 1995, *Request for Relief of Department of Transportation (DOT) Regulations for Shipment of the HALLAM Sodium Tanks*). WHC-SD-WM-TI-759, *Hazard Evaluations for the TWRS Final Safety Analysis Report*, documents findings of the hazard analysis for the 2727-W facility. The 2727-W facility hazard analysis identified several possible scenarios for release of NaOH. Based on the current facility design, it was found that the only credible scenario was a high wind initiated building collapse leading to failure of one tank and subsequent sodium fire. The purpose of this analysis is to estimate the maximum NaOH release rate and resulting toxicological consequences which could be produced by such a scenario. The sodium is also slightly contaminated with ^{22}Na. A determination is therefore also required as to whether release of the ^{22}Na contamination could produce significant consequences.

Analysis Strategy: The analysis is designed to produce a bounding estimate for all of the release scenarios discussed in the facility hazard analysis. The radiological source term evaluation is nonmechanistic in that it assumes the release of the entire facility inventory of ^{22}Na in order to conclusively show that the amount of ^{22}Na present in the sodium is below the level of concern.

5.3.2.10.1 Accident Scenario Assuming No Controls.

Sequence of Events. The initiating event is assumed to be a high wind that causes major damage to the 2727-W building. The building is rated for a 958 Pa (20 lb/ft^2) wind load (WHC-SD-WM-TI-759), which translates to a 113 km/h (70 mph) fastest mile wind speed (ANSI A58.1, *American National Standard - Minimum Design Loads for Buildings and Other Structures*). The 113 km/h (70 mph) fastest mile wind speed has a frequency of exceedance of approximately 2 x 10^{-3}/yr in the 200 East and 200 West Areas (UCRL-53526, *National Phenomena Hazards Modelling Project: Extreme Wind/Tornado Models for Department of Energy Sites*).

Falling building material is assumed to break off a large pipe connection into a tank in such a way that the resultant tank opening faces skyward. After tank damage, the wind is assumed to decrease to a low speed and heavy rain is assumed to begin. The building roof is assumed to have failed in such a way that rain is channeled into the tank opening.

The rain that channels into the open tank (from which the nitrogen cover gas has escaped) causes a vigorous sodium-water reaction that generates large amounts of hydrogen and heat. The hydrogen is assumed to ignite and cause an explosion that further damages and opens the upper half of the tank. The explosion results in a sodium fire that covers the entire upper surface of the sodium in the tank. This scenario is assumed to occur in the half-full tank in order to maximize the exposed sodium area in the tank. Not enough energy is expected to be available to damage the other tanks.

The rain is then assumed to stop and the wind speed to remain low in order to minimize washout of releases and maximize downwind exposures to the sodium combustion product release which is assumed to be converted entirely to NaOH in the moist air.

Given the major building damage from the high wind, the remainder of the scenario leading to the limiting sodium fire is very conservatively estimated to have a probability of 1%. This implies an overall frequency of approximately 2.0×10^{-5}/yr, making this postulated accident well within the "extremely unlikely" category guidelines (Table 5.3.2.10-1).

Results Summary. The postulated maximum release rate for the sodium fire scenario is calculated for a pool fire with a size equal to the maximum internal tank dimensions (i.e., 3.7 m [12 ft] diameter by 6.1 m [20 ft] effective length, or 22.3 m^2 [240 ft^2]). The resulting maximum NaOH release rate is 147 g/s, which causes a very high particulate concentration. (WHC-SD-WM-CN-045, *Consequence Analysis of a Postulated NaOH Release from the 2727-W Sodium Storage Facility.*)

The largest particulate concentration that can typically be supported in the air at a point away from the source is approximately 100 mg/m^3. Data from actual open sodium fires of approximately the same size as the one postulated in the Tank Waste Remediation System analysis indicates that, because of rapid agglomeration and fallout of the combustion particles in the first 50 to 100 m (164 to 328 ft), the air concentration at 100 m (328 ft) downwind is actually much lower than 100 mg/m^3 (less than about 20 mg/m^3 [WHC-SD-WM-CN-045]). Because the effects of short-range fallout cannot be quantified, 100 mg/m^3 is typically conservatively assumed at a distance of at least 100 m (328 ft) downwind of a heavy particulate source (ANSI N46.1, *American National Standard - Guidance for Defining Safety-Related Features of Nuclear Fuel Cycle Facilities*). The concentration at the Site boundary is 0.083 mg/m^3.

For an accident categorized as "extremely unlikely," the onsite receptor toxic limit is ERPG-3. Sodium hydroxide, classified as a corrosive/irritant, has an ERPG-3 onsite toxic limit of 100 mg/m^3 (WHC-SD-WM-SARR-011, *Toxic Chemical Considerations for Tank Farm Releases*). Likewise, for an "extremely unlikely" accident the site boundary receptor toxic limit is ERPG-2 which is 40 mg/m^3 for NaOH.

The total, current 2727-W facility ^{22}Na inventory is estimated to be approximately 0.005 Ci (1.85×10^8 Bq) (WHC-SD-WM-TI-759). The release of the entire facility inventory of ^{22}Na would produce an inhalation dose of 4.3×10^{-3} mSv (4.3×10^{-4} rem) to the onsite receptor at 100 m (328 ft) and 3.6×10^{-6} mSv (3.6×10^{-7} rem) to the Site boundary receptor at 10.9 km (6.8 mi) on the near bank of the Columbia River. Both doses are negligible.

Implications of Results. No onsite or Site boundary risk guidelines are exceeded. However, a control is necessary to protect building design features credited in the analyses.

5.3.2.10.2 Accident Scenario Assuming Controls. Because the sodium fire scenario assuming no controls resulted in toxicological exposure consequences that were below the risk guidelines, no accident scenarios assuming controls were developed.

5.3.2.10.3 Key Accident Scenario Assumptions.

Important to Accident Frequency. The building is assumed to fail because of the effects (including gusts) of a 113 km/h (70 mph) fastest mile wind with a frequency of 2.0×10^{-3}/yr.

Important to Accident Consequence. The trace heaters installed on the sodium storage tanks are not operational.

5.3.2.10.4 Controls. The following controls are applicable to the 2727-W Sodium Storage Facility.

Safety Structures, Systems, and Components. The facility structure has been designated as a Safety-Significant structure, system, and component (Table 5.3.2.10-2). This control ensures that the building will not fail unless the fastest mile wind speed reaches 113 km/h (70 mph).

Technical Safety Requirement Controls. No safety structures, systems, and components are required for this accident scenario. The facility structure is a nonnuclear TSR design feature (toxicological only consequences).

Defense-in-Depth. The Defense-in-Depth controls required for the sodium fire scenario are listed in Table 5.3.2.10-3.

5.3.2.11 Mixing of Incompatible Material - Toxic Vapor Generation.

Purpose of Analysis: The hazard analysis performed for mixing of incompatible material resulting in generation of a toxic vapor identified a rapid, uncontrolled addition of incompatible material that could lead to a release of toxic vapors. The accident scenario assumes a rapid uncontrolled addition of a caustic (sodium hydroxide) to liquid waste of low pH, resulting in the release of ammonia as the result of the solution becoming more basic.

Analysis Strategy: This analysis examines the addition of caustic to a double-contained receiver tank (DCRT). Such an analysis is appropriate for the following reasons.

1. Liquids pumped from the SST system tend to have low pH solutions and require addition of caustic. This addition occurs in a DCRT.

2. Additions of the same amount of caustic will have a greater impact on the concentration in the DCRT than in an SST or a DST because the DCRT has a much smaller volume.

5.3.2.11.1 Accident Scenario Assuming No Controls.

Sequence of Events. For corrosion control purposes, DCRT contents must remain above the hydroxide concentration of 0.01 M. If the hydroxide concentration falls below 0.01 M, caustic may be added to bring the concentration within the corrosion controls.

Consistent with current operational practices, it is assumed that DST wastes are not transferred to DCRTs.

The solubility of ammonia which is contained in the waste is sensitive to the pH level. For this analysis, the maximum concentration of ammonia in liquid waste is 0.51 g/L (WHC-SD-WM-SARR-011, *Toxic Chemical Considerations for Tank Farm Releases*). An increase in pH will lead to a reduction in ammonia solubility and release from the waste. This scenario assumes an addition of NaOH to a DCRT containing low pH waste which leads to a change in the ammonia solubility and its release to the environment. This scenario applies to DCRTs, DSTs, and SSTs.

This accident has been qualitatively assigned a frequency of anticipated as caustic additions to DCRTs is a planned operation.

Results Summary. There are no onsite or offsite radiological consequences. The estimated peak ammonia concentration is 1.6 mg/m^3 onsite, and 0.0013 mg/m^3 offsite. The supporting calculations are documented in WHC-SD-WM-CN-074, *Chemical Reaction in a DCRT Leading to a Toxic Release*.

Implications of Results. The onsite and offsite ammonia concentrations are below the risk guidelines for an anticipated event (i.e., an ERPG-1/PEL-TWA of 17 mg/m^3 [WHC-SD-WM-SARR-011]). Accordingly, no safety structures, systems, and components or Technical Safety Requirement controls are required.

5.3.2.11.2 Accident Scenario Assuming Controls. Because the consequences of the accident scenario assuming no controls are well below the risk guidelines, no additional analysis is required.

5.3.2.11.3 Key Accident Scenario Assumptions. Key assumptions related to the derivation of the accident frequency and calculation of the accident consequences as documented in WHC-SD-WM-CN-074 are as follows.

Important to Accident Frequency. No assumptions have been made in the analysis that are important in relation to the accident frequency.

Important to Accident Consequences. The maximum concentration of ammonia in liquid is 0.51 g/L. Note that the concentration could be as high as 5.3 g/L before the risk guidelines are exceeded.

5.3.2.11.4 Controls.

Representative Accident Scenario

- **Safety Structures, Systems, and Components**—There are no safety structures, systems, and components for this accident.
- **Technical Safety Requirement Controls**—There are no Technical Safety Requirement controls.
- **Defense-in-Depth**—Table 5.3.2.11-1 shows the Defense-in-Depth control for this accident.

5.3.2.12 Mixing of Incompatible Material - Tank Pressurization.

Purpose of Analysis: A mistransfer of incompatible waste to a double-contained receiver tank (DCRT) was identified in the Tank Waste Remediation System facilities hazard analysis as an initiating event for a hazardous material release. This scenario is applicable to DCRTs 244-A, 244-S, and 244-TX. In the analysis, the mistransfer leads to a chemical reaction and subsequent release of radioactive and toxic aerosols to the environment.

Analysis Strategy: The addition of large quantities of acid or acidic waste to a basic waste tank solution has been identified as the bounding case for mixing of incompatible waste. A 416 L (110-gal) transfer of 57 wt% nitric acid would bound the transfer from any single source.

5.3.2.12.1 Accident Scenario Assuming No Controls.

Sequence of Events. The initiating event for the mixing of incompatible material and subsequent tank pressurization scenario assuming that no controls are in place is a postulated mistransfer of 416 L (110 gal) of 57 wt% nitric acid into a DCRT. The receiving DCRT is assumed to contain waste that is sufficiently basic to completely neutralize the incoming acid. This ensures that the maximum heat of reaction per mole of incoming acid is generated and maximizes the heating of waste. Heating of the waste causes vaporization and, consequently, a pressurized buildup of aerosols in the tank headspace. No credit is taken for high-efficiency particulate air (HEPA) filtration such that the aerosols are released directly to the atmosphere.

This accident has been qualitatively assigned a frequency of "anticipated" based on the operational history of mistransfers in Tank Waste Remediation System facilities.

Results Summary. The onsite and offsite radiological and toxicological consequences of incompatible waste tank pressurization with no controls are listed in Table 5.3.2.12-1. The associated calculations for those consequences are documented in WHC-SD-WM-CN-073, *Chemical Reaction in a DCRT*.

Implications of Results. The offsite radiological and toxicological consequences are below the risk guidelines, but the onsite consequences are above the guidelines. Controls are therefore required.

5.3.2.12.2 Accident Scenario Assuming Controls.

Sequence of Events. The control selected to mitigate the consequences of a mistransfer is the presence of HEPA filters on the DCRT ventilation system. The sequence of events leading to the accident is the same as in Section 5.3.2.12.1, "Accident Scenario Assuming No Controls." The release to the environment is reduced by the HEPA filters, with assumed 99.95% efficiency.

Results Summary. The onsite and offsite radiological and toxicological consequences for the scenario assuming controls are presented in Table 5.3.2.12-2. The supporting calculations are documented in WHC-SD-WM-CN-073.

Implications of Results. The onsite consequences of the incompatible waste and resulting tank pressurization with HEPA filters assumed in place are below the risk guidelines.

5.3.2.12.3 Key Accident Scenario Assumptions. Key assumptions related to the derivation of the accident frequency and calculation of the accident consequences are presented below.

Important to Accident Frequency. No assumptions have been made in the analysis that are important in relation to the accident frequency.

Important to Accident Consequences. The following assumptions are important to the determination of accident consequences.

- Acidic waste is 57 wt% nitric acid (12 M).
- Maximum potential acid waste transfer is 416 L (110 gal).
- DCRT waste temperature is 93 °C (200 °F).
- HEPA filters are 99.95% efficient.
- DCRT waste volume is assumed to be two-thirds double-shell tank liquid and one-third double-shell tank solids and this mixture is assumed to bound transfers of both double-shell and single-shell tank wastes.
- The hydroxide content is taken to be at the maximum allowed under DCRT corrosion control limits (10 M OH^-).

5.3.2.12.4 Controls.

Safety Structures, Systems, and Components. HEPA filters are Safety-Significant structures, systems, and components for this incompatible waste accident (Table 5.3.2.12-4).

Technical Safety Requirement Controls. As shown in Table 5.3.2.12-3, there are Technical Safety Requirement controls on the DCRT HEPA filters.

Defense-in-Depth. The Defense-in-Depth controls required for the mixing of incompatible waste-tank pressurization scenario are listed in Table 5.3.2.12-5.

5.3.2.12.5 References.

TWA = time-weighted average.

Table 5.3.2.12-3. Technical Safety Requirement Controls for Mixing of Incompatible Materials—Tank Pressurization.

Control	Safety function	Comments
Transfer controls • Compatibility evaluation to ensure chemical additions are pH ≥ 8 before transfer into tank farm (excluding water and caustic additions transfers)	Prevent heat generation due to acid/base reactions	Control for pH ≥ 8 was selected to meet criticality requirements.
HEPA Filter Control Program • Aerosol test upon installation • Periodic aerosol test	Ensures filtering efficiency of HEPA filter	None

HEPA = high-efficiency particulate air (filter).

Table 5.3.2.12-4. Safety Structures, Systems, and Components for Mixing of Incompatible Materials—Tank Pressurization.

Structures, systems, or components	Safety classification	Safety function	Comments
One stage of HEPA filtration	Safety-Significant	Provide filtration of DCRT headspace gases prior to release	None

DCRT = double-contained receiver tank.
HEPA = high-efficiency particulate air (filter).

Table 5.3.2.12-5. Defense-in-Depth Controls for Mixing of Incompatible Waste—Tank Pressurization.

Control	Function
Tank Farm Waste Compatibility Program	Ensures that waste transfers are compatible with regard to criticality, flammable gas generation, heating, organics, and other safety and operational concerns
Waste transfer procedural controls	Ensures correct routing lineup
Neutralization of all acid waste transfers prior to shipment to DCRT	Ensures that no acidic waste is transferred to DCRT. Corrosion control and energetic reaction prevention

DCRT = double-contained receiver tank.

5.3.2.13 Tank Failure Due to Excessive Loads.

Purpose of Analysis: Postulated tank failure accidents are addressed in this section. Tank failure accidents include dome failure; dome settling (wall failure); and dome, wall, or bottom perforation. Double-shell tanks (DSTs), single-shell tanks (SSTs), double-contained receiver tanks (DCRTs), catch tanks, 200 Series tanks, and miscellaneous interim storage facilities are covered in this section. Tank failure is a safety concern because of the release of radioactive waste to the environment through openings in the walls, bottom, or dome of a tank.

Analysis Strategy: The following accidents were identified in the hazard analysis as those that could lead to structural failure.

- Excessive pressurization of tank dome and walls caused by flammable gas explosion, organic fires, and exothermic reactions
- Seismic forces
- Load drop or structure toppling onto soil above the tank, onto a riser, or into a pump pit
- Excessive external uniform load (e.g., excess soil cover) or concentrated load (e.g., large vehicle on the tank) over the dome
- Aging of the tank structure due to thermal cycling, corrosion, and level cycling
- Excessive vacuum caused by (1) failures in the ventilation system with continued exhaust operation, (2) cooldown after certain accidents (e.g., fire), or (3) cooling of the atmosphere or waste due to the addition of water
- Excessive internal forces due to the storage of waste such as those due to waste level, waste density, or waste temperature
- Water or waste addition to the annulus of a DST that results in uplift of the primary tank
- High concrete temperatures due to loss of cooling as a result of ventilation failure, heat load in excess of design conditions, or thermal characteristics that result in "hot spots"
- Accelerated wall or rebar corrosion or degradation as the result of corrosive chemicals added to the tank.

The postulated tank failure mechanisms that produce the worst consequences are excessive pressurization of the dome and seismic forces. Dome collapse caused by internal pressurization (e.g., H_2 deflagration, organic/nitrate reaction, organic solvent or gasoline fire) and seismic forces are discussed in other sections. The accidents second in potential severity are a load drop event and hazards that resulted in excessive uniform or concentrated load.

No credible scenario was identified that would result in dome collapse resulting from excessive uniform load because the loads required for failure are not attainable with current equipment or tank farm configurations. At present, the largest uniform load is 4,900 to 9,800 kg/m^2 (1,000 to 2,000 lb/ft^2) given a soil density of 2,080 kg/m^3 (130 lb/ft^3) and depth of 2.1 to 4.6 m (7 to 15 ft). (Note that 4.6 m [15 ft] is the dome soil cover near the wall of tanks with 2.4 m [8 ft] of soil cover over the central dome region.) As discussed in WHC-SD-TWR-RPT-002, *Structural Integrity and Potential Failure Modes of the Hanford High-Level Waste Tanks*, dome failure for SSTs and DSTs would require an additional 5.2 m (17 ft) of soil cover. Dome collapse from excessive load was therefore considered to be incredible.

Dome failure is possible due to a concentrated load of 2.8 x 10^5 to 5.4 x 10^5 kg (300 to 600 tons) per WHC-SD-TWR-RPT-002. At present the largest concentrated load weighs less than 2.3 x 10^5 kg (250 tons). This is the crane that was used to lower the mixer pump into Tank 241-SY-101. However, combining a load of this magnitude with several smaller concentrated loads does result in a total concentrated load approaching the limit.

Tank failure due to a load drop event was analyzed. It bounds failures involving excessive vacuum, aging and corrosion, internal loads, waste or waste addition to a DST annulus, high waste temperature (e.g., 241-C-106), high concrete temperatures resulting from loss of cooling, and accelerated wall corrosion and degradation. Calculations show that even if a tank were to fail from these causes, no airborne release would result as the walls fail but the dome remains intact. Load drops, however, can fail the dome with an associated potential airborne release.

The accidents covered in this section are as follows:

- Load drops onto SSTs, DST, DCRTs, and 20-ft-dia SSTs
- Excess concentrated loads on SSTs, DST, 20-ft-dia SSTs, and DCRTs.

Of these accidents, the largest consequences occur as a result of a load drop onto dry salt cake. This can only occur within an SST or DST. The DCRTs contain liquid or sludges. The 20-ft-dia SSTs can contain dry salt cake but the waste level is closer to grade. Failure due to uniform or concentrated load results in less of a consequence due to the ability of the soil to trap the fractured waste.

The load drop can occur onto the soil cover over the tank, onto the pits over the tank (primarily the pump pit), or onto a riser. The worst case is a load drop into the pump pit. The pump pit is chosen because of all the possible drop locations that could result in the load reaching the tank waste, this is structurally the weakest.

It is assumed that a mixer pump is dropped into the pump pit of a DST. A DST is chosen because these are the only tanks likely to contain mixer pumps. Some cover blocks are heavier than mixer pumps but the drop height necessary to break the dome from a cover-block drop is at least

10 times greater because of the larger associated impact area (WHC-SD-WM-TI-782, *Load Drop Evaluation for TWRS FSAR*). Therefore, the worst case is the drop of a mixer pump into a DST.

5.3.2.13.1 Accident Scenario Assuming No Controls.

Sequence of Events. For the load drop scenario assuming no controls, it is postulated that a 9,100 kg (20,000 lb) mixer pump is scheduled for tank insertion. The pump is attached to the crane, righted, and lifted. An operator error (or possibly equipment failure) is assumed to occur such that the pump is lifted high over the tank. (The pump might also be lifted high to clear an obstruction.) When the pump is over the pump pit, the sling breaks, or the pump is lifted even higher and the hook becomes dislodged as it hits the boom, or some other failure occurs that results in a pump drop. The pump drops from a height of 25 m (82 ft) onto the waste. The distances considered in setting the load drop height are as follows:

- 7.0 m (23 ft) from the waste to the dome
- 2.5 m (8.2 ft) from the dome to grade
- 15.5 m (51.0 ft) from grade to the pump bottom
- 17.1 m (56.0 ft) from the bottom of the pump to the top.

The total boom height is 42 m (137.7 ft). This is approximately the height of the boom when the Tank 241-SY-101 mixer pump was lowered into the tank. The drop height coupled with the pump weight results in an impact energy imparted to the pump pit floor of 1.8×10^6 J (1.3×10^6 ft-lb), which exceeds the dome capacity of 6.8×10^5 J (5.0×10^5 ft-lb) (WHC-SD-WM-TI-782). Calculations show that the drop of a mixer pump more than 7.6 m (25 ft) into a pump pit results in a breach of the dome.

The accident frequency assigned to this event is "unlikely" on the basis of consideration of historical data compiled from Occupational Safety and Health Administration records and data from the U.S. Navy (NUREG-0612, *Control of Heavy Loads at Nuclear Power Plants*) on the frequency of load drops.

Results Summary. The onsite and offsite radiological and toxicological consequences of a dropped load that results in tank structural failure are presented in Table 5.3.2.13-1. The supporting calculations are documented in WHC-SD-WM-CN-051, *The Effects of Load Drop, Uniform Load, and Concentrated Loads on Waste Tanks.*

Implication of Results. The onsite and offsite radiological consequences for the scenario assuming no controls are below the risk guidelines, as are the offsite toxicological consequences. The calculated onsite dose consequences for toxicological materials are above the risk guidelines. Consequently, additional controls are required to protect the onsite worker from the consequences of this scenario.

5.3.2.13.2 Accident Scenario Assuming Controls. The controls selected for the load drop scenario are preventive in nature and are presented in Section 5.2.3.13.4, "Controls." These controls prevent a load drop or a tank dome excessive load from causing a tank breach. Consequently, a scenario assuming controls was not developed.

5.3.2.13.3 Key Accident Scenario Assumptions.

Important to Accident Frequency. The accident frequency determination was set on the basis of the predicted number of load drops involving mixer pumps in the proximity of pump pits and tank domes. The Navy data used predicts load drops to occur at a frequency of 3×10^{-4} to 2.5×10^{-5} per lift. Only one or two mixer pump installations or removals are expected at the tank farms each year. The number of mixer pump installations or removals would have to increase significantly before the frequency category would be affected.

Important to Accident Consequences.

- The radiological and toxicological composition of the waste in the load drop scenario is that of DST solids. The waste is dry salt cake. These assumptions result in conservative dose estimates.
- The dose is related to drop height (WHC-SD-WM-CN-051). Calculations show that the drop of a mixer pump more than 7.6 m (25 ft) into a pump pit results in a breach of the dome.
- The dose is also related to the weight dropped (WHC-SD-WM-CN-051). The weight assumed for a load drop event was 9,100 kg (20,000 lb).

5.3.2.13.4 Controls. The following controls are applicable to SSTs, DSTs, aging waste facility tanks, DCRTs, catch tanks, and miscellaneous interim storage facilities as specified in the following tables.

Safety Structure, Systems, and Components. No equipment was identified as necessary to prevent or mitigate the consequences of this accident. Therefore, no equipment was identified as Safety-Class or Safety-Significant.

Technical Safety Requirement Controls. The Technical Safety Requirement controls selected to prevent load drops are identified in Table 5.3.2.13-2. For each Technical Safety Requirement control, the safety function is described and additional comments are provided as appropriate.

The maximum load lift height is set at 20 ft to account for any uncertainties in the load drop calculation (WHC-SD-WM-TI-782) and to be conservative. The other limits contained in Table 5.3.2.13-2 come from calculations performed in WHC-SD-WM-TI-775, *Structural Assessment of Accident Loads*, and WHC-SD-WM-RPT-002.

Defense-in-Depth. In addition to the previously identified Technical Safety Requirement controls, other engineering and administrative controls provide further Defense-in-Depth protection for the public and workers against the risk of load drops. The Defense-in-Depth controls along with their safety function and additional comments are identified in Table 5.3.2.13-3.

Table 5.3.2.13-2. Technical Safety Requirement Controls for Load Drops. (2 sheets)

Control	Safety function	Comments
1.0 SSTs (except 200 Series tanks), DSTs, and AWF tanks		
1.1 Tank Load Control Program Key elements: 1. For critical lifts over SSTs and DSTs: • Hanford Site Hoisting and Rigging Manual (DOE 1993) requirements shall be met • Height of load bottom shall not exceed 6.1 m (20 ft) over the soil or pit floor 2. External load on the tank dome: • SST uniform load shall not be modified • DST uniform loads shall be below 8.3 ft of soil (AY and AZ tank farms, and 7.5 ft of soil (SY, AW, AN, AP tank farms) • 100 Series SST and DST concentrated load shall not exceed 100 tons on a temporary or permanent basis	 Prevents load drop accidents (i.e., reduces the frequency of load drops) Limits load handling over a tank so that in the event the load is dropped the tank dome would not collapse Prevents exceeding external loads that may cause tank dome failure	Critical lifts are defined in the Hanford Site Hoisting and Rigging Manual (DOE 1993) The cover blocks offer little resistance to load drops due to their failure at low bending moments and are not considered in determining compliance with the 20 ft limit. The 20 ft limit considers the largest mixer pump (20,000 lbs) and cover blocks as the limiting loads
2.0 200 Series SSTs		
2.1 Tank Load Control Program Key elements: 1. For critical lifts over the 200 Series SSTs, Hanford Site Hoisting and Rigging Manual (DOE 1993) requirements shall be met 2. External load on the tank dome: • 200 Series uniform loads shall not be modified • 200 Series concentrated load shall not exceed 50 tons on a temporary or permanent basis	 Prevents load drop accidents (i.e., reduces the frequency of load drops) Prevents exceeding 200 Series external tank loads that may cause tank dome failure	Critical lifts are defined in the Hanford Site Hoisting and Rigging Manual (DOE 1993) Compliance with the Hanford Site Hoisting and Rigging Manual (DOE 1993) is sufficient based on the accident risk (i.e., frequency and consequence) 200 Series SST uniform load restrictions are not required because of the large existing margin of safety
3.0 Double Contained Receiver Tanks (DCRTs)		
3.1 Tank Load Control Program Key elements: 1. For critical lifts over the DCRTs, Hanford Site Hoisting and Rigging Manual (DOE 1993) requirements shall be met 2. External load on the tank dome: • Additional DCRT concentrated load shall be prohibited	 Prevents load drop accidents (i.e., reduces the frequency of load drops) Prevents exceeding DCRT external loads that may cause tank failure	Critical lifts are defined in the Hanford Site Hoisting and Rigging Manual (DOE 1993) Compliance with the Hanford Site Hoisting and Rigging Manual (DOE 1993) is sufficient based on the accident risk (i.e., frequency and consequence) DCRT uniform load restrictions are not required because DCRTs are located in vaults whose cover blocks are aboveground

Table 5.3.2.13-2. Technical Safety Requirement Controls for Load Drops. (2 sheets)

Control	Safety function	Comments
4.0 Catch Tanks		
4.1 Tank Load Control Program Key elements: 1. External load on the tank dome: • Catch tank uniform load shall not be modified • Additional catch tank concentrated load shall be prohibited	Prevent load drop accidents over catch tanks and prevent exceeding catch tank external loads that may cause tank dome failure	The requirements of this control are based on existing analysis that shows several catch tanks have soil loads that exceed code allowables To implement this control, barriers (fences) are required to identify and restrict access in the vicinity of catch tanks
5.0 MISFs		
5.1 Tank Load Control Program Key elements: 1. Critical lifts shall not be performed over MISFs 2. External load on the tank dome: • MISF uniform load shall not be modified • Additional MISF concentrated load shall be prohibited	Prevent load drop accidents over MISFs and prevent exceeding MISF external tank loads that may cause tank dome failure	Critical lifts are defined in the Hanford Site Hoisting and Rigging Manual (DOE 1993) The requirements in this TSR are based on the absence of structural analysis on the MISFs To implement this TSR, barriers (fences) are required to identify and restrict access in the vicinity of MISFs

AWF = Aging Waste Facility.
DCRT = double-contained receiver tanks.
DST = double-shell tank.
MISF = miscellaneous inactive storage facility.
SST = single-shell tank.
TSR = Technical Safety Requirement.

Table 5.3.2.13-3. Defense-in-Depth Controls for Load Drops.

Control	Safety function	Comments
A Radiation Protection Program shall be established and implemented consistent with applicable procedures	Provides radiological controls to protect onsite and facility workers	None
A facility Health and Safety Plan shall be established and implemented consistent with applicable procedures	Provides for worker protection by restricting activities in high winds	None
A Job Control System shall be established and implemented consistent with applicable procedures	Provides assurance that work activities including appropriate controls are planned and approved. This includes requirements to place load absorber material around the riser when very heavy loads are installed	None
Operator Training is required prior to performance of activities affecting safety	Provides assurance that operation of facilities are by Hanford Site experienced crews with specific training in these activities	None
Operating procedures shall be established and implemented for activities affecting safety	Provides assurance that operations are performed to approved plant procedures	None
Emergency Response Plan/Procedures shall be established and implemented consistent with applicable procedures	Provides assurance that plans and procedures are in place to respond to emergency conditions	None
Establish criteria and document tank loadings for concentrated and distributed load limits and incremental load changes	Provides controls to maintain dome loads within structural capacity of the tanks	None

5.3.2.14 Flammable Gas Deflagrations.

Purpose of Analysis: This section discusses the hazards and controls associated with the generation, storage, release, and postulated combustion of flammable gases in Tank Waste Remediation System (TWRS) facilities and structures. This hazard poses an unreviewed safety question (USQ) originally identified in 1990 and applicable to a subset of the 177 TWRS underground waste storage tanks. The original USQ has been closed for Tank 241-SY-101, which was the facility originally identified to be of greatest concern, based on (1) analyses documented in LA-UR-92-3196, *A Safety Assessment for Proposed Pump Mixing Operations to Mitigate Episodic Gas Releases in Tank 241-SY-101: Hanford Site, Richland, Washington*, and (2) the installation and operation of a mixer pump that prevents the retention and spontaneous release of large amounts of waste-generated gases. The USQ remains open for the balance of affected TWRS facilities.

The original flammable gas USQ has been replaced by a new USQ determination (TF-96-0433) that reflects an increased understanding of the flammable gas hazard and an accumulation of related field observations and experience. The new USQ clarifies the applicability of the USQ to additional facilities and structures within TWRS and identifies a broader range of accidents and hazards not adequately addressed in the existing TWRS Authorization Basis. The new USQ consolidates all issues related to flammable gas hazards that have a common root cause. Specifically, the new USQ applies to any TWRS engineered structure, container, or receiver managed and operated at TWRS, and at which, Hanford Site high-level waste may be stored in a condition and for a period of time that could result in the generation, accumulation, or release of flammable gas. Per TF-96-0433, *Consolidation of Flammable Gas/Slurry Growth Unreviewed Safety Question Issues*, the Authorization Basis for Tank 241-SY-101 adequately addresses the flammable gas hazard; therefore, the new USQ does not apply to Tank 241-SY-101. The USQ applies to the following:

- Single-shell waste storage tanks
- Double-shell waste storage tanks (except Tank 241-SY-101)
- Aging waste facility storage tanks
- Double-contained receiver tanks (DCRTs)
- Inactive miscellaneous underground storage tanks
- Catch tanks
- 242-S and 242-T Evaporators
- 244-AR Lag Storage Vault Facility

- 244-CR Lag Storage Vault Facility
- Waste transfer systems (e.g., transfer lines, valve pits, diversion boxes, process pits, and clean-out boxes).

A justification for continued operation (JCO) Appendix E has been prepared in correspondence with the new USQ determination. The JCO discusses the flammable gas hazard in each of the facilities addressed by the USQ. In part, the discussion is based on observations and available data. A three-pronged approach to risk management that addresses ventilation, monitoring, and ignition control is also presented in the document. Detailed controls for managing the risk of the flammable gas hazard, and qualitative conclusions regarding the effectiveness of those controls, are provided in Appendix E.

This BIO is consistent with the basis for closure of the original flammable gas USQ for Tank 241-SY-101.

Analysis Strategy: Results of available analysis of flammable gas accident scenarios assuming no controls are presented in the following sections. The presentation of accident analysis results (assuming no controls) serves to illustrate the need for control strategies to manage the risk of flammable gas hazards in TWRS facilities and to emphasize the rigor at which controls need to be applied. The controls presented are consistent with those in Appendix E. The expected efficacy of these controls is based on the judgment documented in the JCO. The TWRS Final Safety Analysis Report will present details of accident scenario analyses with and without credit for hazard control strategies.

The existing Authorization Basis analyses for operations in Tank 241-SY-101 are documented in LA-UR-92-3196. The results of the Tank 241-SY-101 analyses are not repeated in this document.

5.3.2.14.1 Accident Scenario Assuming No Controls.

Sequence of Events. Nuclear waste stored within TWRS facilities is capable of generating flammable gas (i.e., principally hydrogen gas) to varying degrees depending on the type, amount, geometry, and condition of the waste in the array of TWRS waste receptacles. Radioactive waste generates hydrogen through the radiolysis of water, thermolytic decomposition of organic components, and corrosion of a tank's carbon steel walls. Radiolysis and thermolytic decomposition also generate ammonia. Non-flammable gases such as nitrogen, which act as diluents, are also produced. Additional flammable gases, such as methane and an oxidizer, nitrous oxide, are generated by chemical reactions between various degradation products of organic chemicals originally present in the tanks. Volatile or semivolatile organic chemicals in some tanks also produce organic vapors. The gas produced in this generation is either (1) released continually to the tank vapor spaces (historically referred to as a steady state) or (2) retained by the waste matrix. Retained gas may be released in either a spontaneous or induced gas release event that can significantly increase the flammable gas concentration

in the tank vapor space. The flammable gas JCO elaborates on the range of hazardous scenarios, which include:

- Steady-state gas release (more correctly referred to as chronic release)
- Accumulation of released gases in (1) tank dome spaces; (2) sealed pits, risers, and connected air spaces; or (3) waste-intrusive equipment
- Retention of gas within the waste matrix followed by (1) spontaneous or natural release for example, from buoyancy instability or (2) release from waste-disturbing action or motion
- Flammable gas burns (1) beneath the waste surface or (2) in vapor spaces following release from stored waste.

The four analyzed scenarios discussed in this Basis for Interim Operation document are those selected by the Final Safety Analysis Report development process as representative per the hazard identification techniques discussed in the beginning of Chapter 5.0. These analyses are documented in WHC-SD-WM-CN-055, *Flammable Gas Deflagration Consequence Calculations for the Tank Waste Remediation System Basis for Interim Operation.* In all four cases, no credit was taken for any beneficial effects that flammable gas monitoring, ignition control practices, or ventilation could have to either prevent or mitigate an accident. The four scenarios are as follows:

1. Deflagration in a double-shell tank (DST) headspace
2. Deflagration in an aging waste facility (AWF) tank headspace
3. Deflagration in a single-shell tank (SST) headspace
4. Combustion in a DCRT.

The first three cases fundamentally involve the same scenario: the spontaneous release of stored gas (i.e., a gas release event) followed by deflagration of the flammable gas in the tank headspace. The three cases were analyzed to account for known differences in waste characteristics and waste tank physical features and properties. In all three cases, the natural processes for generating gas are assumed to result in retention and accumulation of gas in the waste matrix. Conservative assumptions unique to what is known about DSTs (including AWF tanks) and SSTs are made regarding the maximum amount of gas that can be released into the tank headspace at once. This amount of gas is assumed in each case to be that which when burned imparts enough pressure to the tanks (45 psig for DSTs and AWF tanks, 11 psig for SSTs) to reach a failure limit which leaves the tank intact (i.e., does not result in dome collapse) yet creates multiple unfiltered pathways for the release of tank materials. The detailed basis for the selection of these scenarios, their applicability to individual facilities, and associated implications for graded control strategies will be included in the FSAR.

The gas retained in the waste is conservatively assumed to be released into the tank headspace in such a manner that none escapes through normal ventilation paths. Based on historical gas release data, this assumption is justified as the time for the gas to be released from the waste could be less than the ventilation time constant for the headspace. A small energy source

(0.017 mJ to 0.1 mJ) from any number of causes is assumed to occur. These causes range from static electricity to metal-on-metal contact to faulty electrical equipment. Due to factors related to the size of the underground waste storage tanks, complete combustion of the released gas is assumed (NUREG/CR-5275, *The Effect of Obstacles and Transverse Venting on Flame Acceleration and Transition to Detonation for Hydrogen-Air Mixtures at Large Scale*). The ensuing pressure transient damages the tank and creates unfiltered release pathways such as that resulting from weld failure and displacement of a riser plate. Released radiological and toxicological material originates from the ventilation system and the material entrained from the tank waste by the deflagration. As noted in WHC-SD-WM-CN-055, analysis assumptions and methods critical to the determination of receptor dose are consistent with those documented by Los Alamos National Laboratories in safety analyses developed to provide the Authorization Basis for TWRS operations.

As documented in WHC-SD-WM-CN-055, the consequences of the tank headspace deflagration scenarios are judged to bound consequences of a postulated deflagration in the annulus surrounding the primary tank in a DST or an AWF tank. A deflagration in the annulus is postulated either as the result of a waste transfer routing misalignment or a leak in the primary tank. In either case, it is postulated that sufficient waste could accumulate which would block the annulus ventilation flow paths. Gas generated by the waste could then accumulate and combust assuming the presence of a spark source.

The representative accident for DCRTs involves the steady state generation of flammable gas from waste stored in a DCRT and insufficient air flow to prevent accumulation. Flammable gas is assumed to accumulate in the primary receiver vessel such that a deflagration or detonation occurs from an ignition source. Sources of gas generation and release include radiolysis, organic decomposition, and generation and evolution of ammonia. Vessel rupture and failure of the DCRT vault are postulated. Commensurate releases to the onsite and offsite receptors are documented in WHC-SD-WM-CN-055.

The frequency of deflagrations in DCRTs, DSTs (including AWF tanks) and SSTs is estimated to be "anticipated" (i.e., in the range of 1×10^{-2} to 1 per year) per tank, as documented in WHC-SD-WM-CN-041, *Tank Farm Deflagration Rate Due to Various Ignition Sources* and WHC-SD-WM-RPT-048, *Safety Study of Interim Stabilization of Non-Watchlist Single-Shell Tanks*.

Results Summary. The results of the four representative accident scenarios assuming no controls are summarized in Table 5.3.2.14-1. The supporting calculations are documented in WHC-SD-WM-CN-055.

Implications of Results. The analysis results indicate that the radiological and toxicological risk guidelines are exceeded for the onsite and offsite receptors for the SST headspace deflagration and DCRT combustion scenarios. The radiological and toxicological risk guidelines are exceeded for the onsite receptor for the DST and AWF tank headspace deflagration scenarios. The radiological and toxicological risk guidelines for the offsite receptor, however, are met for the DST and AWF tank headspace deflagration scenarios.

The results clearly imply a need to institute controls to prevent or mitigate hazards associated with flammable gas in TWRS facilities. The accident analysis results do not provide a detailed representation of the flammable gas risk posed by waste stored in every waste receptacle. All waste storage tanks and the balance of waste receivers (e.g., catch tanks or transfer systems) do not contain waste in forms and quantities capable of approaching the consequences presented in these analyses. In the absence of sufficient information to discount or fine tune the need for controls in all facilities, however, the JCO strategy is to expeditiously implement achievable and practical controls to manage postulated flammable gas risks. While doing so, progress towards safety issue resolution and USQ closure will continue to concentrate on remaining uncertainties regarding the quantification of risk and effectiveness of control strategies (Chapter 7.0, "Conclusions").

5.3.2.14.2 Accident Scenario Assuming Controls.

Sequence of Events. Flammable gas controls for the facilities affected by USQ TF-96-0433 are developed and presented in Appendix E. The controls are aimed primarily at prevention of ignition of flammable gas (although certain aspects of the control strategy are mitigative in nature). Provisions for ventilation serve to prevent accumulation of chronically released gases and possibly reduce the time at risk assuming the occurrence of a spontaneous or induced gas release. Flammable gas monitoring requirements serve to validate ventilation effectiveness as well as prevent or halt manned activities when margin of safety is considered to be insufficient (i.e, conditions are such that the flammable gases exist in concentrations greater than 25% of the lower flammability limit). Ignition controls related to work practices and equipment requirements serve to eliminate, to the greatest extent practical, ignition sources.

This three-pronged control strategy (ventilation, monitoring, ignition source control) is assumed to be effective in preventing either the accumulation of flammable gases where ignition sources may be present or to eliminate ignition sources where flammable gases may be present. Therefore, the deflagrations in the three preceding scenarios for DSTs, AWF tanks, and SSTs are assumed to be prevented because of the absence of an ignition source, and the DCRT scenario is assumed to be prevented by the provision of sufficient ventilation to avoid accumulation of gases to flammable concentrations. This document does not present analysis results which quantitatively demonstrate the effectiveness of controls to prevent flammable gas deflagrations.

Results Summary. Not applicable. See discussion on sequence of events. For accident analysis results and implications assuming controls for Tank 241-SY-101, see LA-UR-92-3196.

Implications of Results. Not applicable. See discussion on sequence of events. For accident analysis results and implications assuming controls for Tank 241-SY-101, see LA-UR-92-3196.

5.3.2.14.3 Key Accident Scenario Assumptions. When evaluating proposed changes or discoveries associated with the facilities affected by TF-96-0433, the USQ process provides the means to verify the ongoing applicability of the data in Appendix E. Also as part of the USQ process, changes or discoveries

must be evaluated against the analysis assumptions documented in WHC-SD-WM-CN-055. Areas which may affect the validity of the analyses documented in WHC-SD-WM-CN-055 are listed below.

When evaluating proposed changes or discoveries associated with Tank 241-SY-101, the USQ process will consider the specific assumptions used in LA-UR-92-3196.

Important to Accident Frequency. WHC-SD-WM-CN-041 characterizes the frequency of a deflagration in DSTs and SSTs to be categorized as "anticipated," the highest rate of occurrence. Therefore, it is not necessary to protect assumptions which support this conclusion. Instead, rigorous adherence to the JCO control strategy aimed at reducing frequency of occurrence is required. The same applies to the DCRT scenario frequency determination documented in WHC-SD-WM-RPT-048.

Important to Accident Consequence. The magnitudes of the onsite and offsite receptor consequences depend on numerous key assumptions which may require validation as the result of proposed changes, new information, or discoveries. WHC-SD-WM-CN-055 must be reviewed for a thorough understanding of all important parameters. These include:

- Maximum high-efficiency particulate air filter, prefilter, and de-entrainer loading rates of 200 mrem/h contact dose rate, individually.
- The equivalent of one loaded prefilter volume, one high-efficiency particulate air filter volume, and a prefilter volume are assumed to be deposited in the ventilation duct work for the DST, AWF tank, and SST cases, respectively.
- The DST and AWF tank failure pressure (failure previously defined) is 45 psig. With the exception of the uncertainty regarding a seismic initiator, a gas release and deflagration is not assumed to cause dome collapse. The credibility of tank dome collapse as the result of a flammable gas deflagration will be discussed in the FSAR.
- The SST failure pressure is 11 psig. With the exception of the uncertainty regarding a seismic initiator, a gas release and deflagration is not assumed to cause dome collapse. The credibility of tank dome collapse as the result of a flammable gas deflagration will be discussed in the FSAR.
- Release of additional gases that may be uniquely induced by the motions of an earthquake (for Performance Category 3 existing facility) is not accounted for in this analysis. This is the subject of significant technical uncertainty and will be addressed further in the FSAR.
- The DST case source term is based on DST liquids. The AWF tank case source term is based on AWF liquids. The SST case source term is based on SST solids. The DCRT case source term is based on 5% SST solids and 95% SST liquids by volume.

- To approach conditions which may be postulated to cause dome failure, the capability to retain and release a significant amount of gas must exist. Maximizing the retention and release potential, therefore, involves the assumption that a tank is filled to its waste capacity limit. A full tank also has the effect of minimizing the headspace volume in which the energy of a deflagration would be dissipated, thereby maximizing pressure and possible damage to the tank. Commensurately, the analyses assumed a headspace volume of approximately 1,000 cubic meters.

- The total released materials from the ventilation system and that which is entrained from the waste surface by the deflagration are assumed to be released in 200 seconds. The release duration is particularly important to the toxicological consequence calculation and is based on the analysis methodology documented in LA-UR-92-3196.

- Waste density is assumed to be 1.65 g/cm^3.

NOTE: Released gas compositions vary from tank to tank and are unique to the waste being stored. No explicit assumption has been made in the DST, AWF tank, and SST, representative analyses regarding undiluted gas composition. Rather, it is assumed that gas compositions and amounts released are such that deflagration may result in reaching the tank failure pressure.

5.3.2.14.4 Controls. The controls presented here are based on Appendix E. This chapter does not repeat or paraphrase each individual control. Instead, the basic concepts of the overall control strategy are presented. Appendix E and LA-UR-92-3196 need to be consulted to gain a working understanding of the bases for control derivation.

The flammable gas JCO control strategy is constructed around three factors affecting the nature and extent of postulated flammable gas hazards. These are: (1) waste behavior, (2) the type of operational activity which may be performed at a given TWRS facility, and (3) the region or location within a given TWRS waste receptacle. More specifically:

1. Type of waste behavior which is known or postulated to be possible for a given facility:

   Steady-state gas release
   "Large" gas release event
   "Small" gas release event
   Spontaneous gas release event
   Induced gas release event

   A "large" gas release event is defined to be capable of pressurizing the dome space above atmospheric such that flammable gases may occupy pits, flow out of open risers, and other spaces external to the dome space.

2. The impact of tank farm operational activities on the waste contained in a facility or structure:

   Nonwaste disturbing
   Local waste disturbing
   Global waste disturbing

   Local waste disturbing activities include such work as grab sampling and are not considered to be capable of affecting significant portions of the waste. Global waste disturbing activities, such as salt well pumping, more aggressively affect a larger fraction of the waste.

3. The location or region within a waste receptacle where work activities are being performed:

   Waste intrusive
   Dome intrusive
   Ex-tank intrusive
   Nonintrusive

   Waste intrusive locations include below the waste surface and within the vapor spaces of waste intruding equipment where undiluted waste gas may accumulate. Dome intrusive locations are those between the top of the risers and the waste surface, including ventilation systems up to the first mixing point. Ex-tank intrusive locations are those outside tank openings which are directly connected to the dome space; this region also includes boundaries of greenhouses as described in Appendix E.

These factors are used to specify the aspects of the three-pronged approach to flammable gas risk management (i.e., ventilation, monitoring and ignition control), which are required across the range of TWRS facilities and operational activities. Controls differ from facility to facility, or from activity to activity in a given facility, depending upon each of these factors.

Appendix E refers to two sets of ignition source controls which are each invoked depending on the facility and the type of activity performed in the facility. The ignition source controls address electrical equipment requirements, nonelectrical equipment and materials requirements, and work practices. Set 1 primarily applies to activities and locations which involve direct contact with waste and undiluted waste gases. Set 2 primarily applies to circumstances where flammable gas conditions may be postulated to occur in the dome space or ex-tank locations. To ensure consistent application and interpretation of industry standards used by these control sets, the Flammable Gas Equipment Advisory Board has been formed to oversee the implementation of the ignition source controls.

The detailed requirements for ventilation, monitoring, and ignition control are specified in the Basis for Interim Operation Technical Safety Requirements.

Safety Systems, Structures, and Components. The results of the representative analyses documented in WHC-SD-WM-CN-055 indicate the need for controls to manage the risk of flammable gas hazards. These analyses do not necessarily represent the magnitude of risk that each waste containing TWRS facility or structure poses; risks posed by many individual facilities are judged to be smaller than those associated with the representative scenarios. Because the offsite radiological risk guidelines are exceeded in some cases and onsite guidelines are amply exceeded in all cases; however, it is implied that any facility which is represented by these analyses requires Safety-Class or Safety-Significant structures, systems, and components (Table 5.3.2.14-2). Because of the open status of the USQ and the technical uncertainties associated with the flammable gas safety issue, it is assumed that all installed equipment necessary to implement the flammable gas controls merit a Safety-Class designation. Additional analysis provided by the Final Safety Analysis Report or in support of safety issue resolution and USQ closure may provide refinement to this approach.

Technical Safety Requirement Controls. The fundamental control strategy for all affected facilities is summarized in Table 5.3.2.14-3. The specific controls for each facility are in the Technical Safety Requirements and are derived in the JCO.

Defense-in-Depth. There are no unique and specific Defense-in-Depth measures which apply to the risk management of the flammable gas hazard. The existence of operator training, plant procedures, the job control system, and emergency planning are all acknowledged to support accident prevention and mitigation.

Table 5.3.2.14-1. Results Assuming No Controls Accident Scenario for Flammable Gas Deflagrations.

Scenario	Receptor/hazard	Calculated dose/hazard	Risk guidelines
Double-shell tank headspace deflagration	Offsite/radiological	0.16 mSv (16 mrem)	1 mSv (0.1 rem)
	Onsite/radiological	190 mSv (19 rem)	5 mSv (0.5 rem)
	Offsite/toxicological	0.94	1
	Onsite/toxicological	1,100	1
Aging Waste Facility tank headspace deflagration	Offsite/radiological	0.04 mSv (4 mrem)	1 mSv (0.1 rem)
	Onsite/radiological	44 mSv (4.4 rem)	5 mSv (0.5 rem)
	Offsite/toxicological	0.7	1
	Onsite/toxicological	820	1
Single-shell tank headspace deflagration	Offsite/radiological	5.7 mSv (0.57 rem)	1 mSv (0.1 rem)
	Onsite/radiological	6,500 mSv (650 rem)	5 mSv (0.5 rem)
	Offsite/toxicological	2.3	1
	Onsite/toxicological	1,800	1
Combustion in double-contained receiver tank	Offsite/radiological	3.8 mSv (0.38 rem)	1 mSv (0.1 rem)
	Onsite/radiological	4,400 mSv (440 rem)	5 mSv (0.5 rem)
	Offsite/toxicological	1.1	1
	Onsite/toxicological	1,000	1

NOTE: The frequencies for the DST, AWF tank, and SST cases are for the active mode, i.e., waste intrusive or waste disturbing activities occurring in the tank. Also, accident analysis scenarios and results specific to Tank 241-SY-101 are found in LA-UR-92-3196, A Safety Assessment for Proposed Pump Mixing Operations to Mitigate Episodic Gas Releases in Tank 241-SY-101: Hanford Site, Richland, Washington, Rev. 0, Los Alamos National Laboratory, Los Alamos, New Mexico.

AWF = Aging Waste Facility
DST = double-shell tank

SST = single-shell tank

Table 5.3.2.14-2. Safety Systems, Structures, and Components for Flammable Gas Deflagrations. (2 sheets)

Structures, systems, or components	Safety classification		Safety function	Comments
	SC	SS		
Primary tank leak detection system in all DSTs and AWF tanks	X		Provide indication that corrective action is required to avoid accumulation and deflagration of waste gas in the annulus space	None
The SSCs listed below are required to implement the LA-UR-92-3196 Revised (Rev. 14, March 31, 1995) Level 1 Controls for 241-SY-101:				Refer to LA-UR-92-3196, Rev. 14
1. Mixer Pump	X		1. Reduce the frequency of a flammable gas deflagration by mixing, releasing flammable gases generated and trapped in the waste	
2. Hydrogen Monitor	X		2. Provide indication and alarm for hydrogen gas concentration in the 241-SY-101 vapor space to the operations staff Provide interlock to stop mixer pump operation if H_2 concentration reaches 0.75% (7,500 ppm) by volume	
3. Level Monitoring System	X		3. Provide indication of tank level which directs operation of the mixer pump	
4. Pressure Monitoring System	X		4. Provide indication and alarm for tank dome pressure. Provide interlock to stop mixer pump operation on high pressure	
5. Ventilation Flowmeter	X		5. Provide indication and alarm for ventilation flow rate. Provide interlocks to stop mixer pump operation on high or low flow rate	
6. SY-101 ammonia detection systems	X		6. Detect ammonia in the tank headspace/exhaust gas and alarm on the data acquisition system (DACS) when a high level of ammonia exists	
7. SY-101 temperature monitoring system	X		7. Provide indication and alarm for tank waste temperature. Provide interlock to stop mixer pump operation on high temperature	
Active ventilation in all DSTs, all AWF tanks and the following SSTs: C-105, 106, and SX-101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 114	X		Maintain flammable gas concentrations in tank dome spaces, due to steady state releases, below 25% of the LFL	Active ventilation is required for the listed single shell tanks because the JCO relies on available vapor space sampling data to reach conclusions regarding the steady state release hazard. Therefore, existing ventilation configurations cannot be degraded

Table 5.3.2.14-2. Safety Systems, Structures, and Components for Flammable Gas Deflagrations. (2 sheets)

Structures, systems, or components	Safety classification		Safety function	Comments
	SC	SS		
Passive ventilation for all SSTs not listed above	X		Maintain flammable gas concentrations in tank dome spaces, due to steady state releases, below 25% of the LFL	None
DCRT ventilation flow (244-A, 244-BX, 244-CR, 244-S, 244-TX, 244-U)	X		Safety function is to prevent steady state accumulation of flammable gases	An assessment is required prior to placing new waste types in a DCRT to verify that airflow is sufficient to maintain gas concentrations less than 25% of the LFL Air flow may be provided via waste level dip tubes or other means
Dip-tube air flow for 244-AR vault TK-002	X		Dip tube inlet air must supply at least 3 cfh Safety function is to prevent steady state accumulation of flammable gases	None

AWF = Aging Waste Facility
DCRT = double-contained receiver tank
DST = double-shell tank
GRE = gas release event
JCO = Justification for Continued Operation

Table 5.3.2.14-3. Technical Safety Requirement Controls for Flammable Gas Deflagrations. (2 sheets)

Control strategy	Safety function
1. Dilution by ventilation 2. Gas monitoring (characterization sampling and work activity entry gas monitoring)	Assure that steady state release of flammable gas does not accumulate in flammable concentrations in vapor spaces of TWRS facilities and structures
1. Ignition source controls (Set 2) at all times 2. Work activity entry gas monitoring	Assure that if flammable gas accumulates in vapor spaces not within the direct flow paths of ventilation (such as sealed risers and pits), work activities will not commence
1. Ignition source controls (Set 1) at all times	Prevent the ignition of flammable gases within the waste
1. Ignition source controls (Set 2) in ex-tank and dome intrusive locations at all times 2. Continuing gas monitoring during work activities	Prevent the ignition of flammable gases that may be present as the result of the occurrence of a gas release event and reduce the possibility of the conduct of manned activities during a gas release event. This control strategy addresses "large" GREs as previously defined
1. Ignition source controls (Set 2) for dome-intrusive locations at all times 2. Continuing gas monitoring during work activities	Prevent the ignition of flammable gases that may be present as the result of the occurrence of a gas release event and reduce the possibility of the conduct of manned activities during a gas release event. This control strategy addresses "small" GREs as previously defined
1. Ignition source controls (Set 2) in ex-tank and dome intrusive locations during waste disturbing operations and activities 2. Continuing gas monitoring during manned waste disturbing activities	Prevent the ignition of flammable gases that may be present as the result of a "large" induced GRE and provide information to be used to halt manned activities, as necessary
1. Ignition source controls (Set 2) for dome intrusive locations during waste disturbing operations and activities 2. Continuing gas monitoring during manned waste disturbing activities	Prevent the ignition of flammable gases that may be present as the result of a "small" induced GRE and provide information to be used to halt manned activities, as necessary

Table 5.3.2.14-3. Technical Safety Requirement Controls for Flammable Gas Deflagrations. (2 sheets)

1. Monitoring before energizing equipment inside waste intruding equipment and continuing monitoring during use of equipment, or 2. Purge or flush prior to energizing equipment and during use of equipment, or 3. Ignition controls (Set 1) at all times	Prevent the ignition of flammable gases that may have accumulated in void spaces of waste intrusive equipment
1. The annulus leak detection must be operable and operating in all DSTs and AWF tanks	This provides indication that corrective action is required to avoid the accumulation and deflagration of flammable gas in the annulus space of DSTs and AWF tanks
1. Implement the Level 1 controls required by LA-UR-92-3196	Assure effective mitigation and safe operations of Tank 241-SY-101 with respect to flammable gas hazards
1. Rotary mode core sampling is permitted only per approved Authorization Basis	Prevention of flammable gas deflagration initiated by rotary mode core sampling operations
1. HEPA filter controls - Periodic radiation surveillance - Replacement based on accumulation	Reduce consequences from a possible HEPA filter failure by limiting the inventory available for release
1. Excavation controls reduce the likelihood of inadvertently intruding any structure potentially containing flammable gas	Prevent ignition of flammable gases
1. Excavation controls reduce the likelihood of inadvertently intruding any structure potentially containing flammable gas	Prevent ignition of flammable gases

5.3.2.15 Organic Solvent Fire.

Purpose of Analysis: The purpose of this analysis is to evaluate the risks associated with the presence of separable-phase organic solvents in the Hanford Site waste tanks. If ignited, burning organic solvents can liberate sufficient energy to release hazardous materials from the tanks. This analysis applies to single-shell tanks (SSTs), double-shell tanks (DSTs), and double-contained receiver tanks (DCRTs). The category of DSTs includes aging waste facility tanks. Both 100-series (530,000 gal and larger) and 200-series (55,000 gal) SSTs are included.

Analysis Strategy: An unknown number of waste tanks contain separable organic solvent phases. Not all tanks received solvents, and most of the solvents originally sent to the tanks have since evaporated or undergone chemical degradation to form organic species that would not be present as a separable, liquid phase. Tank 241-C-103 is, however, known to have an organic solvent layer floating on the waste surface. Other tanks have vapor space concentrations of organic solvent vapor higher than can be explained, except by the presence of liquid phase solvents somewhere in the waste.

A screening test has been developed that uses the results of the ongoing tank vapor space sampling program to predict the presence of significant quantities of separable phase solvents in tanks. The screening tests will identify whether or not specific tanks have any remaining separable organic solvent phase. The screening methodology uses vapor characterization data, in conjunction with an evaporation model, to estimate the size of solvent pools that feed vapors into tank headspaces. The screening test predicts whether or not a pool is present. If the screen predicts the presence of a pool, then another means of confirming or denying the presence of a pool must be found. If the screen predicts that a pool is not present, no further confirmation is required. The screening test and model are described in Appendix B of WHC-SD-WM-CN-032, *Analysis of Consequences of Postulated Solvent Fires in Hanford Site Waste Tanks*. When complete, the results of the screening program will identify specific tanks that may contain separate liquid phase organic solvents. To estimate overall risk to the tank farms for this analysis, however, six DSTs and nine SSTs were estimated to potentially contain separate liquid phase organic solvents. Both historical data on tank fill histories and the results from the tank vapor space sampling program for 65 SSTs were used for the estimate. Details on the method of estimation are given in Appendix C of WHC-SD-WM-CN-032.

Definition of Possible Scenarios: This analysis evaluates the frequency and consequences of the following three types of fires for combustion of organic solvent with headspace air.

- **Pool fires**—Pools are either a layer of solvent floating on top of liquid waste or a layer that is trapped in a depression on top of solid waste. In either instance, a pool has an area greater than 1 m^2 (10.8 ft^2). A pool may exist in DCRTs, DSTs, or SSTs.

- **Puddle fires**—Puddles are less than 1 m^2 (10.8 ft^2) in area and exist in a depression in a solid waste surface. Puddles should occur mainly in SSTs because many SSTs have a solid surface that can form a depression for solvent to collect in. However, a few DSTs have a floating crust (e.g., Tank 241-SY-101) that might form a depression where solvent could collect. Therefore, the analyses include puddles for both DSTs and SSTs.

- **Wick-Stabilized Fires**—A wick-stabilized fire configuration would be a sludge or salt cake that is permeated with solvent. The height of the solvent layer would be equal to the height of the solids level. The sludge or salt cake would act as a wick, and the solvent would burn. Wick-stabilized fires may occur in SSTs.

Pools and puddles are distinguished because the screening criteria can differentiate between puddles (smaller than 1 m^2 [10.8 ft^2) and pools (larger than 1 m^2 [10.8 ft^2]). An area of 1 m^2 (10.8 ft^2) is also a useful limit from a consequence point of view, because the burning of a puddle does not generate enough heat or pressure to produce any unmitigated release consequences that exceed risk guidelines.

The important distinctions between pool fires and wick-stabilized fires on salt cake or sludge are the rate of flame spread and ease of ignition. The wick-stabilized fire has a much lower flame spread rate and a higher probability of occurrence than pool fire.

Two other potential reactions involving organic solvent were considered for analysis: solvent reactions with organic-nitrate/nitrite salts and solvent vapors contributing to headspace flammability. Potential condensed phase reactions between organic-nitrate/nitrite salts are analyzed in Section 5.3.2.17 of this BIO. Laboratory tests described in Fauske 1995, *Summary of Laboratory Scoping Tests Related to Organic Solvents Combustion by Nitrate Oxidation and Organic Solvent Ignitability*, show that burning organic solvent can start a condensed phase organic-nitrate/nitrite reaction only if the necessary conditions for the organic-nitrate/nitrite reaction are already present. The organic solvent neither substitutes for the nitrate/nitrite fuel nor enhances the reaction, and the consequences of the organic-nitrate/nitrite reaction far exceed the consequences of a solvent fire.

Solvent vapors would significantly contribute only to headspace flammability (i.e., flammable vapor concentration greater than 25% of the lower flammability limit) given the following two conditions: (1) the tank contained a significant solvent pool (e.g., greater than 1 m^2 [10.8 ft^2] area) or an even larger solvent layer deeper in the waste solids, and (2) the solvent air interface temperature is above about 57 °C (134.6 °F) for fresh solvent or about 72 °C (161.6 °F) for degraded plutonium-uranium extraction solvent like that contained in Tank 241-C-103. Fresh solvent is not realistic for tank wastes but plutonium-uranium extraction solvent may be the most volatile solvent left in the waste tanks. Dunford (1996), *Modeling Solvent Low End Losses During Waste Storage*, demonstrates that higher volatility components have already evaporated from the tanks. Higher temperature tanks are less

likely to contain significant quantities of solvent vapors because the higher temperatures would have caused the more volatile components to evaporate over the many years of storage. The tanks with the higher heat loads have also been actively ventilated for many years. The cooler tanks may have allowed solvent to persist over the many years of storage and are sufficiently cool to limit vapor concentrations to small values as evidenced by sampling in Tanks 241-C-103 and 241-BY-108. Of the 65 tanks vapor sampled, the largest vapor contribution to headspace flammability is about 2% of the lower flammability limit. This result is from Tank 241-C-103, the only tank known to have a separable phase organic pool. On the basis of this evaluation and available headspace vapor sample data, the solvent contribution to headspace flammability can be reasonably assumed to be small. This assumption will be verified as additional tank headspaces are sampled.

Table 5.3.2.15-1 shows which organic solvent scenarios apply to each of the different types of tanks. As indicated by the table and the preceding discussion, accident analyses are only required for solvent pool fires in the three types of tanks, and for wick-stabilized fires in the SSTs.

Because neither the volume nor the particular configurations for organic solvent that may be present in these tanks is known, 18 parametric models were used to evaluate the different potential configurations and to establish the worst-case scenarios. Calculations for all 18 models are given in WHC-SD-WM-CN-032. Only the six bounding scenarios developed in the parametric models are included in this section. The cases are identified both by a letter designator and a descriptive title. The letter designator is taken from the spreadsheet used to calculate the consequences and is included in most tables in this section so that readers may cross-reference to the spreadsheet found in WHC-SD-WM-CN-032. The six cases are as follows.

1. Case Q represents the bounding radiological and toxicological accident for SST wick-stabilized fires.

2. Case G represents the bounding radiological accident for an SST fire.

3. Case H represents the bounding toxicological accident for an SST fire.

4. Case K represents the bounding radiological accident for a DST fire.

5. Case L represents the bounding toxicological accident for a DST fire.

6. Case P represents the bounding radiological and toxicological accident for a DCRT fire.

The bounding cases that maximized the pressure and vacuum did not result in the maximum releases. This was because, in part, of the fact that none of the tanks failed structurally. Therefore, these scenarios

were not further developed. The supporting structural calculations are found in WHC-SD-TWR-RPT-002, *Structural Integrity and Potential Failure Modes of the Hanford High-Level Waste Tanks*.

5.3.2.15.1 Accident Scenario Assuming No Controls.

Sequence of Events. An evaluation of potential initiators that applies to all cases examined, including results from testing laboratories, is given in WHC-SD-WM-CN-032. Lightning and vehicle fuel fires are the only initiators with sufficient energy to ignite solvent pool or puddle fires. A wick-stabilized fire, however, requires less energy to initiate and to maintain the necessary conditions for combustion. Thus, this type of fire may be initiated by lightning, vehicle fuel fires, and hot metal resulting from use of a cutting torch (but not by sparks or slag from welding).

Two other potential initiators exist but are not evaluated in this section as separate accidents: a flammable gas deflagration and an organic-nitrate/nitrite reaction. The consequences of a flammable gas deflagration (Section 5.3.2.14) are much greater than the consequences of a solvent fire. Likewise, the consequences of the organic-nitrate/nitrite reaction (Section 5.3.2.17) are much greater than the consequences of a solvent fire. Because the deflagration consequences would dominate the combined consequences of both accidents, neither a deflagration initiated solvent fire nor an organic-nitrate/nitrite initiated solvent fire is evaluated as a separate accident in this section.

Wick-Stabilized Solvent Fire in SST, Case Q. Solvent possibly could intrude into the underlying sludge or salt cake in an SST following salt well pumping of drainable liquids from a tank. Exposed salt cake saturated with solvent could burn like a candle using the sludge or salt cake as a wick. The burning surface would slowly increase and would eventually cover more of the tank surface than the puddle fire.

For a solvent liquid level equal to the solids level in the tank, the flame propagation rate would be approximately 0.1 cm/sec (WHC-SD-WM-CN-032). If the liquid level were below the solids level, however, ignition would not occur. The case of a solvent liquid level above the solids level is a pool or puddle fire and is addressed later.

The pressure, 30.3 kPa (4.4 psig) and vacuum -4.8 kPa (-0.7 psig) transients resulting from the fire are not large enough to damage the tank structure and create a pathway to the environment. Tank farms 241-SX and 241-C, however, have active ventilation systems and a path to the environment could be created through ruptured high-efficiency particulate air (HEPA) filters. Releases could also occur through risers that do not have covers bolted in place. Unbolted vent covers are assumed to lift at 7 kPa (1 psi), and then fall back into place, sealing the opening when the pressure is relieved. The quantity of solvent burned, 130 kg (286 lb), is limited by oxygen availability, and thus, the fire extinguishes on its own.

The frequency of the scenario assuming no controls on a facility basis is unlikely based on an evaluation of credible ignition sources.

Bounding Radiological SST Fire, Case G. In this scenario, a pool of solvent is postulated to burn on the waste surface of an actively ventilated SST. In this, and all pool scenarios, a pool is required to be 210 m^2 so that flame spread is not limited before the fire is extinguished by oxygen depletion. Unlimited flame spread produces the largest pressure transient.

A flame spread rate of 10 cm/s is used. An upper bound for flame spread rate was chosen after examining several sets of experimental data. One data set was based on experiments conducted on mixtures of tributyl phosphate (TBP) and normal paraffin hydrocarbons (NPH) similar to plutonium-uranium extraction solvent. These mixtures were burned in closed compartments. Flame spread rates varied from 1.3 to 3.3 cm/s. For data based on open air tests with jet fuel, flame spread rates ranged from 8 to 10 cm/s. Although the data for jet fuel may not apply directly to confined solvent fires, the tests provide an experimental basis for defining an upper bound of approximately 10 cm/s for flame spread rates in waste tanks.

The tank does not structurally fail and create a pathway to the environment as a result of either the pressure transient (200 kPa [29 psig]) or the vacuum transient (-0.7 kPa [-0.1 psig]). The high pressure is the result of the small vent path through the filter. See the overpressure assumption in Section 5.3.2.15.3, "Key Assumptions." Tank farms 241-SX and 241-C, however, have active ventilation systems and a path to the environment could be created through ruptured HEPA filters. Releases could also occur through any risers that do not have covers bolted to the flanges. The fire burns until the oxygen is depleted consuming 146 kg (321 lb) of solvent.

The frequency of the scenario assuming no controls on a facility basis is "unlikely" based on an evaluation of credible ignition sources.

Bounding Toxicological SST Fire, Case H. This scenario postulates a 210-m^2 (2,260-ft^2) pool of solvent burns on the waste surface in a passively ventilated SST.

The tank does not structurally fail as a result of either the pressure transient (12.4 kPa [1.8 psig]) or the vacuum transient (-46.9 kPa [-6.8 psig]). The low pressure is the result of the large vent path which includes risers. The pressure transient, however, ruptures the breather filter on the tank creating a release path to the environment through the ventilation system. Releases also could occur through any risers that do not have covers bolted to the flanges. The fire burns until the oxygen is depleted consuming 84 kg (185 lb) of solvent. The frequency of the scenario assuming no controls on a facility basis is "unlikely" based on an evaluation of credible ignition sources.

Bounding Radiological DST Fire, Case K. This scenario postulates that a puddle of solvent (1 m^2 [10.8 ft^2]) burns on top of the waste surface of an actively ventilated DST. This scenario yields the highest theoretical radiological consequences for a DST fire and provides the bounding consequences. However, this scenario is probably not physically possible because the surface of DST waste is expected to be a liquid, and the solvent probably would spread as far as possible over the surface of the waste instead of accumulating as a puddle.

The DST does not structurally fail as a result of either the pressure transient (6.2 kPa [0.9 psig]) or the vacuum transient (-0.69 kPa [-0.1 psig]). The pressure transient is assumed to rupture the HEPA filters on the ventilation system, creating a release path to the environment. Releases also could occur through any risers that do not have covers bolted to the flanges. The fire burns to until the oxygen is depleted consuming 132 kg (291 lb) of solvent. The frequency of the scenario assuming no controls on a facility basis is "unlikely" based on an evaluation of credible ignition sources.

Bounding Toxicological DST Fire, Case L. This scenario postulates that a pool of solvent (210 m^2 [2,260 ft^2]) burns on top of the waste surface of an actively ventilated DST.

The DST does not structurally fail as a result of either the pressure transient (13.8 kPa [2 psig]) or the vacuum-transient (-35.9 kPa [-5.2 psig]). However, the pressure transient is assumed to rupture the HEPA filters on the ventilation system, creating a release path to the environment. Releases also could occur through any risers that do not have covers bolted to the flanges. The fire burns until the oxygen is depleted consuming 92 kg (202 lb) of solvent. The frequency of the scenario assuming no controls on a facility basis is "unlikely" based on an evaluation of credible ignition sources.

Bounding Radiological and Toxicological DCRT Fire, Case P. The same scenario results in the bounding case for both toxicological and radiological consequences for a DCRT fire. In this scenario, a pool of solvent 34 m^2 (366 ft^2) is postulated to burn on top of the waste surface of a DCRT. This pool area is equal to the maximum waste surface area in the DCRT.

The DCRT does not structurally fail as a result of either the pressure transient (126 kPa [18.3 psig]) or the vacuum transient (-8.3 kPa [-1.2 psig]). The vaults surrounding the DCRTs have powered ventilation systems, with ducts to the DCRTs, but no identifiable ventilation inlets to the DCRTs. Therefore, the DCRT is modeled as having a passive ventilation system[1]. The pressure transient is assumed to rupture the HEPA filter on the vault ventilation system, creating a release path to the environment through the vault ventilation system. Releases also could occur through any risers that do not have covers bolted to the flanges. The fire burns until the oxygen is depleted consuming 2.12 kg (4.67 lb) of solvent. The frequency of the scenario assuming no controls on a facility basis is "unlikely" based on an evaluation of credible ignition sources.

Results Summary. Tables 5.3.2.15-2 and 5.3.2.15-3 present the accident consequences and the applicable risk guidelines for both onsite and offsite releases for organic solvent fires assuming no controls.

---

[1]The 244-U DCRT does have an air inlet on the tank. This DCRT has not had any radioactive material transferred through it. The 244-U DCRT will require additional information on ventilation flow to complete calculations for it. Since any accident involving a DCRT would have smaller consequences than an accident with an SST or DST, 244-U is bounded.

Implications of Results. The offsite consequences for all cases are below offsite risk guidelines. However, the onsite radiological consequences exceed the risk guidelines for cases G and Q by a small margin. The onsite toxicological consequences exceed the risk guidelines for cases H, L, P, and Q. Therefore, controls are required.

5.3.2.15.2 Accident Scenario Assuming Controls. As a result of the analysis assuming no controls, Technical Safety Requirement controls have been identified that eliminate two of the three possible initiators, vehicle fuel fires and flame cutting (Section 5.3.2.15.4, "Controls"). Controls have also been identified to reduce the likelihood of an organic solvent fire caused by a lightning strike. However, as discussed in Section 5.3.2.23, "Natural Phenomena," the ability of these controls to prevent an organic solvent fire is uncertain and unquantifiable.

Sequence of Events. The scenario assuming controls is postulated to be an organic solvent fire initiated by lightning, which has a frequency of 3×10^{-5} per year (4.5×10^{-4} on a facility basis). Thus, even with controls, the frequency for the accident remains "unlikely" (1×10^{-4} to 1×10^{-2} per year). The same sequence of events and conditions described for scenarios assuming no controls still apply.

Results Summary. The consequences of the accident scenarios assuming controls are the same as those for accidents with no controls. This is because the selected controls are preventive and as such do not mitigate consequences.

Implications of Results. The offsite consequences for all cases are below the radiological and toxicological risk guidelines. However, the onsite radiological consequences exceed the risk guidelines for cases G and Q by a small margin. Likewise, the onsite toxicological consequences exceed the risk guidelines for cases H, L, P, and Q. Although the guidelines are exceeded for some cases, existing measures provide reasonable assurance that operations can be conducted safely (see Chapter 7.0).

5.3.2.15.3 Key Assumptions.

Important to Accident Frequency. The following assumptions important to accident frequency have been made in the analysis of organic solvent fires:

- The frequencies for the bounding cases assuming no controls are summarized in Table 5.3.2.15-4. The probabilities are also converted from a per tank basis to a facility basis in the table. The column labeled "Number of tanks" is the number of DSTs and SSTs estimated to contain a separable organic solvent phase. All six existing DCRTs were assumed to contain a separable organic solvent phase.

  The frequencies for the bounding cases assuming controls may also be determined from Table 5.3.2.15-4. Accident frequency was calculated by taking the per-tank lightning frequency and multiplying by the number of tanks.

- Two approaches were used to estimate the number of tanks that contain a separate liquid phase of organic solvent:

  The first approach makes an assumption about the total number of tanks that may contain a separable phase, which is then used to predict the aggregate risk from an organic solvent fire for the facility (all tanks). Using historical records about tank transfers, and the results of the vapor space sampling program, nine SSTs and six DSTs were predicted to contain solvent. Because of a lack of information, all six DCRTs are assumed to potentially contain a separate phase. This approach does not identify which tanks may contain solvent. Table 5.3.2.15-4 shows that the number of DSTs that contain solvent can increase substantially without changing the total frequency (facility basis) category of the DSTs. However, an increase of one tank in the SST column would change the total frequency category for wick stabilized fires in SSTs from "unlikely" to "anticipated."

  The second approach uses results from the ongoing vapor space sampling program to identify which tanks actually contain a separable organic solvent phase. This approach is used to identify which tanks should have controls placed on them. As the vapor space sampling program continues and is completed, information about which and how many tanks contain solvent will supersede the assumption made about the total number of tanks in the first approach described above.

Important to Accident Consequences. The following assumptions are important to the calculation of accident consequences for organic solvent fires.

- **HEPA Filter Loading**—Filters are assumed to be changed when they have a maximum contact reading on the filter housing of 2 mSv (200 mrem) per hour. This information is used to calculate the quantity of material on the filter for the maximum release from a ruptured filter. The method and assumptions for calculating the material loading on the HEPA filters is given in WHC-SD-WM-CN-054, *Waste Tank Ventilation System Waste Material Accumulations*.

- **Vent Paths**—Vent paths were postulated at two extremes to evaluate possible cases. A minimal vent path was postulated to evaluate maximum pressure that could be generated by a pool fire. For SSTs, this minimal vent was based on the HEPA vent pipe, a path with an equivalent orifice size of 9.5 cm (3.75 in.). For DCRTs and DSTs, the minimal vent was zero, a conservative default value chosen because a reliable, realistic vent path size is not known. Using zero for maximum pressure cases in DCRTs and DSTs does not result in tank failure, so there is no need to refine the maximum pressure model further. A large vent path was postulated to evaluate maximum vacuum resulting from the cooldown of the tank after the fire extinguishes. A circular opening, 1.27 m (50 in.) in diameter covered by a hinged plate was assumed to open at a pressure

difference of 6.89 kPa (1 psi). This flapper valve was hypothesized to simulate the venting through large risers (in tank pits) that are covered by caps held in place by gravity.

- **Overpressure**—The maximum overpressure resulting from a solvent fire in a DST is calculated to be 30 psig (207 KPa). This pressure will not result in DST failure and is documented in LA-UR-92-3196, *Safety Assessment for Proposed Pump Mixing Operations to Mitigate Episodic Gas Releases in Tank 241-SY-101: Hanford Site, Richland, Washington.* The maximum overpressure calculated for the SST accident is 29 psig (200 kPa), given the SST structure does not fail. A structural analysis, WHC-SD-TWR-RPT-002, predicts that the concrete in the SST dome would crack at a failure pressure of 11 psig (76 kPa). As the dome cracks, more flow openings are created; hence the pressure is maintained constant at the tank failure pressure until all the solvent fire extinguishes because of lack of oxygen. The concrete would maintain adherence to the rebar and the dome would not collapse. The predicted cracking would allow the pressure to vent to the soil above the tank. The approximately 2.4 m (8 ft) of soil on top of the tanks would act as a filter and prevent a release to the atmosphere. Note that consequence calculations conservatively assume that all material is released via unfiltered vent paths.

5.3.2.15.4 Controls.

Safety Structures, Systems, and Components. No Safety-Class or Safety-Significant structures, systems, and components have been identified.

Technical Safety Requirement Controls. Four controls have been identified to reduce the probability of accidents (see Table 5.3.2.15-5). The tanks where these controls are applied are identified by number in Table 5.3.2.15-6.

Out of 177 DSTs and SSTs, 65 SSTs have been vapor space sampled. Forty-eight of the sampled tanks do not have a positive test for organic solvent. Seven of the sampled tanks have a positive test. The results for 10 tanks are inconclusive because ventilation flow information was not available. One hundred twelve of the tanks, including all of the DSTs, have not been vapor space sampled. The tanks that have not been vapor space sampled are assumed to potentially contain separate phase organic solvent, and will have the controls specified in this section applied. The 10 tanks with inconclusive results will have controls applied. The seven tanks that have shown a positive test when vapor space sampled will have the controls specified in this section applied. The 48 tanks that did not have a positive result when vapor space sampled will not have the controls specified in this section applied. All tanks that will have controls applied are identified by a "Yes" in Table 5.3.2.15-6.

Defense-in-Depth. Defense-in-Depth controls are identified in Table 5.3.2.15-7.

Table 5.3.2.15-5. Technical Safety Requirement Controls for Organic Solvent Fires.

Control	Safety function	Comments
Ignition Control Program with the following key elements: 1. Rotary mode core sampling is permitted only per approved authorization basis 2. Vehicle access within the tank farms shall be limited to vehicles whose fuel systems are protected from damage caused by potential collisions with tank structures 3. Physical barriers shall restrict vehicle access to those aboveground structures outside of tank farm boundaries that can direct liquids into waste tanks. Only vehicles with protected fuel systems shall be allowed within barriers 4. Speed limit controls	1. Prevention of organic solvent fires initiated by rotary mode core sampling operations 2. Prevent vehicle fuel system damage in 3. the event of collisions with tank 4. structures within the tank farms. Outside the tank farms where vehicle access can not be controlled, prevent vehicle access to tank structures	None
Emergency Preparedness with the following key element: • Response procedures	Mitigate the consequences of a fire	None
If flame cutting is performed in a location where debris from the cutting could fall on the waste surface in a tank, a device that is capable of catching and holding hot metal debris from the cutting shall be inserted between the cutting operation and the waste surface. This does not apply to sparks or slag from welding	Pieces of hot metal from flame cutting may be capable of igniting salt cake or sludge that has entrained organic solvent in it	None
See the TSR control for lightning protection program (Section 5.3.2.23.2)	See lightning (Section 5.3.2.23.2)	None
Waste Transfer Control Program Key element: All waste transfers shall be evaluated to ensure that the waste transfer does not create an organic solvent hazard outside the BIO safety envelope	Ensure that waste transfers do not create an organic solvent hazard outside the safety envelope established by the BIO (i.e., prevent creation of a new tank with an organic solvent hazard unless the required organic solvent controls are extended to the tank)	None
HEPA Filter Control Program with the following key elements: 1. Periodic radiation survey to monitor HEPA filter loading 2. HEPA filter replacement per change-out criteria, i.e., $\leq$ 2 mSv/h (200 mrem/h)	Reduce consequences from a possible HEPA filter failure by limiting the inventory available	None

BIO = basis for interim operation.
HEPA = high-efficiency particulate air (filter).

5.3.2.16 In-Tank Fuel Fire/Deflagration.

Purpose of Analysis: Risks associated with accidents in which vehicles collide with tank risers and puncture the vehicle fuel tanks are evaluated in this section. Diesel and gasoline powered vehicles routinely enter the tank farms to support surveillance, sampling, maintenance, and construction activities. As identified in the hazards analysis, fuel from a ruptured vehicle fuel tank could spill into a waste storage tank through the damaged tank riser and ignite.

Analysis Strategy: In assessing the results of fuel spills from vehicles, two possible scenarios are considered. The first scenario is a pool fire in which the vehicle fuel burns on the surface of the waste and the second is a headspace deflagration in which vaporized fuel causes the headspace volume to reach the lower flammability limit (LFL) and the headspace is then ignited. The difference between the two scenarios is thus the physical state of the fuel when ignition occurs.

The frequency and consequences for both of these accident scenarios are bounded by the frequency and consequences for the "Organic Solvent Fire," Section 5.3.2.15, and "Flammable Gas Deflagration," Section 5.3.2.14. The scope of the analysis includes double-contained receiver tank (DCRTs), double-shell tanks (DSTs), DST annuli, single-shell tank (SSTs), catch tanks, and miscellaneous interim storage facilities (MISFs). The category of SSTs includes both 100 Series (2 million L or 500,000 gal and larger) and 200 Series (208,000 L or 55,000 gal) 100 Series tanks. The category of DSTs also includes aging waste facility tanks.

5.3.2.16.1 Accident Scenarios Assuming No Controls. Both scenarios assuming no controls are initiated by an errant vehicle that shears off one or more tank risers and ruptures the vehicle fuel tank. The maximum amount of vehicle fuel available in an accident is 227 L (60 gal) (the capacity of the largest fuel tank on any vehicle that enters the tank farms). Some spilled fuel enters the waste tank through the damaged riser and some vaporizes or is aerosolized as the fuel drains into the tank. The remaining portion of the fuel pools on the waste surface.

For both accident scenarios assuming no controls, the frequency category assigned is "unlikely" (10^{-4} to 10^{-2} per year). The frequencies are calculated in WHC-SD-WM-CN-037, *Frequency Analysis of Vehicle Fuel Release Resulting in Waste Tank Fire*.

Sequence of Events - Vehicle Fuel Pool Fire in Waste Tank. The primary assumption for this scenario is that some of the spilled vehicle fuel enters the waste tank but is not immediately ignited. Instead, the fuel pools on the surface of the waste and vaporizes. However, the fuel is ignited before the LFL is reached in the headspace and a pool fire therefore results. This scenario is similar to the organic solvent fire scenario (Section 5.3.2.15) in terms of the amount of fuel burned.

- **Single-Shell Tanks**—For SSTs, this accident scenario would be bounded by the analysis for SSTs given in Section 5.3.2.15. The maximum amount of fuel that would burn in an SST before oxygen extinguishment would be approximately 193 L (51 gal)

(WHC-SD-WM-CN-059, *Calculation Notes That Support Accident Scenario and Consequence Determination of the In-Tank Fuel Fire/ Deflagration*). The energy content and release rate would be about the same for the 193 L (51 gal) as for the maximum amount of solvent that burns in an SST. Therefore, the pressures, vacuums, and release rates generated by the fire would be equivalent to those generated by the organic solvent pool fire accident. Release paths to the environment would be through the ruptured filters on the ventilation system. The tank structure would not fail.

- **Double-Shell Tanks**—For DSTs, this accident scenario would be bounded by the analysis for DSTs given in Section 5.3.2.15. Using the same methodology given in WHC-SD-WM-CN-059 for calculating the equivalent quantity of fuel, the maximum amount of fuel that would burn in a DST before oxygen extinguishment would be about 174 L (46 gal) (WHC-SD-WM-CN-059). The energy content and release rate would be about the same for the 174 L (46 gal) of fuel as for the maximum amount of solvent that burns in a DST. Therefore, the pressures, vacuums, and release rates generated by the fire would be equivalent to those generated by the organic solvent pool fire accident. Release paths to the environment would be through the ruptured filters on the ventilation system. The tank structure would not fail.

- **Double-Shell Tank Annuli**—No calculations were specifically performed for the occurrence of this accident scenario in a DST annulus. This accident scenario would be bounded by the DST analysis in Section 5.3.2.15. A fire would not generate enough pressure to cause the tank to fail. None of the DSTs is known to have leaked; therefore, no waste should be present inside the annulus to contribute to a radiological or toxicological dose. Even if a leak had occurred, the waste would be the same as the waste inside the tank, which was used to calculate consequences for a DST fire. For the same reason, neither the radiological nor toxicological loading of the annulus ventilation system filters would be greater than the loadings for the main tank ventilation system. The contribution of the filters on the main ventilation system is given in Section 5.3.2.15.

- **Double-Contained Receiver Tank**—For DCRTs, this accident scenario would be bounded by the analysis for DCRTs given in Section 5.3.2.15. Using the same methodology given in WHC-SD-WM-CN-059 for calculating the equivalent quantity of fuel, the maximum amount of fuel that would burn in a DCRT before oxygen extinguishment would be about 4 L (1 gal). The energy content and release rate would be about the same for the 4 L (1 gal) of fuel as for the maximum amount of solvent that burns in a DCRT. Therefore, the pressures, vacuums, and release rates generated by the fire would be equivalent to those generated by the organic solvent pool fire. Release paths to the environment would be through the ruptured filters on the ventilation system. The tank structure would not fail.

- **Catch Tanks and MISFs**—No calculations were specifically performed for catch tanks and MISFs. Therefore, whether a pool fire in one of these tanks would cause failure of the tank is unknown. Both types of tanks are of various shapes and sizes, and information about the contents of these tanks is incomplete, but the quantity of waste in the tanks is minuscule compared with the quantity in the large tanks. Most of the waste in these tanks is left over from transfers and processing of the waste in the large tanks. Therefore, it is reasonable to assume that the concentrations of material available for release are no larger than those in the large tanks. Stating on an a-priori basis that this accident would always be bounded by the solvent pool fire accident described in Section 5.3.2.15 is not possible. However, because the quantity of material available for release is smaller and the concentrations of material are no larger, it is reasonable to assume that the consequences of an accident would be bounded by a deflagration as described in Section 5.3.2.14 for SSTs.

Sequence of Events - Vehicle Fuel Deflagration in the Headspace. The primary assumption for this scenario is that some of the spilled fuel enters the waste tank but is not immediately ignited. Instead, the fuel pools on the surface of the waste and begins to vaporize. The LFL is reached and the vaporized fuel ignites in the headspace. This scenario is similar to the flammable gas deflagrations scenarios (Section 5.3.2.14) in terms of the total energy available for combustion and in tank pressures reached during the burn.

The peak pressure from a gasoline (or diesel) burn is approximately equivalent to the peak pressure of a hydrogen burn. This statement is based on information about closed vessel deflagrations in NFPA 1988, *The SFPE Handbook of Fire Protection Engineering*, which relates peak pressure to flame temperatures. More details are provided in WHC-SD-WM-CN-059. The burning velocity of hydrogen is about eight times greater than that of either diesel oil or gasoline. The heats of combustion for both gasoline and diesel fuel are similar (48.1 MJ/kg and 47.5 MJ/kg) (Lewis and Von Elbe, *Combustion, Flames and Explosions of Gases*).

- **Single-Shell Tanks**—Because transfers to SSTs are not allowed, the existing volume of waste in each SST will not increase. The quantity of fuel required to reach the LFL was calculated for each SST by using published waste volumes (WHC-EP-0182-90, *Waste Tank Summary Report for Month Ending September 1995*). The results are given in WHC-SD-WM-CN-059. In 115 SSTs, the headspace could reach the LFL with 227 L (60 gal) or less of diesel or gasoline fuel present. Ignition of the vapor at the LFL could result in failure of the tank structure. The failure mechanism is described in Section 5.3.2.14.

- **Double-Shell Tanks**—The volume of waste in DSTs could either increase or decrease. The LFL can be reached in a full DST (1,057 cm or 416 in. of waste) with 62 L (16.3 gal) of fuel present. A tank containing approximately 411 cm (162 in.) of waste can reach the LFL with 227 L (60 gal) of fuel present. If a tank contains less than 411 cm (162 in.) of waste, the LFL cannot be reached because of the

maximum fuel assumption of 227 L (60 gal). Ignition of the vapor at the LFL could result in failure of the tank structure. The failure mechanism is described in Section 5.3.2.14.

- **Double-Shell Tank Annuli**—The LFL can be reached in the annulus of a DST with 37 L (9.9 gal) of fuel present. The annuli of DSTs are assumed to be empty; therefore, the volume of fuel needed to reach the LFL does not depend on waste volume in the annulus. Because ignition of the vapor at the LFL inside a tank can result in failure of the tank structure, a deflagration in the annulus is assumed to also cause failure of the tank structure. The failure mechanism would be similar to and bounded by that described in Section 5.3.2.14.

- **200 Series Tanks, Double-Contained Receiver Tanks, Catch Tanks, and MISFs**—A 200 Series tank is a SST with a volume of 208,000 L (55,000 gal). DCRTs, catch tanks, and MISFs all have significantly smaller volumes. The LFL could be reached in an empty 200 Series tank with approximately 15 L (3.7 gal) of fuel present. On the basis of this number, it can be assumed that the LFL could be reached in a DCRT, MISF, or catch tank with very little fuel present. No calculations were specifically performed for catch tanks and MISFs. Therefore, whether a deflagration in one of these tanks would cause failure of the tank is not definitely known.

  The tanks are of various shapes and sizes and information about the contents of the tanks is incomplete, but the quantity of waste in these tanks is minuscule compared with the quantity in the large tanks. Most of the waste in these tanks is left over from transfers and processing of the waste in the large tanks. Therefore, it is reasonable to assume that the concentrations of material available for release are no larger than those in the large tanks. Because the quantity of material available for release is smaller and the concentrations of material are no larger, it is reasonable to assume that the consequences of an accident would be bounded by a deflagration as described in Section 5.3.2.14.

Results Summary. The radiological and toxicological consequences for the vehicle fuel pool fire accident scenarios, except for MISFs and catch tanks, are bounded by the cases from Section 5.3.2.15 as listed in Table 5.3.2.16-1.

The radiological and toxicological consequences for a vehicle fuel pool fire in a MISF or catch tank are bounded by the SST flammable gas deflagration accident scenario described in corresponding Section 5.3.2.14.

The consequences for the vehicle fuel/deflagration accident scenario are bounded by the consequences of the DST and SST flammable gas deflagrations given in corresponding Section 5.3.2.14.

Implications of Results. Controls are required because onsite and offsite risk guidelines are exceeded. Specifically, for pool fire "Case G" (from Table 5.3.2.16-1) the onsite radiological consequences exceed

guidelines. For all pool fire cases, the onsite toxicological consequences exceed guidelines. For fuel deflagrations, both the onsite and offsite radiological and toxicological consequences exceed guidelines.

5.3.2.16.2 Accident Scenarios Assuming Controls. The controls specified in Section 5.3.2.16.4, "Controls" prevent the accident by protecting the vehicle fuel tanks from being punctured. A collision may occur, but without a punctured fuel tank, no fuel is released and the accident scenarios cannot occur. Therefore, scenarios assuming controls have not been developed.

5.3.2.16.3 Key Accident Scenario Assumptions.

Important to Accident Frequency. To determine the frequency of the scenarios assuming no controls (i.e., "unlikely" [1×10^{-4} to 1×10^{-2} per year]), the number of vehicle entries per year was assumed to be 520 per year for DSTs and 1,040 per year for SSTs. However, because the controls identified are preventive in nature, the number of vehicle entries per year is not a critical parameter.

Important to Accident Consequences. The following key assumptions are important to the accident consequences.

- The source term for the vehicle fuel pool fire is the same as the source term defined for the organic solvent pool fire in Section 5.3.2.15.
- The source term for the vehicle fuel fire deflagration is the same as defined for DSTs and SSTs in Section 5.3.2.14.
- The largest amount of fuel available to flow into a tank is 227 L (60 gal). This maximum amount applies to both the vehicle fuel pool fire and the vehicle fuel fire deflagration.
- The ventilation model described in Section 5.3.2.15 applies to the vehicle fuel pool fire.
- The structural criteria documented in WHC-SD-TWR-RPT-002, *Structural Integrity and Potential Failure Modes of the Hanford High-Level Waste Tanks*, apply to the vehicle fuel pool fire.

5.3.2.16.4 Controls.

Safety Structures, Systems, and Components. No Safety-Class or Safety-Significant structures, systems, and components have been identified.

Technical Safety Requirement Controls. The Technical Safety Requirement controls shown in Table 5.3.2.16-2 are applicable to all the DCRTs, DSTs (including annuli), SSTs (100 and 200 Series), catch tanks, and MISFs. A vehicle fuel fire deflagration could not occur in all SSTs. However, the vehicle fuel pool fire could occur in all tanks. Because the controls apply to both accident scenarios, the controls must be imposed on all tanks.

Defense-in-Depth. Controls that provide Defense-in-Depth are shown in Table 5.3.2.16-3.

Table 5.3.2.16-2. Technical Safety Requirement Controls for Vehicle Fuel Fire/Deflagration.

Control	Safety function	Comments
Ignition Control Program with the following key elements: 1. Vehicle access within the tank farms shall be limited to vehicles whose fuel systems are protected from damage caused by potential collisions with tank structures 2. Physical barriers shall restrict vehicle access to those above-ground structures outside of tank farm boundaries that can direct liquids into waste tanks. Only vehicles with protected fuel systems shall be allowed within barriers 3. Speed limit controls	Prevent vehicle fuel system damage (i.e., fuel system leaks) in the event of collisions with tank structures within the tank farms. Outside the tank farms where vehicle access can not be controlled, prevent vehicle access to tank structures	None
Emergency Preparedness with the following key element: • Response procedures	Mitigate the consequences of a fire	None

5.3.2.17 Organic Salt-Nitrate Reaction.

Purpose of Analysis: The purpose of this analysis is to discuss the hazards and associated controls which are related to exothermic chemical reactions between organic chemicals contained within the wastes and oxidizers such as sodium nitrate and sodium nitrite which are also contained within the waste.

During the defense mission at the Hanford Site, organic complexants were used during fuel reprocessing, metal recovery operations, and waste management separations. These materials were discharged to the tanks where they mixed with sodium hydroxide, sodium nitrate and nitrite, and other inorganic diluents already present in the tanks. Organic complexants will react with oxidizing materials, such as nitrates or nitrites. This reaction can be accelerated to a rapid combustion by heating to high temperatures (above 220 °C [428 °F]) or by an initiator of sufficient energy.

The principal organic complexants sent to the tanks are glycolic acid, citric acid, HEDTA (hydroxyethylethylenediaminetriacetic acid), and EDTA (ethylenediaminetetraacetic acid). These compounds have been used in metric ton quantities at the Hanford Site. In addition to these complexants, other complexants such as NTA (nitrilotriacetic acid), di (2-ethylhexyl) phosphoric acid, and oxalic acid were also used, but the amounts of these complexants were relatively small and are not well quantified.

The organic complexants were sent to the tank as solutes in waste liquids and posed no hazard. However, since that time, several operations and naturally occurring physical and chemical processes have occurred that affect this hazard (both adversely and beneficially). The most important are blending, with wastes that were low in organic content evaporator concentration and crystallization, settling, draining of waste liquids (in some single-shell tanks [SSTs]) and surface evaporation drying as well as chemical degradation (aging). The effect of these processes on the organic-nitrate hazard has not been fully quantified because of a lack of understanding of the effects of these processes and a lack of data concerning the actual waste conditions. Because the hazard posed is uncertain and not fully analyzed, the potential organic-nitrate hazard is the subject of an Unreviewed Safety Question which is described in determination TF-96-0096, *Condensed-Phase Organic Nitrate Reactions*. The Unreviewed Safety Question applies to all tanks, including double-contained receiver tanks.

Analysis Strategy: The following steps outline the analysis approach for this hazard. Details of the analysis are contained in WHC-SD-WM-CN-058, *Compilation of Calculation Notes in Support of Organic Salt-Nitrate Reactions Safety Analysis*.

1. The species of organic salts that might be present in the wastes were determined based on historical records of organic chemicals originally disposed to the tanks, and theoretical study and experiments of subsequent chemical degradation of these chemicals.

2. Hanford Site tank wastes stored in SSTs have been assessed for chemical runaway using techniques used in the chemical processing industry. The assessment concluded that conditions leading to a chemical runaway in the passively ventilated tanks are not realistic and are assigned to be beyond extremely unlikely in this analysis. In addition, spontaneous runaway of the wastes stored in actively ventilated SSTs is not realistic while ventilation is maintained. Ventilation is required for these tanks to address flammable gas hazards (Section 5.3.2.14). The heat up rate following a loss of ventilation in actively ventilated tanks (i.e., some SSTs, all double-shell tanks [DSTs], and all Aging Waste Facility [AWF] tanks are actively ventilated) has been calculated and experienced for several tanks (e.g., 241-C-106) and is very slow. Heat up to high temperatures is therefore controlled by temperature monitoring and response actions.

   The threshold temperature for significant chemical heating is not known exactly. The waste temperature in tanks is required to be $\leq$ 121 °C (250 °F) to prevent a chemical runaway reaction. This limit is conservatively selected based upon the lowest observed chemical heating of waste surrogates occurring at 150 °C (302 °F). Maintaining the waste at or below steam saturation temperatures will prevent both tank bumps and chemical runaways. The Limiting Condition for Operation temperature limit for SSTs, DSTs, and AWF tanks to prevent tanks bumps (Section 5.3.2.22, "Tank Bump") will conservatively also prevent a chemical runaway. Therefore, temperature monitoring and response actions which are required for these tanks to address tank bump hazards also prevent potential chemical runaway events.

3. Key parameters and lower limits for condensed-phase-propagating-combustion chemical reactions were determined through theoretical analysis and testing of waste surrogates. A range of waste surrogates were tested for reaction characteristics. These surrogates were composed of sodium nitrate and various organic chemicals representative of those used in the process facilities and their expected degradation products. A key conclusion from this testing is that semi-volatile process extractants and solvents (e.g., tributyl phosphate and normal paraffin hydrocarbon) and their principal degradation products (e.g., sodium dibutyl phosphate) do not support propagating combustion reactions.

   The combustion assessment therefore focused on the analysis of the organic complexants and their degradation products. The effort has resulted in fuel, moisture, and temperature limits used to judge the combustibility of the waste and the frequency of ignition. Total organic carbon (TOC) is not a direct measure of combustibility; however, it is the primary available data regarding the organic

content of the waste, and its use in this analysis is conservative. The conservative combustion criterion developed from theory and test results is:

$$\text{wt\% TOC} \geq 4.5 + 17\,X_w$$

Where: wt% TOC is the total organic carbon in the waste calculated as the energy equivalent of sodium acetate and

X_w is the weight fraction of moisture in the waste, up to 0.20. Above 0.20 (20 wt% water) the relationship no longer holds because the mixture becomes liquid continuous. A stoichiometric fuel-oxidizer mixture will not support propagating combustion when moisture exceeds 20 wt%.

A key conclusion is that wastes that contain more than 20 wt% water pose no hazard from propagating combustion reactions. Additionally, waste with low fuel content (less than 4.5 wt% TOC from energetic organic species) also poses no risk from propagating combustion events.

4. Wastes that are stored with a supernatant liquid above the waste solids pose no hazard based on the conclusion of step 3 above. Therefore, the analysis was focused on SSTs with a waste management strategy that removed waste supernate and as much drainable, interstitial liquid as practical to limit environmental contamination from tank leaks.

5. The likelihood and extent of combustible waste being present in the tank farms was assessed based on a review of waste process history and the evaluation of available waste sample data. The assessment of waste processing history (LA-UR-96-989, *History of Organic Carbon in Hanford High Level Waste Tanks: HDW Model*) concluded that waste with high complexant concentrations would be expected in at most only a small fraction of the tanks, those with unique process histories which included the receipt and storage of complexant bearing wastes that did not experience:

   - Waste blending which mixed soluble sodium and aluminum into the organic waste and thus limited the amount of concentration that could occur for the blend.
   - Chemical degradation that would have occurred during high temperatures experienced in the high temperature evaporator campaigns (242-T Evaporator).
   - Significant chemical degradation (aging) during the many years of storage in the tanks.

   In addition, these wastes would need to dry out through evaporation to attain combustible concentrations and conditions.

The physical processes required to concentrate and dry waste to combustible conditions have not been quantitatively evaluated for this safety analysis because of uncertainties in waste processing histories and the phenomena themselves. Rather, historical records and the limited waste sample information regarding fuel, moisture, and temperature have been evaluated to estimate the extent of the hazard in each tank. Analysis of variance techniques were used to evaluate the uncertainty in these estimates. This evaluation indicated a significant variability in the waste conditions within a tank and from tank to tank. Additionally, the evaluation determined that a large uncertainty exists regarding the actual hazard posed by the wastes. Hence, the presence or absolute absence of combustible waste can not be determined explicitly. Each tank waste contains a distribution of organic complexants and moisture, and if statistical techniques are used to extrapolate waste condition estimates to high confidence limits, there is a small probability that some fraction of waste exceeds the combustion criterion. Estimating the amount of combustible waste in each tank in this manner was judged imprudent for estimating risk and assigning controls on a tank-by-tank basis. Rather, these insights, as well as historical waste processing records and available waste sample calorimetry, were used to group the tanks. The estimated hazard posed by organic-nitrates varies significantly and therefore, controls were graded on the basis of these tank groupings. The tank groupings were termed *safe*, *conditionally safe*, and *unsafe*.

Safe—Tanks were placed in the SAFE group if

(1) waste samples were available and showed that TOC was less than 4.5 wt% on a dry basis at the 95 percentile with a 95% confidence, or

(2) waste process histories (Agnew 1996) showed that these tanks received minimal or no organic material and differential scanning calorimetry of waste samples corroborated that the waste had no exothermic energy.

The moisture of the waste was not considered: even if these wastes were dried out, insufficient fuel is present to be combustible. Tanks placed into this category are listed in Table 5.3.2.17-1.

Conditionally Safe—Tanks were placed in the CONDITIONALLY SAFE group if they were judged to pose a small risk when waste moisture was considered, but judged to pose a risk if the wastes were dried out. Tanks placed into this group are listed in Table 5.3.2.17-1. Physical processes that could exacerbate the hazard in CONDITIONALLY SAFE or unsampled tanks, such as drying the wastes, were evaluated to determine if restrictions on operations were warranted until the true hazard is better understood.

Unsafe—Tanks would be placed into the UNSAFE group if they were judged to pose a significant risk regardless of associated moisture content under current conditions. No tanks have been placed in the UNSAFE group.

Note that 82 SSTs have been judged to have insufficient sample data available to categorize them into one of the preceding groups.

6. Conditions for initiating propagating combustion accidents were studied theoretically and through testing of waste surrogates. Theory holds that for a dry (zero total water) stoichiometric mixture of organic fuel and oxidizer, the minimum ignition energy is 3.3 J. This value is about four orders of magnitude larger than for flammable gas mixtures. In addition, experiments show that initiation of the combustion reaction requires reactive material to be raised to the ignition temperature of about 220 °C (428 °F). Testing shows that about 5 wt% moisture can suppress ignition when the energy source is less than 270 J (0.3 Btu) or of limited duration.

7. Scenarios that might result in an organic-nitrate-propagating-combustion accident were postulated and analyzed in a conservative manner to judge the severity of possible events. Parametric analyses indicated that the tank pressure and material release is (1) primarily sensitive to the amount of reactive mass burned and, (2) secondarily to the fuel concentration in the reactive mass and the tank headspace volume available to absorb the energy. Burning between 0.1 to 0.2 m^3 (3.5 to 7.1 ft^3) of waste created tank pressures that would rupture the high-efficiency particulate air filters on SSTs. Burning 1 to 3 m^3 (35.3 to 105.9 ft^3) of waste would overpressurize and crack the dome of a SST. Burning about 1 m^3 (35.3 ft^3) of waste would result in a radiological onsite dose of approximately 600 mSv (60 rem) and an offsite dose of 0.5 mSv (0.05 rem). The consequences of burning a large quantity of waste is discussed later in this section as the representative accident.

5.3.2.17.1 Accident Scenario Assuming No Controls. If enough fuel is present and the waste is sufficiently dry, an organic-nitrate-nitrite propagating combustion event could be initiated by a variety of ignition sources. However, fuel, oxidizers, and temperature (initiators) are all important parameters. Specific conditions of fuel, moisture, and ignition sources are all required to support a propagating combustion.

The scenario without controls begins by assuming a quantity of combustible waste is created by (1) concentrating the organic chemicals contained in the waste added to the tanks, and (2) drying the waste to reactive conditions. Next, an ignition source of sufficient energy and temperature contacts the combustible waste and initiates a combustion reaction. A resulting combustion front spreads through the combustible waste and releases significant energy and gases. The energy release liberates radionuclides and chemicals in gaseous form, and overpressurizes the tank. Overpressurization initiates a release of radiological and toxicological materials from the tank to the environment. The reaction continues until all contiguous combustible waste is consumed.

The consequences from an organic salt-nitrate combustion event are primarily caused by the high temperatures generated during the accident. At the high combustion temperatures, volatile radionuclides and other chemicals are driven off as vapors. The principal elements released, usually

driven off as hydroxide compounds, are cesium, mercury, and sodium. These elements condense into particulates as the exiting gases cool to respective condensation temperatures.

The representative calculation for the accident without controls is selected as 25 m^3 (883 ft^3) of combustible waste based on estimates from analysis of variance techniques, that show that Tank 241-U-105 represents the worst case and there is a 95% confidence that the upper bound for combustible waste (the amount of waste that exceeds the safety criteria) is 25 m^3 (883 ft^3).

For the representative accident, there is enough combustible waste to cause dome failure. The pressure transient reaches the dome failure pressure of 1.75×10^5 Pa (11 psig) at 1,350 seconds (22 min). The dome starts to crack, creating more flow openings; hence, the pressure stays constant at the tank failure pressure until all combustible waste is exhausted and the reaction stops at 2,770 seconds (46 min). The tank then quickly depressurizes. Tank failure does not cause dome collapse.

The headspace heats up because the effluent gases enter the headspace at the reaction temperature of 864 °C (1587 °F). The hot headspace gas in turn transfers heat to the dome and unreacted salt cake by radiation and convection. The peak temperatures predicted for the headspace and the dome wall are 757 °C (1395 °F) and 307 °C (585 °F), respectively.

For this representative transient, most of the material released from the waste is also released from the tank. Because of the high outflow, the aerosols do not have sufficient time to age and fall out. Fallout of airborne aerosol, therefore, is small compared to leakage to the environment. At the end of the transient, 1.1×10^{-2} kg of CsOH remains airborne in the tank, 2.2×10^{-3} kg settles in the tank, and 2.3×10^{-1} kg escapes to the environment. Hence, the fraction of CsOH released is 0.95 of the Cs contained in the combusted 25 m^3 (883 ft^3). Note that the high-efficiency particulate air filter on the tank is ruptured by excessive pressure drop early in the event and its radioactive and toxic burden is discharged to the environment. The amount of this release is trivial when compared with the release from the combustion event.

The hazard analysis qualitatively assigns a frequency of "unlikely" to the representative organic salt-nitrate reaction accident scenario. This frequency is based on "order-of-magnitude" estimates for frequencies of initiators and considering (1) only a few tanks contain large amounts of combustible waste, (2) only a small probability exists for point source ignitors contacting the small portion of combustible waste, and (3) small ignitors are unlikely to ignite moist (but combustible) waste.

Tank farm operations and activities were reviewed to determine which equipment and activities could lead to moderate strength ignition sources (greater than 3 J) being present at the waste surface or within the waste. A review of natural phenomena hazards was also performed to identify potential organic-nitrate ignitors. Lightning was determined to be the only natural phenomenon with sufficient energy and temperature to ignite combustible wastes. Other effects were evaluated such as seismic-induced collisions between in-tank equipment and resultant sparking of equipment; the review

determined that these effects would not produce capable ignitors. Nearby facility or range fires could produce flaming brands and sparks that could affect the top of the tank. However, it was judged that these flaming brands could not enter the tank and fall directly onto the waste surface. The credible ignition sources that have been identified are listed in Table 5.3.2.17-2. Ignition sources that may be strong enough to ignite flammable gases, but not strong enough to ignite organic-nitrate wastes are also listed in Table 5.3.2.17-2.

Results Summary. The consequences of the representative organic salt-nitrate combustion accident have been calculated assuming conservative waste radioactive and toxic chemical concentrations. These consequences are listed in Table 5.3.2.17-3. The supporting calculations are documented in WHC-SD-WM-CN-058.

Implications of Results. The results of the scenario assuming no controls are significantly above the risk guidelines. Therefore, controls are required.

5.3.2.17.2 Accident Scenarios Assuming Controls. Effective controls to mitigate the consequences of organic-nitrate accidents have not been specified; rather, risk is managed by imposing controls to prevent occurrence. Prudent controls designed to prevent a significant accident are described in Section 5.3.2.17.4, "Controls."

The scenario with controls is assumed to be the same as the accident without controls. However, the controls identified in Section 5.3.2.17.4 eliminate possible ignition sources with the exception of lightning. Lightning is discussed in Section 5.3.2.23.2. The frequency category for an organic-nitrate combustion initiated by lightning is "extremely unlikely."

Results Summary. The consequences from the organic-nitrate combustion scenario with controls are the same as for the scenario without controls, except that the toxicological consequences (sum-of-fractions) are based on guidelines for an "extremely unlikely" event. Therefore, the chemical concentration guideline values are higher (ERPG-3 rather than ERPG-2 for onsite and ERPG-2 rather than ERPG-1 for offsite). Consequently, the reported mitigated sum-of-fractions numbers are lower than for the unmitigated accident. The radiological and toxicological consequences of the organic salt-nitrate reaction releases with controls are presented in Table 5.2.3.17-4.

Implications of Results. Even with controls, the offsite and onsite radiological and toxicological consequences are significantly above the risk guidelines. There is a large uncertainty regarding the true hazard posed by the organic chemicals that were sent to the tank farms. The analysis of this section is judged to be quite conservative because several conservative assumptions were made in circumstances when direct measurements of the waste hazards were unavailable. Additionally, several phenomena that reduce risk have not been fully accounted. Therefore, this accident analysis is continuing to be refined. In the interim, important waste management

operations need to be continued, with prudent controls applied (Chapter 7.0 "Conclusions"). Several of the key assumptions and discounted phenomena are now discussed.

The actual fuel content of most of the sampled waste is unknown because most waste samples have been analyzed for total TOC rather than energetics or specific organic species. Therefore, the fuel content is conservatively assumed to be represented by the TOC. That is, all TOC is assumed to be a fuel as energetic as sodium acetate (the most energetic fuel identified during laboratory experiments). This is judged to be conservative as very little of the organic chemicals included in the original waste streams are this energetic. Of the nearly 3,000 metric tons of organic chemicals sent to the tank farms, less than about 1,200 metric tons were complexants and of the complexants added, only a small fraction was acetate (Agnew 1996). Most of the other organic materials sent to the tank farms (e.g., oxalate and process extractants such as TBP [tributyl phosphate] and NPH) do not support condensed-phase propagating combustion reactions.

It is also assumed that all waste that exceeds the organic-nitrate TOC combustion criterion will burn. This is conservative, as experiments with waste simulants indicate the actual minimum TOC value is closer to 6.0 wt% even for the most energetic fuel, sodium acetate, totally dry. Sodium acetate is the reference organic material used and the equations have been normalized to it. Two energetic surrogates were found not to have a lower flammability limit (i.e., even stoichiometric concentrations could not sustain a propagating combustion). These were sodium acetate trihydrate and sodium oxalate.

The chemical decomposition (aging) of organic chemicals has reduced the hazard significantly by destroying the fuel. Studies indicate that organic complexants undergo hydrolytic and radiolytic decomposition (aging) under tank waste conditions. The net effect of aging decreases the potential chemical energy of the waste. Thus, much of the original fuel such as EDTA is likely to degrade to nonfuel species such as oxalate.

The influence of temperature and radiation dose on the rate of aging is not sufficiently defined to quantify the effect aging has had on safe storage. Therefore, no credit for aging was assumed in this safety analysis. Kinetic data for aging are being investigated using waste simulants, and the composition of actual waste will be examined in an effort to quantify aging in the future.

A significant portion of the energetic organic chemicals (fuels) are probably in solution and are therefore not a combustion hazard. The solubility properties of organic complexants are being investigated. Tests with waste simulants indicate that with the important exception of sodium oxalate, all the other sodium carboxylate salts and their principal decomposition products are very soluble in the alkaline supernatant solutions in the tanks.

The measured solubility limit for the energetic complexants (EDTA, nitrilotriacetate, glycolate, succinate, dibutylphosphate, and citrate) is approximately 100 g of organic carbon/L of supernate. Supernatant solutions from 61 tanks have been analyzed for TOC concentration. Only five of these

tank supernatant liquids had total organic carbon concentrations greater than 14 g/L. Because the highest measured value for total organic carbon (approximately 40 g/L) is substantially below the measured limit of 100 g/L, it is anticipated that most or all of the energetic complexants are contained in the liquid phase and are not a combustion hazard.

For this safety analysis, it is assumed that all of the waste in a tank that exceeds the combustion criterion is contained in a single contiguous mass. If the combustible waste were contained in several noncontiguous regions, only the region that was ignited would burn, thereby reducing the severity of the event.

5.3.2.17.3 Key Accident Scenario Assumptions. The key assumptions and parameters used in this accident analysis that relate to facility configuration, facility conditions, and operating practices include:

- Key assumptions that affect accident frequency include:
  - This accident scenario applies to any location where dry, fuel-rich organic waste could exist. Because of the lack of waste condition information (fuel and moisture) in many waste storage facilities, the organic-nitrate runaway and propagating combustion hazard is assumed to be applicable to

    Single-shell waste storage tanks
    Double-shell waste storage tanks
    Aging Waste Facility storage tanks
    Double-contained receiver tanks
    Inactive miscellaneous underground storage tanks
    Catch tanks
    244-AR Vault
    Waste transfer lines.

    Most of the wastes are too dilute in fuel or too wet to support propagating combustion reactions. This analysis assumes that less than ten tanks might contain significant amounts of combustible waste.
  - On the basis of a review of the equipment, operations, and natural phenomena applicable to waste storage and management, the only ignitors capable of igniting reactive wastes are very hot electric filaments, hot metal fragments, or slag from welding/torch-cutting activities, vehicle fuel fires, rotary mode core drilling, lightning, and flammable gas burns.
- Key assumptions that affect accident consequences include:
  - Only the waste which is reactive at the beginning of the accident will react and release radionuclides and toxic chemicals. The reaction does not produce sufficient heat to dry out adjacent or overlying wastes not already reactive at the beginning of the accident. The amount of combustible waste burned in the analysis is based on waste moisture estimates that are applicable to Tank 241-U-105 now (and near-term) under

passive ventilation conditions. Accelerated dryout that might occur under active ventilation conditions could create a larger quantity of combustible waste than has been analyzed.

5.3.2.17.4 Controls.

Safety Structures, Systems, and Components. Safety-Class and Safety-Significant structures, systems, or components that have been selected to provide temperature monitoring for tank bump accident prevention in certain SSTs, DSTs, and AWF tanks (Section 5.3.2.22), as well as Safety-Class and Safety-Significant structures, systems, or components that have been selected to provide active ventilation to prevent flammable gas deflagrations in certain SSTs, DSTs, and AWF tanks (Section 5.3.2.14), also provide protection against the postulated phenomena of organic-nitrate reactions initiated by bulk heat up to undefined elevated waste temperatures. Table 5.3.2.17-7 lists the safety structures, systems, and components selected to prevent the organic salt-nitrate reaction. Such elevated waste temperatures would occur over a presumed long time period, and only during an extended ventilation outage.

Technical Safety Requirement controls. Table 5.3.2.17-5 lists the Technical Safety Requirement controls selected to prevent or mitigate the risk of organic-nitrate condensed-phase propagating combustion accidents. For each control, the safety function is described and additional comments are provided as appropriate.

The Technical Safety Requirements as delineated in Table 5.3.2.17-5 are applicable to the following Tank Waste Remediation System facilities:

- Single-shell waste storage tanks
- Double-shell waste storage tanks
- Aging Waste Facility storage tanks
- Double-contained receiver tanks
- Inactive miscellaneous underground storage tanks
- Catch tanks
- 244-AR Vault
- Waste transfer lines.

A limit on waste temperature of $\leq$ 121 °C ($\leq$ 250 °F) for has been established to ensure that waste does not reach chemical runaway temperature thresholds. Technical Safety Requirements that have been selected to provide temperature monitoring in certain SSTs, DSTs, and AWF tanks consistent with the tank bump accident analysis (Section 5.3.2.22), as well as Technical Safety Requirements that have been selected to provide active ventilation to prevent flammable gas deflagrations in certain SSTs, DSTs, and AWF tanks (Section 5.3.2.14), also provide protection against the postulated phenomena

of organic-nitrate reactions initiated by bulk heat up to undefined elevated waste temperatures. Such elevated waste temperatures would occur over a presumed long time period, and only during an extended ventilation outage.

Defense-in-Depth. Defense-in-Depth protection measures for organic-nitrate exothermic reaction accidents are shown in Table 5.3.2.17-6.

Table 5.3.2.17-1. Organic-Nitrate Waste Grouping.

Organic-nitrate waste group	Applicable facilities	Comments
Pose no hazard because of supernate above the waste solids level	DSTs, AWF tanks, DCRTs, 244-AR TK 001, 002, 003, 004	Salt well pumping of these tanks is not performed. Dry waste solids would only occur if waste heels are left in the tank following pumping and the heel is allowed to dry because of evaporation
SAFE	SSTs: A-101, A-102, A-103, A-106, B-103, B-104, B-106, B-110, B-111, B-201, B-204 BX-101, BX-104, BX-105, BX-106, BX-107, BX-108, BX-109, BX-110, BX-111, BX-112, BY-106 C-101, C-103, C-104, C-105, C-106, C-108, C-109, C-110, C-111, C-112, C-204, S-104, S-109, S-111 SX-102, SX-108, SX-113 T-102, T-104, T-105, T-106, T-107, T-108, T-109, T-111, TX-102, TX-107, TX-118, TY-101, TY-102, TY-103, TY-104, TY-105, TY-106 U-103, U-110, U-111, U-201, U-202, U-203, U-204	Tanks were placed in the SAFE group if its waste has a low organic fuel content and is thus judged to be non-combustible without consideration of waste moisture. That is, even if these wastes were dried out, the waste would not be combustible
CONDITIONALLY SAFE	SSTs: AX-102, C-201, C-202, U-105	Tanks were placed in the CONDITIONALLY SAFE group if they were judged to pose a small risk when waste moisture was considered, but could pose a risk if the waste were dried out
UNSAFE	None	Tanks would be placed into the UNSAFE group if they were judged to pose a significant risk even considering moisture present, or lack there of, under current conditions
Unassigned because of a lack of information and analysis (unsampled)	SSTs: all not listed under SAFE, CONDITIONALLY SAFE, or UNSAFE above Catch Tanks: all MISFs: all Waste transfer lines that contain waste solids	

AWF = Aging Waste Facility.
DCRT = double-contained receiver tank.
DST = double-shell tank.
MISF = miscellaneous inactive storage facility.
SST = single-shell tank.

Table 5.3.2.17-2. Summary of Organic-Nitrate Condensed Phase Ignition Source Evaluation.

Operation	Incident Conditions	Ignition Potential
In-tank instrumentation	Electrical overcurrent	Negligible, ignition not credible
Grinding and drilling operations	Sparks from grinding and drilling operations on or near a riser	Negligible, ignition not credible
Still camera photography	Dropping flash unit onto the waste surface, hot filament contacts waste	Ignition temperatures and energies are possible
Video camera	Dropping light unit onto the waste surface, hot filament contacts waste	Ignition temperatures and energies are possible
Hot metal from welding and torch cutting operations	Hot steel particles or pieces drop and contact the waste	Ignition temperatures and energies are possible
Vehicle operation above the tank	Rupture of fuel tank on aboveground equipment, fuel leakage into the tank, subsequent fire	Ignition temperatures and energies are possible
Rotary-mode core sampling	Loss of bit cooling, failure to shut down drill sampler causes frictional heating of the waste	Ignition temperatures and energies are possible
Lightning strikes	Lightning strike on or near a tank or equipment causes lightning current to reach the waste	Ignition temperatures and energies are possible
Flammable gas burn	Flammable gas burn in the tank headspace ignites the waste	Ignition temperatures are possible

Table 5.3.2.17-3. Radiological and Toxicological Consequences for 25 m^3 Organic-Nitrate Combustion Accident (No controls in place - accident is "unlikely").

Consequences	Onsite dose/exposure		Offsite dose/exposure	
	Calculated dose	Risk guideline	Calculated dose	Risk guideline
Radiological	86,000 mSv (8.6 E+03 rem)	50 mSv (5.0 rem)	71 mSv (7.1 rem)	5 mSv (0.5 rem)
Toxicological (SOF)	1.4 E+05	1 (ERPG-2)	160	1 (ERPG-1)

Notes: The above table is based on the following: Total waste volume = 1582 m^3, Headspace volume = 1657 m^3, TOC = 7.0 wt%, H_2O = 10 wt%, and amount of combustible waste is 25 m^3 (95% confidence on the upper bound of combustible waste = 1.6% for U-105).
ERPG = Emergency Response Planning Guideline.
SOF = sum-of-fractions.

Table 5.3.2.17-4. Radiological and Toxicological Consequences for 25 m^3 Organic-Nitrate Combustion Accident (Controls in place - Accident is "extremely unlikely").

Consequences	Onsite Dose/Exposure		Offsite Dose/Exposure	
	Calculated dose	Risk guideline	Calculated dose	Risk guideline
Radiological	86,000 mSv (8.6 E+03 rem)	100 mSv (10 rem)	71 mSv (7.1 rem)	40 mSv (4.0 rem)
Toxicological (SOF)	1,000	1 (ERPG-3)	120	1 (ERPG-2)

Notes: The above table is based on the following: Total waste volume = 1582 m^3, Headspace volume = 1657 m^3, TOC = 7.0 wt%, H_2O = 10 wt%, and amount of combustible waste is 25 m^3 (95% confidence on the upper bound of combustible waste = 1.6% for U-105).
ERPG = Emergency Response Planning Guideline.
SOF = sum-of-fractions.

Table 5.3.2.17-5. Technical Safety Requirement Controls for Organic-Nitrate Condensed-Phase Combustion Accidents. (3 sheets)

Control	Safety function	Comments
0.0 Temperature Limits A temperature Limit of ≤ 121 °C (250 °F) is applicable to the following: C-106, SX-103, SX-107, SX-108, SX-109, SX-110, SX-111, SX-112, SX-114, DSTs, and AWF tanks	Prevents tank waste from reaching a chemical runaway threshold temperature	Temperature monitoring required to prevent a tank bump is conservatively used to ensure that this chemical runaway threshold is not reached
SST waste temperature controls • The waste temperature shall be ≤ 205 °F (96 °C). DST and AWF Tank Waste Temperature Controls • The waste temperature shall be either: ≤ 195 °F (91 °C) in all levels of the waste. OR ≤ 195 °F (91 °C) in the top 4.6 m (15 ft) of the waste. AND ≤ 215 °F (102 °C) in the waste below 4.6 m (15 ft).		
1.1 Ignition Controls Ignition source controls are applicable unless waste solids are verified to be covered by liquids 1. Flame (torch) cutting and welding shall be prohibited unless provisions for eliminating the potential for hot metal and slag contacting the waste are provided (e.g., catch trays)	Eliminates ignition sources from tanks that could pose an organic-nitrate hazard by preventing moderate or high energy ignition sources from contacting combustible waste	1. Torch cutting and welding - no comment
2. Restraints shall be used on equipment, particularly lights or other equipment with hot filaments or high surface temperatures (greater than 3 J of energy and a temperature of 160 °C [320 °F]), to prevent these energy sources from falling and contacting combustible waste		2. Hot equipment - the temperature limit for contact by hot equipment is set to 160 °C (320 °F) to account for the possibility of localized organic-nitrate chemical self heating in the heated portion of the waste which could raise the waste temperature to the ignition temperature of 230 °C (446 °F)

Table 5.3.2.17-5. Technical Safety Requirement Controls for Organic-Nitrate Condensed-Phase Combustion Accidents. (3 sheets)

Control	Safety function	Comments
4. Physical barriers shall restrict vehicle access to those aboveground structures outside of tank farm boundaries that can direct liquids into waste tanks. Only vehicles with protected fuel systems shall be allowed within barriers		4. No comment
5. Speed limit controls		5. No comment
6. Lightning protection measures shall be imposed as discussed in Section 5.3.2.23.2 to reduce the frequency of lightning current arcing to or through the waste		6. Lightning - no comment
7. All flammable gas ignition controls in respective facility when and where they are required to prevent flammable gas deflagrations		7. A flammable gas deflagration may also be an ignition source for an organic-nitrate combustion event. Therefore, where potential hazards include both flammable gas and organic-nitrate combustion, the controls for flammable gas described in Section 5.3.2.14 also prevent or reduce the potential for organic-nitrate combustion
8. Rotary mode core sampling is permitted only per approved Authorization Basis		8. None
1.2 Moisture Controls 1. Interim stabilization of conditionally safe or unassigned tanks by salt well pumping shall not be performed until sampling and analysis is performed and it is determined that the post-pumped condition does not pose a significant risk (i.e., the post pumped condition does not result in a condition that requires the waste to be placed in the UNSAFE group). See Table 5.3.2.17-1 for the SST waste group status	1. and 2. Prevents removal of tank moisture which protects wastes from potential organic-nitrate combustion events	
2. Emergency pumping in response to tank leaks in conditionally safe or unassigned SSTs shall be limited to the supernate above the solid waste level unless requirement 1 is satisfied or DOE approval of a waiver to this requirement is received		
3. For conditionally safe tanks where moisture is credited in preventing combustible conditions, a surveillance program shall periodically verify by liquid level monitors, visual observation, or other available means that the waste does not dry out to become unsafe	3. Ensures that conditionally safe waste does not dry out to the point where it would be unsafe	

Table 5.3.2.17-5. Technical Safety Requirement Controls for Organic-Nitrate Condensed-Phase Combustion Accidents. (3 sheets)

Control	Safety function	Comments
4. For conditionally safe tanks only, ventilation system design or operating changes that may cause increased moisture loss shall be evaluated for the effect on waste such that creating conditions that would require placing the waste in the unsafe group is prevented	4. Ensures that ventilation system design or operating changes are not made without consideration of the impacts on the tank waste moisture content that prevents organic-nitrate combustion in the tanks	
HEPA Filter Control Program with the following key elements: 1. Periodic radiation survey to monitor HEPA filter loading 2. HEPA filter replacement per change-out criteria, i.e., ≤ 2 mSv/h (200 mrem/h)	Reduce consequences from a possible HEPA filter failure by limiting the inventory available	None
Emergency Preparedness • Response procedures	Mitigates consequences of an organic-nitrate fire	None
Process instrumentation and measuring and test equipment	Prevents consequences of organic-nitrate reaction accident by ensuring identification and traceability of monitoring and detection equipment	The process instrumentation and measuring and test equipment control provide requirements for the instrumentation used to monitor the temperature in accordance with temperature controls

DCRT = double-contained receiver tank.
DST = double-shell tank.
HEPA = high-efficiency particulate air (filter).
mSv = millisievert.
RMCS = rotary mode core sampling.
SST = single-shell tank.

Table 5.3.2.17-6. Defense-in-Depth Controls for Organic-Salt Nitrate Reactions.

Control	Safety Function	Comment
Vehicle positioning spotters	Spotters provide additional level of control in positioning cranes/vehicles	Reduces probability of analyzed accident
Tank Farm Fences	Provide line of demarcation within which Ignition Control Program key elements related to vehicle fuel systems must be met	Fence gates are typically closed and locked
HEPA Filter replacement at 1 mSv/h (100 mrem/h)	Limit inventory available for release. Limit dose rate to workers in vicinity of the filters	None

5.3.2.18 Surface Leak Resulting in Pool.

Purpose of Analysis: Surface leaks of waste that form pools are a safety concern because a fraction of the waste can be resuspended (entrained) in wind blowing over the surface of the pool, or over the surface of contaminated soil where the pool may have soaked into the soil. Resuspended waste can lead to significant inhalation doses to onsite and offsite receptors. In addition, waste surface pools and contaminated soil can produce significant shine doses and skyshine doses to onsite receptors.

Analysis Strategy: Hazardous conditions that can result in leaks of waste to the surface of the soil have been identified in the hazards analysis. The hazardous conditions can be grouped into the following categories:

- Overflows of various pits associated with waste transfer (i.e., pump, valve, and sluice pits; diversion boxes; vault facility pits; and the vent station nozzle pit) caused by leaks from piping, jumpers, valves, or transfer pumps in the pits during transfers
- Overflows of various pits associated with waste transfer caused by misrouting through compromised transfer paths
- Overflows of various storage tank process pits (e.g., double-contained receiver tank [DCRT], double-shell tank [DST], catch tank pump pits) caused by the overfilling of storage tank with waste
- Overflows from various process pits caused by raw water leaks that overfill waste storage tanks connected via open drain lines or risers (includes overflows of DCRTs, DSTs, single-shell tanks [SSTs], and catch tanks)
- Overflows of slurry line cleanout boxes caused by seal leaks from cleanout lines during transfers
- Surface pools caused by leaks from SST temporary above grade transfer (over-the-ground transfer) lines
- Overflows through transfer line encasement risers (requires failure from primary pipe concurrent with a closed or plugged encasement drain)
- Surface pool leaks caused by backflows of waste into service water or flush water supply systems
- Pool leaks inside various interfacing facilities (e.g., 242-S Evaporator) caused by misrouting of waste from tank farms.

The bounding, representative accident selected for detailed analysis (assuming no controls) was an overflow of a process pit caused by a misrouting of waste through an open nozzle. The misroute scenario produces the highest potential leak rate and the largest surface pool of waste in a given time frame. Even when waste is properly routed, leaks

from transfer equipment in the pits (e.g., leaks caused by misaligned jumpers, failed jumper gaskets, failed valve packing, failed pump seal, failed piping welds) can result in an overflow of a pit, but a longer time is required than in the misroute scenario. The misroute accident therefore bounds scenarios involving leaks from jumpers, valves, or piping within the pit. Surface pools of waste that could be caused by subsurface leaks from buried portions of transfer lines are covered in Section 5.3.2.19.

5.3.2.18.1 Accident Scenario Assuming No Controls.

Sequence of Events. For the scenario assuming no controls, the waste is postulated to be misrouted into a process pit where the cover blocks have been removed and the pit drain is closed. The misroute is postulated to involve aging waste facility waste because this type of waste has the highest inhalation dose potential of the three waste types. The accident analysis assumes the waste is misrouted into the 241-A-A valve pit. Evaluation of the accident scenarios with pit volumes smaller than valve pit 241-A-A (15 m^3 [530 ft^3]) indicated potential for larger surface pools or spray leaks. The potential is due to a combination of smaller pit volume and potentially inadequate transfer system covers. The accident scenario assuming no controls is not affected by the size of the pit since the entire liquid volume available is assumed to result in a surface pool (HNF-2296, *Justification for Continued Operation of Transfer Lines Having Structures with Less Volume than 241-A-A Valve Pit*).

The waste transfer pump is assumed to continue operating for 12 hours before the leak is visually observed and the transfer pump is shut off. The waste flow rate into the pit is conservatively assumed to be the run out flow rate of the transfer pump (1,136 Lpm [300 gpm]), based on tank farm pump performance curves. Over a 12-hour period, this results in a total spill volume of 817,650 L (216,000 gal).

While the pit is filling with waste and before the nozzle becomes submerged, aerosols are generated from splatter and splashing. After the nozzle becomes submerged and as the pit fills, aerosols are resuspended from the surface of the liquid in the pit (from welling, wave action). The waste rapidly fills the pit, overflows to the ground surface, and spreads out on the soil surface until the transfer pump is shut off at 12 hours.

While the surface pool is growing, liquid aerosols are resuspended in wind blowing over the surface of the pool. After the transfer pump is shut off, the pool is postulated to soak into the ground. The leak occurs when the ambient temperature is below the saturation temperature of the waste. Dissolved salts crystallize out of solution while the pool soaks in, leaving a surface layer of contamination. Entrained sludge particulates in the waste are also postulated to be filtered out and left on the surface of the soil. Particulate surface layer contamination is postulated to be resuspended as the soil dries out for an indefinite time period after the transfer pump has been shut off.

The onsite receptor is assumed to be exposed to aerosols generated from splatter, splashing, and resuspension while the pit is filling and to aerosols resuspended from the surface pool as it is forming during the first 12 hours

of the accident. The onsite receptor is also exposed to shine and skyshine dose for the 12-hour exposure period. The offsite receptor is assumed to be exposed to the aerosols released during the first 12 hours of the accident and to waste particulates resuspended from the contaminated soil surface for an additional 24 hours after the transfer pump has been shut off and the waste has soaked into the soil.

The frequency category of the accident is determined on the basis of the likelihood of the initiating event. Tank farm operating experience indicates that waste leaks into process pits are "anticipated" events. WHC-SD-WM-CN-049, *Calculation Notes for Surface Leak Resulting in Pool, TWRS FSAR Accident Analysis*, summarizes several occurrence reports containing accounts where waste leaked into process pits during transfers. Between 1972 and 1996, the occurrence reporting database includes five accounts of waste being misrouted through compromised transfer paths into process pits.

Results Summary. The onsite and offsite radiological and toxicological consequences calculated for the valve pit overflow are summarized and compared against the risk guidelines for the "anticipated" frequency category in Table 5.3.2.18-1. The onsite dose includes 84 mSv (8.4 rem) from shine and 910 mSv (91 rem) from skyshine. Supporting calculations are documented in WHC-SD-WM-CN-049.

Implications of Results. The radiological consequences of the representative accident exceed both the onsite and offsite risk guidelines. The onsite toxicological consequences also exceed the risk guidelines. Therefore, safety structures, systems, and components; Technical Safety Requirement controls; or both are required.

5.3.2.18.2 Accident Scenario Assuming Controls.

A suite of controls was selected to prevent misrouting through open nozzles into pits and to prevent jumpers from disconnecting during transfers. These controls include programs to ensure configuration management of transfer routings, administrative procedures to require independent verification of valve lineups before transfers, and administrative procedures that require leak tests of jumpers following jumper changes. In addition, a TSR exists to blank off all open nozzles in pits where waste could be misrouted.

The scenario assuming controls takes credit for the just-described controls to prevent high flow rate leaks into process pits. Given the preventive controls, a maximum transfer equipment leak rate of 1.3 L/s (20 gpm) was assumed. To mitigate transfer equipment leaks inside process pits, the process pit leak detectors and their alarms were elevated to Safety-Class status. In addition, a Technical Safety Requirement control was selected to ensure operators shut off the transfer pump following activation of the pit leak detector. In addition, a Technical Safety Requirement control was selected to ensure the pit cover is on during transfers, which would limit the release of aerosols from the pit during the leak and limit shine and skyshine doses to the onsite receptor.

Sequence of Events. The sequence of the accident assuming controls is as follows:

- An equipment leak (e.g., gasket failure) inside a cleanout box with an interior volume of 0.2 m^3 (7.1 ft^3) causes a low volume leak (maximum leak rate assumed to be 1.3 L/s [20 gpm]).
- The COB drain is assumed to be plugged at the time of the leak.
- The COB cover is on at the time of the leak.
- The COB leak detector is assumed to alarm after 51 mm (2 in.) of waste have built up in the bottom of the pit.
- Flow is assumed to continue for 30 minutes after the leak detector alarms, allowing time for operators to respond to the alarm and to shut off the appropriate transfer pump.
- After the pump is shut off, 20% of the waste contained in a 3,048-m (10,000-ft), 77-mm- (3-in.-) diameter transfer line is assumed to drain back through the leakage path.
- Aerosols are generated inside the COB from splatter, splashing, and spraying while the pump is running.
- Convection currents in the COB are assumed to keep some aerosols in suspension after the transfer pump is shut off.
- Aerosols are expelled through gaps in the COB cover because of liquid displacement, the heat load in the COB, atmospheric pressure changes, and wind effects.

Results Summary. The onsite and offsite radiological and toxicological consequences of the accident assuming controls are summarized and compared with the risk guidelines in Table 5.3.2.18-2. Supporting calculations are documented in WHC-SD-WM-CN-049.

Implications of Results. The controls selected to mitigate equipment leaks inside the COB are shown to be at the onsite radiological risk guidelines. Additionally, the offsite radiological dose and onsite and offsite toxicological exposure consequences are below the risk guidelines.

5.3.2.18.3 Key Assumptions. Assumptions related to the derivation of the accident frequency and calculation of the accident consequences are documented in WHC-SD-WM-CN-049. Key assumptions are listed below.

Important to Accident Frequency. There are no key assumptions related to the accident frequency estimate.

Important to Accident Consequences.

- The controls selected to prevent misroutes through open nozzles into waste transfer-associated structures and to prevent jumpers from disconnecting are assumed to preclude high flow rate leaks.

- The maximum leak rate into the waste transfer-associated structures, given the preventative controls, is assumed to be 1.3 L/s (20 gpm) from a degraded jumper gasket.
- A transfer system-associated structure $\geq$ 15 m^3 (530 ft^3) will totally contain the leak.
- The leak is assumed to occur in a COB.
- The pit leak detector alarm is assumed to annunciate after 51 mm (2 in.) of waste have built up in the COB.
- The operator is assumed to shut down the appropriate transfer pump 30 minutes after the leak detector alarm goes off.
- Supplemental covers in addition to the transfer system covers are assumed to limit the spray-leak-generated aerosol.

5.3.2.18.4 Controls. The following controls are applicable to waste transfers and waste transfer facilities, as specified in the associated tables. See Section 5.3.2 for additional discussion of how the selected controls prevent or mitigate hazardous conditions and accidents caused by waste transfer misrouting.

Safety Structures, Systems, and Components. Tables 5.3.2.18-3 lists the Safety-Class and Safety-Significant structures, systems, and components selected to mitigate the risk of surface leaks that would result in pools. For each safety structure, system, and component, the safety function is described, and additional comments are provided as appropriate.

Technical Safety Requirement Controls. Table 5.3.2.18-4 lists the Technical Safety Requirement controls selected to mitigate the risk of surface leaks resulting in pools. For each control, the safety function is described and additional comments are provided as appropriate.

Defense-in-Depth. In addition to the identified safety structures, systems, and components and Technical Safety Requirement controls, other engineering and Administrative Controls provide further Defense-in-Depth protection for the public and workers against the risk of surface leaks resulting in pools. The Defense-in-Depth controls are identified in Table 5.3.2.18-5 along with their safety function and additional comments, as appropriate.

5.3.2.19 Subsurface Leak Resulting in Pool.

Purpose of Analysis: This accident analysis covers leaks from buried or bermed transfer lines as potential initiators of surface pools of waste. Transfer line leaks at high flow rates that are in excess of the natural infiltration rate of the soil can result in surface pools of waste because the soil beneath the leak can become supersaturated with liquid so that the waste plume expands upwardly. Capillary action and hydraulic force (if the leak occurs at high pressure on top of the line) can contribute to the formation of surface pools. Leaks from unencased, bermed transfer lines can result in surface pools of waste if "piping" phenomena wash out the berm.

Accidents that result in surface pools of waste are of safety concern because radioactive aerosols and particulates can be resuspended by wind flowing over the pool surface or by wind flowing over a contaminated soil surface, should the waste pool soak into the soil. Resuspended aerosols and particulates can be inhaled by downwind receptors. Large pools of waste or contaminated areas of soil also can present a significant shine and skyshine hazard to onsite receptors.

Analysis Strategy: Waste is transferred in the tank farms by using three basic kinds of transfer lines: unencased direct buried or bermed lines, buried concrete encased lines, or buried pipe-in-pipe transfer lines. In general, unencased direct buried or bermed lines are used for transfers out of single-shell tanks (SSTs) (i.e., for interim stabilization of SSTs). Concrete encased lines are used for transfers between SSTs and double-shell tanks and for some transfers from interfacing facilities. The cross-site transfer line is concrete encased. Pipe-in-pipe transfer lines are generally used for transfers in the newer double-shell tank farms and for transfers to and from the 242-A Evaporator.

Leaks from transfer lines have occurred and are considered to be one of the more likely accidents within Tank Waste Remediation System. Mechanisms postulated to result in leaks from all three types of lines include aging, corrosion, erosion, thermal stress, water hammer, undermining caused by leaks from nearby pipes, seismic stress, and excavation accidents. This analysis covers transfer line leaks that are caused by internal initiators. Leaks initiated by excavation accidents are analyzed in Section 5.3.2.21, "Spray Leak from Underground Waste Transfer Lines," and leaks initiated by seismic events are covered in Section 5.3.2.23, "Natural Phenomena."

A leak from an unencased, bermed line was selected as the representative case for detailed analysis for the following reasons.

- The unencased lines are older, in direct contact with the soil, and more prone to failure than the encased lines.
- The surface pools that can develop if "piping" phenomena wash out a berm are larger than the pools that can develop as a result of leaks from buried lines.

- Leaks into concrete or pipe encasements will tend to flow back to process pits. Should the encasements leak, the volume of waste leaked to the soil will be smaller than from unencased lines.

- Leaks from concrete and pipe encasements will be under low pressure and oriented downward, so that surface pools will be far less likely to form than in the bermed, unencased pipe leak scenario.

5.3.2.19.1 Accident Scenario Assuming No Controls.

Sequence of Events. The bounding representative accident selected for detailed analysis is a leak from an unencased bermed line during a submersible pump transfer from an SST. The leak is assumed to be catastrophic (i.e., 100% of pipe flow leaks into the soil). The flow rate through the leak is the maximum flow rate of the submersible transfer pump (i.e., 189 Lpm [50 gpm]). The leak which erodes the embankment material, continues for 12.5 hours, until a 141,953-L (37,500-gal) surface pool of waste covering a surface area of 1,672 m^2 (2,000 yd^2) is formed. The leak occurs when the ambient temperature is significantly below the saturation temperature of the waste. The dissolved salts in the waste crystallize out of solution as the pool spreads and thereby limit the penetration of waste into the soil. While the pump is running, it is assumed the surface of the pool remains liquid.

After the leak is detected and the transfer pump is shut off, the remaining liquid waste soaks into the soil. Because of the filtering effect of the soil, the crystallized salts and any entrained solid precipitates carried in the waste stream are postulated to be deposited in the top few centimeters of soil.

While the pump is running and the pool is growing, aerosols are resuspended by wind blowing over the liquid surface. After the pump is shut off and the waste soaks into the soil, particulate surface contamination is resuspended as the soil drys. This resuspension continues indefinitely (until the leak site is remediated, e.g., sprayed with water to limit resuspension or covered with gravel).

The onsite and offsite receptors are exposed to resuspended aerosols and particulates from the liquid pool and contaminated soil. After the waste has soaked into the soil, the onsite receptor is exposed for 12 hours to particles resuspended from the contaminated soil surface and also to shine and skyshine. For the first 12.5 hours of the accident, the offsite receptor is exposed to resuspended waste from the surface of the growing liquid pool. For an additional 24 hours, the offsite receptor is exposed to waste particles resuspended from the contaminated soil.

The transfer lines used for interim stabilization of SSTs are beyond their intended 5-year design life. Because these lines are in contact with the soil, they are prone to corrosion failures. Therefore, on the basis of site experience, the initiating event (a leak from an unencased bermed line) is considered to be an "anticipated" event.

Results Summary. The onsite and offsite radiological and toxicological consequences of a subsurface leak resulting in a surface pool assuming no controls are presented in Table 5.3.2.19-1. The onsite radiological dose is the summation of 2.9 Sv (290 rem) resulting from inhalation and 0.24 Sv (24 rem) resulting from shine and skyshine. The supporting calculations are documented in WHC-SD-WM-CN-057, *Calculation Notes for Subsurface Leak Resulting in Pool, TWRS FSAR Accident Analysis.*

Implication of Results. The radiological consequences to the onsite and offsite receptors exceed the risk guidelines values of 5 mSv (0.5 rem) and 1 mSv (0.1 rem), respectively, for an "anticipated" event. The toxicological consequences to the onsite receptor exceed the risk guidelines. Therefore, controls are required.

5.3.2.19.2 Accident Scenario Assuming Controls.

Sequence of Events. For the scenario assuming controls, operator action is credited with limiting the duration of the release and limiting the volume of waste material leaked. Operator surveillance of unencased bermed lines every 30 minutes during SST submersible pump transfers is required to detect pipe failures and berm washouts.

Shortly after surveillance, a leak is assumed to occur and to wash out the berm. The transfer continues for 30 minutes until the operator passes by the leak point at the next surveillance interval. Thirty minutes after detection of the leak, the appropriate transfer pump is shut down.

The leak continues for 1 hour at the maximum flow rate of 189 Lpm (50 gpm) and releases 11,356 L (3,000 gal) of waste. Line holdup also flows through the leakage path. During the hour in which the transfer pump is running, aerosols are released from the growing liquid pool. After the pump is shut off, the waste soaks into the ground (a conservative assumption).

The onsite receptor is exposed to resuspended aerosols from the growing liquid pool for 1 hour before being evacuated to an upwind staging area. In addition, the onsite receptor is exposed to direct shine and skyshine radiation from the growing pool for 1 hour. The offsite receptor is exposed to resuspended aerosols from the growing liquid pool for 1 hour and to resuspended particulates from the contaminated ground for an additional 24 hours. No credit is taken for emergency response within the 24 hours to minimize resuspension by covering the leak.

The frequency of the scenario assuming controls is the same as the frequency of the scenario assuming no controls because no credit is taken for controls that would reduce the likelihood of the event.

Results Summary. The onsite and offsite radiological and toxicological consequences of a subsurface leak resulting in a surface pool assuming controls are presented in Table 5.3.2.19-2. The onsite radiological dose is the summation of 0.38 mSv (38 mrem) resulting from inhalation and 3.9 mSv (390 mrem) resulting from shine and skyshine. The offsite toxicological sum-of-fractions value is higher than the onsite because the maximum release

rate occurs after 1 hour, by which time the onsite receptor has been relocated out of the plume. The supporting calculations are documented in WHC-SD-WM-CN-057.

Implication of Results. The onsite and offsite radiological and toxicological consequences are below the risk guidelines for the scenario assuming controls.

5.3.2.19.3 Key Assumptions. Assumptions related to the derivation of the accident frequency and calculation of the accident consequences are documented in WHC-SD-WM-CN-057. Other key assumptions are listed here.

Important to Accident Frequency. No key assumptions are associated with accident frequency.

Important to Accident Consequences. Key assumptions associated with the accident consequences are as follows:

1. The waste leaked is SST waste containing 33 vol% entrained solids.
2. The leak occurs at the maximum submersible pump flow rate of 190 Lpm (50 gpm).
3. Unencased bermed transfer line surveillances are performed every 30 minutes.
4. Upon detection of the leak, 30 minutes pass before the operator turns off the appropriate transfer pump and evacuates the onsite receptor to a safe distance upwind.
5. After the transfer pump is shut off, 1,514 L (400 gal) of line holdup is assumed to drain back through the leak path. (This assumption effectively prohibits submersible pumping of the T Tank Farm.)

5.3.2.19.4 Controls. The following controls are applicable to waste transfers through single-walled direct buried or bermed lines, concrete encased lines, and pipe-in-pipe encased lines as specified in the associated tables. See Section 5.3.2 for additional discussion of how the selected controls prevent or mitigate hazardous conditions and accidents caused by waste transfer misrouting.

Safety Structures, Systems, and Components. The Safety-Class and Safety-Significant structures, systems, and components selected to mitigate the risk of surface pools resulting from subsurface leaks are listed in Table 5.3.2.19-3. For each safety structure, system, and component, the safety function is described and additional comments are provided as appropriate.

Technical Safety Requirement Controls. The Technical Safety Requirement controls selected to mitigate the risk of surface pools resulting from subsurface leaks are listed in Table 5.3.2.19-4. For each Technical Safety Requirement control, the safety function is described and additional comments are provided as appropriate.

Defense-in-Depth. In addition to the previously identified safety structures, systems, and components and Technical Safety Requirement controls, other engineering and administrative controls provide further Defense-in-Depth protection for the public and workers against the risk of surface pools resulting from subsurface leaks. The Defense-in-Depth controls are identified in Table 5.3.2.19-5 along with their safety function and additional comments, as appropriate.

Table 5.3.2.19-1. Consequences of a Subsurface Leak Resulting in Pool Assuming No Controls.

Receptor/hazard	Calculated dose/exposure	Risk guidelines (anticipated)
Onsite radiological	3.1 Sv (310 rem)	5 mSv (0.5 rem)
Offsite radiological	7.1 E-03 Sv (0.71 rem)	1 mSv (0.1 rem)
Onsite toxicological sum-of-fractions	16.7	1 (≤ERPG-1)
Offsite toxicological sum-of-fractions	3.0 E-02	1 (≤PEL-TWA)

ERPG = Emergency Response Planning Guideline.
mSv = millisievert.
PEL-TWA = permissible exposure limit, time weighted average.

Table 5.3.2.19-2. Consequences of a Subsurface Leak Resulting in Pool Assuming Controls.

Receptor/hazard	Calculated dose/exposure	Risk guidelines (anticipated)
Onsite radiological	4.2 mSv (0.42 rem)	5 mSv (0.5 rem)
Offsite radiological	0.65 mSv (0.065 rem)	1 mSv (0.1 rem)
Onsite toxicological sum-of-fractions	2.4 E-03	1 (≤ERPG-1)
Offsite toxicological sum-of-fractions	5.4 E-03	1 (≤PEL-TWA)

ERPG = Emergency Response Planning Guideline
mSv = millisievert.
PEL-TWA = permissible exposure limit, time weighted average.

Table 5.3.2.19-3. Safety Structures, Systems, and Components for Subsurface Leak Resulting in Pool.

Structures, systems, or components	Safety classification		Safety function	Comments
	SC	SS		
Waste transfer piping concrete encasement	X	--	Ensure that a leak in the primary waste transfer system piping is directed to a waste transfer-associated structure	See controls for surface leak resulting in pool, Section 5.3.2.18
Waste transfer pipe-in-pipe encasement	X	--	Ensure that a leak in the primary waste transfer system piping is directed to a waste transfer-associated structure	See controls for surface leak resulting in pools, Section 5.3.2.18
Tank level detection systems	--	X	Provides tank waste level to support performance of periodic material balances during waste transfers to detect waste leaks	Applicable to SSTs, DSTs, AWF tanks, DCRTs, and catch tanks
Salt well flow totalizer	--	X	Provide total salt well flow to support performance of periodic material balances during waste transfers to detect waste leaks	

AWF = Aging Waste Facility.
DCRT = double-contained receiver tank.
DST = double-shell tank.
SC = Safety-Class.
SS = Safety-Significant.
SST = single-shell tank.

Table 5.3.2.19-4. Technical Safety Requirement Controls for Subsurface Leak Resulting in Pool.

Control	Safety function	Comments
Waste Transfer Control Program Key elements: Single-walled direct buried/ bermed line surveillance during waste transfers (once per 12 hours for salt well pumping and once per 30 minutes for submersible pumping) Material balances shall be performed periodically during waste transfers Configuration management Independent route verification during transfer setup Monitoring of interconnected tanks for level increase Double-valve isolation on interconnected line	Detect a waste transfer line leak Detect a waste transfer line leaks and misroutes Prevent misroutings Prevent misroutings Detect misroutings	The surveillance times are based on a maximum salt well pumping flow rate of 15 Lpm (4 gpm) and a maximum submersible pumping flow rate of 189 Lpm (50 gpm)
Encasement seal loop valves are not in the closed position	Ensure that if the primary pipe leaks during waste transfer, the encasement will drain to the waste transfer-associated structure	
Emergency Preparedness Response procedure	Mitigate consequences to onsite personnel	

Table 5.3.2.19-5. Defense-in-Depth Controls for Subsurface Leak Resulting in Pool.

Control	Safety function	Comments
Active unencased transfer lines are pressure tested once a year unless successful transfer completed in the line within the year	Reduces likelihood of leaks	
Direct buried and bermed, unencased pipe is heat trace and insulated	Protect pipe from damage due to thermal shock or damage due to freezing	Insulation may have deteriorated. Heat trace on most lines are inactive
Test risers are located every 100 ft along concrete-encased transfer lines	Periodic swabbing provides confidence that transfer lines are sound	
Walkdowns are performed once/shift to detect surface leaks from cross-site line	Provides backup to material balance for leaks that might surface	
Test risers are provided on long pipe-encased transfer line	Swabbing can detect prior failure in line, minimize likelihood of leak during transfer through that line	
Some pipe-encased transfer lines are equipped with active encasement leak detectors	Detect leak during transfer, provide backup to pit leak detection	Can also be used as Safety-Class substitute for pit leak detection

5.3.2.20 Spray Leak in Structure or From Overground Waste Transfer Line.

Purpose of Analysis: Hanford Site waste is pumped under pressure during waste transfer operations. A breach of containment along a transfer route during a transfer could result in a pressurized spray release. Pressurized spray releases are a safety concern because, depending on waste pressure and leak dimensions, they can be relatively efficient generators of respirable-sized aerosols.

Analysis Strategy: Historically, the majority of spray leaks have occurred inside process pits (i.e., pump pits, valve pits, and sluice pits) along transfer routes. A spray leak inside a valve pit was selected for analysis because the number of piping connections, and thus the number of potential leak sites, is greater than in other types of process pits. In addition, there may be multiple valve pits along a given transfer route.

Spray leaks can also occur inside process pits not along normal transfer routes where waste could be inadvertently misrouted, inside diversion boxes, inside vault used in single-shell tank and double-shell tank transfers (e.g., 244-AR Vault, CR Vault), inside cleanout boxes along slurry transfer lines, from encasement risers on pipe-encased transfer lines, inside flush pits or service buildings, from above grade components of flush water systems, from temporary overground transfer lines, and inside the 204-AR Waste Unloading Facility. Spray leaks at these locations are judged to be bounded or represented by the analyzed case based on an estimated lower or equivalent frequency of occurrence or consequence.

Spray leaks from buried portions of transfer lines are mitigated by soil cover. Leaks sufficiently large to wash away the soil would not be an efficient generator of respirable-sized aerosols but could result in a surface waste pool. This scenario was analyzed in Section 5.3.2.19. It is conceivable that a spray leak could occur in a transfer line uncovered by excavation activities. This scenario is analyzed in Section 5.3.2.20. A seismic event could also initiate spray leaks should it occur coincident with a waste transfer. This scenario is analyzed in Section 5.3.2.23.3.

5.3.2.20.1 Accident Scenario Assuming No Controls.

Sequence of Events. The Tank Waste Remediation System facilities spray leak accident scenario assuming no controls postulates that a spray leak develops in a valve pit as a result of one of the following mechanisms:

- Breach in the pressure boundary of piping, a jumper, or a valve
- Leak in piping, a jumper, or a valve body caused by erosion, corrosion, thermal stress, fatigue, weld flaws, or manufacturing flaws
- Leak at a jumper-transfer pipe connection as the result of human error (e.g., misalignment of the jumper) or gasket failure

- Leak at valve gasket, packing, or seal that has degraded as the result of radiation hardening, aging, and thermal stress

- Leak at a valve seal caused by torque generated in jumper connections.

The spray is postulated to occur during a transfer of aging waste (67 vol% liquid and 33 vol% solids) through the pit. Aging waste is selected for the bounding analysis as it produces the highest dose, on a per liter basis, of all tank waste types.

The pit cover blocks (i.e., the primary barriers to release) are postulated to be off at the time of the leak. The spray is postulated, because of its momentum, to emit up and out of the pit and directly into the atmosphere. The uncovered spray leak is assumed to continue unabated for 24 hours. The onsite receptor is assumed to be exposed to the plume of aerosols generated by the spray for 12 hours, and the offsite receptor is assumed to be exposed to the entire 24-hour passage of the plume.

The frequency of the valve pit spray leak accident scenario is based on the frequency of the initiating event. In this case, the initiating event is the equipment leak that results in the pressurized spray release during a transfer. The initiating event frequency is considered to be in the "anticipated" category (1×10^{-2} to 1×10^{0} events/yr). This frequency is justified by Hanford Site experience.

Results Summary. The onsite and offsite radiological and toxicological consequences of a valve pit spray leak assuming no controls are presented in Table 5.3.2.20-1. The associated calculations are documented in WHC-SD-WM-CN-048, *Calculation Notes in Support of TWRS FSAR Spray Leak Accident Analysis*.

Implication of Results. The radiological consequences of a valve pit spray leak to the onsite and offsite receptors exceed the risk guidelines. The toxicological consequences to the onsite receptor exceed the risk guidelines. Consequently, controls are required.

5.3.2.20.2 Accident Scenario Assuming Controls.

Sequence of Events. The valve pit spray leak accident scenario assuming controls postulates that a spray leak occurs inside a covered valve pit. In assuming controls, it is postulated that the spray impacts pit cover blocks. The cover blocks are credited with preventing the direct emission of the aerosols generated by the spray to the atmosphere.

Although the cover blocks are credited for knocking down the spray, they are not sealed and, therefore, do not ensure the total containment of aerosols. Leak paths exist through gaps around the blocks and associated drain ports, access hatches, and valve handle penetrations. The aerosols, generated by the spray are assumed to be released via the leak paths. Expulsion of air is the result of a release of pressure created by temperature and humidity increases in the pit and from liquid displacement. The concentration of respirable-sized particles in the expelled air is assumed to be 100 mg/m^3.

The frequency of the valve pit spray leak scenario assuming controls is the same as the scenario assuming no controls (i.e., "anticipated") because the controls selected do not affect the frequency of initiating events.

Results Summary. The onsite and offsite radiological and toxicological consequences of a valve pit spray leak assuming controls are presented in Table 5.3.2.20-2. The associated calculations are documented in WHC-SD-WM-CN-048.

Implication of Results. The offsite radiological consequences and the onsite and offsite toxicological consequences of a valve pit spray leak assuming controls are well below the risk guidelines.

The onsite radiological consequences for the bounding, representative accident exceed the risk guidelines by a factor of eight. Although the onsite guidelines are exceeded for the valve pit spray scenario assuming controls, the identified controls (i.e., valve pit cover blocks) provide adequate assurance that operations can be conducted safely on an interim basis. This conclusion is based on the following considerations.

- The spray leak was modeled using conservative assumptions in order to maximize the release of respirable aerosol.

- To provide a bounding consequence, the representative analysis is based on a transfer of aging waste. Although transfers of aging waste may be made, transfers typically involve double-shell and single-shell tank wastes. WHC-SD-WM-CN-048 also evaluates the consequences of a spray of double-shell tank waste inside a valve pit, a spray of single-shell tank waste inside a pump pit, and a spray of single-shell tank waste inside a double-contained receiver tank pump pit. The corresponding onsite consequences assuming controls are reduced from 4×10^{-2} Sv (4 rem) for the aging waste case to 1.3×10^{-2} Sv (1.3 rem), 2.6×10^{-3} Sv (0.26 rem), and 5.6×10^{-3} Sv (0.56 rem), respectively.

- To provide a bounding consequence, the representative analysis evaluates a transfer of waste containing 33 vol% solids. This value is based on the upper operating limit of the 242-A Evaporator. Typical transfers contain a lower solids content. WHC-SD-WM-CN-048 evaluates the sensitivity of the spray leak consequences as a function of solids content and waste type. For a spray leak in a valve pit involving waste containing 5 vol% solids, the onsite consequences assuming controls are 6×10^{-3} Sv (0.6 rem) for aging waste, 2.3×10^{-3} Sv (0.23 rem) for double-shell tank waste, and 1.5×10^{-3} Sv (0.15 rem) for single-shell tank waste.

- For the scenario assuming controls, the pit drain is assumed to be closed to maximize the quantity of air expelled as a result of liquid displacement. Pit leak detectors were not selected as a mitigative control for spray leaks; however, the detectors are present in all active process pits and have been designated as Safety-Class structures, systems, and components based on analyses of surface leaks resulting in pools (Section 5.3.2.18). Functional leak detectors would limit the duration of the spray for cases where

the pit drain was closed and would reduce the volume of aerosol displaced from the pit. The Final Safety Analysis Report will quantify the reduction in consequences associated with crediting leak detectors.

- A complete halt of waste transfers is not possible without stopping interim stabilization and waste retrieval activities because both activities further significant long-term safety improvement initiatives.

5.3.2.20.3 . Key Assumptions. Key assumptions related to the derivation of the accident frequency and calculation of the accident consequences as documented in WHC-SD-WM-CN-048 are presented below.

Important to Accident Frequency. There are no key assumptions associated with the spray leak accident frequency.

Important to Accident Consequences. The following are assumptions important to the accident consequences.

- For the scenario without controls, the spray is assumed to occur at maximum transfer pump pressure of 2.17 x 10^6 Pa (300 psig).
- The cover blocks provide tortuous leak paths.
- Maximum waste temperature during transfers is assumed to be 49 °C (120 °F).
- For the scenario assuming controls, the pit drain is assumed to be closed to maximize the quantity of air expelled because of liquid displacement.

5.3.2.20.4 Controls. The following controls are applicable to waste transfers and waste transfer facilities, as specified in the associated tables. See Section 5.3.2 for additional discussion of how the selected controls prevent or mitigate hazardous conditions and accidents caused by waste transfer misrouting.

Safety Structures, Systems, and Components. Table 5.3.2.20-3 lists the Safety-Class and Safety-Significant structures, systems, and components selected to prevent or mitigate the risk of waste transfer system spray leaks. The table includes the represented case (i.e., a spray leak in a valve pit) and other potential spray leak locations. For each safety structure, system, and component listed in the table, the safety function is described and additional comments are provided, as appropriate.

Technical Safety Requirement Controls. Table 5.3.2.20-4 lists the Technical Safety Requirement controls selected to prevent or mitigate the risk of waste transfer system spray leaks. The table includes the represented case (i.e., a spray leak in a valve pit) and other potential spray leak locations. For each Technical Safety Requirement control listed in the table, the safety function is described and additional comments are provided as appropriate.

Defense-in-Depth. In addition to the above identified safety structures, systems, and components and Technical Safety Requirements, other engineering and Administrative Controls provide further Defense-in-Depth protection for the public and workers against the risk of waste transfer system spray leaks. The Defense-in-Depth controls are identified in Table 5.3.2.20-5 with the safety function and additional comments included, as appropriate.

Table 5.3.2.20-3. Safety Structures, Systems, and Components for Spray Leaks. (2 sheets)

Structures, systems, or components	Safety classification		Safety function	Comments
	SC	SS		
1.0 Spray leaks inside process pits,* diversion boxes, vaults, and cleanout boxes				
Transfer System Covers	X	--	Knockdown spray, limit release of aerosols to the atmosphere	Waste transfer-associated structure covers are also a mitigative feature for other accidents and provide radiation protection (i.e., shielding) for facility workers
2.0 Spray leaks from encasement risers (for pipe-in-pipe transfer lines)				
None required	--	--	--	See Table 5.3.2.21-4 for Technical Safety Requirement controls
3.0 Spray leaks from service water supply system components coincident with backflows of waste				
3.1 Pressure switch interlock to waste transfer pump(s) or alarm in service water system connections to the waste transfer system	X	--	Prevent backflow of waste into the service water line and potential leaks in structures (e.g. service pits) without mitigative safety structures, systems, and components preventing direct release to the atmosphere (i.e., covers, leak detectors)	The pressure switch in the service water lines connected to the waste transfer system are not automatically interlocked to some waste transfer pumps (e.g., waste transfer pumps in interfacing facilities that transfer waste to tank farms). An acceptable alternative is isolation of the service water line by two closed valves and a pressure switch with an alarm in a continuously monitored area. Pressure switch alarm procedures would require the immediate shutdown of the transfer pump on alarm
3.2 Backflow preventers in service water system connections to the waste transfer system	--	X	Prevent contamination of the service water system via backflow of waste into service water line	The hazardous condition of concern is contamination of the raw water system and not specifically a spray leak
4.0 Spray leaks from single-shell tank overground transfer lines				
4.1 OGT encasements and connections	X	--	Confine leak from the primary piping and ensure that a leak is directed to the encasement leak detection system	The OGT pipe encasement shall be designed to withstand the design basis earthquake and high wind
4.2 OGT concrete shielding system	X		Prevent vehicle collisions with the OGT system that could result in a loss of integrity of the primary and encasement pipe	
5.0 Spray leaks inside actively ventilated tanks				
5.1 Stack CAM and interlock to exhaust fan	X	--	Ensure exhaust fan is shut down should exhaust HEPA filters break through	Aerosol-laden air could eventually saturate the HEPA filters, resulting in their failure
6.0 Spray leaks inside the 204-AR Waste Unloading Facility				
6.1 Stack CAM and interlock to exhaust fan	X	--	Ensure exhaust fan is shut down should exhaust HEPA filters break through Prevents unfiltered aerosol release to the atmosphere	Aerosol-laden air could eventually saturate the HEPA filters, resulting in their failure

Table 5.3.2.20-3. Safety Structures, Systems, and Components for Spray Leaks. (2 sheets)

Structures, systems, or components	Safety classification		Safety function	Comments
	SC	SS		
6.2 204-AR Waste Unloading Facility Structure including west exterior doors	--	X	Knock down/confine spray within facility	The primary mitigative control is the 204-AR Waste Unloading Facility effluent stack CAM interlock to the ventilation exhaust fan. Verify that the west exterior rollup door and the west exterior personnel access door are closed during waste transfers physically connected to the 204-AR Waste Unloading Facility

*Includes valve pits, central and feed pump pits, sluice pits, leak detection pits, annulus pump pits, flush pits, and catch tank pump pits.

CAM = continuous air monitor
HEPA = high-efficiency air filter
OGT = overground transfer
SC = Safety-Class
SS = Safety-Significant

Table 5.3.2.20-4. Technical Safety Requirement Controls for Spray Leaks. (2 sheets)

Control	Safety function	Comments
General applicability		
Transfer System Cover removal controls	Provides compensatory measures for cover removal during transfers	None
1.0 Spray leaks inside process pits,* diversion boxes, vault pits, and cleanout boxes		
1.1 Transfer System Cover operability	Operable covers mitigate spray leak by knocking down/confining the spray. This controls ensures covers are operable when the waste transfer-associated structure is physically connected to the waste transfer piping during waste transfer	An exception is allowed if the waste transfer-associated structure is separated by two locked valves and continuous monitoring for spray leaks is provided
1.2 Transfer pump administrative lock controls	Eliminates motive force for unplanned transfers	To address spray leaks that may occur during inadvertent waste transfer pump starts, either the waste transfer-associated covers shall be operable or the waste transfer pump(s) physically connected to waste transfer-associated structures shall be locked out
1.3 Transfer Controls Key elements: • Double valve isolation on interconnected lines • Configuration management shall be applied to waste transfer routes • The waste transfer route configuration shall be independently verified prior to transfers	 Double valve isolation on lines interconnecting with the transfer route provides compensatory protection to prevent a spray leak in an interconnected waste transfer-associated structure when the cover is off Configuration management and independent verification of waste transfer routes serves to prevent mistransfers	
2.0 Spray leaks from encasement risers (pipe-in-pipe transfer lines)		
2.1 Hydrostatic test valve on encasement drain line (if one exists) shall not be closed	Ensures that if the primary pipe leaks during waste transfer, the encasement will drain to the waste transfer-associated structure	Control prevents pressurizing encasement risers which could result in above grade spray release

Table 5.3.2.20-4. Technical Safety Requirement Controls for Spray Leaks. (2 sheets)

Control	Safety function	Comments
3.0 Spray leaks from service water supply components due to backflow of waste		
3.1 Service water pressure detection systems	Ensure operability of pressure switch and interlock or alarm. This ensures pressure switch and interlock systems or alarms are operable during waste transfers, transfer line flushing, pump priming, and transfer line pressure testing	Includes the pressure switch/waste transfer pump interlock systems used for connections to the permanent service water system and for pressure switch/interlock systems used for connections to temporary, above grade raw water systems. Temporary above grade water lines are used for flushing and priming of SST salt well systems Note: Pressure switch/waste transfer pump interlocks or alarm shall be operable during waste transfers to prevent backflow of waste into raw water lines. To address backflow of waste during inadvertent waste transfer pump starts, either the pressure switch/waste transfer pump interlock shall be operable or the waste transfer pump(s) physically connected to the raw water line shall be locked out
4.0 Spray leaks from SST overground transfer lines		
4.1 Transfer Controls Key element: use of OGT concrete shielding system or vehicle restrictions around OGT lines.	Ensure the OGT line is protected from vehicle collisions that could result in a loss of integrity of the primary and encasement pipes Ensure worker radiation protection by design feature or administrative control	--
5.0 Spray leaks inside actively ventilated tanks		
5.1 Stack CAM and exhaust fan interlock operability	Ensures interlock is operable during transfers out of the facility and during tank farm transfers through routes physically connected to the unloading facility	--
6.0 Spray leaks inside the 204-AR Waste Unloading Facility		
6.1 Stack CAM and exhaust fan interlock operability	Ensures interlock is operable during transfers out of the facility and during tank farm transfers through routes physically connected to the unloading facility	--
6.2 Verify that the west exterior rollup door and the west exterior personnel access door are closed during waste transfers physically connected to the 204-AR Waste Unloading Facility.	Knock down spray, limit release of aerosols to the atmosphere	--

*Includes valve pits, central and feed pump pits, sluice pits, leak detection pits, annulus pump pits, service pits, and catch tank pump pits.

CAM = continuous air monitor
OGT = overground transfer
SST = single-shell tank

Table 5.3.2.20-5. Defense-in-Depth Controls for Transfer System Spray Leaks.* (2 sheets)

Control	Safety function	Comments
1.0 Spray leaks inside process pits*, diversion boxes, vault pits, and cleanout boxes		
1.1 Repositioned jumpers are leak tested with pressurized water (where available) before initiating waste transfers. Cameras lowered through penetrations in the cover block are used to verify initial jumper integrity during the leak test. Where water is not readily available, the jumper leak test is performed during the initial stages of the transfer	Reduce the likelihood of a spray leak from a failed or misaligned jumper	--
1.2 Process pit and vault pit leak detectors and interlocks to waste transfer pumps	Limit duration of spray release. The liquid fraction of the release will drain past the leak detector	Leaks that produce low flow rates of liquid may not be detected
1.3 Catch tank weight factor instrumentation (for leaks inside diversion boxes)	Limit duration of spray release	The liquid fraction of spray leaks inside diversion boxes drain to catch tanks. The WF instrumentation will eventually detect the leak
1.4 Material balances (performed periodically during waste transfers)	Limit duration of spray release	Material balances are typically performed by comparing level changes in the source and receipt tanks and adjusting for line holdup. The material balances will eventually discover the discrepancy caused by the spray leak
1.6 COB leak detectors (where they exist)	Limit duration of release	More effective when COB cover is on
1.7 COBs on some slurry lines from the 242-A Evaporator have been upgraded. The cleanout lines were sealed with a flange, and a gasketed and bolted fit flange assembly replace the old sheet metal lid. The flange assembly is vented through an HEPA filter to remove radioactive particulates. A pressure gauge is provided to alert workers of a buildup of pressure within the COB	The upgraded design items provide confinement in the event of a spray	--
1.8 COBs drain to slurry line encasements	Prevent filling and pressurizing of the COB	--
2.0 Spray leaks from encasement risers (pipe-in-pipe transfer lines)		
2.1 Encasement leak detectors and interlocks with waste transfer pumps (where available)	Ensure transfer pump is shutdown upon detection of leak from primary transfer pipe. Prevents pressurization and potential spray leak from test riser	--
2.2 Process pit leak detector and transfer pump interlocks	Ensure transfer pump is shutdown upon detection of leak from primary transfer pipe. Prevents pressurization and potential spray leak from test riser	Encased transfer lines between tank farms have encasement leak detectors. Encased lines running within a tank farm generally do not. For encased lines running within a tank farm, process pit leak detectors are relied on to shut down transfer pumps should the primary line leak
2.4 Material balances are performed periodically during waste transfers	Limit duration of release that fill and pressurize encasement line	--

Table 5.3.2.20-5. Defense-in-Depth Controls for Transfer System Spray Leaks.* (2 sheets)

Control	Safety function	Comments
3.0 Spray leaks from raw water systems due to backflow of waste		
3.1 Isolation valves; two manual valves are closed to isolate the flush system when not in use	Prevent backflow of waste into the raw water supply	Isolation valves are not effective at preventing backflows during flushing operations as the valves will be open
3.3 Check valves	Prevent backflow of waste into the raw water supply	--
3.4 Quick disconnect (for salt well systems)	Provide seal to prevent spray to atmosphere when temporary raw water line disconnected	--
3.5 Valve position limit switches/interlocked to transfer pump(s)	Prevent backflow of waste into raw water supply	Permissive allows waste transfer pump to operate only when the isolation valves are closed
4.0 Spray leaks from single-shell tank overground transfer lines		
4.1 Encasement leak detectors	Will eventually detect small leak from primary line that may be producing a spray	--
4.2 Periodic material balances during transfer	May eventually detect spray leak from primary line	--
4.3 Heat trace	Prevent freezing, potential rupture of primary line	--
4.4 Insulation	Prevent freezing, potential rupture of primary line. Also provides additional mitigative barrier to spray release	--
4.5 Primary EPDM pipe	Designed to minimize potential for a leak	--
4.6 Radiation monitors may be used along OGT route	Detect leaks from OGT system.	--
4.7 Raw water radiation monitors	Detect contamination of raw water system	--
4.8 Encasement leak detectors	Backup pit leak detectors	--
5.0 Spray leaks inside the 204-AR Waste Unloading Facility		
5.1 Ventilation system HEPA filters	Remove radioactive aerosol particulates generated in the spray from the exhaust air	--
5.2 Catch tank ventilation system deentrainer and heater	Removing moisture reduces the relative humidity of air exhausted from catch tank area. These items prevent moisture plugging of downstream HEPA filters	The potentially pressurized portion of piping in the facility where spray leaks could occur is near the catch tank vent inlet
5.3 Mechanical equipment room and unloading area CAMs	May detect spray leak. Alarm will result in manual shutdown of transfer pumps	--
5.4 High DP alarms across HEPA filters/interlocked with exhaust fan	Indicate plugging of HEPA filters, which could be caused by aerosols generated in a spray leak	--
5.5 Low DP alarms across HEPA filters	Indicative of gross breakthrough of filter, which could result in an unmitigated release of aerosols	--

*Some of the controls is this list may be determined to be Safety-Class or Safety-Significant for other accidents

CAM = continuous air monitor
COB = cleanout box
DP = differential pressure
EPDM = ethylene-propylene-diene monomer
HEPA = high-efficiency particulate air (filter)
OGT = overground transfer
WF = weight factor

5.3.2.21 Spray Leak from Underground Waste Transfer Lines.

Purpose of Analysis: Tank waste is routinely pumped through underground waste transfer lines. The majority of the underground transfer lines are double-contained piping systems. Other transfer lines are contained within concrete encasements or are directly buried. A construction excavation accident involving powered digging equipment (e.g., a backhoe) could conceivably breach waste transfer piping resulting in the formation of either a spray release or surface pool.

Analysis Strategy: Analyses of surface pools and spray leaks are presented in Sections 5.3.2.18 and 5.2.3.20. Initiating events considered are related to transfer piping equipment failures (e.g., valve failure) and associated human errors (e.g., jumper misalignment). This analysis evaluates damage to underground transfer piping by powered digging equipment associated with excavation activities as the initiating event. The consequence calculations presented in Section 5.2.3.20 for scenarios assuming no controls are judged to be both bounding and representative of spray leaks and surface pools initiated by an excavation accident.

5.3.2.21.1 Accident Scenario Assuming No Controls.

Sequence of Events. It is postulated that construction activities in the vicinity of a waste transfer line require powered digging equipment to uncover a portion of an underground utility. It is assumed that an error occurs such that the transfer line is not properly identified and located. The digging equipment is assumed to strike and breach the transfer line. It is assumed that either a transfer is in progress at the time of the excavation or that a transfer is started before the repair is made. No credit is taken for corrective action on the part of the equipment operator. Depending on the extent of the damage, either a spray or pool is assumed to occur.

It is not possible to determine prior to the actual event whether this accident will result in the formation of a surface pool or a spray release. From a probability standpoint both outcomes are equally likely. However, a spray release resulting in the aerosolization of large quantities of material in the respirable particle range is considered the most limiting scenario. Because both types of releases are equally likely outcomes of the accident and because the spray release bounds the consequences of both, the spray release scenario was chosen for analysis.

No differentiation is made regarding the type of transfer line damaged by the digging equipment. It is assumed that the damage is sufficient to breach direct-buried pipes: both the secondary and primary pipes of double-contained piping systems, and both the concrete encasement and primary pipe of concrete-encased systems. Note, however, that the consequences referenced in Section 5.3.2.21.2, "Accident Scenario Assuming Controls", are based on aging waste, which would only be transferred through double-contained piping systems.

The scenario assuming no controls is judged to fall within the "anticipated" frequency category. This judgment is based on reported incidents of inadvertent damage to subsurface utilities and services caused by excavation activities.

Results Summary. The onsite and offsite radiological and toxicological consequences of either a spray leak or a surface pool resulting from an excavation accident are bounded by those calculated for a valve pit spray leak (Section 5.3.2.20).

Implication of Results. The radiological consequences to the onsite and offsite receptors exceed the risk guidelines for the spray leak scenario. The toxicological consequences to the onsite receptor exceed the risk guidelines for the spray leak scenario. Consequently, safety structures, systems, and components and/or Technical Safety Requirement controls are required.

5.3.2.21.2 Accident Scenario Assuming Controls.

Sequence of Events. The controls selected for spray leaks and surface pools initiated by excavation activities are presented in Section 5.3.2.21.4, "Controls." The controls prevent the event by ensuring that powered digging equipment is not used in the vicinity of transfer lines.

5.3.2.21.3 Key Assumptions.

Important to Accident Frequency. No key assumptions are associated with accident frequency.

Important to Accident Consequences. It is assumed that the consequences of spray leaks and surface pools initiated by excavation activities are bounded by events initiated by other mechanisms as analyzed in Section 5.3.2.20.

5.3.2.21.4 Controls.

Safety Structures, Systems, and Components. No safety structures, systems, and components are required for the spray leak from underground waste transfer lines scenario.

Technical Safety Requirement Controls. Table 5.3.2.21-1 lists the Technical Safety Requirement controls selected to prevent spray leaks and surface pools initiated by excavation activities.

In addition to the preventive controls, a mitigative control was elevated to Technical Safety Requirement status on the basis of the severity of the consequences calculated for the scenario assuming no controls (see Key Element 3 in Table 5.3.2.21-1).

Defense-in-Depth. The Defense-in-Depth controls for the spray leak from underground waste transfer line scenario are identified in Table 5.3.2.21-2 along with the respective safety functions and additional comments, as appropriate.

Table 5.3.2.21-1. Technical Safety Requirement Controls for Spray Leak and Surface Pools from Underground Waste Transfer Lines.

Control	Safety function	Comments
Excavation Control Program Key elements: 1. An excavation permit shall be required when excavating in areas where waste transfer lines exist. Key requirements of the permitting process shall include: a. Composite map for the planned excavation site b. Radiological evaluation of the planned excavation activity c. Physical marking of ground surface d. Approval of the proposed excavation by the tank farm cognizant facility engineer and the facility manager or delegate e. Hand-digging only is allowed within approximately 5 ft of a waste transfer line	Prevents leaks in waste transfer lines caused by excavation activities by ensuring: • Excavation activities are not inadvertently performed near waste transfer lines • Excavation activities are carefully controlled when required near waste transfer lines	
2. Waste transfers shall not be conducted in transfer lines located within approximately 15 ft of ongoing excavation activities	Prevents leaks in waste transfer lines caused by excavation activities by ensuring that excavation activities are not performed near waste transfer lines during waste transfers	
3. The excavation supervisor shall ensure that communication systems are available at the job site and that the excavation crew knows how to contact tank farm operations immediately upon indication of a waste transfer leak or other abnormal situation	Mitigates waste transfer leaks caused by excavation activities by prompt shutdown of the waste transfer pump	Calculation note S-CLC-G-00132 calculates the consequences of 40-min spray. Although reduced, the radiological consequences still exceed risk guidelines for the bounding spray leak source term
4. Aboveground labelling of waste transfer lines outside of tank farm fences	Prevents leaks in waste transfer lines caused by excavation activities by ensuring that excavation activities are not inadvertently performed near waste transfer lines outside of tank farms	
5. Waste transfer through lines uncovered by excavation activities shall be prohibited unless radiation protection controls are established, approved, and implemented that replace the shielding provided by the removed soil	Prevents transfers through waste transfer lines that are uncovered by excavation activities that could cause worker radiation doses exceeding limits established by the radiation protection program	This control was selected based on worker safety considerations

Table 5.3.2.21-2. Defense-in-Depth Controls for Spray Leak and Surface Pools from Underground Waste Transfer Lines.

Control	Safety function	Comments
Material balances (performed periodically during waste transfers)	Limit duration of spray release or size of surface pool	Material balances are typically performed by comparing level changes in the source and receipt tanks and adjusting for line holdup. The material balances will eventually discover the discrepancy caused by the spray leak

5.3.2.22 Tank Bump.

Purpose of Analysis: The purpose of this analysis is to provide a bounding estimate of consequences resulting from a tank bump so that controls necessary to maintain risk at acceptable levels can be defined. The thermal phenomenon known as a tank bump occurs when steam stored in the waste causes a waste rollover and a rapid pressurization of the tank headspace. If the waste contains a sufficient heat load, steam bubbles are trapped in sludge and then suddenly released to the tank dome space because of buoyant instabilities. A tank bump is a safety concern because of the potential for a release of aerosolized waste to the environment.

Analysis Strategy: For a tank bump to occur, the waste temperature must be at or above the local saturation temperature; this requires a heat generation rate greater than 7,600 W (26,000 Btu/h), assuming no active ventilation. Saturation temperature of tank liquid waste is 104 °C (220 °F) at atmospheric pressure because of dissolved salt content in the waste, as discussed in WHC-SD-WM-ER-198, *Development of a Dynamic Computer Simulator for Aging Waste Tank Operations and Safety Assessment*. At heat generation rates below 7,600 W (26,000 Btu/h), sufficient heat is transferred by natural conduction to the surrounding soil to maintain waste temperature below 104 °C (220 °F).

An amount of sludge is also required for a tank bump to occur. Tank sludge contains the highest density of heat-producing isotopes, is generally nonconvective, and is highly viscous. The heat source in sludge provides a location for steam to generate. The high viscosity of the sludge contributes to the nonconvective nature. The high viscosity and hydrostatic head trap the steam generated in the sludge.

Tanks containing higher waste levels will result in higher tank bottom pressures so that the corresponding saturation temperature will be higher. This means that the energy stored before a bump will be higher and the bump, should it happen, will be stronger. However, higher temperatures will have to be reached in tanks with higher waste levels before steam begins to form.

Hanford Site waste tanks that presently have a heat generation rate of 7,600 W (26,000 Btu/h) or higher and contain sludge are Tank 241-C-106; Tank 241-A-104; Tank 241-A-105; Tank 241-SY-101; several tanks in the 241-AN, 241-AP, and 241-SX tank farms; and the aging waste facility (AWF) tanks. Tanks 241-A-104 and 241-A-105 are not considered to have the proper initial conditions for a tank bump because they have been without active ventilation for several years and the waste temperatures have stabilized well below 104 °C (220 °F).

The AWF tanks currently represent the upper bound on heat load and radionuclide content (i.e., dose contributor) for the tanks that pose a tank bump threat. AWF Tank 241-AZ-101 has nearly twice the heat load of any other AWF tank. Therefore, a postulated tank bump in Tank 241-AZ-101 is used as the bounding accident analysis.

A steam release is similar to a tank bump in that both involve the release of pressurized steam, but the tank bump involves a waste rollover with much greater quantities of steam released into the tank vapor space. A tank bump event is bounding for any steam release events.

5.3.2.22.1 Accident Scenario Assuming No Controls. For the accident scenario assuming no controls, it is postulated that active ventilation for Tank 241-AZ-101 is lost for an indefinite amount of time, and tank temperatures begin to rise without detection. No intervention is undertaken to remove potential heat sources (e.g., mixer pumps) or to provide alternate waste cooling methods (e.g., water addition). The temperature of the tank waste is postulated to rise above local saturation throughout the tank.

Heat builds up in the sludge as energy produced by radioactive decay of fission products is released. Heat input from other sources is not considered. As the waste material reaches the local saturation temperature, steam is generated. The steam is trapped in the sludge because of the high viscosity of the sludge and the hydrostatic head.

Sufficient steam is assumed to be generated that the sludge becomes buoyant and the hydrostatic head is overcome. Alternatively, some physical mechanism (agitation of the sludge through an external mechanism) provides the stored steam with a release path or enhances the buoyancy of the sludge.

The released steam travels through the overlaying supernate and carries a significant amount of sludge with it. This results in the steam and high heat sludge contacting the supernate. The heat stored in the sludge and steam is transferred to the supernate. This heat transfer condenses the steam and raises the temperature of the supernate. The cycle then begins again at a higher temperature. If the tank supernate is already at or near saturation, the steam will not condense but will travel completely through the supernate to the tank headspace. As the steam travels through the supernate, the mass of steam increases from two mechanisms. First, because of the reduction in hydrostatic head, supernate that was held in the liquid phase by the pressure flashes to steam. Second, supernate that was already at local saturation absorbs heat from the superheated sludge and flashes to steam. The steam mass increase results in a pressure increase of the tank headspace. Steam volume is also increased from expansion of the steam bubbles as the static head to which they are subjected decreases. In addition, the heat and steam produce fluid velocities high enough to carry liquid and solid particles into the tank risers. All pump pit and sluice pit cover blocks are postulated to be off during this time. Vapor and particles are released to the environment through unfiltered pathways.

The Tank 241-AZ-101 waste conditions were modeled with the GOTH thermal hydraulics computer code, a transient computer program used to model multi-phase flow (WHC-SD-WM-CN-022, *Evaluation of Potential and Consequences of Steam Bump in High-Heat Waste Tanks and Assessment and Validation of GOTH Computer Code*). The release quantities provided by the GOTH computer model had two distinct components. The first component is the release caused by fluid dynamics (i.e., the event produces fluid velocities such that the waste is carried out the open riser by momentum). The second component is the release caused by pressurization effects (i.e., the increase in the tank headspace pressure above atmospheric pressure forces waste out of the tank to

a region of lower pressure). In reality, the tank risers are covered with either equipment (e.g., pumps) or flanges that are bolted in place. The only release pathway is through pit drain lines. Because of bends in the pit drain lines, very little of the fluid dynamic portion of the release is actually expected to occur. Inclusion of the fluid dynamic portion of the release, therefore, is conservative.

The scenario without controls is assigned a frequency of "unlikely" on the basis of initiating event frequency and heating of tank waste without detection and intervention. Given current Tank 241-AZ-101 waste conditions, a ventilation outage of approximately 90 days would be required for vapor generation to occur (WHC-SD-WM-CN-022). Extreme conditions (e.g., an earthquake) would be necessary to cause such an extended outage.

Results Summary. The onsite and offsite radiological and toxicological consequences of a tank bump are presented in Table 5.3.2.22-1. The associated calculations are documented in WHC-SD-WM-CN-043, *Tank Bump Consequence Analysis*.

Implications of Results. The accident consequence results indicate that the onsite radiological and toxicological consequences for the tank bump accident exceed risk guidelines. Therefore controls are required.

5.3.2.22.2 Accident Scenario Assuming Controls. The controls selected for the tank bump scenario are preventive in nature and are presented in Section 5.2.3.22.4, "Controls." These controls prevent tank waste from reaching saturation temperatures, thereby precluding the tank bump event. Tank waste is prevented from reaching saturation temperatures by the monitoring of tank waste temperatures. Should a rising temperature trend be detected, the controls provide a minimum of one week during which time potential heat sources (e.g., mixer pumps) would be eliminated, or waste cooling techniques (e.g., ventilation, water addition) would be initiated.

5.3.2.22.3 Key Accident Scenario Assumptions.

Important to Accident Frequency. The unmitigated accident frequency was assumed to be "unlikely" on the basis of the postulated occurrence of a major event that could preclude restart of active ventilation systems within 25 days. The 25-day recovery period was based on Tank 241-AZ-101 initial temperature being approximately 200 °F (93 °C). The calculated heat up of Tank 241-AZ-101 is 0.9 °F per day. Most double-shell tanks also contain a large hydrostatic head. At 4.6 m (15 ft) of hydrostatic head, the saturation temperature increases approximately 12 °C (20 °F). Therefore, a higher allowable temperature of 105 °C (220 °F) can be assumed at waste depths greater than 4.6 m (15 ft). Because the single-shell tanks of concern do not contain large hydrostatic heads and cannot receive additional transfers, the lower temperature limit applies to the entire waste volume. Higher initial tank temperature would require a shorter recovery period.

Important to Accident Consequences. The radiological composition of the waste in the tank bump scenario was assumed to be that of AWF tank liquids and solids, and the toxicological composition of the waste was conservatively assumed to be equivalent to double-shell tank liquids and solids.

5.3.2.22.4 Controls.

Safety Structures, Systems, and Components. The Safety-Significant structures, systems, and components selected to prevent or mitigate the risk from tank bumps are listed in Table 5.3.2.22-2. No structures, systems, and components were determined to be Safety-Class.

Technical Safety Requirement Controls. The Technical Safety Requirement controls selected to prevent tank bumps are listed in Table 5.3.2.22-3. The controls selected also provide protection against a postulated "chemical runaway" accident (Section 5.3.2.17). For each Technical Safety Requirement control, the safety function is described and additional comments are provided as appropriate.

Defense-in-Depth. In addition to the structures, systems, and components and Technical Safety Requirements identified in Table 5.3.2.22-3, other engineering and Administrative Controls provide the public and workers with further Defense-in-Depth protection against the risk of tank bumps. The Defense-in-Depth controls are identified in Table 5.3.2.22-4 along with the safety function and additional comments, as appropriate.

Table 5.3.2.22-2. Safety Structures, Systems, and Components for Tank Bumps.

Structures, systems, or components	Safety classification		Safety function	Comments
	SC	SS		
Tank waste temperature monitoring system (241-C-106; 241-SX-103, 107, 108, 109, 110, 111, 112, 114; all double-shell tanks; and all aging waste facility tanks)		X	Monitor tank waste temperature to provide operators with information on the existing temperatures in the waste so that necessary actions can be taken to prevent reaching temperatures at which tank bumps or steam release events could occur	A steam release event is a specific type of tank bump Also provides protection against a postulated "chemical runaway" accident (Section 5.3.2.17)
Tank waste level detection system (double-shell tanks and aging waste facility tanks)		X	Monitor tank waste level to support implementing the tank temperature controls	Also provides protection against a postulated "chemical runaway" accident (Section 5.3.2.17)

SC = Safety-Class
SS = Safety-Significant

Table 5.3.2.22-3. Technical Safety Requirement Controls for Tank Bumps.

Control	Safety function	Comments
1.1 Tank waste temperature monitoring system (and, if required, level detection system) shall be operable with the following tank waste temperature limits: For SSTs, ≤ 96 °C (205 °F) For DSTs and AWF tanks, ≤ 91 °C (195 °F), for all waste levels OR ≤ 91 °C (195 °F) in the top 15 ft of the waste AND ≤ 102 °C (215 °F) in the waste below 15 ft	Ensure that tank waste temperature monitoring system (and, if required, tank waste level monitoring system) is operable and that temperatures at which a tank bump or steam release event could occur are not reached	The specific waste temperature limits for SSTs and DSTs/AWF tanks were established during the development of the TSRs by the accident analysts and operations personnel Temperatures must be maintained below those that could result in a tank bump or steam release Control also provides protection against a postulated "chemical runaway" accident (Section 5.3.2.17)
1.2 AC ensures that waste transfers do not result in DST or AWF tanks with high sludge level and high heat load where ventilation system failure could result in tank bumps	Prevent the development of tanks with a high tank sludge level and high heat load where if tank cooling were lost a tank bump could occur prior to restoration of tank cooling (i.e., a tank outside the safety envelope)	Control also provides protection against a postulated "chemical runaway" accident (Section 5.3.2.17)
1.3 Process instrumentation and measuring and testing equipment	Ensures instrumentation used to monitor temperature is maintained	Control also provides protection against a postulated "chemical runaway" accident (Section 5.3.2.17)

AC = Administrative Control
AWF = Aging Waste Facility
DST = double-shell tank
SST = single-shell tank
TSR = Technical Safety Requirement

Table 5.3.2.22-4. Defense-in-Depth Controls for Tank Bumps.

Control	Safety function	Comments
Active ventilation or other heat removal mechanisms shall be maintained	Maintain sludge and supernatant temperatures below the required control levels for tanks with a potential for tank bump	Control also provides protection against a postulated "chemical runaway" accident (Section 5.3.2.17)
Sludge mixing by in-tank mixer pump or other mechanisms could be used	Render the sludge incapable of storing steam	Effects of heat contribution from mixer pumps would require evaluation prior to use
Pump pit and sluice pit cover blocks shall be in place whenever the conditions for initiation of a tank bump are present (i.e., active ventilation system down indefinitely)	Provide containment and confinement function in the event of a tank bump and limit onsite and offsite radiological and toxicological exposures	Control also provides protection against a postulated "chemical runaway" accident (Section 5.3.2.17)
Emergency Response Plan/ Procedures shall be in place and implemented in response to emergency conditions resulting from a tank bump	Protect onsite personnel and facility workers from unnecessary radiological and toxicological exposure in the event of a tank bump	Emergency response plan identified as an Interim Operational Safety Requirement Administrative Control for other accidents Control also provides protection against a postulated "chemical runaway" accident (Section 5.3.2.17)

5.3.2.23 Natural Phenomena. Requirements in DOE 5480.23, *Nuclear Safety Analysis Reports*, and the associated implementing guidance in DOE-STD-3009-94, *Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports*, mandate that accidents initiated by natural phenomena are to be considered in safety analysis accident analyses. Natural phenomena accident assessments differ from the assessments of accidents with other initiators. Natural phenomena assessments must address specific design (or evaluation) performance goals for new and existing systems, structures, and components depending on the potential consequences of accidents as outlined in DOE 5480.28, *Natural Phenomena Hazards Mitigation*[1], and summarized for the Hanford Site in Appendix C, "Site Characteristics," Table C1-33. DOE 5480.28 invokes the requirements of the following standards:

- DOE-STD-1020-94, *Natural Phenomena Hazards Design and Evaluation Criteria for Department of Energy Facilities*
- DOE-STD-1021-93, *Natural Phenomena Hazards Performance Categorization Criteria for Structures, Systems, and Components*
- DOE-STD-1022-94, *Natural Phenomena Hazards Site Characterization Criteria*
- DOE-STD-1023-95, *Natural Phenomena Hazards Assessment Criteria*
- DOE-STD-1024-92, *Guidelines for Use of Probabilistic Seismic Hazard Curves at Department of Energy Sites.*

Table 5.2-4 summarizes the natural phenomena analyzed as accident initiators in the TWRS facilities. A number of potential accidents were postulated for each natural phenomenon listed in Table 5.2-4 and were assigned to the consequence and frequency categories as discussed earlier in this chapter. Based on the hazards evaluation and accident analysis selection process, accident types initiated by high wind, lightning, and seismic events were selected for further analysis as summarized in the following subsections. The seismic load, wind load, and lightning strike frequencies are consistent with those found in Appendix C, Table C1-33.

5.3.2.23.1 High Wind. High winds at TWRS pose a natural phenomenon hazard because winds could initiate single or multiple accidents from a common cause. Straight winds and tornadoes at the Hanford Site are characterized in Appendix C, Section C1.4, "Environmental Description."

Purpose of the Analysis: Accidents initiated by high winds are assessed to establish the need for and effectiveness of safety SSCs and TSRs. To assure the level of conservatism is appropriate for facility characteristics such as hazards to people and the environment as well as cost, DOE-STD-1020-94, provides guidance for facility-appropriate design wind speeds depending on the facility hazard category and Performance

[1]Although DOE 5480.28 has been rescinded, the contractor is obligated by the existing contract to meet the requirements in this order. DOE 420.1, *Facility Safety*, replaces DOE 5480.28 and contains the same natural phenomena requirements.

Category of equipment. For existing category 2 facilities with Performance Category 3 equipment such as the underground storage tanks, a straight "fastest mile" wind speed of 70 mph and a return frequency of 10^{-3}/yr is used for the evaluation basis (Appendix C, Table C1-33). Analysis of wind-blown missiles is not required by DOE-STD-1020-94, for existing category 2 facilities with Performance Category 3 equipment. More severe wind speeds are considered only in Beyond Evaluation Basis Accident assessments.

For the accidents considered herein, wind gusts rather than straight winds are appropriate to characterize accident likelihoods. High wind gusts are expected events at the Hanford Site as shown in Table 5.3.2.23.1-1. Wind gusts in excess of 100 km/h have been experienced during every month of the year, with the highest wind gusts recorded at the Hanford Meteorological Station (mid-way between the 200 E and 200 W tank farm areas) of 129 km/h in January 1972 and January 1990.

Analysis Strategy: A number of potential wind-related accidents were identified by the hazards analysis. On the basis of hazards evaluation and accident analysis selection process, three accidents initiated by high wind were selected for further analysis. The associated accident scenarios involve (1) the transport of waste samples, (2) the collapse of a crane boom, and (3) a tear or puncture of a flexible receiver bag. These scenarios are discussed below.

Accident Scenarios Assuming No Controls. The three wind scenarios identified previously are analyzed as independent accidents because it is unlikely that a single wind storm would initiate all three accidents. However, the likelihood of any of the wind-initiated accidents without controls is the sum of the likelihoods of the three accidents presented which is in the "anticipated" frequency bin.

Part A. Sample Cask Transport Vehicle Crash. Tank waste samples are routinely collected and sent to onsite laboratories for sample analysis and waste characterization. Once collected, waste samples are placed in either an onsite transport cask or a pig, and then loaded onto a transport vehicle. Once loaded onto the transport vehicle, "ownership" of the waste transfers from TWRS to Transportation and Packaging. The containers are transported using WHC-SD-TP-SARP-002, *Safety Analysis Report for Packaging (On-site) Onsite Transport Cask*, as the safety and Authorization Basis for the onsite transport cask or WHC-SD-TP-SARP-001, *Sample Pig Transport System Safety Analysis for Report Packaging (On-site)*, for pigs. Each document shows compliance with the transport performance standards of 10 CFR 71, "Additional Requirements for Type B Packages," through either cask design or a combination of cask design and administrative controls. Accident assessments, including potential failure mechanisms for the containers (crush, puncture, fire) are documented explicitly in the safety analysis reports for packaging. Because the safety analysis reports for packaging provide the Authorization Basis for cask and pig transport, their transport is not considered further in this BIO.

Part B. Crane Boom Collapse in High Winds.

- **Sequence of Events**—This scenario postulates that a mobile crane operating with heavy loads in a tank farm is subjected to a high wind gust. The gust collapses the crane boom and causes the crane load to fall on an underground waste storage tank riser. In turn, the riser then punctures the tank dome. The contribution of the crane boom collapse to the load impact is uncertain. The boom would absorb energy during its deformation, but depending on its failure mode, could also add to the total impact. Because of the uncertainty in impact load, the consequences of the crane boom collapse and dome puncture are assumed bounded by the drop of a mixer pump in a pit as analyzed in Section 5.3.2.13.

  The frequency of occurrence of the wind-induced failure was estimated qualitatively based on (1) a conservative crane drop frequency of 3×10^{-4} per lift, and (2) an assumption that no more than five percent of such drops are related to high winds. This assumption is believed conservative because available failure statistics do not show any wind-induced failures, perhaps because crane lifts are usually not performed in high winds. Using an estimated 1,000 heavy lifts per year above underground tanks results in a drop frequency without controls of 1.5×10^{-2}/yr. Finally, it is estimated that no more than ten percent of the load drops would hit risers and cause a puncture of the dome. This estimate is based on crane operators' tendency to avoid areas with potentially vulnerable equipment below and to minimize the length of load paths for heavy loads. Although the collapse of the crane boom could increase the impact area over the tanks and thereby increase the likelihood of impacting a tank riser, the collapse would also distribute the impact over a larger area and may not have enough impact to cause a riser to puncture the dome. Therefore, the likelihood of a wind-induced drop of a heavy load without controls that results in a punctured tank dome is estimated as 1.5×10^{-3}/yr or in the "unlikely" frequency category.

- **Results Summary**—The onsite and offsite radiological and toxicological consequences of the wind-induced crane boom collapse is represented and bounded by the consequences of the drop of a mixer pump in a pit. Mixer pump analysis is located in Section 5.3.2.13. The crane boom collapse resulting in the puncture of a riser through the tank dome is considered more likely than the drop of a mixer pump in a pit because of the number of heavy lifts over the tanks, and the consequences of the punctured dome would be less severe than the drop of a mixer pump in a pit.

- **Implications of Results**—Because the scenario assuming no controls exceeds the onsite toxicological risk guidelines, controls are required.

Part C. Flexible Receiver Bag Failure. A flexible receiver is an engineered system of components used to wash, contain, transport, and dispose of contaminated equipment upon removal from underground waste storage tanks. The flexible receiver is bolted onto a 4-in. or 6-in. tank riser and is

supported by four hydraulically controlled legs that rest on the ground surface above the tank dome. The first flexible receiver station above the riser contains a spray ring that uses high pressure water to wash contaminates from the equipment;contaminated wash-water drains back to the underground tank. The equipment is then withdrawn through a pipe spool into a flexible receiver bag that provides containment of the contaminated equipment. The cylindrical receiver bag is initially folded (like an accordion), and then unfolds as a crane withdraws the equipment from the tank riser. The bag is sealed at the top, and as the equipment is withdrawn above the tank riser, the bottom is sealed with a cable. Cutters then separate the flexible bag from unused bag material. The flexible receiver bag inflates with air that is drawn from the tank headspace, through the riser, and to the washing station. When used on a tank that is ventilated actively and drawn down to a slight vacuum, the bag tends to collapse around the instrument with a minimum of air inflation. The flexible receiver bags are made of an abrasion-resistent, tear-resistent fabric.

- **Sequence of Events**—A wind-induced failure of a flexible receiver bag containing contaminated equipment removed from an underground waste storage tank was postulated. Failure of the flexible receiver bag occurs when the equipment has been withdrawn above the riser and just prior to sealing the bottom. High winds cause the crane and supported equipment to swing and tear or puncture the bag in the area where the bottom seal would have been placed. Because the equipment is fully withdrawn, it offers no resistance against the riser, and only moderate resistance by the bag guide rods. The maximum amount of contaminates is present when the equipment is fully withdrawn.

  During preoperational testing, crane operators reported difficultly in precisely positioning a loaded flexible receiver in winds greater than about 32 km/h (20 mph). For winds up to 64 km/h (40 mph), it is assumed crane operators could manage a loaded flexible receiver if necessary. For wind gusts at 97 km/hr (60 mph) it is assumed a loaded flexible receiver would be essentially out of control. Therefore, it is assumed that winds gusts of 97 km/h (60 mph) are sufficient to cause the flexible receiver to swing and puncture or tear the fabric. As listed in Table 5.3.2.23.1-1, such wind gusts occur once every 2 years. Operations estimate that flexible receivers withdraw equipment no more than 24 days per year. Without administrative controls, the combined frequency of operating the flexible receiver and having wind speeds of 97 km/hr (60 mph) is then

  Frequency = (1 high wind/2 yr) (24 days operation/365 days per year)
  $= 3 \times 10^{-2}$ occurrences per year ("anticipated").

- **Results Summary**—The onsite and offsite radiological and toxicological exposures for the flexible receiver bag failure are shown in Table 5.3.2.23.1-2. The supporting calculations are documented in WHC-SD-WM-CN-061, *Releases from Failure of a Flexible Receiver Bag in High Winds.*

- **Implications of Results**—Because the scenario consequences assuming no controls are within the risk guidelines, no safety SSC or TSR controls are required. However, Defense-in-Depth controls are identified.

Accident Scenario Assuming Controls. Assuming controls are in place to preclude crane activities in high wind, and assuming the controls work as intended, the crane boom collapse accident is prevented. The flexible receiver bag failure accident without controls is within the risk guidelines; therefore, a case with controls was not calculated.

Key Accident Scenario Assumptions.

Important to Accident Frequency. For the collapse of the crane boom in high winds, the following key assumptions apply:

- As many as 1,000 lifts of heavy equipment and cover block occur over the tanks per year (note that as many as 6,000 lifts could occur per year and still remain within the "unlikely" frequency category)
- The number of crane drops per lift is 3×10^{-4}, and 5% of these are related to wind
- The likelihood of hitting a riser and puncturing the riser through the dome given a load drop is 0.1.

There are no key assumptions important to accident frequency for the flexible receiver bag failure scenario that is in the "anticipated" frequency category.

Important to Accident Consequences. For the collapse of the crane boom in high winds, see key assumptions in Section 5.3.2.13.

For the failure of a flexible receiver in high winds, the following key assumption applies:

- For the scenario assuming no controls, the source term associated with the flexible receiver bag failure assumes a pre-accident maximum radiation field of 10 R/h on contact with the receiver bag. However, because the controls identified for the flexible receiver bag scenario are preventive in nature, the contact dose rate is not a critical parameter.

High Wind Controls. High wind controls are outlined below and apply to all mobile crane activities.

Safety SSCs. No Safety-Class or Safety-Significant SSCs are associated with high winds.

TSR Controls. TSRs for operations in high winds are given in Table 5.3.2.23.1-3. Mobile crane activities used for lifting cover blocks from pump and valve pits and for supporting equipment being installed or removed from waste tanks are managed through compliance with DOE/RL-92-36, *Hanford Site Hoisting and Rigging Manual*, with close coordination of Tank Farm

operations. The manual requires wind speed be considered before starting a lift and prohibits lifts if weather conditions are adverse to safe load-handling operations.

Defense-in-Depth. Procedures provide Defense-in-Depth protection against consequences of a flexible receiver bag failure. Use of the flexible receiver constitutes a critical lift subject to the requirements of DOE/RL-92-36, including the requirement that wind speed be considered before starting a lift (Table 5.3.2.23.1-4).

5.3.2.23.2 Lightning. Lightning strikes at the tank farms are a safety concern because they are potential initiators of in-tank flammable gas deflagrations, organic solvent fires, or organic salt-nitrate reactions. Sections 5.3.2.14, 5.3.2.15, and 5.3.2.17 discuss the consequences of these three accident scenarios. This section addresses the likelihood of accident scenarios initiated by lightning and establishes the basis for lightning controls.

Operational records report no incidence of lightning strikes on a tank riser or appurtenance during the 50-year history of the Hanford Site. However, these records do indicate that a number of lightning strikes have hit 200 East and 200 West Area structures, power poles, and transformers. Recent research on lightning as a potential accident initiator at the tank farms is reported in WHC-SD-WM-ES-387, *Probability, Consequences, and Mitigation for Lightning Strikes to Hanford Site High-Level Waste Tanks*. WHC-SD-WM-ES-387 establishes that, after conservatively accounting for detection frequency and uncertainties, the observed lightning strike frequency at the tank farms is 0.06 strikes/yr/km^2 (0.02 strikes/yr/mi^2).

Accident Scenarios Assuming No Controls. The three lightning scenarios (in-tank flammable gas ignition, organic solvent fire, organic salt-nitrate reaction) have been evaluated independently. Analysis to date suggests accident independence (i.e., an accident of one type is unlikely to lead to another); however, the likelihood of any lightning-initiated accident is the sum of the likelihoods of the three accidents. The sum of the likelihoods places the three scenarios in the "unlikely" frequency category.

Flammable Gases Ignited by Lightning.

- **Sequence of Events**—Lightning is postulated to strike over a tank farm and ignite flammable gases in one or more underground waste storage tanks.

  A gas release event caused by a low pressure weather system that is also accompanied by lightning is considered more likely than a random gas release event and an independent lightning strike. For flammable gas mixtures that require comparatively low energies for ignition, the nominal area of a tank farm is appropriate to bound the area at risk because a strike anywhere over the tank farm could potentially cause ignition of one or more tanks with flammable gas mixtures exceeding the lower flammability limit. The tank farm area is taken to include the fenced area plus a margin around the fence. A factor of 1.5 was applied to the nominal tank farm dimensions (150 m on a side) to account for a margin around the fence. The resulting area is about 0.05 km^2 (225 m on a side). This value conservatively bounds the value of 0.02 km^2 used in WHC-SD-WM-ES-387. Using an area of 0.05 km^2 and an average

frequency of 0.06 strikes/yr/km^2, the likelihood of a strike over a tank farm is 3 x 10^{-3}/yr. Conditional probabilities of the tank farm containing one or more tanks with flammable gas mixtures given the lightning strike also apply.

For the ignition of flammable gases, the lightning strike must occur when flammable gas is present at concentrations above the lower flammability limit in one or more tanks. Such time-at-risk periods may occur randomly from gas release events (GREs) or follow GREs induced by the low-pressure weather system that also causes the lightning. Studies show the combined frequencies of a random GRE and a lightning strike are unlikely (WHC-SD-WM-CN-041, *Tank Farm Deflagration Rates Due to Various Ignition Sources*).

The combined frequencies of a lightning strike and a low pressure weather system causing a GRE with the resultant mixture above the lower flammability limit is not well understood. Observations have shown increased hydrogen concentrations in the headspace of tanks during or after low pressure weather systems but they have never approached the lower flammability limit (WHC-SD-WM-ES-387). The combined frequency was conservatively estimated as 3 x 10^{-5} occurrences per year for each SST farm and 3 x 10^{-4} occurrences per year for each DST farm (WHC-SD-WM-CN-041). Using 12 farms with SSTs and 6 farms with DSTs, the likelihood of a storm causing a GRE and a lightning-initiated ignition of flammable gases is 3.6 x 10^{-4} occurrences per year for SSTs ("unlikely"), and 1.8 x 10^{-3} occurrences per year for DSTs ("unlikely").

- **Results Summary**—The onsite and offsite radiological and toxicological exposures resulting from lightning-initiated flammable gas deflagrations and other initiators are presented in Section 5.3.2.14. The likelihood of lightning initiating flammable gas ignition is categorized as "unlikely."

- **Implications of Results**—The flammable gases ignited by lightning scenario without controls exceeds the risk guidelines, therefore, controls are required.

Organic Solvent Fire Initiated by Lightning.

- **Sequence of Events**—This scenario postulates that a lightning strike ignites an individual underground waste storage tank containing a combustible concentration of organic solvents.

  Using the observed 0.06 strikes/yr/km^2 (0.02 strikes/yr/mi^2) as an estimate of lightning strike frequency, and considering the cross-sectional area of a large underground tank to be bounded by 500 m^2 (5,382 ft^2), the likelihood of a direct strike over a particular tank is 3 x 10^{-5}/yr and can be characterized as "extremely unlikely." This value is considered appropriate for use as an organic solvent initiator where a comparatively high energy is required to ignite the solvent. Assuming 15 tanks are capable of supporting an organic solvent fire (WHC-SD-WM-CN-041) and the likelihood of ignition given a lightning strike is unity, the

expected frequency for all tanks would be 5×10^{-4} fires per year ("unlikely"). Assuming an ignition frequency of one given the lightning strike is conservative because (1) data show lightning strikes at the Hanford Site are less energetic than lightning typical of this latitude (WHC-SD-WM-ES-387), (2) the tank geometry must be favorable to arcing in or near the waste surface, and (3) most energy would preferentially dissipate through the comparatively conductive steel shells, concrete, and rebar.

- **Results Summary**—The onsite and offsite radiological and toxicological exposures resulting from lightning-initiated organic solvent fires are presented in Section 5.3.2.15. The likelihood of lightning initiation an organic solvent fire is categorized as "unlikely."

- **Implications of Results**—The organic solvent fire initiated by lightning scenario without controls exceeds the risk guidelines, therefore, controls are required.

Organic Nitrate-Salt Reaction Initiated by Lightning.

- **Sequence of Events**—This scenario postulates that lightning strikes an individual underground waste storage tank containing organic nitrates and initiates an organic nitrate-salt reaction.

  For the initiation of an organic nitrate-salt reaction, the lightning must strike a tank that can sustain an organic nitrate-salt reaction. As for organic solvent ignition, a direct strike over a particular tank is conservatively assessed at 3×10^{-5}/yr. The likelihood of ignition of organic nitrates given a lightning strike is estimated at 0.1 because (1) data shows lightning strikes at the Hanford Site are less energetic than lightning typical of this latitude (WHC-SD-WM-ES-387), (2) the tank geometry must be favorable to arcing in or near the waste surface, and (3) most energy would preferentially dissipate through the comparatively conductive steel shells, concrete, and rebar. Assuming 10 tanks are capable of supporting an organic nitrate fire (Section 5.3.2.17) and a 0.1 likelihood of a lightning-induced organic nitrate fire, the expected frequency would be 3×10^{-5} fires per year ("extremely unlikely").

- **Results Summary**—The onsite and offsite radiological and toxicological exposures resulting from lightning-initiated organic nitrate-salt reactions and other initiators are presented in Section 5.3.2.17. The likelihood of lightning initiating an organic nitrate-salt reaction is categorized as "extremely unlikely."

- **Implications of Results**—Because the organic nitrate-salt reaction initiated by lightning scenario without controls exceeds the risk guidelines, controls are warranted.

Accident Scenarios Assuming Controls. Controls related to lightning strikes have been identified and are presented in the control section that follows. The ability of these controls to prevent ignition of flammable gas,

organic solvents, or organic nitrate-salt reactions remains uncertain and unquantifiable. Therefore, the scenarios assuming controls are assumed the same as the accidents without controls. Consequences of these scenarios are presented in Sections 5.3.2.14, 5.3.2.15, and 5.3.2.17. The frequency categories for the ignition of flammable gases and organic solvents remain "unlikely," and the frequency category for the initiation of an organic nitrate-salt reaction remains "extremely unlikely." Note that lightning may dissipate without causing an ignition source if the strike point is well grounded to the underground tank system or away from the tanks.

Key Accident Scenario Assumptions.

Important to Accident Frequency. The key accident scenario assumption important to the accident frequency is that after conservatively accounting for detection frequency and uncertainties, the observed lightning strike frequency at TWRS facilities was 0.06 strikes/yr/km^2.

Important to Accident Consequences. Sections 5.3.2.14, 5.3.2.15, and 5.3.2.17 discuss the key accident assumptions important to accident consequences.

Lightning Controls. Lightning controls are outlined below and apply to all intrusive activities in tank farms. See Tables 5.3.2.23.2-1 and 5.3.2.23.2-2.

Safety Structures, Systems, and Components. No Safety-Class or Safety-Significant SSCs are associated with lightning protection.

Technical Safety Requirement Controls. Because waste-intrusive activities may increase the likelihood of flammable gases being present above the lower flammability limit, or tank-intrusive activities may increase the likelihood of ignition of organic solvent fires or the initiation of an organic nitrate-salt reaction, a Technical Safety Requirement is imposed as illustrated in Table 5.3.2.23.2-1.

Defense-in-Depth. Additional programs and procedures provide Defense-in-Depth protection against impacts from lightning strikes as shown in Table 5.3.2.23.2-2. The Planned Safety Improvement described below will also contribute to Defense-in-Depth.

Planned Safety Improvements. The following safety improvements are planned to reduce the possibility of a lightning-initiated flammable gas deflagration, organic solvent fire, or organic salt-nitrate reaction.

- Additional grounded air terminals will be installed on 43 existing poles in 9 tank farms.
- Necessary corrective actions will be taken to ground tank risers and to bond instrumentation in risers to meet the lightning protection requirements in National Fire Protection Association (NFPA) 780, *Standard for the Installation of Lightning Protection Systems.*

These planned TWRS design improvements were recommended by the evaluation in WHC-SD-WM-ES-387.[1] As concluded in WHC-SD-WM-ES-387, these lightning protection improvements are for the single-shell tanks (SSTs) only, because a different design makes the double-shell tanks (DSTs) (including the AWF tanks) significantly less vulnerable to lightning effects.

5.3.2.23.3 Seismic Events. Seismic events at the tank farms pose a natural phenomenon hazard because they could initiate an accident or initiate multiple accidents from a common cause. The potential for earthquakes at the Hanford Site is predominately from regional crustal faults rather than faults related to the tectonic plate subduction zones located near the Pacific coast. No evidence of surface faulting exists in the immediate vicinity of the tank farms where the exposed surfaces primarily consist of sands, gravels, and silts deposited through a series of prehistoric cataclysmic floods.

Purpose of the Analysis: Seismic accident analyses are performed to establish the need for and effectiveness of safety SSCs and TSRs. To ensure the level of conservatism is appropriate for facility characteristics such as hazards to personnel, the public, and the environment, as well as cost, DOE-STD-1020-94 provides guidance for facility-appropriate design accelerations. Use of specific guidance depends on the facility hazard category and Performance Category of equipment. For existing Hazard Category 2 facilities with Performance Category 3 equipment such as the underground storage tanks, a peak horizontal ground acceleration of 0.19 *g* and a return frequency of 10^{-3}/yr is used as the evaluation basis acceleration (WHC-SD-W236A-TI-002, *Probabilistic Seismic Hazard Analysis DOE Hanford Site*) (Appendix C, Table C1-33). Accelerations of this magnitude, usually associated with Modified Mercalli Intensity Levels of

[1]The recommended design improvements from the evaluation in WHC-SD-WM-ES-387 also included assuring the independence of the existing lightning ground system from the tank farm electrical ground. As reported in WHC-SD-WM-ER-604, *Lightning Hazards Remediation Summary of Hanford Site Single Shell Tanks*, the separation of the existing lightning ground system from the tank farm electrical ground has been verified as adequate.

VII or greater (ORNL-NSIC-28, *Earthquakes and Nuclear Power Plant Designs*), have never been recorded at the Hanford Site. More severe accelerations are considered only in beyond evaluation basis accident assessments.

Analysis Strategy: Although the actual damage to TWRS facilities from postulated seismic events is uncertain, an acceptable estimate based on worldwide experience of typical damage to structures as a function of the acceleration was used. Additionally, potential failures with small or incidental releases masked by failures with large releases were neglected.

Typical effects and characteristics of an earthquake with a peak horizontal ground acceleration of 0.19 *g* include the following (ORNL-NSIC-28):

1. Difficult to stand
2. Ordinary masonry may crack
3. Weak chimneys may fall
4. Noticed by vehicle drivers
5. Waves appear on ponds
6. Ponded water becomes turbid with mud.

By comparing these characteristics with potential failure initiators of various structures and potential initiators of high-consequence accidents considered in the preceding sections, two types of seismically induced accidents dominate: (1) spray leaks and (2) seismically induced GREs and deflagrations of flammable gas. Due to the known leak sensitivity of jumper connections subjected to torque in valve pits, spray leaks may occur because of seismic forces acting on various pipe connections. Seismic excitation of tank sludge is assumed to cause release of associated entrained gases to tank headspaces. The gas is then assumed to ignite from seismically induced mechanical or electrical sparks. Multiple occurrences of seismically induced spray leaks and deflagrations may be possible, and depending on their locations, onsite and offsite consequences may be partially additive.

Characteristics of accelerations larger than the evaluation basis acceleration used to screen events include (ORNL-NSIC-28):

1. At 0.24 *g*, collapse of ordinary non-reinforced masonry walls and chimneys; collapse of towers and stacks

2. At 0.3 *g*, threshold acceleration for damage to ordinary foundations and potential underground pipe breaks

3. At 0.45 *g*, bending or misalignment of rails causing derailment

4. At 0.6 *g*, most ordinary masonry and frame buildings are destroyed.

On the basis of these characteristic failures and structural analyses of the underground storage tanks (WHC-SD-TWR-RPT-002, *Structural Integrity and Potential Failure Modes of the Hanford High-Level Waste Tanks*), tank failures or collapse of major structures would not be expected for the

evaluation basis earthquake. Likewise, neither major pipe ruptures nor the derailment and leakage of a loaded railcar at 204-AR are expected at a peak horizonal acceleration of 0.19 *g*.

Accidents at other TWRS facilities (such as the less than 90-day storage pad, 244-AR vault, and ventilation systems) could also occur. However, because their source terms are small compared with those of the spray leak and seismically induced deflagration, their consequences would have a small contribution to the consequences of the selected accident types. While not characteristic of a 0.19 *g* earthquake, pipe ruptures causing surface pools would also have small consequences compared to a seismically-initiated hydrogen deflagration. Minor damage to roads, bridges, and communications equipment would not be expected to impede evacuation.

Accident Scenario Assuming No Controls.

- **Sequence of Events**—A seismic event with a peak horizontal ground acceleration of 0.19 *g* and a likelihood of 10^{-3}/yr initiates one or more spray leaks during a transfer; the pumps are conservatively assumed to continue operating. Because damage to reinforced concrete and foundations is characteristic of accelerations of 0.3 *g* or larger (ORNL-NSIC-28), the valve pit cover blocks can be assumed to remain in place and undamaged in the earthquake. However, to conservatively account for all potential sources of spray leaks, this seismic analysis does not credit the cover blocks for mitigating the accident consequences.

  The probability of spray leaks and deflagrations resulting from the selected seismic events are not well understood and are conservatively assumed unity. Therefore, the seismically induced accidents are assigned the same frequency as the initiating event frequency, i.e., that of the evaluation basis earthquake, and thus fall in the unlikely frequency category.

- **Results Summary**—Conservative assessments of the onsite and offsite radiological and toxicological exposures for a spray leak in a valve pit are given in Section 5.3.2.20. Conservative assessments of the onsite and offsite radiological and toxicological exposures for hydrogen deflagrations in a DST and an SST are given in Section 5.3.2.14.

- **Implications of Results**—The consequences of the seismically induced spray leak exceed the onsite risk guidelines. Therefore, controls are required. Multiple occurrences of spray leaks similar to or less severe than the analyzed case in Section 5.3.2.20 can be postulated to occur and to exceed the associated guidelines.

  The consequences of the seismically induced SST deflagration exceed both onsite and offsite risk guidelines. The consequences of a seismically induced DST deflagration exceed the onsite risk guidelines. Therefore, controls are required. Multiple occurrences of deflagrations similar to or less severe than the analyzed cases can be postulated to occur and to exceed the associated guidelines.

Accident Scenario Assuming Controls

- **Sequence of Events**—Seismic controls have been identified and are presented in the following discussion. The mitigation strategy for spray leaks is to terminate waste transfers upon detection of the event to limit the amount of material released. The mitigation strategy for seismically induced waste tank deflagrations is to evacuate nonessential personnel. The scenario is the same except the mitigation strategies are invoked. Based on the characteristic failures of a 0.19 *g* earthquake, failures of structures that would impede evacuating personnel would not be expected.

- **Results Summary**—The ability of the selected controls to mitigate consequences of the spray leaks and flammable gas deflagrations remains uncertain and unquantifiable. Because most of the exposure to personnel for this scenario occurs immediately following the seismic event, evacuation of personnel from the immediate vicinity of the release site may have limited success. Therefore, the consequences assuming controls are conservatively assumed the same as the accident without controls.

- **Implications of Results**—Implementation of controls following a seismic event would mitigate consequences of the postulated accident scenarios. The seismic initiator is unique in that all personnel would be immediately aware of the potential for accidents because of ground shaking. Operators would respond to terminate waste transfers, provide for surveillance, initiate recovery actions, and initiate evacuation of nonessential personnel. Evacuation would limit the exposure duration of workers at risk to potential radiological and toxicological materials.

Key Accident Scenario Assumptions

- **Important to Accident Frequency**—Assumptions important to the accident frequency are as follows:

  - The seismic event assumes an evaluation basis earthquake with a peak horizontal ground acceleration of 0.19 *g* and a return frequency of 10^{-3} occurrences per year.

- **Important to Accident Consequences**—Assumptions important to the accident consequences are:

  - The integrity of the underground storage tanks and the rail system to 204-AR is not compromised by the evaluation basis acceleration of 0.19 *g* or less.

  - Valve pits and their cover blocks are not credited with mitigating the accident consequences.

  See flammable gas deflagrations and spray leak assumptions important to consequences in Sections 5.3.2.14 and 5.3.2.20.

Seismic Controls. Seismic controls are outlined below and apply to all TWRS facilities.

Safety SSCs. No Safety-Class or Safety-Significant SSCs are associated with seismic protection.

TSR Controls. As summarized in Table 5.3.2.23.3-1, administrative Emergency Preparedness controls mitigate the consequences of the seismic event by terminating waste transfers and intrusive activities as well as providing for surveillance and recovery actions.

Defense-in-Depth. No Defense-in-Depth items are specifically associated with seismic protection.

Receptor/hazard	Calculated dose/exposure		Risk guideline
	Without controls	With controls	Anticipated
Offsite/radiological	2.9 E-04 mSv (2.9 E-02 mrem)	*	1 mSv (100 mrem)
Onsite/radiological	1.4 E-01 mSv (14 mrem)	*	5 mSv (500 mrem)
Offsite/toxicological sum-of-fractions	2.4 E-06	*	1
Onsite/toxicological sum-of-fractions	0.78	*	1

Note: The flexible receiver bag failure is in the anticipated frequency category.
*The accident without controls is within risk guidelines and therefore a case with controls was not calculated.
mSv = millisievert

Table 5.3.2.23.1-3. Technical Safety Requirement Controls for High Winds.

Control	Safety function	Comments
Administrative control to require compliance with dome loading controls including the *Hanford Site Hoisting and Rigging Manual* (DOE-RL-92-36)*	Prevent load handling accidents that could damage Hazard Category 2 facilities or safety SSCs causing a significant uncontrolled release of radioactive or hazardous material or loss of safety function	

*DOE-RL-92-36 requires wind speed be considered before starting a lift and prohibits lifts if weather conditions are adverse to safe load-handling operations. The Manual also requires securing of the crane in accordance with manufacturer recommendations when a local weather storm warning exists.

Table 5.3.2.23.1-4. Defense-in-Depth Controls for High Wind.

Control	Safety function	Comments
Compliance with *Hanford Site Hoisting and Rigging Manual* (DOE/RL-92-36)	Compliance with manual would prevent flexible receiver bag failure in high winds	Although uncontrolled accident is within risk guidelines, compliance with manual provides Defense-in-Depth by preventing the accident

Table 5.3.2.23.2-1. Technical Safety Requirement Controls for Lightning as an Accident Initiator.

Control	Safety function	Comments
Administrative Controls: • Restriction on waste-intrusive activities for flammable gas tanks with lightning activity within 50 miles • Restriction of tank-intrusive activities for organic solvent and organic nitrate tanks with lightning activity within 50 miles • Secure elevated equipment in the lowest position with lightning activity within 50 miles	Ensures that activities resulting in gas releases are minimized, and therefore reduces the likelihood of ignition of flammable gas. Reduces the likelihood of a organic solvent fire or organic nitrate-salt reaction by removing potential lightning dissipation paths in the tanks and reduces the likelihood of a strike by lowering equipment	Flammable gas tanks are analyzed in Section 5.3.2.14. Waste-intrusive activities may cause a GRE in flammable gas tanks. Tank-intrusive activities may provide ready-paths for lightning dissipation through equipment or crane booms into the waste

*The Hanford Meteorological Station (HMS) located mid-way between the 200 East and 200 West Areas monitors lightning strikes with an instrument link to a regional electronic monitoring station. Tank farm operations are notified when lightning strikes within 80 km (50 miles) of the tank farms.

GRE = gas release events.

Table 5.3.2.23.2-2. Defense-in-Depth Controls for Lightning as an Accident Initiator.

Control	Safety function	Comments
Compliance with the contractor's health and safety plan	Provides for worker protection from lightning impacts*	
Ground tank risers, appurtenances, and intrusive equipment	Reduces the frequency of a lightning-initiated flammable gas ignition, organic solvent fire, or organic salt-nitrate reaction	Promotes the dissipation of lightning energy outside of the waste volume

*The requirements of WHC-SD-WM-HSP-002, Tank Farms Health and Safety Plan, provide Defense-in-Depth to workers, by directing workers to leave the tank farm if lightning strikes within 8 km (5 mi).

Table 5.3.2.23.3-1. Technical Safety Requirement Controls for Seismic Event.

Control	Safety function	Comments
Administrative Controls: • Emergency preparedness - Response procedures	Provides for mitigative actions to control potential releases by terminating transfers and provides provisions for surveillance and recovery actions	These controls manage the risk of uncontrolled releases of radioactive and toxic materials caused by an earthquake and limit direct risk of exposures to facility workers

5.4 ENGINEERED AND ADMINISTRATIVE CONTROLS

This section describes the criteria used for control decisions and identifies the controls for the individual hazardous conditions identified for TWRS facilities and operations. Control decision criteria are discussed in Section 5.4.1. The following controls identified for individual hazardous conditions are presented in this section.

- Safety structures, systems, and components (SSCs) and Technical Safety Requirements (TSRs) for hazardous conditions with significant consequences to the public and onsite workers (Section 5.4.2, "Public and Onsite Worker Protection")
- Safety SSCs and TSRs for anticipated hazardous conditions with significant consequences to the facility worker (Section 5.4.3, "Facility Worker Protection")
- Controls for hazardous conditions with the potential for significant environment consequences (Section 5.4.4, "Environmental Protection").

Controls that provide Defense-in-Depth are identified in Section 5.3 for the analyzed representative accidents. Defense-in-Depth controls for individual hazardous conditions are not contained in this Basis for Interim Operation document, but will be included in the Tank Waste Remediation System Final Safety Analysis Report.

5.4.1 Control Decision Criteria

Decisions on classifying SSCs as Safety-Class and Safety-Significant, selecting required TSR controls, identifying Defense-in-Depth controls, and identifying additional controls specifically for environmental protection were developed with a disciplined methodology and process using established control decision criteria. The control decision methodology and process are summarized in Section 5.2 with detailed descriptions provided in WHC-SD-WM-TI-773, *Hazards Analysis Results Report*, and Dunford 1996. Applying this control decision methodology and process, controls were derived on the basis of control decision criteria, the best available information, and the collective expertise and experience of the participating hazard and accident analysts, engineering, operations, and management personnel.

The control decision criteria are based on the following documents.

DOE 5480.23, *Nuclear Safety Analysis Reports*.

DOE 5480.22, *Technical Safety Requirements*

DOE-STD-3009-94, *Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports*.

WHC-CM-4-46, *Nonreactor Facility Safety Analysis Manual*, Section 6, "Technical Safety Requirements," Rev. 1, and Section 9, "Safety Classification of Structures, Systems, and Components," Rev. 2.

Appendix B of Section 6 and Table 1 of Section 9 of WHC-CM-4-46 contain the fundamental control decision criteria followed in selecting TSRs and classifying safety SSCs, respectively. Two modifications were made to these criteria. Instead of using the referenced risk guidelines in WHC-CM-4-46 (Section 7, "Risk," Rev. 4), more conservative risk guidelines prescribed by the U.S. Department of Energy were used (Tables 5.3-2 and 5.3-3). Additionally, the U.S. Department of Energy, Richland Operations Office has directed the development and implementation of TSR controls for the toxicological hazards (Wagoner 1996, *Approval of Tank Waste Remediation System (TWRS) Basis for Interim Operation [BIO]*). For accidents where the toxicological consequences are of primary concern, TSR controls are developed consistent with criteria used to develop radiological controls. Controls designated to prevent or mitigate radiological consequences that exceed both the radiological and toxicological risk guidelines are evaluated to ensure that the controls also protect against toxicological hazards. If the radiological controls are determined to be adequate, separate TSR controls for toxicological hazards are not developed; however, the TSR bases are expanded to include toxicological hazards. A principal criterion used in determining the necessary and sufficient controls required to protect the public and onsite workers was the comparison of postulated accident frequency and consequences to the risk guidelines.

Additional criteria that guided control decisions were the following.

- Controls are primarily limited to existing SSCs. Exceptions were made if the control could be rapidly implemented and no reasonable alternative existed.[1]
- Control preferences are as follows:
  1. Controls that prevent the accident versus those that mitigate its consequences
  2. Passive engineered versus active engineered controls
  3. Engineered controls versus administrative controls.
- Controls providing significant Defense-in-Depth are classified as safety SSCs or are elevated to a TSR control.
- TSRs are <u>not</u> developed for postulated accidents resulting in only environmental consequences.[2]

[1]Although control decisions were primarily limited to existing SSCs, the control decision process did identify new SSCs or significant modifications to existing SSCs as possible alternative or additional controls. New safety SSCs that may further reduce the risk of a postulated accident, especially accidents that exceed the risk evaluation guidelines with existing controls, are candidates for cost-benefit analysis and future implementation.

[2]For accidents with significant environmental consequences where controls are required beyond those identified for the protection of the safety of the public, onsite workers, and facility workers, additional controls specifically for environmental protection are identified (see Section 5.4.4). These specific environmental controls are implemented through TWRS programs and procedures and are enforced through existing environmental regulations, permits, and agreements.

- SSCs are not classified Safety-Class or Safety-Significant solely for preventing or mitigating postulated accidents resulting in environmental consequences.

Other criteria that were important considerations in control decisions are listed below.

- Control reliability, availability, and maintainability
- Control effects on facility workers (i.e., increased radiation doses or toxicological exposures - ALARA [As Low As Reasonably Achievable] issues)
- Control optimization and integration
- Control cost/benefit
- Control human factors impacts
- Control impacts on TWRS mission.

The assessment of alternative controls with respect to the above criteria was based on the knowledge and experience of cognizant operations, engineering, safety analysis, and management personnel. For example, when evaluating alternative controls to prevent or mitigate a postulated accident, the reliability, availability, and maintainability of potential safety SSCs were assessed qualitatively based on discussions with TWRS operating and engineering personnel.

Systems with known high failure rates, low availability, or maintainability problems were either not selected or multiple controls were selected. The estimated reliability of a safety SSC, along with the postulated accident frequency and consequences, provided a qualitative estimate of risk that was considered in assessing the sufficiency of a safety SSC control. Where judged necessary, additional controls were identified. Human reliability was similarly considered, with an assumed error rate of 1×10^{-2} per year. Where historical experience showed that a potential control was not sufficiently singularly reliable, it was either not selected or multiple controls were selected. In a limited number of cases, a human factors task analysis was performed and quantified (e.g., assessment of operator response time to shut down a waste transfer pump following receipt of an alarm).

Because control decisions depend on the postulated accident consequence analyses, the conservatism of the accident analyses also influenced control decisions. As required by DOE 5480.22 and Section 6 of WHC-CM-4-46,[3] key initial conditions in the accident analysis that are under the control of an operator are identified and protected by TSR controls.

[3] Refer to Appendix F, "Sitewide Controlled Manual Cross-Reference Table," of the BIO for cross-walk between sitewide controlled manuals (e.g., WHC-CM-X-XX) superseded by Fluor Daniel Hanford, Inc., procedures (e.g., HNF-PRO-X-XXX).

The control decisions were generally qualitative, except for the comparison of calculated accident analysis results with the risk guidelines. Control decisions were documented in accordance with the procedure for selecting controls (Dunford 1996, *Tank Waste Remediation System Final Safety Analysis Report Selection of Systems, Structures, and Components and Technical Safety Requirements*) and are presented in this Basis for Interim Operation report as interim controls. The application of safety SSC and TSR controls to all hazardous conditions identified for TWRS facilities and operations is presented in the following sections. The TWRS Final Safety Analysis Report may revise or refine these interim controls and will further discuss the derivation of controls in Chapter 5.0, "Derivation of TSRs."

5.4.2 Public and Onsite Worker Protection

The safety SSC and TSR (Footnote 2 on previous page) controls for hazardous conditions with the potential for significant public (S3) and onsite worker (S2) radiological or chemical exposures are presented in Table 5.4-1. The table is organized by the representative accidents analyzed in Section 5.3. Following each representative accident are the hazardous conditions (S3 and S2) represented by the accident.

5.4.3 Facility Worker Protection

Safety SSCs and TSRs (Footnote 2 on previous page) applicable to anticipated hazardous conditions with the potential for significant radiological or chemical exposure to the facility worker (F3, S1) are presented in Table 5.4-2. The safety SSC and TSR controls identified in Table 5.4-1 that protect the public and onsite workers also protect the facility worker.

5.4.4 Environmental Protection

Hazardous conditions with significant environmental consequences (E3 or E2) are identified in the hazard analysis. For many of these hazardous conditions, the controls identified to protect the public, onsite worker, and facility worker also provide protection for the environment. A listing of all the hazardous conditions with significant environmental consequences (E3 and E2) and the applicable safety SSCs and TSRs that also provide environmental protection is provided in Table 5.4-3.

When controls selected to protect the public, onsite workers, and facility workers do not adequately protect the environment, additional required controls are identified, including the following:

- High-efficiency particulate air filters
- pH control to reduce corrosion
- Cathodic protection on transfer lines
- Temperature limits on tanks and waste transfers

- Deactivation of cribs, ponds, and ditches
- Sealing off of waste streams
- Salt well pumping
- Leak detection
- Provisions to prevent equipment from penetrating the bottom of the tank.

A complete list of environmental controls will be provided in the TWRS Final Safety Analysis Report.

114SX-04.c.2.a	Release of radioactive aerosols from Tank 241-SX-114 head space to atmosphere due to exhauster HEPA filter seal failure	HEPA filter seal failure	None required	None required	SS: Ventilation CAM Interlock Syss	LCO: Ventilation Stack CAM Interlock Syss	Controls based on accident analysis (Unfiltered Release).	S2
106C-11E	Release of unfiltered tank atmosphere from Tank 241-C-106 due to damaged ductwork	Damage to ventilation ductwork upstream of filters	None required	None required	None required	None required	No controls required based on accident analysis (Unfiltered Release).	S2
106C-11L	Release of radioactive and/or hazardous material from Tank 241-C-106, through HEPA filter path, due to human error in installation of filter	Improper installation of HEPAs	None required	None required	SS: Ventilation CAM Interlock Syss	LCO: Ventilation Stack CAM Interlock Syss	Controls based on accident analysis (Unfiltered Release).	S2
114SX-04.b.1.b.1b	Release of radioactive aerosols from Tank 241-SX-114 head space to atmosphere due to failure of exhaust ducting from seismic event (mechanical disruption)	Ducting failure from seismic activity	None required	None required	None required	AC: Emergency Prep (Seismic)	Controls based on accident analysis (Unfiltered Release and Natural Phenomena - Seismic).	S2
114SX-04.c.1	Release or radioactive aerosols from Tank 241-SX-114 head space to atmosphere due to mechanical failure of exhauster HEPA filter	Plenum structure failure pierces filter	None required	None required	SS: Ventilation CAM Interlock Syss	LCO: Ventilation Stack CAM Interlock Syss AC: HEPA Filter Cntrls (Source Term)	Controls based on accident analysis (Unfiltered Release).	S2
114SX-04.c.2.b	Release of radioactive aerosols from Tank 241-SX-114 head space to atmosphere due to exhauster defective HEPA filter	Defective HEPA filter	None required	None required	SS: Ventilation CAM Interlock Syss	LCO: Ventilation Stack CAM Interlock Syss	Controls based on accident analysis (Unfiltered Release).	S2
114SX-04.c.2.d	Release of radioactive aerosols from Tank 241-SX-114 head space to atmosphere due to exhauster HEPA filter installation errors	Improper installation (human error)	None required	None required	SS: Ventilation CAM Interlock Syss	LCO: Ventilation Stack CAM Interlock Syss	Controls based on accident analysis (Unfiltered Release).	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
CRN-09-1	Release of radioactive and/or toxic materials from ventilation system due to damage caused by crane operation	Human error in positioning crane load	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analyses (Unfiltered Release; and Tank Failure Due to Excessive Loads).	S2
CRN-10-1	Release of radioactive and/or toxic materials from ventilation system due to damage caused by crane operation	Mechanical failure in positioning crane load	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analyses (Unfiltered Release; and Tank Failure Due to Excessive Loads).	S2
FIRE IN CONTAMINATED AREA (Section 5.3.2.3)								
CRN-05	Release of radioactive and/or toxic materials from pits and risers due to fuel tank fire in crane or support vehicle (see In-Tank Equipment Installation for tank fires)	Human error in positioning crane load	None required	AC: Ign Cntrls (Vehicles)	None required	AC: Emergency Prep (Fire in Contaminated Area)	Controls based on accident analysis (Fire in Contaminated Area).	S2
102AW-04-STRU03	Release of radioactive particulate from Tank 241-AW-102 central pump pit due to re-suspension	Equipment drop during crane work	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads, Vacuum, or Degradation) to reduce frequency of load drops.	S2
102AW-04-TEMP	Release of radioactive particulate from Tank 241-AW-102 central pump pit due to fire	Pump motor electrical fire	None required	None required	None required	AC: Emergency Prep (Fire in Contaminated Area)	Controls based on accident analysis (Fire in Contaminated Area).	S2
102S-02.b1	Release of radioactive aerosols to atmosphere from Tank 241-S-102 pump pit due to flammable gas generated in pump pit igniting and burning paint off pump pit walls	Jumper leak + H2 evolution (or ammonia) + Spark	SC: Trans Leak Detect Syss SS: Tank Level Detect Sys	LCO: Trans Leak Detect Syss AC: Ign Cntrls AC: Flammable Gas Mon Cntrls AC: Trans Cntrls (Leak Prevention/ Detect)	None required	AC: Emergency Prep (Fire in Contaminated Area)	Controls based on BIO Appendix E and accident analyses (Surface Leak Resulting in Pool; and Fire in Contaminated Area).	S2

EVAPORATOR DUMP (Section 5.3.2.4)								
102AW-02-PRES 102AW-02-TEMP	Release of radioactive aerosols from Tank 241-AW-102 due to pressurization	Evaporator dump when intrusive activity is occurring which causes pressurization	None required	None required	None required	None required	No controls required based on accident analysis (Evaporator Dump).	S2
102AW-02-PRES08	Release of radioactive aerosols from Tank 241-AW-102 due to positive pressure	Evaporator dump of hot liquid generates aerosols and pressurizes the tank	None required	None required	None required	None required	No controls required based on accident analysis (Evaporator Dump).	S2
102AW-02-PRES09	Release of radioactive aerosols from head space of Tank 241-AW-102 due to positive pressure (lower energy than tank bump)	Loss of fan with airlift circulators running, generating aerosols and pressurizing the tank	None required	None required	None required	None required	No controls required based on accident analysis (Evaporator Dump).	S2
102AW-09-TEMP	Release of aerosols from Tank 241-AW-102 vapor space due to pressurization	Transfer of hot solution from facility, generates aerosols and pressurizes the tank	None required	None required	None required	None required	No controls required based on accident analysis (Evaporator Dump).	S2
102S-04.a3	Release of radioactive aerosols trapped in gases throughout Tank 241-S-102 waste to the atmosphere due to periodic release of toxic gases (lower energy than tank bump)	Waste growth (bump) due to chemistry within the waste coupled with crust movement	None required	None required	None required	None required	No controls required based on accident analysis (Evaporator Dump).	S2
244AR-03.a.05	Release of radioactive aerosols from tanks headspace due to ventilation system blockage	Ventilation and risers blocked while jetting occurring	None required	None required	None required	None required	No applicable SSCs or TSRs - Hazardous condition not credible for steam jetting because steam has been isolated from 244-AR.	S2
244AR-03.a.08	Release of radioactive aerosols created by boiling waste to the cell atmosphere	Steam being supplied to tank heating/cooling coils	None required	None required	None required	None required	No applicable SSCs or TSRs - Hazardous condition not credible for steam jetting because steam has been isolated from 244-AR.	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
I-242A-2-FLW-A	Release of aerosols to the atmosphere through unsealed cracks in the cover blocks due to over pressurization of the receiver tank and possible structural damage to the tank	Human error - pump is run at maximum speed	None required	None required	None required	None required	No controls required based on accident analysis (Evaporator Dump).	S2
I-242A-2-FLW-B	Release of aerosols to the atmosphere through 12 inch opening in inlet station due to over pressurization of the receiver tank and possible structural damage to the tank	Human error - pump is run at maximum speed	None required	None required	None required	None required	No controls required based on accident analysis (Evaporator Dump).	S2
I-242A-2-VSC-A	Release of aerosols in receiver tank due to tank burp from over concentration, potential to generate conditions similar to Tank 241-SY-101, "Tank Burp" due to hydrogen being trapped in thick solution (lower energy than tank bump)	Human error - over concentration of slurry at evaporator	None required	None required	None required	None required	No controls required based on accident analysis (Evaporator Dump).	S2
I-242A-3-FLW-A	Release of aerosols to the atmosphere through unsealed cracks in the cover blocks due to over pressurization of the feed tank and possible structural damage to the tank	Uncontrolled pot dump at evaporator (loss of electricity or air)	None required	None required	None required	None required	No controls required based on accident analysis (Evaporator Dump).	S2
I-242A-3-FLW-B	Release of aerosols to the atmosphere through 12 inch opening in inlet station due to over pressurization of the feed tank and possible structural damage to the tank	Uncontrolled pot dump at evaporator (loss of electricity or air)	None required	None required	None required	None required	No controls required based on accident analysis (Evaporator Dump).	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
I-242A-7-FLW-A	Release of aerosols through the risers due to loss of instrument air which causes an uncontrolled evaporator dump and failure to detect changes in feed tank pressure	Compressor fails and 241-AW Tank Farm air supplied from 242-A	None required	None required	None required	None required	No controls required based on accident analysis (Evaporator Dump).	S2
I-242A-7-FLW-B	Release of aerosols through the risers due to loss of instrument air which causes an uncontrolled evaporator dump and failure to detect changes in feed tank pressure	Valve inadvertently closed, 241-AW Tank Farm air supplied from 242-A	None required	None required	None required	None required	No controls required based on accident analysis (Evaporator Dump).	S2
I-242A-7-FLW-C	Release of aerosols through the risers due to loss of instrument air which causes an uncontrolled evaporator dump and failure to detect changes in feed tank pressure	Filter plugged, 241-AW Tank Farm air supplied from 242-A	None required	None required	None required	None required	No controls required based on accident analysis (Evaporator Dump).	S2
ITK-05	Release of radioactive and/or hazardous material from point of in-tank access (non-fire, non-explosion) due to intrusive activity	Tank burps from intrusive activity	None required	None required	None required	None required	No controls required based on accident analysis (Evaporator Dump).	S2
STEAM INTRUSION FROM INTERFACING SYSTEM (Section 5.3.2.5)								
I-242A-6-CMP-A	Release (steam) of aerosols to the atmosphere through unsealed cracks in the cover blocks due to over pressurization of the receiver tank	Human error - steam block valve inadvertently left opened	None required	None required	None required	AC: HEPA Filter Cntrls (Source Term)	Controls based on accident analysis (Steam Intrusion from Interfacing Syss).	S3
I-222S-1-LVL-A	Release (steam) of aerosols and entrained particulates to atmosphere through ventilation due to over pressurization of 244-S DCRT caused by sending just steam to tank farm	Human error - failing to shut off steam after Tank 219-S-102 is empty	None required	None required	None required	AC: HEPA Filter Cntrls (Source Term)	Controls based on accident analysis (Steam Intrusion from Interfacing Syss).	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
I-222S-2-PRS-A	Release (steam) of aerosols and particulates to atmosphere through ventilation due to over pressurization of 244-S DCRT caused by sending just steam to tank farm	Steam reducer valve fails open	None required	None required	None required	AC: HEPA Filter Cntrls (Source Term)	Controls based on accident analysis (Steam Intrusion from Interfacing Syss).	S2
I-242A-2-CMP-B	Release to the atmosphere through unsealed cracks in the cover blocks due to over pressurization of the receiver tank	Steam block valves inadvertently opened or left open	None required	None required	None required	AC: HEPA Filter Cntrls (Source Term)	Controls based on accident analysis (Steam Intrusion from Interfacing Syss).	S3
I-PFP-2-TMP-B	Release (steam) of aerosols and entrained particulate from 244 TX ventilation system due to saturating HEPAs with steam sending higher pressure steam to steam jet, gassing it out	Failure of steam reducer	None required	None required	None required	AC: HEPA Filter Cntrls (Source Term)	Controls based on accident analysis (Steam Intrusion from Interfacing Syss).	S2
I-PUREX-1-LVL-A	Release of aerosols from Tank 241-AW-105 through cracks in the cover block due to pressurizing tank from transfer of steam	Human error - failure to shut off steam jet when U-3 is empty	None required	None required	None required	AC: HEPA Filter Cntrls (Source Term)	Controls based on accident analysis (Steam Intrusion from Interfacing Syss).	S2
I-PUREX-2-PRS-A	Release (steam) of aerosols and particulates through cracks in the cover block from the receiver tank due to tank pressurization which gases out the steam jet	Steam reducer fails	None required	None required	None required	AC: HEPA Filter Cntrls (Source Term)	Controls based on accident analysis (Steam Intrusion from Interfacing Syss).	S2
I-PUREX-3-LVL-A	Release of aerosols from Tank 241-AW-105 through cracks in the cover block due to pressurizing tank from transfer of steam	Human error - failure to shut off steam jet when U-3 is empty	None required	None required	None required	AC: HEPA Filter Cntrls (Source Term)	Controls based on accident analysis (Steam Intrusion from Interfacing Syss).	S2
I-PUREX-4-PRS-A	Release of aerosols and particulates through cracks in the cover block from the receiver tank due to tank pressurization which gases out the steam jet	Steam reducer fails	None required	None required	None required	AC: HEPA Filter Cntrls (Source Term)	Controls based on accident analysis (Steam Intrusion from Interfacing Syss).	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
I-TPLANT-2-CMP-A	Release (steam) of aerosols and entrained particulates to atmosphere through ventilation due to over pressurization of 244-S DCRT caused by sending just steam to the tank farm	Human error - steam block valve inadvertently opened or failure to close valve when Tank 15-1 is low	None required	None required	None required	AC: HEPA Filter Cntrls (Source Term)	Controls based on accident analysis (Steam Intrusion from Interfacing Syss).	S2
XS-02-FLOW02	Release of aerosols and particulate from DCRT ventilation filter due to transfer of steam from PFP steam jet into DCRT headspace	Human error (failure to shut off steam jet at completion of transfer) which causes DCRT ventilation filter failure	None required	None required	None required	AC: HEPA Filter Cntrls (Source Term)	Controls based on accident analysis (Steam Intrusion from Interfacing Syss).	S2
LEAK FROM RAILCAR/TANK TRAILER (Section 5.3.2.6)								
204AR-01H	Release of airborne and waterborne contaminates outside building on track spur, and potential contamination in unloader room from rail car due to spilling rail car contents	Rail car rupture due to collision with other or a derailment	None required	None required	None required	AC: Source Inventory Cntrls	Controls based on accident analysis (Leak from Railcar/ Tank Trailer).	S2
204AR-01I	Release of airborne and waterborne contaminates outside building on track spur, and potential contamination in unloader room from rail car due to leak	Rail car leak due to tanker corrosion or other degradation	None required	None required	None required	AC: Source Inventory Cntrls	Controls based on accident analysis (Leak from Railcar/ Tank Trailer).	S2
204AR-02A	Release of liquid radioactive material and toxic chemicals outside and inside the 204AR building from the trailer due to collision which causes a spill	Tank trailer damage due to running into the building and causing the tank contents to spill	None required	None required	None required	AC: Source Inventory Cntrls	Controls based on accident analysis (Leak from Railcar/ Tank Trailer).	S2
204AR-02B	Release of radioactive material and toxic chemicals from trailer due to structural degradation of trailer	Tank trailer damaged due to corrosion or other degradation	None required	None required	None required	AC: Source Inventory Cntrls	Controls based on accident analysis (Leak from Railcar/ Tank Trailer).	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
204AR-09B	Release of airborne and radiation contamination in the unloader room from trailer or rail car leak due to high level in sump pit	Catastrophic leak from a large liquid source such as a trailer or rail car	None required	None required	None required	AC: Source Inventory Cntrls	Controls based on accident analysis (Leak from Railcar/ Tank Trailer).	S2
204AR-09C	Release of airborne and radiation contamination in the unloader room from rail car due to gross overfilling of catch tank	Gross overfilling of catch tank either from large source such as the trailers or rail cars or continual pumping of transfer water through a leaky pipe	None required	None required	None required	AC: Source Inventory Cntrls	Controls based on accident analysis (Leak from Railcar/ Tank Trailer).	S2
204AR-09D	Release of radioactive liquid waste in the unloader room from the rail car or trailer due to failed rail car or trailer	Failed tank car or rail car (initially full of liquid waste) overflowing the catch tank and sump pit	None required	None required	None required	AC: Source Inventory Cntrls	Controls based on accident analysis (Leak from Railcar/ Tank Trailer).	S2
SUBSURFACE LEAK REMAINING SUBSURFACE (Section 5.3.2.7)								
102S-01.b3	Radioactive liquid released to the soil subsurface from leaks in transfer lines SL-140, SN-242. (Plume)	Line leak during saltwell pumping (corrosion)	SS: Pipe Encasements	AC: Trans Pump Admin Lock Cntrls	SS: Trans Leak Detect Syss SS: Tank Level Detect Syss SS: Salt Well Flow Totalizer	LCO: Trans Leak Detect Syss AC: Trans Cntrls (Leak Detect/Cntrl)	Controls based on accident analysis (Subsurface Leak Remaining Subsurface).	S2
102AW-04-STRU04	Release of liquid radioactive waste from Tank 241-AW-102 central pump pit due to leak to soil	Piping leak and leak from pump pit due to equipment drop	SC: Trans Sys Cvr	LCO: Trans Sys Cvrs AC: Trans Pump Admin Lock Cntrls AC: Trans Sys Cvr Removal Cntrls AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads; and Surface Leak Resulting in Pool).	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
102AW-04-STRU05	Release of liquid radioactive waste from Tank 241-AW-102 central pump pit due to leak to soil	Piping leak and leak from pump pit due to seismic event	SS: Pipe Encasements	AC: Trans Pump Admin Lock Cntrls	SS: Trans Leak Detect Syss SS: Tank Level Detect Syss	LCO: Trans Leak Detect Syss AC: Trans Cntrls (Leak Detect/Cntrl) AC: Emergency Prep (Seismic)	Controls based on accident analyses (Subsurface Leak Remaining Subsurface; and Natural Phenomena - Seismic).	S2
XS-01-FLOW07	Release of liquid radioactive waste to the soil from transfer piping from SST to DCRT due to leakage (plume)	Pipe failure from various causes	None required	AC: Trans Cntrls (Mis-routing) AC: Trans Pump Admin Lock Cntrls	SS: Tank Level Detect Syss SS: Salt Well Flow Totalizer	AC: Trans Cntrls (Leak Detect/Cntrl)	Controls based on accident analysis (Subsurface Leak Remaining Subsurface) for single walled pipes.	S2
XS-02-FLOW04	Release of liquid radioactive waste to soil from transfer pipe (non-pool) subsurface plume	Failure to adjust waste pH prior to transfer causes leak	SS: Pipe Encasements	AC: Trans Pump Admin Lock Cntrls	SS: Trans Leak Detect Syss SS: Tank Level Detect Syss	LCO: Trans Leak Detect Syss AC: Trans Cntrls (Leak Detect/Cntrl)	Controls based on accident analysis (Subsurface Leak Remaining Subsurface).	S2
XS-37-FLOW02	Release of radioactive liquid waste to soil from transfer piping due to leak of liquid waste from concrete encasement (subsurface plume)	Leak of transfer piping with encasement leak or blocked drain to catch tank (liquid oozes out concrete encasement)	SS: Pipe Encasements	AC: Trans Cntrls (Mis-routing) AC: Trans Pump Admin Lock Cntrls	SS: Trans Leak Detect Syss SS: Tank Level Detect Syss	LCO: Trans Leak Detect Syss AC: Trans Cntrls (Leak Detect/Cntrl)	Controls based on accident analysis (Subsurface Leak Remaining Subsurface).	S2
XS-48-FLOW	Release of liquid waste to soil from transfer piping between B-Plant and 241-ER-152 diversion box due to leak (plume)	Piping failure from various causes	SS: Pipe Encasements	AC: Trans Cntrls (Mis-routing) AC: Trans Pump Admin Lock Cntrls	SS: Trans Leak Detect Syss SS: Tank Level Detect Syss	LCO: Trans Leak Detect Syss AC: Trans Cntrls (Leak Detect/Cntrl)	Controls based on accident analysis (Subsurface Leak Remaining Subsurface).	S2
UNPLANNED EXCAVATION/DRILLING IN CRIB/DITCH/POND (Section 5.3.2.8)								
CDP-10	Release of radioactive contamination to soil surface from excavation or drilling in cribs, ditches or ponds that disturbs radioactive material	Excavation or drilling	None required	None required	None required	None required	No controls required based on accident analysis (Unplanned Excavation/Drilling in Pond/Crib/Ditch).	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
EE-17	Radioactive and hazardous material release from inactive equipment due to excavation error	Excavation into abandoned or inactive equipment	None required	None required	None required	None required	No controls required based on accident analysis (Unplanned Excavation/Drilling in Pond/Crib/Ditch).	S2
CAUSTIC SPRAY LEAK (Section 5.3.2.9)								
107AN-02-PRES	Release of caustic aerosol from caustic truck transfer piping due to spray leak	Piping/hose leak initiated by various causes	None required	AC: Caustic Transfer Controls	None required	AC: Caustic Transfer Controls	Controls based on accident analysis (Caustic Spray Leak).	S2
107AN-01-LEVE01	Release of caustic material from truck tank due to leak (aerosol spray)	Open valve on truck with pressurized tank transfer.	None required	AC: Caustic Transfer Controls	None required	AC: Caustic Transfer Controls	Controls based on accident analysis (Caustic Spray Leak).	S2
107AN-01-LEVE02	Release of caustic material from truck tank due to leak (aerosol spray)	Truck tank leak	None required	None required	None required	None required	No controls required based on low accident frequency.	S2
107AN-01-TEMP02	Spray release of caustic material from truck tank due to high temperature	Fire in gas tank	None required	None required	None required	None required	No controls required based on low accident frequency.	S2
107AN-02-PRES02	Release of caustic material from transfer piping due to high pressure (aerosol spray)	Hose disconnect	None required	AC: Caustic Transfer Controls	None required	AC: Caustic Transfer Controls	Controls based on accident analysis (Caustic Spray Leak).	S2
SODIUM FIRE (Section 5.3.2.10)								
2727W-06	Release of hazardous materials from 2727-W due to sodium-water reactions	High wind or tornado destroys building with rain/snow	SS: 2727W Building	None required	None required	None required	Controls based on accident analysis (Sodium Fire).	S2
2727W-02	Release of hazardous material from 2727-W due to sodium fire	Vehicle crashes into building and ignites sodium	SS: 2727W Building	None required	None required	None required	Controls based on accident analysis (Sodium Fire).	S2
2727W-03	Release of hazardous material from 2727-W due to sodium fire	Lightning	None required	None required	None required	None required	No controls required based on low accident frequency.	S2
2727W-04	Release of hazardous material from 2727-W due to sodium fire	Overhead power line falls through building	None required	None required	None required	None required	No controls required based on low accident frequency.	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
2727W-05	Release of hazardous material from 2727-W due to sodium fire	Nitrogen tank overpressurizes sodium tank, ignites sodium	None required	None required	None required	None required	No controls required based on low accident frequency.	S2
MIXING OF INCOMPATIBLE MATERIAL - TOXIC VAPOR GENERATION (Section 5.3.2.11)								
XS-26-PRES XS-26-TEMP	Release of toxic vapors from Tank 241-SY-102 due to chemical reaction	Mistransfer of incompatible waste causes chemical reaction	None required	None required	None required	None required	No controls required based on accident analysis (Mixing of Incompatible Waste - Toxic Vapor Generation).	S2
102AW-02-LEVE01	Release of toxic gases from Tank 241-AW-102 due to accumulations of gases	Slurry growth	None required	None required	None required	None required	No controls required based on accident analysis (Mixing of Incompatible Waste - Toxic Vapor Generation).	S2
102AW-02-PRES02	Release of toxic gases from Tank 241-AW-102 due to chemical reaction in waste	Transfer of incompatible waste to Tank 241-AW-102 causes tank gas accumulation	None required	None required	None required	None required	No controls required based on accident analysis (Mixing of Incompatible Waste - Toxic Vapor Generation).	S2
ITK-05-I	Release of radioactive and/or hazardous material from point of in-facility access due to gas release from in-facility waste during intrusive activity (non-fire, non-explosion)	Gas release from in-facility waste during intrusive activity	None required	None required	None required	None required	No controls required based on accident analyses (Mixing of Incompatible Waste - Toxic Vapor Generation).	S2
XS-03-PRES02 XS-21-PRES (244-S-DCRT)	Release of toxic vapors from 244 TX DCRT due to decreased ability to keep vapors in solution (fan on)	Heating of DCRT or chemical adjustment	None required	None required	None required	None required	No controls required based on accident analysis (Mixing of Incompatible Waste - Toxic Vapor Generation).	S2
XS-03-PRES05	Release of toxic vapors from DCRT due to increased concentrations in DCRT atmosphere	Transfer of steam from PFP causing evolution of toxic gases due to heating tank	None required	None required	None required	None required	No controls required based on accident analysis (Mixing of Incompatible Waste - Toxic Vapor Generation).	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
XS-03-TEMP02	Release of toxic vapor from DCRT due to chemical reaction	Chemical reaction in DCRT toxic vapor	None required	None required	None required	None required	No controls required based on accident analysis (Mixing of Incompatible Waste - Toxic Vapor Generation).	S2
XS-13-PRES03	Release of toxic vapors due to chemical reaction from 241-U-301B	Draining of incompatible chemicals to catch tank	None required	None required	None required	None required	No controls required based on accident analysis (Mixing of Incompatible Waste - Toxic Vapor Generation).	S2
XS-20-FLOW04	Release of toxic vapors from 244 TX DCRT due to chemical reaction with incompatible material in 244-S DCRT	Mixing contents of 244 TX and 244-S due to misrouting causes chemical reaction	None required	None required	None required	None required	No controls required based on accident analysis (Mixing of Incompatible Waste - Toxic Vapor Generation).	S2
MIXING OF INCOMPATIBLE MATERIAL - TANK PRESSURIZATION (Section 5.3.2.12)								
I-222S-1-RXN-A	Release of aerosols and/or toxic vapors from receiver tank due adverse chemical reactions from incompatible waste	Transfer of incompatible waste	None required	AC: Trans Cntrls (pH)	None required	AC: HEPA Filter Cntrls (Aerosol Testing)	Controls based on accident analysis (Mixing of Incompatible Waste - Tank Pressurization).	S2
102AW-02-TEMP 102AW-08-TEMP	Release of radioactive aerosols from Tank 241-AW-102 due to positive pressure	Chemical reaction heating up and/or agitating tank causes positive pressure in tank	None required	AC: Trans Cntrls (pH)	None required	None required	The Trans control for this hazardous condition is solely pH control because of the larger volumes in waste storage tanks compared to the analyzed accident.	S2
102AW-02-TEMP01	Release of radioactive aerosols from Tank 241-AW-102 due to boiling waste	High heat waste causing boiling	SS: Temperature Mon Sys SS: Waste Tank Level Detect Sys	LCO: DST and AWF Tanks Waste Temperature Cntrls AC: Trans Cntrls (Tank Bump Topography)	None required	None required	Controls based on accident analysis (Tank Bump) for DST & AWF tanks.	S2
106C-01G	Release of radioactive and/or hazardous material from Tank 241-C-106 tank, due to waste reaction causing local discharge of contamination through blown HEPAs or out cover blocks	Addition of acid to tank	None required	AC: Trans Cntrls (pH)	None required	None required	The transfer control for this hazardous condition is solely pH control because of the larger volumes in waste storage tanks compared to the analyzed accident.	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
106C-01H	Release of radioactive and/or hazardous material from Tank 241-C-106, through blown HEPAs or out cover blocks due to tank boiling with vent path blocked or failed	Tank boiling with lack of vent path	SS: Temperature Mon Sys SS: Waste Tank Level Detect Sys	LCO: SST Waste Temperature Cntrls AC: Trans Cntrls (Tank Bump Topography)	None required	None required	Controls based on accident analysis (Tank Bump) for SSTs.	S2
106C-01M	Release of radioactive and/or hazardous material from Tank 241-C-106, due to high temperature in the waste tank	Exothermic, chemical reaction in tank due to inadvertent addition to tank	None required	AC: Trans Cntrls (pH)	None required	None required	The transfer control for this hazardous condition is solely pH control because of the larger volumes in waste storage tanks compared to the analyzed accident.	S2
106C-12F	Release of radioactive and/or hazardous material from Tank 241-C-106 tank due to waste reaction in tank	Added chemicals to tank instead of normal water addition	None required	AC: Trans Cntrls (pH)	None required	None required	The transfer control for this hazardous condition is from the representative accident Mixing of Incompatible Material - Tank Pressurization and is solely pH control because of the larger volumes in waste storage tanks compared to the analyzed accident.	S2
107AN-02-FLOW01	Release of radioactive aerosols from Tank 241-AN-107 due to surface chemical reaction	Transfer of incompatible chemical to tank via chemical addition system due to vendor or paperwork error	None required	AC: Trans Cntrls (pH)	None required	None required	The transfer control for this hazardous condition is from the representative accident Mixing of Incompatible Material - Tank Pressurization and is solely pH control because of the larger volumes in waste storage tanks compared to the -- analyzed accident.	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
107AN-02-FLOW02	Release of toxic vapors from Tank 241-AN-107 due to surface chemical reaction	Transfer of incompatible chemical to tank via chemical addition system due to vendor or paperwork error	None required	AC: Trans Cntrls (pH)	None required	None required	The transfer control for this hazardous condition is from the representative accident Mixing of Incompatible Material - Tank Pressurization and is solely pH control because of the larger volumes in waste storage tanks compared to the analyzed accident.	S2
CCF-01	Radioactive and hazardous release from tanks due to extended loss of ventilation (over 6 months)	Sustained loss of offsite power	None required	None required	None required	None required	No controls required based on low accident frequency.	S2
CCF-20	Release of radioactive and hazardous aerosols/ vapors from tanks due to chemical reactions between waste and added materials	Reactive chemical additions to two tanks	None required	AC: Trans Cntrls (pH)	None required	None required	The transfer control for this hazardous condition is solely pH control because of the larger volumes in waste storage tanks compared to the analyzed accident.	S2
I-222S-2-FLW-C	Release of aerosols and/ or toxic vapors from receiver tank due adverse chemical reactions from incompatible waste	Human error - incorrect valve line up	None required	AC: Trans Cntrls (pH)	None required	None required	Controls based on accident analysis (Mixing of Incompatible Waste - Tank Pressurization).	S2
I-BPLANT-2-FLW-D	Release of aerosols and/ or toxic vapors from receiver tank due to transfer of incompatible waste from B Plant	Human error - communication error between B Plant and TWRS causes transfer of incompatible waste	None required	AC: Trans Cntrls (pH)	None required	None required	Controls based on accident analysis (Mixing of Incompatible Waste - Tank Pressurization).	S2
XS-02-FLOW03	Release of toxic gases (oxides of nitrogen) from DCRT due to chemical reaction	Chemical reaction between sodium nitrite (DCRT) and nitric acid (PFP transfer) due to failure to adjust waste pH prior to transfer	None required	AC: Trans Cntrls (pH)	None required	None required	Controls based on accident analysis (Mixing of Incompatible Waste - Tank Pressurization).	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
XS-03-TEMP01	Release of radioactive aerosols from 244 TX DCRT headspace due to positive pressure	Chemical reaction in DCRT causes positive pressure	None required	AC: Trans Cntrls (pH)	SS: HEPA Filters (244-S, 244 TX, 244-A)	AC: HEPA Filter Cntrls (Aerosol Testing)	Controls based on accident analysis (Mixing of Incompatible Material - Tank Pressurization).	S2
XS-13-PRES01	Release of radioactive aerosols from 241-U-301B catch tank due to chemical reaction	Draining of incompatible chemicals to catch tank	None required	None required	None required	None required	No controls required based on accident analysis (Mixing of Incompatible Material - Tank Pressurization).	S2
XS-20-FLOW01	Release of radioactive aerosols from 244 TX DCRT due to chemical reaction	Transfer of incompatible waste to 244 TX DCRT due to improper valve lineup	None required	AC: Trans Cntrls (pH)	SS: HEPA Filters (244-S, 244 TX, 244-A)	AC: HEPA Filter Cntrls (Aerosol Testing)	Controls based on accident analysis (Mixing of Incompatible Material - Tank Pressurization).	S2
XS-20-FLOW03	Release of radioactive aerosols from 244 TX DCRT due to positive pressure caused by chemical reaction	Chemical reaction of 244-S material with contents of 244 TX caused by misrouting	None required	None required	None required	None required	No controls required based on accident analysis (Mixing of Incompatible Waste - Tank Pressurization).	S2
XS-26-PRES01	Release of radioactive aerosols from Tank 241-SY-102 due to chemical reaction	Mis-transfer of incompatible waste causes chemical reaction	None required	None required	None required	None required	No controls required based on accident analysis (Mixing of Incompatible Material - Tank Pressurization).	S2
TANK FAILURE DUE TO EXCESSIVE LOADS (Section 5.3.2.13)								
CRN-03	Release of radioactive and/or toxic materials from tank due to dome collapse	Human error results in excessive weight on dome	None required	AC: Dome Loading Cntrls (Excessive Loads)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S3
CRN-04	Release of radioactive and/or toxic materials from tank due to dome collapse	Crane or rigging failures drop load resulting in large impact to dome	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S3
CRN-11	Radioactive or toxic material release from tank due to boom failure and tank/equipment damage and dome collapse	Human error: improper load assembly, rigging, crane overloaded	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S3

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
102AW-04-STRU01A	Release of liquids, solids and/or vapors from Tank 241-AW-102 due to dome collapse caused by excessive dome loading	Equipment drop during crane work causes excessive dome loading	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S3
102AW-04-STRU02	Release of liquids, solids and/or vapors from Tank 241-AW-102 due to dome collapse caused by excessive dome loading	Violation of limits on dome loading	None required	AC: Dome Loading Cntrls (Excessive Loads)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S3
102S-05.a1a	Release of radioactive aerosols from Tank 241-S-102 to atmosphere due to dome collapse	Excess gravel overburden	None required	AC: Dome Loading Cntrls (Excessive Loads)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S3
102S-05.a1aa	Release of radioactive aerosols from Tank 241-S-102 to atmosphere due to dome collapse	Large vehicle traffic over tank	None required	AC: Dome Loading Cntrls (Excessive Loads)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S3
106C-01X	Release of radioactive and/or hazardous material from Tank 241-C-106, dome structural damage and/or personnel injury due to overload of tank dome	Overweight vehicles over top of tank	None required	AC: Dome Loading Cntrls (Excessive Loads)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S3
106C-01Y	Release of radioactive and/or hazardous material from Tank 241-C-106, dome structural damage and/or personnel injury due to overload of tank dome	Flooding over top of tank	SS: Service Water Flow Totalizer	LCO: Tank Service Water Intrusion Mon Program	None required	None required	Controls based on accident analyses (Surface Leak Resulting in Pool).	S3
114SX-06.a.1a	Release of radioactive aerosols from Tank 241-SX-114 waste to atmosphere due to dome collapse	Gravel overburden Large vehicle	None required	AC: Dome Loading Cntrls (Excessive Loads)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S3
CP-SET-04	Release of radioactive or toxic material from waste tank due to dome collapse	Excessive weight on tank dome (static load of platform)	None required	AC: Dome Loading Cntrls (Excessive Loads)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S3
CP-SET-05	Release of radioactive or toxic material from waste tank due to dome collapse caused by load drop	Mechanical failure of equipment causes load drop	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S3

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
CP-SET-06	Release of radioactive or toxic material from waste tank due to dome collapse caused by load drop	Human error causes load drop	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S3
CRN-03-IA	Release of radioactive and/or toxic materials from facility due to containment top collapse	Human error results in excessive weight on top of containment	None required	AC: Dome Loading Cntrls (Excessive Loads)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S2
CRN-04-IA	Release of radioactive and/or toxic materials from facility due to MISF containment collapse	Crane or rigging failures drop load resulting in large impact to top of containment	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S2
CRN-09	Release of radioactive and/or toxic materials from ventilation system due to crane damage	Human error in positioning crane load	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S2
CRN-10	Release of radioactive and/or toxic materials from ventilation system due to crane damage	Mechanical failure in positioning crane load	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S2
CRN-11-IA	Release of radioactive and/or toxic materials from facility due to containment top collapse or equipment damage by boom failure	Human error: improper load assembly, rigging, crane overloaded	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S2
CRN-12	Radioactive or toxic material release from tank due to boom failure and tank/equipment damage and dome collapse	Mechanical failure: corrosion, faulty materials	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S3
CRN-12-IA	Release of radioactive and/or toxic materials from facility due to containment top collapse or equipment damage by boom failure	Mechanical failure: corrosion, faulty materials	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
ITK-FR-04	Release of radioactive aerosols from tank due to tank collapse	Equipment becomes lodged in riser, efforts to remove pull riser out of tank causing loss of structural integrity leading to tank collapse	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S3
ITK-FR-19	Release of radioactive aerosols from tank due to dome collapse	Hydraulic jacks on assembly stand are operated while assembly is bolted to flange tearing out riser and destroying tank integrity leading to dome collapse	None required	None required	None required	None required	No controls required based on low accident frequency.	S3
TANK FAILURE DUE TO VACUUM OR DEGRADATION (Section 5.3.2.13)								
114SX-06.a.3	Release of radioactive aerosols from Tank 241-SX-114 waste to the atmosphere due to dome collapse caused by loss of strength due to aging	Long term aging resulting in tank degradation	None required	None required	None required	None required	No controls required based on accident analysis (Tank Failure Due to Excessive Loads).	S3
102AW-02-PRES03	Release of liquids, solids and/or vapors from Tank 241-AW-102 due to dome collapse caused by excessive vacuum	Blocked ventilation inlet causes excessive vacuum leading to dome collapse	None required	None required	None required	None required	No controls required based on accident analysis (Tank Failure Due to Excessive Loads).	S3
102AW-02-PRES04	Release of liquids, solids and/or vapors from Tank 241-AW-102 due to dome collapse caused by excessive vacuum	Condensation of vapors causes excessive vacuum leading to dome collapse	None required	None required	None required	None required	No controls required based on accident analysis (Tank Failure Due to Excessive Loads).	S3
102AW-02-PRES05	Release of liquids, solids and/or vapors from Tank 241-AW-102 due to dome collapse caused by excessive vacuum	Sub-cooling of vapor during equipment flushing causes excessive vacuum leading to dome collapse	None required	None required	None required	None required	No controls required based on accident analysis (Tank Failure Due to Excessive Loads).	S3
102AW-02-PRES06	Release of liquids, solids and/or vapors from Tank 241-AW-102 due to dome collapse caused by excessive vacuum	Ventilation imbalance causes excessive vacuum leading to dome collapse	None required	None required	None required	None required	No controls required based on accident analysis (Tank Failure Due to Excessive Loads).	S3

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
102AW-02-PRES07	Release of liquids, solids and/or vapors from Tank 241-AW-102 due to dome collapse caused by excessive vacuum	Wrong size portable ventilator chosen for support work causes excessive vacuum leading to dome collapse	None required	None required	None required	None required	No controls required based on accident analysis (Tank Failure Due to Excessive Loads).	S3
102AW-03-LEVE03	Release of liquids, solids and/or vapors from Tank 241-AW-102 due to dome collapse caused by floating the primary tank within the annulus	Misrouting of liquid waste to the annulus causes floating of primary tank and subsequent dome collapse	None required	None required	None required	None required	No controls required based on accident analysis (Tank Failure Due to Excessive Loads).	S3
102S-04.d1	Release of radioactive aerosols contained in Tank 241-S-102 vapor space to the atmosphere due to low pressure causing dome collapse	Misoperation of exhauster during saltwell pumping	None required	None required	None required	None required	No controls required based on accident analysis (Tank Failure Due to Excessive Loads).	S3
102S-05.a3	Release of radioactive aerosols from Tank 241-S-102 to atmosphere due to dome collapse	Past thermocycling of tank	None required	None required	None required	None required	No controls required based on accident analysis (Tank Failure Due to Excessive Loads).	S3
102S-05.a3a	Release of radioactive aerosols from Tank 241-S-102 to atmosphere due to dome collapse	Long term aging	None required	None required	None required	None required	No controls required based on accident analysis (Tank Failure Due to Excessive Loads).	S3
106C-01A	Release of radioactive and/or hazardous material from Tank 241-C-106, structural damage and dome collapse due to tank low pressure	Air inlet plugged due to icing/dust	None required	None required	None required	None required	No controls required based on accident analysis (Tank Failure Due to Excessive Loads).	S3
106C-01B	Release of radioactive and/or hazardous material from Tank 241-C-106, structural damage and dome collapse due to tank low pressure	Inlet air valve closed	None required	None required	None required	None required	No controls required based on accident analysis (Tank Failure Due to Excessive Loads).	S3

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
106C-01C	Release of radioactive and/or hazardous material from Tank 241-C-106, structural damage, and dome collapse due to tank low pressure	Exhauster damper positioned incorrectly	None required	None required	None required	None required	No controls required based on accident analysis (Tank Failure Due to Excessive Loads).	S3
106C-01D	Release of radioactive and/or hazardous material from Tank 241-C-106, structural damage and dome collapse due to tank low pressure	Wrong sized portable exhauster	None required	None required	None required	None required	No controls required based on accident analysis (Tank Failure Due to Excessive Loads).	S3
106C-01E	Release of radioactive and/or hazardous material from Tank 241-C-106, structural damage and dome collapse due to tank low pressure	Subcooling of tank vapor space due to water addition of flushing	None required	None required	None required	None required	No controls required based on accident analysis (Tank Failure Due to Excessive Loads).	S3
114SX-04.a.2	Radioactive aerosols released from failed tank dome due to vacuum produced by valving error.	Human error: Valve out flammable watch list (Tank 241-SX-109) butterfly valve	None required	None required	None required	None required	No controls required based on accident analysis (Tank Failure Due to Excessive Loads).	S3
114SX-04.a.3	Release of radioactive aerosols from Tank 241-SX-114 to atmosphere due to high temperatures causing dome concrete strength loss	No ventilation flow High ambient temperature conditions Resulting in tank degradation	None required	None required	None required	None required	No controls required based on accident analysis (Tank Failure Due to Excessive Loads).	S3
114SX-04.b.1.a.2	Release of radioactive material from Tank 241-SX-114 to atmosphere due to high temperature in the dome leading to dome collapse (long term closure of butterfly valve)	Human error: Closure of Tank 241-SX-114 exhaust butterfly valve isolating tank from exhaust plenum Resulting in tank degradation	None required	None required	None required	None required	No controls required based on accident analysis (Tank Failure Due to Excessive Loads).	S3

I-242A-4-TMP-A	Release of radioactive material from Tank 241-AW-102 caused by ignition of organics in Tank C-100 which pressurizes the drain line and propagates the fire down the line to Feed Tank 241-AW-102	Faulty control of vacuum to CA-1 vessel causing pot to boil with organic layer available	None required	None required	None required	None required	No controls required based on low accident frequency.	S3
I-BPLANT-1-CMP-E	Release of tank waste due to fire in receiver tank from transferring organics from B Plant	Human error - tank containing organics in B Plant rupture and spills organics to the drains which eventually end up in Tank 24-1 and an inadvertent transfer to tank farms	None required	AC: Ign Cntrls (Organic Solvent) AC: Trans Cntrls (Organic Solvent)	None required	AC: HEPA Filter Cntrl (Source Term) AC: Emergency Prep Program (Organic Solvent)	Controls based on accident analysis (Organic Solvent Fire).	S3
I-PFP-1-CMP-E	Release of high level waste from receiver tank due to fire from organics transferred from PFP	Excess organic material added to waste results in fire	None required	AC: Ign Cntrls (Organic Solvent) AC: Trans Cntrls (Organic Solvent)	None required	AC: HEPA Filter Cntrl (Source Term) AC: Emergency Prep Program (Organic Solvent)	Controls based on accident analysis (Organic Solvent Fire).	S3
IN-TANK FUEL FIRE/DEFLAGRATION (Section 5.3.2.16)								
EE-05-a	Release of radioactive or hazardous materials from SST tank due to external fires	Run-away vehicle or truck shears off one or more risers, ruptures gasoline tank	None required	AC: Ign Cntrls (Vehicle)	None required	AC: Emergency Prep (In-tank Fuel Fire)	Controls based on accident analysis (In-Tank Fuel Fire/ Deflagration).	S3
EE-05-b	Release of radioactive or hazardous materials from DST tank due to external fires	Run-away vehicle or truck shears off one or more risers, ruptures gasoline tank	None required	AC: Ign Cntrls (Vehicle)	None required	AC: Emergency Prep (In-tank Fuel Fire)	Controls based on accident analysis (In-Tank Fuel Fire/ Deflagration).	S3
102AW-03-TEMP01	Release of liquids, solids and/or vapors from Tank 241-AW-102 due to dome collapse caused by an fire/explosion in the annulus	Fire/Explosion of flammable liquid spilled into annulus via a riser	None required	AC: Ign Cntrls (Vehicles)	None required	AC: Emergency Prep (In-tank Fuel Fire)	Controls based on accident analysis (In-Tank Fuel Fire/ Deflagration).	S3

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
102AW-03-TEMP02	Release of radioactive aerosols from Tank 241-AW-102 due to fire/ explosion in annulus damaging primary tank	Flammable concentration of gases in annulus vapor space due to spill of fuel into annulus and spark source	None required	AC: Ign Cntrls (Vehicles)	None required	AC: Emergency Prep (In-tank Fuel Fire)	Controls based on accident analysis (In-Tank Fuel Fire/ Deflagration).	S2
102AW-09-COMP02	Release of radioactive waste aerosols from Tank 241-AW-102 due to fire in fuel spilled in waste tank causing dome collapse	Spill of fuel from external source plus fuel reaching flash point or being aerosolized plus ignition source	None required	AC: Ign Cntrls (Vehicles)	None required	AC: Emergency Prep (In-tank Fuel Fire)	Controls based on accident analysis (In-Tank Fuel Fire/ Deflagration).	S3
102S-03.b3	Release of radioactive aerosols to atmosphere from Tank 241-S-102 due to burning fuel flowing into waste tank due to ignition of fuel from ruptured gas tank.	Vehicle drives into open riser puncturing gas tank + Ignition	None required	AC: Ign Cntrls (Vehicles)	None required	AC: Emergency Prep (In-tank Fuel Fire)	Controls based on accident analysis (In-Tank Fuel Fire/ Deflagration).	S2
102S-03.b4	Release of radioactive aerosols to atmosphere from Tank 241-S-102 due to burning fuel flowing into waste tank causing dome collapse	Vehicle drives into open riser puncturing gas tank + Ignition + Flammable organic vapors in tank	None required	AC: Ign Cntrls (Vehicles)	None required	AC: Emergency Prep (In-tank Fuel Fire)	Controls based on accident analysis (In-Tank Fuel Fire/ Deflagration).	S3
EE-04-a	Release of radioactive and hazardous materials from SST tank due to external fires	Vehicle accident involving propane, diesel or gasoline delivery	None required	AC: Ign Cntrls (Speed Limits)	None required	AC: Emergency Prep (In-tank Fuel Fire)	Controls based on accident analysis (In-Tank Fuel Fire/ Deflagration).	S3
EE-04-b	Release of radioactive and hazardous materials from DST tank due to external fires	Vehicle accident involving propane, diesel or gasoline delivery	None required	AC: Ign Cntrls (Speed Limits)	None required	AC: Emergency Prep (In-tank Fuel Fire)	Controls based on accident analysis (In-Tank Fuel Fire/ Deflagration).	S3
LDUA 2-2	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of hydraulic fluid	Structural failure of hydraulic system	None required	AC: Ign Cntrls	None required	AC: Emergency Prep	Controls based on BIO Appendix E.	S3

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
VEH-07-I	Release of radioactive or toxic material from MISF due to riser being sheared off and possibly vehicle gas tank ruptured and fire	Vehicle moving near facility risers	None required	AC: Ign Cntrls (Vehicles)	None required	AC: Emergency Prep (In-Tank Fuel Fire/ Deflagration)	Controls based on accident analysis (In-Tank Fuel Fire/ Deflagration).	S2
ORGANIC SALT-NITRATE REACTION (Section 5.3.2.17)								
RSR-07-I	Release of radioactive or toxic material from facility due to in-facility fire or explosion during riser removal activity (chosen to represent all organic nitrate tanks)	Spark from failure to use non-sparking tools or sparks from welding, cutting, grinding, etc.	SS: Temperature Mon Sys	LCO: SST Waste Temperature Cntrls LCD: DST and AWF Tank Waste Temperature Cntrls AC: Ign Cntrls (Organic Salt-Nitrate) AC: Moisture Cntrls AC: Process Instrumentation and Measuring and Test Equipment	None required	AC: HEPA Filter Cntrl Program (Source Term) AC: Emergency Prep Program (Organic Salt-Nitrate)	Controls based on accident analysis (Organic Salt-Nitrate Reaction).	S2

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
XS-41B-LEVE03	Release of radioactive waste to surface from vent station nozzle pit due to overflow	Failure to empty catch tank, causing overflow of tank and pit due to transfer failure	SC: Trans Leak Detect Syss SS: Tank Level Detect Syss	LCO: Trans Leak Detect Syss AC: Trans Cntrls (Leak Prevention/ Detect/Cntrl)	SC: Trans Leak Detect Syss SS: Tank Level Detect Syss SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs LCO: Trans Leak Detect Syss AC: Trans Cntrls (Leak Detect/Cntrl) AC: Emergency Prep (Significant Release) AC: Trans Pump Admin Lock Cntrls AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Surface Leak Resulting in Pool).	S2
XS-52-FLOW02	Release of radioactive waste from Tank 244-CR-003 to surface due to overflow (pool)	Mis-valving or valve failure during cross-site transfer causes overflow	SC: Trans Leak Detect Syss SS: Tank Level Detect Syss	LCO: Trans Leak Detect Syss AC: Trans Cntrls (Leak Prevention/ Detect/Cntrl)	SC: Trans Leak Detect Syss SS: Tank Level Detect Syss SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs LCO: Trans Leak Detect Syss AC: Trans Cntrls (Leak Detect/Cntrl) AC: Emergency Prep (Significant Release) AC: Trans Pump Admin Lock Cntrls AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Surface Leak Resulting in Pool).	S2
SUBSURFACE LEAK RESULTING IN POOL (Section 5.3.2.19)								
XS-07-FLOW02	Release of radioactive waste to soil from transfer piping out of 244 TX DCRT due to leak in primary pipe and encasement	Corrosion of inner and outer pipe	SC: Pipe Encasements	AC: Encasement Seal Loops	SS: Tank Level Detect Syss SS: Salt Well Flow Totalizer	AC: Trans Cntrls (Leak Detect/Cntrl) AC: Emergency Prep (Significant Release)	Controls based on accident analysis (Subsurface Leak Resulting in Pool).	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
XS-07-FLOW06	Release of radioactive waste to soil from transfer pipe out of 244 TX DCRT due to leak in primary pipe and encasement	Water hammer causes failure of primary pipe and encasement	SC: Pipe Encasements	AC: Trans Pump Admin Lock Cntrls AC: Encasement Seal Loops	SS: Tank Level Detect Syss SS: Salt Well Flow Totalizer	AC: Trans Cntrls (Leak Detect/Cntrl) AC: Emergency Prep (Significant Release)	Controls based on accident analysis (Subsurface Leak Resulting in Pool; and Surface Leak Resulting in Pool).	S2
102AW-01-FLOW02	Release of radioactive waste to soil from transfer piping which runs to Tank 241-AW-102 due to leak from primary pipe and encasement	Excavation accident fails primary pipe and encasement	None required	AC: Excavation Cntrls	None required	None required	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines).	S2
102AW-01-FLOW03	Release of radioactive waste to soil from transfer pipe to Tank 241-AW-102 due to leak of radioactive waste from primary pipe and encasement	Corrosion of inner and outer pipe cause failure of primary pipe and encasement	SC: Pipe Encasements	AC: Encasement Seal Loops	SS: Tank Level Detect Syss SS: Salt Well Flow Totalizer	AC: Trans Cntrls (Leak Detect/Cntrl) AC: Emergency Prep (Significant Release)	Controls based on accident analysis (Subsurface Leak Resulting in Pool).	S2
102AW-01-FLOW04	Release of radioactive waste to soil from transfer pipe to Tank 241-AW-102 due to leak of radioactive waste from primary pipe and encasement	High structural loading from traffic or cranes fails primary pipe and encasement	None required	None required	None required	None required	No controls required based on low accident frequency.	S2
102AW-01-FLOW05	Release of radioactive waste to soil from transfer piping to Tank 241-AW-102 due to leak from primary pipe and encasement	Seismic event fails primary pipe and encasement	SC: Pipe Encasements	AC: Encasement Seal Loops	SS: Tank Level Detect Syss SS: Salt Well Flow Totalizer	AC: Trans Cntrls (Leak Detect/Cntrl) AC: Emergency Prep (Significant Release) AC: Emergency Prep (Seismic)	Controls based on accident analyses (Subsurface Leak Resulting in Pool; and Natural Phenomena - Seismic).	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
102AW-01-FLOW06	Release of radioactive waste to soil from transfer pipe to Tank 241-AW-102 due to leak of radioactive waste from primary pipe and encasement	Undermining due to leak of nearby pipes cause failure of primary pipe and encasement	SC: Pipe Encasements	AC: Encasement Seal Loops	SS: Tank Level Detect Syss SS: Salt Well Flow Totalizer	AC: Trans Cntrls (Leak Detect/Cntrl) AC: Emergency Prep (Significant Release)	Controls based on accident analysis (Subsurface Leak Resulting in Pool).	S2
102AW-01-FLOW07	Release of radioactive waste to soil from transfer pipe to Tank 241-AW-102 due to leak of radioactive waste from primary pipe and encasement	Water hammer cause failure of primary pipe and encasement	SC: Pipe Encasements	AC: Trans Pump Admin Lock Cntrls AC: Encasement Seal Loops	SS: Tank Level Detect Syss SS: Salt Well Flow Totalizer	AC: Trans Cntrls (Leak Detect/Cntrl) AC: Emergency Prep (Significant Release)	Controls based on accident analysis (Subsurface Leak Resulting in Pool).	S2
CP-GRT-02	Release of radioactive or toxic material to soil surface (pool) from transfer line due to puncture of line during transfer	Human error AND Mechanical failure of push pipe integrity inside the transfer line	None required	AC: Excavation Cntrls	None required	None required	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines)	S3
CP-MSP-01	Release of radioactive or toxic material to soil surface (pool) from transfer line due to puncture of line during transfer	Human error caused puncture to transfer line during push operations	None required	AC: Excavation Cntrls	None required	None required	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines)	S2
CP-SSP-01	Release of radioactive or toxic material to soil surface (pool) from transfer line due to puncture of line during transfer	Human error caused puncture to transfer line during push operations.	None required	AC: Excavation Cntrls	None required	None required	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines)	S3
CP-SSP-16	Release of radioactive or toxic material to soil surface (pool) from transfer line due to puncture of line during transfer	Human error AND Mechanical failure of push pipe integrity inside the transfer line	None required	AC: Excavation Cntrls	None required	None required	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines)	S3
CRN-03-IB	Release of radioactive and/or toxic materials from facility due to MISF containment collapse	Human error results in excessive weight on top of containment	None required	AC: Dome Loading Cntrls (Excessive Loads)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
CRN-04-IB	Release of radioactive and/or toxic materials from facility due to MISF containment collapse	Crane or rigging failures drop load resulting in large impact to top of containment	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S2
CRN-21-IB	Release of radioactive or toxic materials from aboveground facility bottom due to loss of vertical load control, dropping crane load into facility (surface pool)	Human error: improper load assembly, rigging, positioning error	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S2
CRN-22-IB	Release of radioactive or toxic materials from aboveground facility bottom due to loss of vertical load control, dropping crane load into facility (surface pool)	Mechanical failure: corrosion, faulty materials, hydraulics	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	S2
W058-INTEG01a	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak	Failure of primary and encasement piping due to corrosion plus mitigative features failure	SC: Pipe Encasements	AC: Encasement Seal Loops	SS: Tank Level Detect Syss SS: Salt Well Flow Totalizer	AC: Trans Cntrls (Leak Detect/Cntrl) AC: Emergency Prep (Significant Release)	Controls based on accident analysis (Subsurface Leak Resulting in Pool).	S2
W058-INTEG01b	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak	Failure of primary and encasement piping due to unrecognized material flaw plus mitigative features failure	SC: Pipe Encasements	AC: Encasement Seal Loops	SS: Tank Level Detect Syss SS: Salt Well Flow Totalizer	AC: Trans Cntrls (Leak Detect/Cntrl) AC: Emergency Prep (Significant Release)	Controls based on accident analysis (Subsurface Leak Resulting in Pool).	S2
W058-INTEG03a	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak	Failure of primary and encasement piping due to external event (airplane crash, volcanism, etc)	SC: Pipe Encasements	AC: Encasement Seal Loops	SS: Tank Level Detect Syss SS: Salt Well Flow Totalizer	AC: Trans Cntrls (Leak Detect/Cntrl) AC: Emergency Prep (Significant Release) AC: Emergency Prep (Seismic)	Controls based on accident analyses (Subsurface Leak Resulting in Pool; and Natural Phenomena - Seismic).	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
XS-07-FLOW04	Release of radioactive waste to soil from transfer piping of 244 TX-DCRT due to leak in primary pipe and encasement	Seismic event fails primary pipe and encasement	SC: Pipe Encasements	AC: Encasement Seal Loops	SS: Tank Level Detect Syss SS: Salt Well Flow Totalizer	AC: Trans Cntrls (Leak Detect/Cntrl) AC: Emergency Prep (Significant Release) AC: Emergency Prep (Seismic)	Controls based on accident analyses (Subsurface Leak Resulting in Pool; Natural Phenomena - Seismic).	S2
XS-07-FLOW05	Release of radioactive waste to soil from transfer pipe out of 244 TX DCRT due to leak in primary pipe and encasement	Undermining due to leak of nearby pipes cause failure of primary pipe and encasement	SC: Pipe Encasements	AC: Encasement Seal Loops	SS: Tank Level Detect Syss SS: Salt Well Flow Totalizer	AC: Trans Cntrls (Leak Detect/Cntrl) AC: Emergency Prep (Significant Release)	Controls based on accident analysis (Subsurface Leak Resulting in Pool).	S2
XS-52-FLOW01	Release of radioactive waste to surface from transfer piping to Tank 244-CR-003 due to leak (pool)	Failure of pipe from various causes	SC: Pipe Encasements	AC: Trans Cntrls (Mis-routing) AC: Encasement Seal Loops	SS: Tank Level Detect Syss SS: Salt Well Flow Totalizer	AC: Trans Cntrls (Leak Detect/Cntrl) AC: Emergency Prep (Significant Release)	Controls based on accident analysis (Subsurface Leak Resulting in Pool).	S2
SPRAY LEAK IN STRUCTURE OR FROM OVERGROUND WASTE TRANSFER LINES (Section 5.3.2.20)								
XS-06-FLOW02	Release of liquid radioactive waste from DCRT transfer piping to Tank 241-SY-102 due to spray leak in DCRT pump pit	Pipe failure in DCRT pump pit causing spray leak	None required	AC: Trans Cntrls (Mis-routing) AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S3
102AW-01-FLOW 102AW-04-PRES	Release of radioactive aerosol from transfer pipe which runs from DCRT to Tank 241-AW-102 due to spray leak into open underground structure	Piping leak due to thermal stress of transferring hot solution in cold pipe	None required	AC: Trans Cntrls (Mis-routing) AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S3

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
102AW-01-FLOW01	Release of liquid radioactive waste aerosols from transfer pipe to Tank 241-AW-102 due to spray leak into open underground structure	Piping leak due to corrosion caused by transferring high temperature waste	None required	AC: Trans Cntrls (Mis-routing) AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S3
102AW-13-FLOW01	Release of radioactive waste aerosols due to spray leak of waste from flush pit	Backflow of waste to flush pit with valve or pipe leak and cover block off	SC: Pressure Switch Interlocks or Alarms (Water Service Lines) SS: Backflow Prevention Devices	LCO: Service Water Pressure Detect Syss AC: Trans Pump Admin Lock Cntrls AC: Trans Cntrls (Mis-routing)	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S3
204AR-07A	Release of liquid radioactive waste and high airborne in unloading room from the Tank 241-AY-102 due to reverse pumping of Tank 241-AY-102 contents back to 204-AR	Pump in pit 02D starts and pumps back to the 204-AR building through the transfer piping and leaks	None required	AC: Trans Pump Admin Lock Cntrls AC: Trans Cntrls (Mis-routing)	SC: 204-AR CAM Interlock SS: 204-AR Building	LCO: Ventilation Stack CAM Interlock Syss	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines) with additional controls to address 204-AR spray leaks.	S2
COB-01	Release of radioactive and/or hazardous material from COB due to spray leak	Flange, gasket or valve, spray leak with COB lid removed	None required	AC: Trans Pump Admin Lock Cntrls AC: Trans Cntrls (Mis-routing)	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S3
I-222S-1-CMP-C	Release (potential spray leak) of 222-S lab waste to atmosphere in diversion box or 244-S Pump Pit due to increased corrosion from failure to add sodium hydroxide	Human error - failure to add sodium hydroxide	None required	AC: Trans Cntrls (Waste Compatibility) AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines); and Mixing of Incompatible Material - Tank Pressurization.	S2
I-222S-2-LEK-B	Release of 222-S lab waste to the atmosphere due to spray leak at the diversion box or pump pit, caused by corrosion in the pipe	Corrosion in pipe line	None required	AC: Trans Cntrls (Mis-routing) AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S2

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
I-222S-2-LEK-E	Release of 222-S lab waste to the atmosphere due to spray leak at the diversion box or pump pit, caused by rupture at pipe connections from a seismic event	Seismic event	None required	AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls AC: Emergency Prep (Seismic)	Controls based on accident analyses (Spray Leak in Structure or from Overground Waste Transfer Lines; and Natural Phenomena - Seismic).	S2
I-242A-1-LEK-B	Release of waste from Feed Tank 241-AW-102 to the atmosphere due to spray leak at the diversion box or pump pit, caused by corrosion in the pipe	Corrosion in pipe line	None required	AC: Trans Pump Admin Lock Cntrls AC: Trans Cntrls (Mis-routing)	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines).	S2
I-242A-1-LEK-E	Release of waste from Feed Tank 241-AW-102 to the atmosphere due to spray leak at the diversion box or pump pit, caused by rupture at pipe connections	Seismic event causes spray leak	None required	AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls AC: Emergency Prep (Seismic)	Controls based on accident analyses (Spray Leak in Structure or from Overground Waste Transfer Lines; and Natural Phenomena - Seismic).	S2
I-242A-2-LEK-B	Release of slurry tank waste to the atmosphere due to spray leak at the diversion boxes or pump pit, caused by corrosion in the pipe	Corrosion in pipe line	None required	AC: Trans Pump Admin Lock Cntrls AC: Trans Cntrls (Mis-routing)	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines).	S2
I-242A-2-LEK-E	Release of slurry tank waste to the atmosphere due to spray leak at the diversion box or pump pit, caused by rupture at pipe connections	Seismic event causes leak	None required	AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls AC: Emergency Prep (Seismic)	Controls based on accident analyses (Spray Leak in Structure or from Overground Waste Transfer Lines; and Natural Phenomena - Seismic).	S2

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
I-242S-2-LEK-B	Release of contaminated water to the atmosphere due to spray leak at the diversion box or pump pit, caused by corrosion in the pipe	Corrosion in pipe line causes spray leak	None required	AC: Trans Pump Admin Lock Cntrls AC: Trans Cntrls (Mis-routing)	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines).	S2
I-242S-2-LEK-E	Release of contaminated water to the atmosphere due to spray leak at the diversion box or pump pit, caused by rupture at pipe connections from seismic event	Seismic event	None required	AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls AC: Emergency Prep (Seismic)	Controls based on accident analyses (Spray Leak in Structure or from Overground Waste Transfer Lines; and Natural Phenomena - Seismic).	S2
I-242S-4-LEK-E	Release of contaminated water to the atmosphere due to spray leak at the diversion box or pump pit, caused by rupture at pipe connections from an seismic event	Seismic event causes spray leak	None required	AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls AC: Emergency Prep (Seismic)	Controls based on accident analyses (Spray Leak in Structure or from Overground Waste Transfer Lines; and Natural Phenomena - Seismic).	S2
I-BPLANT-1-CMP-B	Release (spray leak) of low level waste at diversion box from transfer of low pH material resulting in increased corrosion in pipe	Human error - failure to add sodium hydroxide leads to corrosion and leak in pipe	None required	AC: Trans Cntrls (Waste Compatibility) AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analyses (Spray Leak in Structure or from Overground Waste Transfer Lines; and Mixing of Incompatible Material - Tank Pressurization).	S2
I-BPLANT-2-LEK-B	Release of low level waste to the atmosphere due to spray leak at the diversion box or pump pit, caused by corrosion in the pipe	Corrosion in pipe line causes spray leak	None required	AC: Trans Pump Admin Lock Cntrls AC: Trans Cntrls (Mis-routing)	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines).	S2

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
I-PUREX-3-CMP-B	Release (spray leak) of TRU waste from PUREX at diversion box due to leak from increased corrosion caused by transfer of acidic waste	Human error - failure to add sodium hydroxide to low level waste results in spray leak	None required	AC: Trans Pump Admin Lock Cntrls AC: Trans Cntrls (Waste compatibility)	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines; and Mixing of Incompatible Material - Tank Pressurization).	S2
I-PUREX-4-LEK-B	Release of TRU waste from PUREX to the atmosphere due to spray leak at the diversion box or pump pit, caused by corrosion in the pipe	Corrosion in pipe line causes spray leak	None required	AC: Trans Pump Admin Lock Cntrls AC: Trans Cntrls (Mis-routing)	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines).	S2
I-PUREX-4-LEK-E	Release of TRU waste from PUREX to the atmosphere due to spray leak at the diversion box or pump pit, caused by rupture at pipe connections from seismic event	Seismic event causes spray leak	None required	AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls AC: Emergency Prep (Seismic)	Controls based on accident analyses (Spray Leak in Structure or from Overground Waste Transfer Lines; and Natural Phenomena - Seismic).	S2
I-TPLANT-1-CMP-B	Release (spray) of low level waste at diversion box from transfer of lower pH material resulting in increased corrosion in pipe	Human error - failure to add sodium hydroxide causes corrosion and associated spray leak	None required	AC: Trans Cntrls (Waste Compatibility) AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines; and Mixing of Incompatible Tank Pressurization).	S2
I-TPLANT-2-LEK-B	Release of low level waste to the atmosphere due to spray leak at the diversion box or pump pit	Corrosion in pipe line causes spray leak	None required	AC: Trans Pump Admin Lock Cntrls AC: Trans Cntrls (Mis-routing)	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines).	S2
I-TPLANT-2-LEK-E	Release of low level waste to the atmosphere due to spray leak at the diversion box or pump pit, caused by rupture at pipe connections from seismic event	Seismic event causes spray leak	None required	AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls AC: Emergency Prep (Seismic)	Controls based on accident analyses (Spray Leak in Structure or from Overground Waste Transfer Lines; and Natural Phenomena - Seismic).	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
OGT-EXT3-01A	Release of radioactive or hazardous aerosols from the primary pipe due to spray leak caused by truck crash into piping system	Human error, line struck by truck	SC: OGT Concrete Shielding Sys	AC: Trans Cntrls (OGT protection) AC: Trans Pump Admin Lock Program AC: Ign Cntrls (Speed Limit)	None required	None required	Controls based on accident analyses (Spray Leak in Structure or from Overground Waste Trans Lines; and In-Tank Fuel Fire/Deflagration).	S3
OGT-FLOW1-03A	Release of radioactive or hazardous aerosols from the primary pipe due to spray leak caused by misdirected flow	Spray leak caused by JR-1 (3-way valve) mispositioned to flush, two check valves fail, flush disconnect fails (check valve), reverse flow to external flush fixture and release to the environment	SC: Pressure Switch Interlocks or Alarms (Water Service Lines)	LCO: Service Water Pressure Detect Syss AC: Trans Cntrls (Mis-routing) AC: Trans Pump Admin Lock Cntrls	None required	None required	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S3
OGT-FLOW2-02	Release of radioactive or hazardous aerosols from the primary pipe due spray leak caused by over-rated pump	Installation of incorrect pump and failure of inner pipe, failure of weld on flange of outer pipe, isolation valves closed on secondary pipe drains and no concrete shield in place	SC: OGT Concrete Shielding Sys	AC: Encasement Seal Loops AC: Trans Cntrls (OGT protection) AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs SC: OGT Encasement and Connections	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S3
OGT-NP3-01	Release of radioactive or hazardous aerosols from the primary pipe due spray leak caused by seismic event	Failure of line and concrete shielding during seismic event	None required	None required	SC: OGT Encasement and Connections	AC: Emergency Prep (Seismic)	Controls based on accident analysis (Natural Phenomena - Seismic) and seismic qualification of OGT Encasement and Connections.	S3
OGT-NP3-02	Release of radioactive or hazardous aerosols from the primary pipe due to leak caused by high wind	Pipe is blown off supports and no concrete shielding in place	None required	None required	SC: OGT Encasement and Connections	None required	Controls based on qualification of OGT Encasement and Connections for high winds.	S3

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
OGT-TEMP1-02	Release of radioactive or hazardous vapors/aerosols from the primary pipe due to spray leak caused by high temperatures	Vehicle accident above ground starts fire, melt the EPDM hose causing a leak to secondary pipe, pumping occurring, fire fails gasket and facilitates a release to atmosphere	SC: OGT Concrete Shielding Sys	AC: Trans Cntrls (OGT protection) AC: Ign Cntrls (Speed Limit)	None required	None required	Controls based on accident analyses (Spray Leak in Structure or from Overground Waste Transfer Lines; and In-Tank Fuel Fire/ Deflagration).	S2
W058-FLOW15	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak	Computer failure or human error causing misrouting of material when flow path is not completely connected	None required	AC: Trans Pump Admin Lock Cntrls AC: Trans Cntrls (Mis-routing)	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S3
W058-FLOW16	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak	External leak of valve or valves to the valve pit	None required	AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S3
W058-FLOW17a	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak	Failure of jumper due to misalignment (human error) plus mitigative features failure	None required	AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S3
W058-FLOW17b	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak	Failure of jumper due to gasket failure plus mitigative features failure	None required	AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S3
W058-FLOW17c	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak	Failure of jumper due to corrosion plus mitigative features failure	None required	AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S3

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
W058-FLOW18	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak	Computer failure or human error causing misrouting of material when flow path is not completely connected	None required	AC: Trans Pump Admin Lock Cntrls AC: Trans Cntrls (Mis-routing)	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S3
W058-FLOW19	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak	External leak of valve or valves to the valve pit plus mitigative features failure	None required	AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S3
W058-FLOW20a	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak	Failure of jumper due to misalignment (human error) plus mitigative features failure	None required	AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S3
W058-FLOW20b	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak	Failure of jumper due to gasket failure plus mitigative features failure	None required	AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S3
W058-FLOW20c	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak	Failure of jumper due to corrosion plus mitigative features failure	None required	AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S3
W058-INTEG32	Release of radioactive supernate or slurry aerosols to the atmosphere due to a spray leak from test risers located near SY-A and SY-B valve pits	Failure of primary piping and path for spray leak from test riser plus mitigative features failure	None required	AC: Encasement Seal Loops AC: Trans Pump Admin Lock Cntrls AC: Trans Cntrls (Mis-routing)	None required	None required	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S3

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
W058-INTEG34	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak	External event (airplane crash, etc)	None required	None required	None required	None required	No controls required based on low accident frequency.	S3
W058-INTEG35	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak	Seismic event	None required	AC: Trans Cntrls (Mis-routing) AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls AC: Emergency Prep (Seismic)	Controls based on accident analyses (Spray Leak in Structure or from Overground Waste Transfer Lines; and Natural Phenomena - Seismic).	S3
W058-INTEG36	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak	External event (airplane crash, etc)	None required	None required	None required	None required	No controls required based on low accident frequency.	S3
W058-INTEG37	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak	Seismic event	None required	AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls AC: Emergency Prep (Seismic)	Controls based on accident analyses (Spray Leak in Structure or from Overground Waste Transfer Lines; and Natural Phenomena - Seismic).	S3
XS-01-TEMP01	Release of steam-aerosol from transfer piping in pump pit due to steam hammer and resulting pipe damage	Extended recirculation and consequential heating of saltwell liquid with sudden opening of valve when cover block is open	None required	AC: Trans Pump Admin Lock Cntrls AC: Trans Cntrls (Mis-routing)	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
XS-06-FLOW03	Release of liquid radioactive waste from transfer piping from PFP to DCRT due to spray leak in DCRT pump pit	Pipe failure in DCRT pump pit causing spray leak	None required	AC: Trans Pump Admin Lock Cntrls AC: Trans Cntrls (Mis-routing)	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S3
XS-06-FLOW04	Release of liquid radioactive waste from transfer piping from an SST to a DCRT due to spray leak (SPUTTER) of saltwell liquor from DCRT pump pit	Pipe failure	None required	AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S2
SPRAY LEAK FROM UNDERGROUND WASTE TRANSFER LINES (Section 5.3.2.21)								
EE-16	Release of radioactive and hazardous material from transfer line spray leak due to excavation error	Excavation into waste transfer line during a transfer	None required	AC: Excavation Cntrls	None required	None required	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines).	S3
102AW-01-TEMP	Release of liquid radioactive waste aerosols from transfer pipe to Tank 241-AW-102 due to spray leak of liquid waste from transfer pipe leak	Piping leak due to exceeding the design temperature of the pipe by transferring high temperature waste	None required	AC: Trans Cntrls (Mis-routing) AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines).	S3
CP-RMV-03	Release of radioactive or toxic material from transfer line through the push pipe during removal activities	Human error	None required	AC: Excavation Cntrls	None required	None required	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines).	S3
I-222S-2-LEK-C	Release of 222-S lab waste to the atmosphere due to spray leak at the rupture of the line	Inadvertent excavation of line	None required	AC: Excavation Cntrls	None required	None required	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines).	S2
I-242A-1-LEK-C	Release of waste from Feed Tank 241-AW-102 to the atmosphere due to spray leak at the rupture of the line	Inadvertent excavation of line causes spray leak	None required	AC: Excavation Cntrls	None required	None required	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines).	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
I-242A-2-LEK-C	Release of slurry tank waste to the atmosphere due to spray leak at the rupture of the line	Inadvertent excavation of line causes spray leak	None required	None required	None required	None required	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines).	S2
I-242S-2-LEK-C	Release of contaminated water to the atmosphere due to spray leak at the rupture of the line from excavation	Inadvertent excavation of line causes spray leak	None required	AC: Excavation Cntrls	None required	None required	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines).	S2
I-BPLANT-2-LEK-C	Release of low level waste to the atmosphere due to spray leak at the rupture of the line from excavation	Inadvertent excavation of line causes spray leak	None required	AC: Excavation Cntrls	None required	None required	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines).	S2
I-PFP-2-LEK-C	Release of TRU mixed waste to the atmosphere due to spray leak at the rupture of the line	Inadvertent excavation of line	None required	AC: Excavation Cntrls	None required	None required	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines).	S2
I-PFP-3-LEK-C	Release of TRU mixed waste to the atmosphere due to spray leak at the rupture of the line	Inadvertent excavation of line	None required	AC: Excavation Cntrls	None required	None required	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines).	S2
I-PUREX-2-LEK-C	Release of TRU waste from PUREX to the atmosphere due to spray leak at the rupture of the line from inadvertent excavation	Inadvertent excavation of line causes spray leak	None required	AC: Excavation Cntrls	None required	None required	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines).	S2
I-PUREX-4-LEK-C	Release of TRU waste from PUREX to the atmosphere due to spray leak at the rupture of the line from excavation	Inadvertent excavation of line causes spray leak	None required	AC: Excavation Cntrls	None required	None required	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines).	S2
I-TPLANT-2-LEK-C	Release of low level waste to the atmosphere due to spray leak at the rupture of the line from excavation	Inadvertent excavation of line causes spray leak	None required	AC: Excavation Cntrls	None required	None required	Controls based on accident analysis (Spray Leak from Underground Waste Transfer Lines).	S2
NP-08	Radioactive and hazardous material releases from transfer pipes due to seismic event (possible spray leak)	Seismic event shears pipes and encasements during transfer	None required	None required	None required	AC: Emergency Prep (Seismic)	Controls based on accident analysis (Natural Phenomena - Seismic).	S3

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
TANK BUMP (Section 5.3.2.22)								
102AW-02-TEMP02	Release of radioactive aerosols from Tank 241-AW-102 due to tank bump	High heat waste combined with loss of ventilation contributes to tank bump	SS: Temperature Mon Sys SS: Tank Level Detect Sys	LCO: DST and AWF Tanks Waste Temperature Cntrls AC: Trans Cntrls (Waste Compatibility) AC: Process Instrumentation and Measuring and Test Equipment	None required	None required	Controls based on accident analysis (Tank Bump).	S2
102AW-09-TEMP01	Release of radioactive aerosols from Tank 241-AW-102 atmosphere due to tank bump	High heat waste plus loss of cooling and/or mixing pump (not yet installed) operation	SS: Temperature Mon Sys SS: Tank Level Detect Sys	LCO: DST and AWF Tanks Waste Temperature Cntrls AC: Trans Cntrls (Waste Compatibility) AC: Process Instrumentation and Measuring and Test Equipment	None required	None required	Controls based on accident analysis (Tank Bump).	S2
114SX-05.b.2	Release of radioactive aerosols from Tank 241-SX-114 head space to atmosphere due to sudden flashing of water added to tank for cooling	Flashing (adding cold liquid to hot tank contents)	None required	None required	None required	None required	No controls required based on low accident frequency.	S2
XS-26-TEMP01	Release of radioactive aerosols from Tank 241-AW-102 due to tank bump	High heat waste plus loss of cooling contributes to tank bump	SS: Temperature Mon Sys SS: Tank Level Detect Sys	LCO: SST Waste Temperature Cntrls LCO: DST and AWF Tanks Waste Temperature Cntrls AC: Trans Cntrls	None required	None required	Controls based on accident analysis (Tank Bump).	S2
WASTE TRANSPORT VEHICLE ACCIDENT (Section 5.3.2.23)								
VEH-03	Release of radioactive or toxic material from cask due to damage to transport casks during a high wind/tornado	High wind/tornado	None required	None required	None required	None required	None (All control activity deferred to packaging safety analyses).	S2
VEH-02	Release of radioactive or toxic material from cask due to damage to transport casks during seismic event	Seismic event	None required	None required	None required	None required	None (All control activity deferred to packaging safety analyses).	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
VEH-02-I	Release of radioactive or toxic material from MISF samples in transport casks due to seismic damage	Seismic event	None required	None required	None required	None required	None (All control activity deferred to packaging safety analyses).	S2
VEH-03-I	Release of radioactive or toxic material from MISF samples in transport casks due to high wind/ tornado damage	High wind/tornado	None required	None required	None required	None required	None (All control activity deferred to packaging safety analyses).	S2
NATURAL PHENOMENA - HIGH WIND (Section 5.3.2.23)								
CRN-13-a	Release of radioactive or toxic material from tank/equipment damage and dome collapse due to boom failure	High wind	None required	AC: Dome Loading Cntrls (High Wind)	None required	None required	Controls base on accident analysis (Natural Phenomena - High Wind).	S3
CRN-13-IA	Release of radioactive and/or toxic materials from below ground facility due to containment top collapse or equipment damage by boom failure	High wind or seismic event	None required	AC: Dome Loading Cntrls (High Wind)	None required	AC: Emergency Prep (Seismic)	Controls base on accident analyses (Natural Phenomena - High Wind; and Natural Phenomena - Seismic).	S2
CRN-13-IC	Release of radioactive and/or toxic materials from facility due to containment top collapse damage by boom failure	High wind or seismic event	None required	AC: Dome Loading Cntrls (High Wind)	None required	AC: Emergency Prep (Seismic)	Controls base on accident analyses (Natural Phenomena - High Wind; and Natural Phenomena - Seismic).	S2
CRN-23	Release of radioactive or toxic materials from tank due to loss of vertical load control, dropping crane load into tank, onto tank bottom (subsurface leak)	High wind or seismic event	None required	AC: Dome Loading Cntrls (High Wind)	None required	AC: Emergency Prep (Seismic)	Controls base on accident analyses (Natural Phenomena - High Wind; and Natural Phenomena - Seismic).	S2
CRN-23-IA	Release of radioactive or toxic materials from underground facility bottom due to loss of vertical load control, dropping crane load into facility (subsurface leak)	High wind or seismic event	None required	AC: Dome Loading Cntrls (High Wind)	None required	AC: Emergency Prep (Seismic)	Controls base on accident analyses (Natural Phenomena - High Wind; and Natural Phenomena - Seismic).	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
ABOVE GROUND STRUCTURE FAILURE (Section 5.3.2.23)								
ITK-FR-08	Release of radioactive aerosols/vapors from flex receiver due to structural failure	High winds tear flex receiver bag	None required	None required	None required	None required	No controls required based on accident analysis (Above Ground Structure Failure).	S2
CRN-11-IB	Release of radioactive and/or toxic materials from facility due to equipment damage by boom failure	Human error: improper load assembly, rigging, crane overloaded	None required	None required	None required	None required	No controls required based on accident analysis (Above Ground Structure Failure).	S2
CRN-12-IB	Release of radioactive and/or toxic materials from facility due to equipment damage by boom failure	Mechanical failure: corrosion, faulty materials	None required	None required	None required	None required	No controls required based on accident analysis (Above Ground Structure Failure).	S2
CRN-13-IB	Release of radioactive and/or toxic materials from above ground facility due to equipment damage by boom failure	High wind or seismic event	None required	None required	None required	None required	No controls required based on accident analysis (Above Ground Structure Failure).	S2
CRN-18	Release of radioactive or toxic material from above ground tank equipment due to dropping crane load	Human error: improper load assembly, rigging, crane overloaded	None required	None required	None required	None required	No controls required based on accident analysis (Above Ground Structure Failure).	S2
CRN-18-I	Release of radioactive or toxic material from aboveground facility equipment due to dropping crane load	Human error: improper load assembly, rigging, crane overloaded	None required	None required	None required	None required	No controls required based on accident analysis (Above Ground Structure Failure).	S2
CRN-19-I	Release of radioactive or toxic material from aboveground facility equipment due to dropping crane load	Mechanical failure: corrosion, faulty materials	None required	None required	None required	None required	No controls required based on accident analysis (Above Ground Structure Failure).	S2
CRN-20-I	Release of radioactive or toxic material from aboveground facility equipment due to dropping crane load	High wind or seismic event	None required	None required	None required	None required	No controls required based on accident analysis (Above Ground Structure Failure).	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
CRN-23-IB	Release of radioactive or toxic materials from aboveground facility bottom due to loss of vertical load control, dropping crane load into facility	High wind or seismic event	None required	None required	None required	None required	No controls required based on accident analysis (Above Ground Structure Failure).	S2
CRN-25-IB	Release of radioactive or toxic material from aboveground MISF due to swinging load into equipment caused by loss of lateral load control	Human error: improper load assembly, rigging, positioning error	None required	None required	None required	None required	No controls required based on accident analysis (Above Ground Structure Failure).	S2
CRN-26-IB	Release of radioactive or toxic material from aboveground MISF due to swinging load into equipment caused by loss of lateral load control	Mechanical failure: corrosion, faulty materials, hydraulics, outriggers in soft soil	None required	None required	None required	None required	No controls required based on accident analysis (Above Ground Structure Failure).	S2
CRN-27-IB	Release of radioactive or toxic material from aboveground MISF due to swinging load into equipment caused by loss of lateral load control	Mechanical failure: corrosion, faulty materials, hydraulics, outriggers in soft soil	None required	None required	None required	None required	No controls required based on accident analysis (Above Ground Structure Failure).	S2
ITK-FR-03	Release of radioactive aerosols from tank and/or receiver due to equipment jam in riser	Equipment becomes lodged in riser, efforts to remove pull riser out of tank causing breach of tank & receiver containment	None required	None required	None required	None required	No controls required based on accident analysis (Above Ground Structure Failure).	S2
ITK-FR-22	Release of radioactive aerosols from flex receiver due to tank gas release	Tank gas release pressurizes bag and causes bag to rupture	None required	None required	None required	None required	No controls required based on accident analysis (Above Ground Structure Failure).	S2
LDUA 5-40	Release of contamination from TRIC and tank riser due to damage during wind storm	High winds	None required	None required	None required	None required	No controls required based on accident analysis (Above Ground Structure Failure).	S2

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
NP-05	Radioactive and hazardous material release from tanks, nearby ground surfaces, and ventilation systems due to above grade disturbances	High winds	None required	None required	None required	None required	No controls required based on accident analysis (Above Ground Structure Failure).	S2
NATURAL PHENOMENA - LIGHTNING (Section 5.3.2.23)								
NP-03	Radioactive and hazardous material releases from tanks due to fire in tanks	Lightning strikes riser in tank farm	None required	AC: Ign Cntrls (Lightning)	None required	None required	Controls based on accident analysis (Natural Phenomena - Lightning).	S2
EE-01	Release of radioactive and toxic materials from tanks due to external force and fire	Aircraft crash	None required	None required	None required	None required	No controls required based on low accident frequency.	S3
ITK-11-I	Release of radioactive or toxic material from facility due to in-facility fire or explosion during intrusive activity	Lightning, range fire, or seismic event ignites facility vapors	None required	AC: Ign Cntrls (Lightning)	None required	AC: Emergency Prep (Seismic)	Controls based on accident analyses (Natural Phenomena - Lightning; and Natural Phenomena - Seismic).	S2
LDUA 5-43	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of flammable gas	Lightning strikes VPM in raised position	None required	AC: Ign Cntrls (Lightning)	None required	None required	Controls based on analyzed accident Natural Phenomena - Lightning.	S3
NP-11	Radioactive and hazardous material releases from tank farms due to lava flow	Eruption of molten lava from fissures	None required	None required	None required	None required	No controls required based on low accident frequency.	S3
NATURAL PHENOMENA - SEISMIC EVENTS (Section 5.3.2.23)								
NP-07	Radioactive and hazardous material releases from tanks and ventilation systems due to seismic event	Seismic event collapses domes	None required	None required	None required	AC: Emergency Prep (Seismic)	Controls based on accident analysis (Natural Phenomena - Seismic).	S3
102S-05.a2	Release of radioactive aerosols from Tank 241-S-102 to atmosphere due to dome collapse	Seismic event (common mode failure)	None required	None required	None required	AC: Emergency Prep (Seismic)	Controls based on accident analysis (Natural Phenomena - Seismic).	S3

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
114SX-04.b.1.b.2b	Release of radioactive aerosols to atmosphere from Tank 241-SX-114 waste due to heat induced tank dome collapse	Ducting failure due to seismic activity coupled with failure to respond Resulting in tank degradation	None required	None required	None required	AC: Emergency Prep (Seismic)	Controls based on accident analysis (Natural Phenomena - Seismic).	S3
244AR-02.a.14	Release of radioactive aerosols from waste contained in tanks (4) and building due to earthquake	Seismic event collapses building and four tanks	None required	None required	None required	AC: Emergency Prep (Seismic)	Controls based on accident analysis (Natural Phenomena - Seismic).	S3
244AR-05.a.02	Release of radioactive material from facility due to seismic event which causes building collapse without cell collapse	Seismic event damages facility structure	None required	None required	None required	AC: Emergency Prep (Seismic)	Controls based on accident analysis (Natural Phenomena - Seismic).	S2
CCF-18	Release of radioactive and hazardous materials from tanks due to dome collapses	Fire in tank propagates to connecting tank and both tanks collapse during cooldown from negative tank pressure	None required	None required	None required	None required	No controls required based on accident analysis (Organic Solvent Fire/Organic Salt-Nitrate Reaction) which shows that tank will not collapse.	S3
CCF-19	Release of radioactive and hazardous materials from tanks due to dome collapses	Fire in tank causes pressure transient that leads to GRE in connecting tank with subsequent fire and tank collapses from negative tank pressure	None required	None required	None required	None required	No controls required based on extremely low accident frequency.	S3
CRN-13-b	Release of radioactive or toxic material from tank/equipment damage and dome collapse due to boom failure	Seismic event	None required	None required	None required	AC: Emergency Prep (Seismic)	Controls based on accident analysis (Natural Phenomena - Seismic).	S3

Table 5.4-1. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S3 and S2 Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Cons
NP-13	Radioactive and hazardous material releases from tanks due to excessive weight on dome	Accumulations of heavy snow followed by heavy rain	None required	None required	None required	None required	No controls required based on accident analysis (Tank Failure Due to Excessive Loads).	S3

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ABBREVIATION LIST: Admin = Administrative Cons = Consequence Cntrls = Controls Detect = Detection Ign = Ignition Mon = Monitoring Prep = Preparedness Sys = Systems Trans = Transfer TSR = Technical Safety Requirement							
102AW-02-LEVE	Release of radioactive aerosols from Tank 241-AW-102 annulus due to the presence of radioactive liquid waste in Tank 241-AW-102 annulus	Primary tank leakage from various causes	None	None	SC: Primary Tank Leak Detect Syss SS: HEPA Filters	LCO: Primary Tank Leak Detect Syss	These controls address this hazardous condition by indicating leak and minimizing release.
102AW-02-LEVE02A	Release of radioactive aerosols from Tank 241-AW-102 annulus ventilation system due to the presence of radioactive liquid waste in the annulus	Mis-routing of transfer to annulus instead of primary tank	None	AC: Trans Cntrls (Mis-routing)	SS: HEPA Filters SC: Primary Tank Leak Detect Syss	LCO: Primary Tank Leak Detect Syss	These controls address this hazardous condition by indicating mis-transfer and minimizing exposure.
102AW-04-LEVE01	Release of radioactive aerosols from Tank 241-AW-102 central pump pit due to accumulation of radioactive liquids in the central pump pit	Leak of primary piping	None	None	SC: Trans Sys Cvrs SC: Trans Leak Detect Syss	LCO: Trans Sys Cvrs LCO: Trans Leak Detect Syss AC: Trans Cntrls (Mis-routing) AC: Trans Pump Admin Lock Cntrls AC: Trans Sys Cvr Removal Cntrls	These controls address this hazardous condition by indicating leak and minimizing releases.
102AW-04-LEVE02	Release of radioactive aerosols from Tank 241-AW-102 central pump pit due to accumulation of radioactive liquids in the central pump pit	Misrouting through an open jumper plus clogged drain	None	AC: Trans Cntrls (Leak Prevention/ Detect/Cntrl)	SC: Trans Leak Detect Syss SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Cntrls (Leak Prevention/ Detect/Cntrl) AC: Trans Pump Admin Lock Cntrls	These controls address this hazardous condition by indicating leak and minimizing exposure.
102AW-04-LEVE03	Release of radioactive aerosols from Tank 241-AW-102 central pump pit due to accumulation of radioactive liquids in the central pump pit	Dissolution of residual contamination in central pump pit caused by erroneous use of raw water	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
102AW-04-LEVE04	Release of radioactive aerosols from Tank 241-AW-102 central pump pit due to accumulation of radioactive liquids in the central pump pit	Dissolution of residual contamination in central pump pit caused by pit cleaning plus clogged drain	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
102AW-04-PRES01	Release of radioactive particulate from Tank 241-AW-102 central pump pit due to pressurization	Loss of primary tank ventilation causes pressurization of pump pit.	SC: DST/AWF Ventilation	LCO: DST and AWF Tank Ventilation Syss AC: Flammability Cntrls (Pressurization)	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	These controls address this hazardous condition by monitoring ventilation operation and cover block status.
102AW-04-PRES02	Release of radioactive particulate from Tank 241-AW-102 central pump pit due to its being open to atmosphere	Removal of cover block	None	None	SC: DST/AWF Ventilation	LCO: DST and AWF Tank Ventilation Syss	These controls address this hazardous condition by minimizing release.
102AW-08-COMP06	Release of toxic gases from Tank 241-AW-102 tank vapor space due to production and migration of toxic gases from sludge	Chemical reactions in waste causes production of toxic gases	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Health & Safety Plan.
102AW-09-COMP03	Release of toxic vapors from a separable organic layer in Tank 241-AW-102 due to fuel spill into tank	External event (fuel spill)	None	AC: Ign Cntrls (Vehicles)	None	None	This control addresses this hazardous condition by preventing fuel spill.
102AW-09-COMP04	Release of toxic vapors from a separable organic layer in Tank 241-AW-102	Core sampling (NPH) releases trapped vapors	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Health & Safety Plan.
102AW-09-COMP05	Release of toxic vapors from a separable organic layer in Tank 241-AW-102 due to error in transfer	Generator erroneous transfer of insoluble organic material	None	AC: Trans Cntrls (Organic Solvent)	None	None	This control addresses this hazardous condition by preventing mis-transfers.
102S-02.d3	Release of radioactive aerosols to atmosphere from Tank 241-S-102 pit due to burning fuel on top of pit caused by ignition of gas from ruptured gas tank.	Vehicle drives into pit cover puncturing gas tank + Ignition	None	AC: Ign Cntrls (Vehicles)	None	AC: Emergency Prep (Fire in Contaminated Area)	These controls address this hazardous condition by preventing fuel spill and minimizing exposure.
102S-06.a	Release of radioactive aerosols from Tank 241-S-102 vapor space to atmosphere due to ventilation system failure	Filter plugged	None	AC: HEPA Filter Cntrl (Filter Efficiency)	None	AC: HEPA Filter Cntrls (Source Term)	These controls address this hazardous condition by limiting source buildup.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
106C-01K	Release of radioactive and/or hazardous material from Tank 241-C-106 tank due to high temperature	Water evaporation	SC: SST Ventilation SS: Temperature Mon	LCO: SST Ventilation Syss LCO: SST Waste Temperature Cntrls	SS: Ventilation Sys CAM Interlock	LCO: Ventilation Stack CAM Interlock Syss AC: HEPA Filter Cntrls (Source Term)	These controls address this hazardous condition by maintaining tank vacuum, monitoring tank temp and CAM interlock mitigating releases.
106C-01S	Release of radioactive and/or hazardous material from Tank 241-C-106 caused by low level in waste tank due to high temperature	Water evaporation	SC: SST Ventilation SS: Temperature Mon	LCO: SST Ventilation Syss LCO: SST Waste Temperature Cntrls	SS: Ventilation Sys CAM Interlock	LCO: Ventilation Stack CAM Interlock Syss AC: HEPA Filter Cntrls (Source Term)	These controls address this hazardous condition by maintaining tank vacuum, monitoring tank temp and CAM interlock mitigating releases.
106C-01Sa	Release of radioactive and/or hazardous material from Tank 241-C-106, due to low tank level because of tank leak	Waste tank leak	SS: Temperature Mon	LCO: SST Waste Temperature Cntrls	SS: Tank Level Detect Sys SS: Temperature Mon	LCO: SST Waste Temperature Cntrls	These are applicable controls from the Tank Bump accident analysis. Temperature monitoring prevents one possible tank failure cause and is a possible indicator of tank leak (tank heat-up). Facility worker exposure controlled by Radiation Protection Program.
106C-01T	Release of radioactive and/or hazardous material from Tank 241-C-106 due to low level in waste tank	Failure to add water to tank	SC: SST Ventilation	LCO: SST Ventilation Syss	None	AC: HEPA Filter Cntrls (Source Term)	These controls address the hazardous condition by maintaining tank vacuum.
106C-06A	Release of radioactive and/or hazardous material from Tank 241-C-106 pump pit, due to pump pit being opened to atmosphere	Cover blocks removed	None	None	SC: SST Ventilation	LCO: SST Ventilation Syss	These controls address this hazardous condition by minimizing release.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
106C-06F	Release (minor) of radioactive and/or hazardous material from Tank 241-C-106 pump pit, due to pump pit high level	Plugged pit drain while adding water	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
106C-06G	Release (minor) of radioactive and/or hazardous material from Tank 241-C-106 pump pit due to pump pit high level	Plugged pit drain with rain or snow melt intrusion	SC: Trans Leak Detect Syss	LCO: Trans Leak Detect Syss AC: Trans Pump Admin Lock Cntrls AC: Trans Cntrls (Leak Prevention/ Detect/Cntrl)	None	None	These controls address this hazardous condition by notifying personnel of leak.
106C-06H	Release (minor) of radioactive and/or hazardous material from Tank 241-C-106 pump pit due to pump pit high level	Plugged pit drain during pit cleaning, cover blocks are off	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
106C-06K	Release of radioactive and/or hazardous material from Tank 241-C-106 pump pit due to decreased pump pit structural integrity caused by drop	Equipment drop during crane work	None	AC: Dome Loading Cntrls (Lifting Cntrls)	None	None	This control addresses this hazardous condition by preventing equipment drop.
106C-10F	Release of radioactive and/or hazardous material from Tank 241-C-106, potential spread of contamination due to reverse air flow if intake HEPAs damaged	Loss of tank active ventilation	SC: SST Ventilation	LCO: SST Ventilation Syss	None	AC: HEPA Filter Cntrls (Source Term)	These controls address the hazardous condition by maintaining tank vacuum.
106C-10K	Release of radioactive and/or hazardous material from Tank 241-C-106, spread of contamination, due to ventilation air intake open to atmosphere	HEPA filter breach	SC: SST Ventilation	LCO: SST Ventilation Syss	None	AC: HEPA Filter Cntrls (Source Term)	These controls address the hazardous condition by maintaining tank vacuum.
106C-10L	Release of radioactive and/or hazardous material from Tank 241-C-106, spread of contamination, due to ventilation air intake open to atmosphere	Air intake ductwork damaged	SC: SST Ventilation	LCO: SST Ventilation Syss	None	AC: HEPA Filter Cntrls (Source Term)	These controls address the hazardous condition by maintaining tank vacuum.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
106C-11A	Release of radioactive and/or hazardous material from Tank 241-C-106, due to HEPA filter damage	HEPA filters plugged	None	None	None	AC: HEPA Filter Cntrls (Source Term)	These controls address the hazardous condition by maintaining tank vacuum.
106C-11G	Release of tank atmosphere through exhauster drain from Tank 241-C-106 due to leak or failure to add water routinely	Loss of exhauster seal pot water due to leak or failure to add water routinely	None	None	SS: Ventilation CAM Interlock Syss	LCO: Ventilation Stack CAM Interlock Syss	These controls address this hazardous condition by minimizing unfiltered releases.
106C-11H	Release of radioactive and/or hazardous material from Tank 241-C-106 due to condensate backing up into filters, de-entrainer or heater	Exhauster seal pot water freezing due to loss of heat trace	None	None	SS: Ventilation CAM Interlock Syss	LCO: Ventilation Stack CAM Interlock Syss AC: HEPA Filter Cntrls (Source Term)	These controls address this hazardous condition by minimizing filter source term accumulation, filter degradation and mitigating filter breakthrough.
106C-11I	Release of radioactive and/or hazardous material from Tank 241-C-106 due to moisture carryover into HEPAs causing loss of efficiency	Exhauster heater failure	None	None	SS: Ventilation CAM Interlock Syss	LCO: Ventilation Stack CAM Interlock Syss AC: HEPA Filter Cntrls (Source Term)	These controls address this hazardous condition by minimizing filter source term accumulation, filter degradation and mitigating filter breakthrough.
106C-11N	Release of radioactive and/or hazardous material from Tank 241-C-106, through HEPA filter path, due to filter degradation over time	HEPA filter degradation	None	None	SS: Ventilation CAM Interlock Syss	LCO: Ventilation Stack CAM Interlock Syss AC: HEPA Filter Cntrls (Source Term)	These controls address this hazardous condition by minimizing filter source term accumulation, filter degradation and mitigating filter breakthrough.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
106C-12A	Release of radioactive and/or hazardous material from Tank 241-C-106 due to tank falling below level limit, caused by excessive tank evaporation from high temperature	Pit drain plug, water addition fails	SC: SST Ventilation SS: Temperature Mon	LCO: SST Ventilation Syss LCO: SST Waste Temperature Cntrls	SS: Ventilation CAM Interlock Syss	LCO: Ventilation Stack CAM Interlock Syss AC: HEPA Filter Cntrls (Source Term)	These controls address this hazardous condition by maintaining tank vacuum, inspection of HEPA filters, and mitigating filter breakthrough.
106C-12B	Release of radioactive and/or hazardous material from Tank 241-C-106 due to low tank level	Water addition tank truck breakdown	SC: SST Ventilation SS: Temperature Mon	LCO: SST Ventilation Syss LCO: SST Waste Temperature Cntrls	SS: Ventilation CAM Interlock Syss	LCO: Ventilation Stack CAM Interlock Syss AC: HEPA Filter Cntrls (Source Term)	These controls address this hazardous condition by maintaining tank vacuum, inspection of HEPA filters, and mitigating filter breakthrough.
106C-12C	Release of radioactive and/or hazardous material from Tank 241-C-106 due to low tank level because of increased evaporation	Water addition tank truck leak	SC: SST Ventilation SS: Temperature Mon	LCO: SST Ventilation Syss LCO: SST Waste Temperature Cntrls	SS: Ventilation CAM Interlock Syss	LCO: Ventilation Stack CAM Interlock Syss AC: HEPA Filter Cntrls (Source Term)	These controls address this hazardous condition by maintaining tank vacuum, inspection of HEPA filters, and mitigating filter breakthrough.
106C-12D	Release of radioactive and/or hazardous material from Tank 241-C-106 due to excessive tank evaporation from high temperature which causes tank to fall below level limit	Tank level instrumentation fails, does not prompt water addition	SC: SST Ventilation SS: Temperature Mon	LCO: SST Ventilation Syss LCO: SST Waste Temperature Cntrls	SS: Ventilation CAM Interlock Syss	LCO: Ventilation Stack CAM Interlock Syss AC: HEPA Filter Cntrls (Source Term)	These controls address this hazardous condition by maintaining tank vacuum, inspection of HEPA filters, and mitigating filter breakthrough.
107AN-01-LEVE03	Release of caustic material from truck tank due to leak	Failure to secure truck	None	AC: Caustic Transfer Controls	None	AC: Caustic Transfer Controls	Controls based on accident analysis (Caustic Spray Leak).
107AN-03-FLOW	Release of concentrated caustic solution to surface from transfer piping due to backflow of caustic	Low temperature causes backflow	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Health & Safety Plan.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
114SX-04.a.1a	Radioactive aerosols released from Tank 241-SX-114 head space, via tank ventilation (requires failure of outlet filter), to the atmosphere due to exhauster failure	Exhauster failure Mechanical Low temperature (thermocouple in exhaust duct not insulated picks up radiated temperature from ductwork.)	SS: Ventilation CAM Interlock Syss	LCO: Ventilation Stack CAM Interlock Syss	None	AC: HEPA Filter Cntrls (Source Term)	These controls address the hazardous condition by detecting unfiltered releases. MVS - 6/19/98 - These controls now address the hazardous condition by preventing continuing release of radioactive material if the filters fail.
114SX-04.a.1b	Radioactive aerosols released from Tank 241-SX-114 head space, via tank ventilation (requires failure of outlet filter), to the atmosphere due to exhauster failure	Filter plugged	SC: SST Ventilation	LCO: SST Ventilation Syss	None	AC: HEPA Filter Cntrls (Source Term)	These controls address the hazardous condition by maintaining tank vacuum.
114SX-04.a.4	Release of radioactive aerosols from Tank 241-SX-114 headspace to atmosphere due to inlet HEPA filter failure coupled with exhauster failure	Filter failure	None	None	None	AC: HEPA Filter Cntrls (Source Term)	MVS 6-19-98 - The control addresses the hazardous condition by limiting the source term available for release should a filter blow out.
114SX-04.b.1.a.1	Release of radioactive aerosols from Tank 241-SX-114 headspace to atmosphere due to inlet HEPA filter failure coupled with exhaust butterfly valve closure	Human error: Closure of Tank 241-SX-114 exhaust butterfly valve isolating tank from exhaust plenum	None	None	None	AC: HEPA Filter Cntrls (Source Term)	MVS 6-19-98 - The control addresses the hazardous condition by limiting the source term available for release should a filter blow out.
114SX-04.b.1.b.1a	Release radioactive aerosols released from Tank 241-SX-114 head space to the atmosphere due to ventilation system ducting failure (with failed inlet filter)	Ducting failure from bad welds	None	None	None	AC: HEPA Filter Cntrls (Source Term)	MVS 6-19-98 - The control addresses the hazardous condition by limiting the source term available for release should a filter blow out.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
114SX-04.b.1.c.1	Release of radioactive aerosols from Tank 241-SX-114 head space to atmosphere due to exhauster failure and multiple filter failure	Exhauster failure Fan failure Filter rupture (low differential pressure shutdown) Resulting in tank degradation	SC: SST Ventilation	LCO: SST Ventilation Syss	None	AC: HEPA Filter Cntrls (Source Term)	These controls address the hazardous condition by maintaining tank vacuum.
114SX-04.b.1.d.1	Release of radioactive aerosols from Tank 241-SX-114 head space to atmosphere due to exhauster filter plugging (requires failure of inlet filter)	Exhaust filter plugging plus inlet filter failure	SC: SST Ventilation	LCO: SST Ventilation Syss	None	AC: HEPA Filter Cntrls (Source Term)	These controls address the hazardous condition by maintaining tank vacuum.
114SX-04.b.5	Release of radioactive aerosols from Tank 241-SX-114 head space to atmosphere due to failure of exhauster HEPA filters	No ventilation flow High ambient temperature conditions Leading to filter failure	None	None	None	AC: HEPA Filter Cntrls (Source Term)	MVS 6-19-98 - The control addresses the hazardous condition by limiting the source term available for release should a filter blow out.
204AR-01A	Release and spread of airborne radiological contamination from the rail car due to over pressurization	Over pressure in the rail car due to chemical reaction, rupture disk fails	None	None	None	AC: Source Inventory Cntrls	This control addresses this hazardous condition by limiting exposure.
204AR-01B	Release of airborne contamination and toxic chemical exposure to worker from the rail car due to high ambient temperature	Over pressure in the rail car due to high ambient temperature, rupture disk fails	None	None	None	AC: Source Inventory Cntrls	This control addresses this hazardous condition by limiting exposure.
204AR-01C	Release of airborne contamination and toxic chemical exposure to worker from the rail car due to chemical reaction causing over pressurization	High temperature in the rail car due to chemical reaction of the rail car contents, rupture disk fails	None	None	None	AC: Source Inventory Cntrls	This control addresses this hazardous condition by limiting exposure.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
204AR-01D	Release and spread of airborne contamination and toxic chemical exposure to worker from the rail car due to leaking rail car caused by high ambient temperature and over pressurization of car tank	High ambient temperature causing pressurization of rail car and possible leakage, failed rupture disk	None	None	None	AC: Source Inventory Cntrls	This control addresses this hazardous condition by limiting exposure.
204AR-01J	Release of airborne contamination from overflowing catch tank due to overfilling through priming line	Priming line inadvertently fills up rail car and overflows rail car through its vent line to the catch tank	None	None	SC: Trans Leak Detect Syss	LCO: Trans Leak Detect Syss AC: Trans Pump Admin Lock Cntrls	These controls address this hazardous condition by indicating leakage.
204AR-01K	Release of airborne contamination from unloader room due to overflowing catch tank	During sluicing operations, fill up rail car and overflow through its vent line to the catch tank	None	None	SC: Trans Leak Detect Syss	LCO: Trans Leak Detect Syss AC: Trans Pump Admin Lock Cntrls	These controls address this hazardous condition by indicating leakage.
204AR-02E	Release of radioactive material and toxic chemicals from trailer due to damage caused by trailer jack failure	Leak from tank trailer due to trailer jack failure	None	None	SC: Trans Leak Detect Syss	LCO: Trans Leak Detect Syss AC: Trans Pump Admin Lock Cntrls AC: Source Inventory Cntrls	These controls address this hazardous condition by notifying personnel of leak.
204AR-02F	Release of airborne contamination from unloader room due to overflowing catch tank	Priming line inadvertently fills up trailer and overflows trailer through vent line to the catch tank	None	None	SC: Trans Leak Detect Syss	LCO: Trans Leak Detect Syss AC: Trans Pump Admin Lock Cntrls	These controls address this hazardous condition by indicating leakage.
204AR-03A	Release of contamination and airborne release around the catch tank area and chemical exposure in mechanical equipment room from catch tank or Sodium Nitrate Tank due to failed tank	Sodium Nitrite Tank #2 either fails or has a drain valve open and empties its contents to the floor drains in the mechanical equipment room	None	None	SC: Trans Leak Detect Syss	LCO: Trans Leak Detect Syss AC: Trans Cntrls (Leak Detect/Cntrl) AC: Trans Pump Admin Lock Cntrls	These controls address this hazardous condition by minimizing leak size.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
204AR-03B	Release of airborne contamination around the catch tank area and chemical exposure in mechanical equipment room from the Sodium Nitrite Tank #2 due to overfilling and spilling to catch tank.	Sodium Nitrite Tank #2 overfilled and contents spilled into floor drains	None	None	SC: Trans Leak Detect Syss	LCO: Trans Leak Detect Syss AC: Trans Pump Admin Lock Cntrls	These controls address this hazardous condition by indicating leakage.
204AR-04A	Release of airborne and waterborne contamination from high level in the catch tank due to Sodium Hydroxide Tank #3 failure	Sodium Hydroxide Tank #3 failure or drain valve open which empties contents into the floor drains	None	None	SC: Trans Leak Detect Syss	LCO: Trans Leak Detect Syss AC: Trans Cntrls (Leak Detect/Cntrl) AC: Trans Pump Admin Lock Cntrls	These controls address this hazardous condition by minimizing leak size.
204AR-04B	Release of airborne contamination around the catch tank area and chemical exposure in mechanical equipment room from the Sodium Hydroxide Tank #3 and catch tanks due to overfilling of the Sodium Hydroxide Tank	Sodium Hydroxide Tank #3 overfilled and contents spilled into the floor drains	None	None	SC: Trans Leak Detect Syss	LCO: Trans Leak Detect Syss AC: Trans Pump Admin Lock Cntrls	These controls address this hazardous condition by indicating leakage.
204AR-04C	Release of chemicals to the mechanical equipment room environment from the Sodium Nitrite Tank due to adding chemicals too quickly	Adding caustic chemicals too quickly to the tank - human error	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Health & Safety Plan.
204AR-04D	Release of sodium hydroxide particulates from the Sodium Hydroxide Tank due to thermal stress to piping and eventual valve leakage of Sodium Hydroxide Tank piping	Adding too much sodium hydroxide resulting in high temperatures	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Health & Safety Plan.
204AR-04E	Release of sodium hydroxide particulates from the Sodium Hydroxide Tank due to damage to the chemical addition pump diaphragm	Adding steam heat to the coils resulting in high temperatures	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Health & Safety Plan.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
204AR-05B	Release of toxic chemicals and worker exposure from chemical addition piping due to over pressure of piping and subsequent damage	Over pressure while running chemical addition pump due to dead heading the pump	None	None	SC: Trans Leak Detect Syss	LCO: Trans Leak Detect Syss AC: Trans Pump Admin Lock Cntrls	These controls address this hazardous condition by indicating leakage.
204AR-06A	Release of liquid radioactive waste to the unloader room or caustic chemicals to the mechanical equipment room from the priming water piping or transfer piping due to over pressurization of piping	Raw water supply pressure higher than normal	None	None	SC: Trans Leak Detect Syss	AC: Trans Leak Detect Syss	These controls address this hazardous condition by minimizing leak.
204AR-06B	Release of liquid radioactive waste to the unloader room or caustic chemicals to the mechanical equipment room from the priming water piping or transfer piping due to over pressurization of piping	Water hammer in priming piping from raw water supply	None	None	SC: Trans Leak Detect Syss	LCO: Trans Leak Detect Syss	These controls address this hazardous condition by minimizing release.
204AR-06C	Release of airborne contamination from unloader room due to overflowing catch tank	High flow through the priming line and transfer piping due to misalignment which fills up the rail car or trailer and overflows it to the catch tank	None	None	SC: Trans Leak Detect Syss	LCO: Trans Leak Detect Syss AC: Trans Pump Admin Lock Cntrls	These controls address this hazardous condition by indicating leakage.
204AR-07B	Release of contaminated water to encasement outside of 204-AR building and floor drains inside building from the transfer piping due to over pressure and leakage from raw water flush	Over pressure of raw water through transfer piping during post transfer flush	None	None	SC: Trans Leak Detect Syss	LCO: Trans Leak Detect Syss AC: Trans Cntrls (Leak Detect/Cntrl) AC: Trans Pump Admin Lock Cntrls	These controls address this hazardous condition by minimizing leak size.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
204AR-09F	Release of airborne contamination and increased radiation levels from catch tank due to blocked catch tank ventilation and over pressure of catch tank	Ventilation to the catch tank is blocked off with heaters on, resulting in a catch tank high pressure	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
204AR-11A	Release of airborne radioactivity from unloader room due to loss of confinement caused by power failure	Loss of confinement due to power failure and total loss of ventilation fan	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
204AR-11B	Release of airborne radioactivity from unloader room due to loss of confinement caused by low ventilation flow	Loss of confinement due to low ventilation flow	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
204AR-11C	Release of airborne contamination from the unloader room due to failure of ventilation fan	Failure of EF-1 fan resulting in loss of confinement	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
204AR-11D	Release of airborne contamination from the unloader room due to blocked ventilation flow	No ventilation flow because of damper closed	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
204AR-11E	Release of airborne contamination from the unloader room due to plugged ventilation flow	No ventilation flow because of plugged HEPA filter	None	None	None	AC: HEPA Filter Cntrls (Source Term)	These controls address this hazardous condition by limiting filter blowout source term.
213 W-01	Release of radioactive and/or hazardous materials in 213-W work room due to error in repackaging or instrument repair	Handling error (forklift, spills, etc)	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
213 W-02	Release of radioactive and/or hazardous materials in 213-W work room due to error in repackaging or instrument repair	Failure of tools	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
213 W-09	Release of radioactive and/or toxic materials from 213-W due to structural failure of building	Loss of control of vehicle in vicinity of building	None	AC: Ign Cntrls (Vehicles)	None	None	This control addresses this hazardous condition by minimizing vehicle accidents.
244AR-01.a.03	Radioactive aerosols released from tank headspace exit building through the inlet side of the canyon ventilation system due to mechanical failure	Failure of vessel venting with open vents to cell atmosphere and jetting operations occurring plus failure of exhaust fans	None	None	None	None	No applicable SSCs or TSRs - Hazardous condition not credible for steam jetting because steam has been isolated from 244-AR.
244AR-01.b.01	Radioactive aerosols released from tank headspace and exit building through the inlet side of the canyon ventilation system due to mechanical failure	Fan Failure with jetting occurring	None	None	None	None	No applicable SSCs or TSRs - Hazardous condition not credible for steam jetting because steam has been isolated from 244-AR.
244AR-01.b.02	Radioactive aerosols released from tank headspace and exit building through the inlet side of the canyon ventilation system due to mechanical failure	HEPA filter plugged with jetting occurring	None	None	None	AC: HEPA Filter Cntrls (Source Term)	These controls address this hazardous condition by limiting filter blowout source term. Hazardous condition not credible for steam jetting because steam has been isolated from 244-AR.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
244AR-01.b.03	Radioactive aerosols released from tank headspace and exit building through the inlet side of the canyon ventilation system due to human error	Damper closed with jetting occurring	None	None	None	AC: HEPA Filter Cntrls (Source Term)	These controls address this hazardous condition by limiting filter blowout source term. Hazardous condition not credible for steam jetting because steam has been isolated from 244-AR.
244AR-01.c.01	Release of radioactive aerosols from vessel headspace into canyon atmosphere due to vessel ventilation failure	Plugged vessel ventilation system filters	None	None	None	AC: HEPA Filter Cntrls (Source Term)	These controls address this hazardous condition by limiting filter blowout source term.
244AR-01.c.02	Release of radioactive aerosols from vessel headspace into canyon atmosphere due to ventilation system failure	Vessel ventilation system fan shutdown or failure	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
244AR-01.c.03	Release of radioactive aerosols from vessel headspace into canyon atmosphere due to human error	Valve closed in exhaust flow path	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
244AR-01.c.08	Release of radioactive aerosols from vessel headspace into canyon atmosphere due tank rupture	Plugged tank vents with gas evolution in tank contents	SC: TK-002 244-AR level dip tube flow	LCO: 244-AR TK-002 Ventilation Sys	None	None	These controls address the hazardous condition by indicating absence of ventilation flow.
244AR-01.c.10	Release of radioactive aerosols from vessel headspace into canyon atmosphere due to plugged ventilation system	Air purge operating with ventilation system plugged	None	None	None	AC: HEPA Filter Cntrls (Source Term)	These controls address this hazardous condition by inspection of HEPA filters.
244AR-01.c.11	Release of radioactive aerosols from vessel headspace into canyon atmosphere due to ventilation system filter plugging	Air heaters off (steam supplied)	None	None	None	AC: HEPA Filter Cntrls (Source Term)	These controls address this hazardous condition by inspection of HEPA filters.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
244AR-02.a.08	Release of radioactive liquid into cells due to jumper leak causing release of aerosols through cracks	Jumper leak (general)	SC: Trans Leak Detect Syss	LCO: Trans Leak Detect Syss AC: Trans Pump Admin Lock Cntrls AC: Trans Cntrls (Leak Prevention/ Detect/Cntrl)	None	None	These controls address this hazardous condition by notifying personnel of leak.
244AR-02.a.09	Release of radioactive liquid to soil from leaking sump filled by leaking jumper	Jumper leak (general)	SC: Trans Leak Detect Syss	LCO: Trans Leak Detect Syss AC: Trans Cntrls (Leak Prevention and Mis-routing) AC: Trans Pump Admin Lock Cntrls	SS: Salt Well Flow Totalizer SC: Trans Leak Detect Sys SS: Tank Level Detect Sys	LCO: Trans Leak Detect Syss AC: Trans Cntrls (Leak Detect/Cntrl) AC: Emergency Prep (Significant Release)	These are applicable controls from the Subsurface Leak Remaining Subsurface accident analysis. These controls also address this hazardous condition for worker risk by notifying personnel of leak.
244AR-02.a.10	Release of radioactive liquid into cells due to jumper leak	Jumper (B Plant to AY Tank Farm through cell) leak	SC: Trans Leak Detect Syss	LCO: Trans Leak Detect Syss AC: Trans Pump Admin Lock Cntrls AC: Trans Cntrls (Leak Prevention/ Detect/Cntrl)	None	None	These controls address this hazardous condition by notifying personnel of leak.
244AR-02.a.11	Release of radioactive liquid to soil from leaking sump filled by leaking jumper	Jumper (B Plant to AY Tank Farm through cell) leak	SC: Trans Leak Detect Syss	LCO: Trans Leak Detect Syss AC: Trans Cntrls (Leak Prevention and Mis-routing) AC: Trans Pump Admin Lock Cntrls	SS: Salt Well Flow Totalizer SC: Trans Leak Detect Sys SS: Tank Level Detect Sys	LCO: Trans Leak Detect Syss AC: Trans Cntrls (Leak Detect/Cntrl) AC: Emergency Prep (Significant Release)	These are applicable controls from the Subsurface Leak Remaining Subsurface accident analysis. These controls also address this hazardous condition for worker risk by notifying personnel of leak.
244AR-02.a.12	Release of radioactive liquid into cells due to tank leak	Tank leak	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

244AR-03.a.06	Release of radioactive aerosols from tanks headspace due to steam pressure control failure for jetting system	Jetting operation with failure of jetting steam pressure regulation	None	None	None	None	No applicable SSCs or TSRs - Hazardous condition not credible for steam jetting because steam has been isolated from 244-AR.
244AR-03.a.13	Release of radioactive aerosol being jetted from tank or sump due to overflow into sump	Jetting activities moving material from sump or another tank	None	None	None	None	No applicable SSCs or TSRs - Hazardous condition not credible for steam jetting because steam has been isolated from 244-AR.
244AR-03.a.14	Release of radioactive liquid being jetted from tank or sump due to overflow of tank	Inter-facility tank transfers	None	None	None	None	No applicable SSCs or TSRs - Hazardous condition not credible for steam jetting because steam has been isolated from 244-AR.
244AR-07.a.02	Radioactive contamination back flow into steam system due to steam supply failure	Steam supply failure	None	None	None	None	No applicable SSCs or TSRs - Hazardous condition not credible for steam jetting because steam has been isolated from 244-AR.
244AR-07.a.03	Radioactive contamination back flow into steam system due to compressed air failure	Steam supply failure and air blow failure	None	None	None	None	No applicable SSCs or TSRs - Hazardous condition not credible for steam jetting because steam has been isolated from 244-AR.
244AR-07.a.04	Exposure to low concentrations of radioactive material	Excess water used in steam jet flush	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
90D-01	Release of radioactive and toxic aerosols/ vapors from 90 Day Storage Pad due to container breach	Container breach from internal chemical, thermal or radiolysis reactions; corrosion, freeze-thaw cycles	None	None	None	AC: Emergency Prep (Significant Release)	This control addresses this hazardous condition by minimizing personnel exposure.
90D-02	Release of radioactive and toxic aerosols/ vapors from 90 Day Storage Pad due to container breach	Container breach from external impact from handling error, forklift, handling equipment airborne missile from wind, seismic	None	None	None	AC: Emergency Prep (Seismic)	This control addresses this hazardous condition by minimizing personnel exposure.
90D-03	Release of radioactive and toxic aerosols/ vapors from 90 Day. Storage Pad due to container breach	Container breach from airborne missile from wind, or from a seismic event	None	None	None	AC: Emergency Prep (Seismic)	This control addresses this hazardous condition by minimizing personnel exposure.
90D-04	Release of radioactive and toxic aerosols/ vapors from 90 Day Storage Pad due to fire or explosion	Waste ignition from spontaneous combustion, incompatible wastes, heat from sun, waste handling or other human activities	None	None	None	AC: Emergency Prep (Fire)	This control addresses this hazardous condition by minimizing personnel exposure.
90D-06	Release of radioactive and toxic aerosols/ vapors from Intermediate Holding Area due to container breach	Container breach from internal chemical, thermal or radiolysis reactions; corrosion, freeze-thaw cycles	None	None	None	AC: Emergency Prep (Significant Release)	This control addresses this hazardous condition by minimizing personnel exposure.
90D-07	Release of radioactive and toxic aerosols/ vapors from Intermediate Holding Area due to container breach	Container breach from external impact from handling error, forklift, handling equipment airborne missile from wind, seismic	None	None	None	AC: Emergency Prep (Seismic)	This control addresses this hazardous condition by minimizing personnel exposure.
90D-08	Release of radioactive and toxic aerosols/ vapors from Intermediate Holding Area due to container breach	Container breach from airborne missile from wind, or from a seismic event	None	None	None	AC: Emergency Prep (Seismic)	This control addresses this hazardous condition by minimizing personnel exposure.

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
90D-11	Release of radioactive and toxic aerosols/ vapors from waste transport vehicle due to loss of waste confinement	Failure to secure waste, vehicle accident, improper packaging, waste reactions	None	None	None	AC: Emergency Prep (Significant Release)	This is controlled by the SARP.
CCF-02	Radioactive and hazardous release from tanks due to short term loss of ventilation	Loss of offsite power	None	AC: HEPA Filter Cntrls (Filter Efficiency 244-S, TX, and A only)	None	AC: HEPA Filter Cntrls (Source Term)	These controls address this hazardous condition by inspection of HEPA filters.
CCF-03	Degraded ventilation performance at 702-A due to condensed water vapors on HEPAs	Sustained loss of water supply (month)	None	None	SS: Ventilation CAM Interlock Syss	LCO: Ventilation Stack CAM Interlock Syss AC: HEPA Filter Cntrls (Source Term)	These controls address this hazardous condition by minimizing filter source term accumulation, filter degradation and mitigating filter breakthrough.
CCF-04	Degraded ventilation performance at 702-A due to condensed water vapors on HEPAs	Sustained loss of steam supply	None	None	SS: Ventilation CAM Interlock Syss	LCO: Ventilation Stack CAM Interlock Syss AC: HEPA Filter Cntrls (Source Term)	These controls address this hazardous condition by minimizing filter source term accumulation, filter degradation and mitigating filter breakthrough.
CCF-16	Subsurface releases of radioactive or hazardous material due to leaks in multiple tanks	Tanks, tank penetrations and tank components deteriorate due to corrosion	SC: Temperature Mon	LCO: SST Waste Temperature Cntrols AC: Trans Cntrls (pH)	SC: Primary Tank Leak Detect SS: Tank Level Detect Sys SC: Temperature Mon	LCO: Primary Tank Leak Detect Syss LCO: SST Waste Temperature Cntrls	These are applicable controls from the Flammable Gas Deflagrations - DST accident analysis. Temperature monitoring prevents one possible tank failure cause and is a possible indicator of tank leak (tank heat-up). PH control on transfers to tank farm maintain tank waste pH.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
CDP-01	Release of radioactive contamination to soil surface from crib or ditch due to animal intrusion	Animal intrusion into crib or ditch	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
CDP-03	Release of radioactive contamination to soil surface from inactive pond due flooding in crib or ditch	Flooding	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
CDP-06	Release of radioactive contamination to atmosphere from inactive pond due to high wind/ tornado disturbing inactive pond	High winds/ tornadoes	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
CDP-08	Release of airborne radioactive contamination from contaminated vegetation due to fire in weed growth on top of cribs or ditches	Range fire	None	None	None	AC: Emergency Prep (Fire in Contaminated Area)	This control addresses this hazardous condition by minimizing exposure.
COB-02	Release of radioactive and/or hazardous material from COB due to spray leak	Flange, gasket or valve, spray leak with COB lid in place	None	AC: Trans Cntrls (Mis-routing) AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs SC: Trans Sys Supplemental Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls AC: Trans Cntrls (Leak Detect/Cntrl) AC: Trans Pump Admin Lock Cntrls JCO: Supplemental Cvrs	These are applicable controls from the Spray Leak in Structure or from Overground Waste Transfer Lines accident analysis. These controls also address this hazardous condition for worker risk by prevention/minimizing of leak.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
COB-03	Release of radioactive and/or hazardous material from COB due to spray leak	Piping leak into COB due to chemical reaction degrading pipe, lid in place	None	AC: Trans Cntrls (Mis-routing) AC: Trans Cntrls (Leak Prevention/ Detect/Cntrl) AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs SC: Trans Sys Supplemental Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls AC: Trans Cntrls (Leak Detect/Cntrl) AC: Trans Pump Admin Lock Cntrls JCO: Supplemental Cvrs	These are applicable controls from the Spray Leak in Structure or from Overground Waste Transfer Lines accident analysis. These controls address this hazardous condition for worker risk by preventing mis-transfers and minimizing exposure.
COB-05a	Release of radioactive and/or hazardous material from COB due to existing contamination inside COB and lid removed	Inspection of COB	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
COB-05b	Release of radioactive and/or hazardous material from COB due to existing contamination inside COB and lid off during high wind	High wind with COB cover off	None	None	SC: Trans Sys Cvrs SC: Trans Sys Supplemental Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls JCO: Supplemental Cvrs	These controls address this hazardous condition by minimizing release.
COB-05c	Release of radioactive and/or hazardous material from COB due to flooding	Flooding of COB due to rain/snow melt	None	None	SC: Trans Sys Leak Detect	LCO: Trans Sys Leak Detect	These controls address this hazardous condition by minimizing release.
COB-05d	Release of radioactive and/or hazardous material release from COB due to vehicle accident	Vehicle accident involving COB	None	AC: Ign Cntrls (Vehicle)	None	None	This control addresses this hazardous condition by minimizing vehicle accidents.
COB-05e	Release of radioactive and/or hazardous material from COB due to seismic event	Seismic event	None	None	None	AC: Emergency Prep (Seismic)	This control addresses this hazardous condition by minimizing exposure.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
COB-05f	Release of radioactive and/or hazardous material from COB due to existing contamination inside COB and COB lid off	Human error leaving COB lid off	SC: Trans Sys Cvrs SC: Trans Sys Supplemental Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls JCO: Supplemental Cvrs	None	None	These controls address this hazardous condition by minimizing exposure.
COB-06a	Release of radioactive and/or hazardous material from COB due to COB caisson pressurized	Weather heatup with HEPA filter plugged	None	None	None	None	No applicable SSCs or TSRs -Hazardous condition not credible because COBs are not airtight (No HEPA filters).
COB-06b	Release of radioactive and/or hazardous material from COB due to COB caisson pressurized	Leak into COB with HEPA filter plugged	None	None	SC: Trans Sys Cvrs SC: Trans Sys Supplemental Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls JCO: Supplemental Cvrs	These controls address this hazardous condition by prevention/ minimizing of leak. (No HEPA filters in COB configuration).
CP-GRT-01	Personnel exposure to contaminated pipe string due to removal of pipe during grouting	Contaminated soil in pipe	None	None	None	None	No applicable TSRs or SSCs - Facility worker exposure controlled by Radiation Protection Program.
CP-MSP-02	Release of radioactive or toxic material to soil (plume) remaining subsurface from transfer line due to puncture of line during transfer	Human error caused puncture to transfer line during push operations	None	AC: Excavation Cntrls	SC: Pipe Encasements SC: Trans Leak Detect Syss SS: Tank Level Detect Syss SS: Salt Well Flow Totalizers	LCO: Trans Leak Detect Syss AC: Trans Cntrls AC: Emergency Prep (Significant Release)	Controls based on accident analysis. (Subsurface Leak Remaining Subsurface and Spray Leak from Underground Transfer Lines).
CP-MSP-09	Release of isotope source to the soil surface due to load drop	Human Error caused load drop	None	None	None	None	No applicable TSRs or SSCs - Facility worker exposure controlled by Radiation Protection Program.
CP-MSP-11	Release of radioactive material to the soil surface due to crushed sensor package	Human Error: Heavy load inadvertently set on top of sensor package	None	None	None	None	No applicable TSRs or SSCs - Facility worker exposure controlled by Radiation Protection Program.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
CP-RMV-01	Release of radioactive or toxic material to soil (plume) remaining subsurface from inactive transfer line damaged during push operations	Human error caused puncture to inactive transfer line during push operations	None	AC: Excavation Cntrls	None	None	This control addresses the hazardous condition by preventing line puncture.
CP-RMV-02	Personnel exposure to high level waste contamination on surface of pipe string due contact with leaking waste	Human error caused puncture to inactive transfer line during push operations	None	None	None	None	No applicable TSRs or SSCs - Facility worker exposure controlled by Radiation Protection Program.
CP-RMV-04	Personnel exposure to radiation through push pipe due to puncture of tank dome	Human error results in removal of sample canister containment	None	None	None	None	No applicable TSRs or SSCs - Facility worker exposure controlled by Radiation Protection Program.
CP-SET-01	Release of radioactive or toxic material from above ground structure due to load movement	Mechanical failure of equipment causes load to swing into above ground structure	None	AC: Dome Loading Cntrls (Lifting Cntrls)	None	None	This control addresses the hazardous condition by controlling lifting activities.
CP-SET-02	Release of radioactive or toxic material from above ground structure due to load movement	Human error causes load to swing into above ground structure	None	AC: Dome Loading Cntrls (Lifting Cntrls)	None	None	This control addresses the hazardous condition by controlling lifting activities.
CP-SET-09	Release of isotope source from the MSP to the soil surface due to load drop	Human error causes load drop	None	None	None	None	No applicable TSRs or SSCs - Facility worker exposure controlled by Radiation Protection Program.
CP-SET-11	Release of radioactive material from the MSP to the soil surface due to crushing of the sensor package	Human error: Heavy load is inadvertently set on top of the sensor package	None	None	None	None	No applicable TSRs or SSCs - Facility worker exposure controlled by Radiation Protection Program.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
CP-SSP-02	Release of radioactive or toxic material to soil (plume) remaining subsurface from transfer line due to puncture of line during transfer	Human error caused puncture to transfer line during push operations	None	AC: Excavation Cntrls	SC: Pipe Encasements SC: Trans Leak Detect Syss SS: Tank Level Detect Syss SS: Salt Well Flow Totalizer	LCO: Trans Leak Detect Syss AC: Trans Cntrls AC: Emergency Prep (Significant Release) AC: Excavation Cntrls	Controls Selected (from Subsurface Leak Remaining Subsurface and Spray Leak From Underground Waste Transfer Lines).
CP-SSP-06	Personnel exposure to contaminated soil sample while removing sampling canister from pipe sleeve	Human error	None	None	None	None	No applicable TSRs or SSCs - Facility worker exposure controlled by Radiation Protection Program.
CP-SSP-09	Personnel exposure to contaminated pipe string caused by failure of sampling canister soil catcher to close properly	Mechanical failure	None	None	None	None	No applicable TSRs or SSCs - Facility worker exposure controlled by Radiation Protection Program.
CP-SSP-10	Personnel exposure to puff release of contaminated dust (particulates) caused by air movement as the sample canister is withdrawn from pipe sleeve	Contaminated inner tube	None	None	None	None	No applicable TSRs or SSCs - Facility worker exposure controlled by Radiation Protection Program.
CP-SSP-11	Release of contamination to environment due to dropping of the sample canister during transfer of sample from pipe to the shipping cask	Human error - workers drop sample canister or fail to handle properly	None	None	None	None	No applicable TSRs or SSCs - Facility worker exposure controlled by Radiation Protection Program.
CP-SSP-12	Release of contamination to environment due to dropping of the sample canister during transfer of sample from pipe to the shipping cask	Mechanical failure of the sample canister	None	None	None	None	No applicable TSRs or SSCs - Facility worker exposure controlled by Radiation Protection Program.
CP-SSP-13	Release of contamination to environment due to dropping of the sample canister during transfer of sample from outer push pipe to the shipping cask	High wind	None	None	None	None	No applicable TSRs or SSCs - Facility worker exposure controlled by Radiation Protection Program.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
CP-SSP-14	Release of contamination to environment due to dropping of the repackaged soil sample container	Human error - workers drop sample canister or fail to handle properly	None	None	None	None	No applicable TSRs or SSCs - Facility worker exposure controlled by Radiation Protection Program.
CRN-01	Release of radioactive and/or toxic materials from riser due to breach by crane movement	Human errors or failure to follow safe work practices	None	AC: Dome Loading Cntrls (Lifting Cntrls)	None	None	This control addresses this hazardous condition by controlling lifts.
CRN-01-I	Release of radioactive and/or toxic materials from riser breach due to crane movement	Human errors or failure to follow safe work practices	None	AC: Dome Loading Cntrls (Lifting Cntrls)	None	None	This control addresses this hazardous condition by controlling lifts.
CRN-02	Release of radioactive and/or toxic materials from riser due to breach by crane movement	Mechanical failures of crane (brakes, throttle)	None	AC: Dome Loading Cntrls (Lifting Cntrls)	None	None	This control addresses this hazardous condition by controlling lifts.
CRN-05-I	Release of radioactive and/or toxic materials from surface contamination and fuel tank on crane or support vehicle due to fuel tank fire (see In-Facility Equipment Installation for facility fires)	Human error in positioning crane load	None	AC: Ign Cntrls (Vehicles) AC: Dome Loading (Lifting Cntrls)	None	AC: Emergency Prep (Fire in Contaminated Area)	These controls address this hazardous condition by preventing fuel spill and minimizing exposure.
CRN-06-I	Release of radioactive and/or toxic materials from surface contamination and fuel tank on crane or support vehicle due to fuel tank fire (see In-Facility Equipment Installation for facility fires)	Mechanical failure in positioning crane load causes crane fuel tank rupture and fire	None	AC: Ign Cntrls (Vehicles) AC: Dome Loading (Lifting Cntrls)	None	AC: Emergency Prep (Fire in Contaminated Area)	These controls address this hazardous condition by preventing fuel spill and minimizing exposure.
CRN-17	Release of radioactive or toxic material from tanks due to power failure from crane hitting power lines/ supplies	Human error: improper load assembly, rigging, crane positioning	None	AC: Dome Loading Cntrls (Lifting Cntrls)	None	None	This control addresses this hazardous condition by controlling lifts.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
CVR-01	Release (greater than expected) of radioactive or hazardous material from pit due to lifting cover blocks	Failure to monitor or improper monitoring	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
CVR-01-I	Release of greater than expected amount of radioactive or hazardous material from pit upon lifting coverblocks due to monitoring failure	Failure to monitor or improper monitoring	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
CVR-02	Release (greater than expected) of radioactive or hazardous material from pit due to lifting cover blocks	Mechanical failure of equipment in pit (corrosion, leaks, etc)	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
CVR-02-I	Release of greater than expected amount of radioactive or hazardous material from pit upon lifting coverblocks due to mechanical failures	Mechanical failure of equipment in pit (corrosion, leaks, etc)	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
CVR-03	Release (greater than expected) of radioactive or hazardous material from pit due to lifting cover blocks	Wind or dust devil	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
CVR-03-I	Release of greater than expected amount of radioactive or hazardous material from pit upon lifting coverblocks due to windy conditions	Wind or dust devil	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
CVR-12-I	Release of radioactive or hazardous material from pit upon lifting coverblocks due to incorrect spraying of fixative	Spraying of fixative (soil cement) causes spray of material out of pit	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
CVR-13-I	Release of radioactive or hazardous material from pit upon lifting coverblocks due to open nozzles or risers in pit	Open nozzles or risers in pit with radioactive or hazardous material inside	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
CVR-14-I	Injury of worker from biological hazards (spiders, snakes, etc.) due to open nozzles or risers in pit	Open nozzles or risers in pit with biological hazards (spiders, snakes, etc.) inside	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Health and Safety Plan.
DCN-02	Release of radioactive or toxic material outside immediate area from equipment removed from tank due to decontamination of equipment	Miss direction of cleaning spray (human error)	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
EE-02	Release of radioactive contaminants from Tank Farms due to external fires	Range fire	None	None	None	AC: Emergency Prep (Fire in Contaminated Area)	This control addresses this hazardous condition by minimizing exposure.
EE-09	Surface flooding at tank farm	Water line breaks and causes flooding at tank farm	None	AC: Tank Service Water Intrusion Mon Program	None	None	This control addresses this hazardous condition by detecting water line breakage.
I-222S-1-CMP-A	Release of 222-S lab waste from transfer line due to leak from rapid corrosion caused by transfer of pH 1 solution	Human error - failure to add sodium hydroxide	None	AC: Trans Cntrls (pH)	None	None	This control addresses this hazardous condition by controlling transfers.
I-222S-2-FLW-A	Release (steam) of aerosols and particulates to the atmosphere due to reverse flowing steam into Tank 219-S-102 which saturates the HEPAs	Block valve inadvertently closed at tank farms and transfer via this line	None	AC: Trans Cntrls (Mis-routing)	None	None	This control addresses this hazardous condition by preventing mis-routing. Hazardous condition not credible because steam supply in 200W disconnected.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
I-242A-2-CMP-A	Release (potential for leak) to tank annulus (secondary confinement) caused by damage to feed tank due to overfilling of tank	Valve failure or inadvertently opened valve	None	None	SC: Primary Tank Leak Detect Syss	LCO: Primary Tank Leak Detect Syss	Controls address this hazardous condition by indicating leak and minimizing releases.
I-242A-4-FLW-A	Release of diluted high level waste to the ground through risers after unmitigated over filling of Tank 241-AW-102 and annulus with condensate	Tube rupture of raw water in condenser	SC: Trans Leak Detect Syss	LCO: Trans Leak Detect	SC: Trans Leak Detect Syss SC: Primary Tank Leak Detect Syss SC: Trans Sys Cvrs SC: Trans Sys Supplemental Cvrs	LCO: Trans Sys Cvrs LCO: Trans Leak Detect Syss LCO: Primary Tank Leak Detect Syss AC: Trans Pump Admin Lock Cntrls AC: Trans Sys Cvr Removal Cntrls JCO: Supplemental Cvrs	These controls address this hazardous condition by indicating leak and minimizing release.
I-242A-6-FLW-A	Release of diluted high level waste to the ground through risers after unmitigated over filling of Tank 241-AW-102 and annulus with raw water	Rupture of raw water line in condenser/pump room	SC: Trans Leak Detect Syss	LCO: Trans Leak Detect	SC: Trans Leak Detect Syss SC: Primary Tank Leak Detect Syss SC: Trans Sys Cvrs SC: Trans Sys Supplemental Cvrs	LCO: Trans Sys Cvrs LCO: Trans Leak Detect Syss LCO: Primary Tank Leak Detect Syss AC: Trans Pump Admin Lock Cntrls AC: Trans Sys Cvr Removal Cntrls JCO: Supplemental Cvrs	These controls address this hazardous condition by indicating leak and minimizing release.
I-242A-6-FLW-C	Release of contaminated aerosols to the 242-A Evaporator building through the drain lines, potential worker hazard	Higher vacuum at evaporator than at tank farms	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
I-242S-1-PRS-A	Release of airborne contaminates through cracks due to over pressurization of 242-S building and contamination of control room where tank farm controls are located	Exhaust fan failure	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
I-242S-1-TMP-A	Release of contaminated water to the ground outside of the 242-S Evaporator due to unmitigated leak in the pump room from the fire protection system's frozen and ruptured line	Low ambient temperature freezes and breaks pipe	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
I-242S-4-LEK-B	Release of contaminated water to the atmosphere due to spray leak at the condenser room, caused by corrosion in the pipe	Corrosion in pipe line	None	None	None	None	This is not a TWRS related event.
I-242T-3-FLW-A	Release of high level waste to the ground surface by overflowing the "new" diversion box caused by opened or leaking valve	Block valve inadvertently opened or leaking	None	None	None	AC: Emergency Prep (Significant Release)	This control addresses this hazardous condition by minimizing exposure.
I-242T-4-FLW-A	Release of high level waste to the ground surface from overflowing the "new" diversion box due to failure of 242-T building and rupture of tanks in 242-T	Catastrophic failure of the building due to aging effects	None	None	None	AC: Emergency Prep (Significant Release)	This control addresses this hazardous condition by minimizing exposure.
I-PFP-1-LVL-A	Release (underground) of TRU mixed waste at DCRT pit due to potential to send steam vapor to 244 TX DCRT, potential for thermal expansion to damage transfer pipe and leak to encasement pipe which drains to DCRT pit	Human error - failing to stop transfer to 244 TX when Tank D-5 is empty	SS: Pipe Encasements	AC: Trans Cntrls AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs SC: Trans Sys Supplemental Cvrs SS: Pipe Encasements SS: Trans Leak Detect Syss	LCO: Trans Sys Cvrs LCO: Trans Leak Detect Syss AC: Trans Cntrls AC: Trans Sys Cvr Removal Cntrls JCO: Supplemental Cvrs	These controls address this hazardous condition by indicating leakage and minimizing exposure.
I-PFP-3-FLW-C	Release of TRU mixed waste from 244 TX overfilling due to transfer error	Transferring from Tank D-7 or Tank D-8 to Tank D-5 while transferring from Tank D-5 to 244 TX	None	AC: Trans Cntrls (Leak Prevention/ Detect/Cntrl)	SC: Trans Leak Detect Syss SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Cntrls (Leak Prevention/ Detect/Cntrl) AC: Trans Pump Admin Lock Cntrls	These controls address this hazardous condition by indicating leak and minimizing exposure.

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
I-PUREX-1-TMP-A	Release from Tank 241-AW-105 through cracks in the cover block due to pressurizing tank from addition of hot waste to the tank	Human error - adding caustic (sodium hydroxide) to waste or transferring to U-3 via a steam jet and transferring from U-3 to Tank 241-AW-105 before the waste cools	SC: DST/AWF Ventilation	LCO: DST and AWF Tank Ventilation Syss	None	None	These controls address this hazardous condition by maintaining tank vacuum.
I-PUREX-2-PRS-B	Release of aerosols through cracks in the cover block due to pressurizing the receiver tank from an extended air purge of the transfer line	Extended air purge after transfer (mechanical failure)	SC: DST/AWF Ventilation	LCO: DST and AWF Tank Ventilation Syss	None	None	These controls address this hazardous condition by maintaining tank vacuum.
I-PUREX-3-TMP-A	Release of aerosols from Tank 241-AW-105 through cracks in the cover block due to pressurizing tank from addition of hot waste	Human error - adding caustic (sodium hydroxide) to waste or transferring to U-3 via a steam jet and transferring from U-3 to Tank 241-AW-105 before the waste cools	SC: DST/AWF Ventilation	LCO: DST and AWF Tank Ventilation Syss	None	None	These controls address this hazardous condition by maintaining tank vacuum.
I-PUREX-4-PRS-B	Release of aerosols through cracks in the cover block due to pressurizing the receiver tank from an extended air purge of the transfer line	Extended air purge after transfer (mechanical failure)	SC: DST/AWF Ventilation	LCO: DST and AWF Tank Ventilation Syss	None	None	These controls address this hazardous condition by maintaining tank vacuum.
I-PUREX-5-FLW-A	Release of aerosols through cracks in cover block due to pressurizing receiver tank caused by transferring waste with steam which heats the waste	Multiple deactivation locks removed and valves opened or multiple valves leaking	SC: DST/AWF Ventilation	LCO: DST and AWF Tank Ventilation Syss	None	None	These controls address this hazardous condition by maintaining tank vacuum.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
ITK-01-I	Release of radioactive and/or hazardous material from point of in-facility access due to chemical/thermal reaction (non-fire, non-explosion)	Chemical/thermal reaction of materials in equipment/waste	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
ITK-03	Release of radioactive and/or hazardous material from point of in-tank access (non-fire, non-explosion) due to intrusive activity	Contaminated equipment removed or reused	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
ITK-03-I	Release of radioactive and/or hazardous material from point of in-facility access due to equipment removal (non-fire, non-explosion)	Contaminated equipment removed or reused	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
ITK-04	Release of radioactive and/or hazardous material from point of in-tank access (non-fire, non-explosion) due to earthquake or high wind with open access	Seismic event or high wind when access open	None	None	None	AC: Emergency Prep (Seismic)	This control addresses this hazardous condition by minimizing personnel exposure.
ITK-07	Radioactive and/or hazardous material release from tank below grade (non-fire, non-explosion) due to intrusive activity	Dropped equipment in tank from human error or equipment failures (also see crane operations) Penetration of tank with linear-force, high pressure, or rotational equipment from human error or equipment failure	None	AC: Dome Loading Cntrls (Lifting Cntrls)	None	None	These are applicable controls from the Tank Failure Due to Excessive Loads accident analysis. This control also addresses this hazardous condition for worker risk by preventing equipment drop.
ITK-FR-01	Release of radioactive or hazardous material from flex receiver due to flushing with insufficient drainage	Riser not drained correctly or drain clogged causing plugging of riser	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
ITK-FR-02	Release of radioactive or hazardous material from flex receiver due to equipment jam in riser and non-procedural efforts to dislodge	Equipment becomes lodged in riser upon retrieval and non-procedural efforts to remove provide release path for tank material and/or flush water	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
ITK-FR-05	Release of radioactive or hazardous material from flex receiver due to structural failure	Human error tears flex receiver bag	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
ITK-FR-06	Release of radioactive or hazardous material from flex receiver due to structural failure	Equipment failure/ misalignment tears flex receiver bag (crane operation, hydraulic jack stand)	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
ITK-FR-07	Release of radioactive or hazardous material from flex receiver due to structural failure	Structural degradation	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
ITK-FR-14	Release of radioactive or hazardous material from flex receiver due to leak from flanges	Non-acceptable torque on bolts connecting bellows - torque too low not enough pressure for adequate seal, to high destroys seal material	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
ITK-FR-15	Release of radioactive or hazardous material from flex receiver due to errors in installation	Incorrect installation of receiver provides release path (misalignment of bellows)	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
ITK-FR-18	Release of radioactive or hazardous material from flex receiver due to damage from operation of hydraulic jacks	Hydraulic jacks on assembly stand are operated while assembly is bolted to flange damaging flex receiver or riser creating release path	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
ITK-FR-20	Release of radioactive or hazardous material from flex receiver due to wrong bag being used	Containment bag is too short to hold equipment being withdrawn from tank, condition goes unnoticed until containment is lost	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
ITK-FR-21	Release of radioactive or hazardous material from flex receiver due to operation in extreme weather	Operation in cold weather compromises strength of flex receiver, equipment breaks providing release path	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
ITK-FR-23	Release of radioactive or hazardous material from flex receiver due to equipment failure	Plexiglass window on receiver breaks causing release path	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
ITK-FR-26	Release of radioactive or hazardous material from flex receiver due to leak from bag	Equipment mispositioned in receiver bag creating inappropriate seal and leak	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
ITK-FR-28	Release of radioactive or hazardous material from flex receiver due to containment breach during transfer	Receiver trailer falls over with bagged equipment attached ripping bag and creating release path	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
LDUA 1-10	Worker exposure due to leak of waste into LDUA components	Line plug	None	None	None	None	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
LDUA 1-11	Worker exposure due to leak of waste into LDUA components	Line break	None	None	None	None	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.
LDUA 1-34	Worker exposure due to operation error or mechanical failure	Operator error or mechanical failure	None	None	None	None	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.
LDUA 2-13	Worker exposure due to leak of waste into LDUA components	Line plug	None	None	None	None	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.
LDUA 2-14	Worker exposure due to leak of waste into LDUA components	Line break	None	None	None	None	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.
LDUA 2-50	Worker injury due to equipment damage	Human error, software bug	None	None	None	None	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.
LDUA 2-53	Worker exposure due to contamination in LDUA	LDUA contamination - due to in-tank activities	None	None	None	None	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.
LDUA 2-54	Worker injury due to industrial accidents	Industrial accidents	None	None	None	None	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
LDUA 3-1	Release of radioactive aerosols from the TRIC due to filter plug and pressurization	TRIC filter inlet plugs (dust, ice, etc.)	None required	None required	None required	None required	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.
LDUA 3-15	Release of radioactive aerosols from the TRIC due to filter plug and pressurization	HEPA filter plugs with frozen condensation	None required	LCO: SST Ventilation Syss - Passive	None required	None required	This control addresses the hazardous condition by assuring that passive ventilation system is functioning.
LDUA 3-19	Worker injury due to general industrial hazards	General industrial hazards (e.g. during end effector change out)	None	None	None	None	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.
LDUA 3-2	Release of contamination from LDUA due to loss of containment	Door not sealed, loss of glove	None required	None required	None required	None required	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.
LDUA 3-20	Worker injury due to electric shock	Electric shock hazards during hook-up and maintenance	None	None	None	None	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.
LDUA 3-21	Release of contamination to ground from LDUA due to impact from pressurized water/ decontamination system	500-psi water (from decontamination system) causes impact hazards	None required	None required	None required	None required	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.
LDUA 3-22	Release of contamination from riser and TRIC due to loss of confinement	Riser valve open while end effectors being placed in TRIC	None required	None required	None required	None required	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
LDUA 3-23	Release or radioactive aerosols from riser due to spark igniting flammable gas	Plug gauge (carbon steel) becomes stuck in riser during riser characterization	SC: SST Ventilation	LCO: SST Ventilation Syss - Active LCO: SST Ventilation Syss - Passive AC: Flammable Gas Mon Cntrls	None required	AC: HEPA Filter Cntrls (Source Term)	Controls based on BIO Appendix E.
LDUA 3-24	Release of contamination from TRIC due to load drop	TRIC dropped from crane	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	This control addresses the hazardous condition by preventing load drop.
LDUA 3-25	Release of contamination from LDUA due to incorrect installation	VPM adapter, HEPA, Gloves, Door, incorrectly installed/sealed (leaks)	None required	None required	None required	None required	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.
LDUA 3-28	Release of contamination from riser due to high winds	High winds stress riser	None required	None required	None required	None required	No controls required based on accident analysis (Above Ground Structure Failure).
LDUA 3-4	Worker exposure due to purge system overpressure - increased contamination in TRIC	Purge system overpressure (VPM auxiliary hookup)	None	None	None	None	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.
LDUA 3-5	Worker exposure due to loss of decontamination water flow	Loss of decontamination water flow	None	None	None	None	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.
LDUA 3-7	Worker exposure due to plug in decontamination line resulting in poor decontamination	Decontamination water line plugs due to solids	None	None	None	None	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
LDUA 4-10	Worker exposure due to ignition of flammable gas inside VPM	Loss of supply air from VPM outer tube.	None	None	None	None	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.
LDUA 4-11	Worker injury due to blow out of housing panel	Supply pressure on with the VPM housing gate closed	None	None	None	None	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.
LDUA 4-27	Release of contamination due to thermal degradation of VPM housing	Thermal expansion/ contraction of atmosphere in housing while in storage	None required	None required	None required	None required	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.
LDUA 4-30	Release of contamination due to corrosion of VPM	Poor decontamination, caustic waste contacts arm, causes corrosion of VPM	None required	None required	None required	None required	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.
LDUA 4-39	Worker exposure due to loss of computer controls/requires manual retrieval of mast	Loss of computer	None	None	None	None	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.
LDUA 4-40	Worker exposure due to insufficient decontamination	Mast tubes not sufficiently decontaminated prior to removal	None	None	None	None	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.
LDUA 4-43	Worker injury due to industrial hazards	Industrial hazards during maintenance	None	None	None	None	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

LDUA 4-8	Worker exposure due to leak of waste into LDUA components	Line plug	None	None	None	None	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.
LDUA 4-9	Worker exposure due to leak of waste into LDUA components	Line break	None	None	None	None	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.
LDUA 5-17	Worker injury due to inadvertent motion of valve	Operator error, improperly positioned valves	None	None	None	None	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.
LDUA 5-21	Worker injury due to shock load damaging equipment	Shock load causes damage	None	None	None	None	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.
LDUA 5-23	Release of hazardous material to environment from truck battery due to inadvertent spill/ potential ignition	Truck battery acid spill, deflagration	None required	None required	None required	None required	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.
LDUA 5-29	Release of contamination from LDUA or riser due to spark igniting flammable gas	Truck backs into tank farm equipment (e.g., riser, pump pit)	SC: SST Ventilation	LCO: SST Ventilation Syss - Active LCO: SST Ventilation Syss - Passive AC: Ign Cntrls (Vehicles) AC: Flammable Gas Mon Cntrls	None required	AC: HEPA Filter Cntrls (Source Term)	Controls based on BIO Appendix E.
LDUA 5-30	Release of contamination from LDUA or riser due to damage from vehicles	Truck moves after setup	None required	AC: Ign Cntrls (Vehicles)	None required	None required	This control addresses the hazardous condition by minimizing vehicle accidents.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
LDUA 5-31	Release of contamination due to transport vehicle accident.	Vehicle accident during transport	None required	None required	None required	None required	None (All control activity deferred to packaging safety analysis).
LDUA 5-32	Worker injury due to vehicle engine fire	Vehicle engine fire	None	None	None	None	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.
LDUA 5-33	Release of contamination from LDUA or riser due to damage from vehicles	Failure to deploy outriggers or premature retraction of outriggers	None required	None required	None required	None required	No controls required based on accident analysis (Above Ground Structure Failure).
LDUA 5-35	Worker exposure due to misalignment of mast arm during insertion creating external contamination	Misaligning during insertion	None	None	None	None	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.
LDUA 5-36	Release of contamination from LDUA or riser due to damage from improper operation	Attempting to lower VPM to horizontal while arm is in riser	None required	None required	None required	None required	No controls required based on accident analysis (Above Ground Structure Failure).
LDUA 5-39	Release of contamination from LDUA or riser due to equipment failure causing riser damage	Brakes not operating as designed	None required	None required	None required	None required	No controls required based on accident analysis (Above Ground Structure Failure).
LDUA 5-41	Release of contamination from TRIC and tank riser due to damage during seismic event	Seismic event	None required	None required	None required	AC: Emergency Prep (Seismic)	Controls based on analyzed accident Natural Phenomena - Seismic.
LDUA 5-42	Release of contamination from LDUA or riser due to damage from vehicle operation resulting in fire	Other truck impact	None required	AC: Ign Cntrls (Vehicles)	None required	AC: Emergency Prep (Fire in Contaminated Area)	The controls address the hazardous condition through minimization of vehicle accidents and the appropriate response to fires.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
LDUA 5-44	Release of contamination from LDUA or riser due to damage from vehicle operation	Heavy rain or ponded surface water or flood	None required	None required	None required	None required	No controls required based on accident analysis (Above Ground Structure Failure).
LDUA 6-28	Worker injury due to communication failure	Communication failure between control locations and TRIC during maintenance	None	None	None	None	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.
LDUA 6-29	Worker injury due to lifting	Lifting injuries in moving heavy cable	None	None	None	None	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.
LDUA 6-30	Worker injury due to electric shock	Electrical malfunction	None	None	None	None	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.
LDUA 6-5	Worker injury due to fire	Fire	None	None	None	None	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.
LDUA 6-7	Worker injury due to electric shock	Impact, severing of cable by heavy equipment	None	None	None	None	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.
LDUA 7-12	Worker injury due to accident when parking trailer	Collision with obstacles during parking of trailer	None	None	None	None	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.
LDUA 7-13	Worker injury due to electric shock	Improper grounding - bonding	None	None	None	None	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.

LDUA 7-14	Worker injury due to electric shock	Electrical shock hazards during hook-up	None	None	None	None	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.
LDUA 7-16	Worker injury due to electric shock	Dust in electronic distribution disconnects and junction box	None	None	None	None	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.
LDUA 7-3	Worker injury due to slipping hazard	Slipping hazards	None	None	None	None	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.
LDUA 7-4	Worker injury due to fire	Fire in trailer	None	None	None	None	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.
LDUA 7-6	Worker injury due to trailer falling over	Wind	None	None	None	None	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.
LDUA 7-7	Worker injury due to trailer falling over	Seismic event	None	None	None	None	No applicable SSC's or TSR's - Facility worker injury controlled by Health and Safety Plan.
LDUA/EREE 1-10	Worker exposure due to leak of waste into EREE	Line break	None	None	None	None	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
LDUA/EREE 1-29	Worker exposure due to operator error/ mechanical failure	Operator error or mechanical failure	None	None	None	None	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.
LDUA/EREE 1-30	Worker exposure due to operator error/ mechanical failure	Operator error or mechanical failure	None	None	None	None	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.
LDUA/EREE 1-9	Worker exposure due to leak of waste into EREE	Line plug	None	None	None	None	No applicable SSC's or TSR's - Facility worker exposure controlled by Radiation Protection Program.
NP-01	Radioactive and hazardous material release from tanks and ventilation system due to loss of electric power	Lightning strikes power distribution system	None	AC: Ign Cntrls (Lightning)	None	None	This control addresses this hazardous condition by stopping intrusive activities and minimizing potential exposure to worker if ventilation is lost.
NP-06	Radioactive and hazardous material releases from tanks, nearby ground surfaces, and ventilation systems due to above ground disturbances	High wind	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
NP-12	Radioactive and hazardous material releases from tanks due to ventilation system failures	Dust storms/dust devils	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
NP-14	Radioactive and hazardous material releases from tanks due to loss of power to ventilation systems	Severe hail	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
OGT-FLOW1-01	Personnel exposure to radioactive or hazardous material in the primary pipe due to pump failure	Pump failure, material settles in line (crystallization) and plugs line prohibiting transfer/waste is sitting in line and creates increased exposure to personnel	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
OGT-OPS1-01	Release of radioactive or hazardous material from the primary pipe due to line crushing from equipment drop	Drop shield blocks on transfer line during disassembly after pumping complete, potential to break primary and secondary line	None	AC: Dome Loading Cntrls (Lifting Cntrls)	None	None	This control addresses this hazardous condition by preventing equipment drop.
OGT-SPEC1-01	Personnel exposure to radioactive or hazardous material in the primary pipe due to loss of electrical supply	Loss of flow leading to line plug and the need to remove/replace, unclog line	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
RSR-01	Release of radioactive and/or toxic material upon opening of riser due to human error	Human error - improper contamination control, failure to monitor (rad or sniff), improper monitoring	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
RSR-01-1	Release of radioactive and/or toxic material from the vapor space due to opening of riser	Human error - improper contamination control, failure to monitor (rad or sniff), improper monitoring	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
SFF-01	Release of radioactive and/or toxic materials during sniff sampling due to human error or instrument failure	Improper sniffing technique or instrument failure, failure to perform radiation monitoring, improper monitoring, or instrument failure	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
VSU-01	Release of residual contamination and/or hazardous material from VSU due to VSU lid being left off	VSU lid is left off due to human error, wind blows	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
VSU-02	Release of residual contamination and/or hazardous material from VSU due to VSU lid being left off	VSU lid is left off due to human error, rain/snow melt seeps out bottom of VSU	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
VSU-03	Release of residual contamination and/or hazardous material from VSU due to VSU wall degradation	VSU wall degradation over time	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
VSU-04	Release of residual contamination and/or hazardous material from VSU due to internal VSU pressurization	Covered VSU pressurizes due to ambient temperature heat-up	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Radiation Protection Program.
XS-01-PRES02	Release of liquid radioactive waste from transfer pipe due to damaged saltwell pump	Leak from pump or seal from various causes	None	AC: Trans Cntrls (Leak Prevention and Mis-routing) AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs SC: Trans Sys Supplemental Cvrs SC: Trans Leak Detect Syss SS: Salt Well Flow Totalizer SS: Tank Level Detect Sys	LCO: Trans Sys Cvrs LCO: Trans Leak Detect Syss AC: Trans Cntrls (Mis-rout/Leak Detect/Cntrl) AC: Trans Pump Admin Lock Cntrls AC: Trans Sys Cvr Removal Cntrls AC: Emergency Prep (Significant Release) JCO: Supplemental Cvrs	These controls address this hazardous condition for worker risk by indicating leak and minimizing releases. The applicable controls for environmental release are identified from the Subsurface Leak Resulting in Pool accident analysis.
XS-01-TEMP02	Release of steam-aerosol from transfer piping in pump pit due to steam hammer and resulting pipe damage	Extended recirculation and consequential heating of saltwell liquid with sudden opening of valve when cover block is in place	None	None	SC: Trans Sys Cvrs SC: Trans Sys Supplemental Cvrs SC: Trans Sys Leak Detect	LCO: Trans Sys Cvrs LCO: Trans Sys Leak Detect JCO: Supplemental Cvrs	This control addresses this hazardous condition by indicating leakage and minimizing exposure. Liquid flashing to steam in not credible.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
XS-02-FLOW06	Release of liquid radioactive waste from DCRT due to overflowing of PFP sending tank (in facility)	Reverse flow caused by jumper misalignment	None	AC: Trans Cntrls (Mis-routing)	None	None	This control addresses this hazardous condition by preventing mis-routing.
XS-03-LEVE	Release of radioactive liquids from DCRT "annulus" (vault) due to DCRT leak	Corrosion or structural failure of DCRT or associated piping	None	None	SC: Trans Sys Cvrs SC: Trans Leak Detect Syss SS: Tank Level Detect Sys SS: Salt Well Flow Totalizer	LCO: Trans Sys Cvrs LCO: Trans Leak Detect Syss AC: Trans Cntrls (Mis-routing) AC: Trans Pump Admin Lock Cntrls AC: Trans Sys Cvr Removal Cntrls AC: Trans Cntrls (Material Balance)	These controls address this hazardous condition for worker risk from a Subsurface Leak Resulting in Pool by indicating leak and minimizing releases. These are also applicable controls from the Subsurface Leak Resulting in Pool accident analysis for environmental concerns. (DCRTs normally only contain waste during transfers)
XS-03-PRES01	Release of toxic vapors from DCRT due to increased concentrations in DCRT atmosphere	Tank isolated from forced ventilation with gas evolution	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Health & Safety Plan.
XS-03-PRES01A	Release of radioactive aerosols from DCRT headspace due to positive pressure	Loss of ventilation flow due to failure of ventilation fans causes positive pressure in tank	None	AC: HEPA Filter Cntrls (Filter Efficiency 244-S, TX, and A only)	SC: Trans Sys Cvrs SS: HEPA Filters	AC: HEPA Filter Cntrls (Source Term) AC: Trans Sys Cvrs	These controls address this hazardous condition by inspection of HEPA filters and cover block status.
XS-03-PRES02	Release of radioactive aerosols from DCRT headspace due to positive pressure	Dampers inadvertently closed causing positive pressure in tank	None	AC: HEPA Filter Cntrls (Filter Efficiency 244-S, TX, and A only)	SC: Trans Sys Cvrs SS: HEPA Filters	AC: HEPA Filter Cntrls (Source Term) AC: Trans Sys Cvrs	These controls address this hazardous condition by inspection of HEPA filters and cover block status.
XS-03-PRES03	Release of radioactive aerosols from DCRT headspace due to positive pressure in DCRT	Ductwork damage due to external event causes positive pressure in DCRT	None	AC: HEPA Filter Cntrls (Filter Efficiency 244-S, TX, and A only)	SC: Trans Sys Cvrs SS: HEPA Filters	AC: HEPA Filter Cntrls (Source Term) AC: Trans Sys Cvrs	These controls address this hazardous condition by inspection of HEPA filters and cover block status.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
XS-03-PRES04	Release of radioactive aerosols from DCRT headspace due to positive pressure	Loss of power causes positive pressure in tank	None	AC: HEPA Filter Cntrls (Filter Efficiency 244-S, TX, and A only)	SC: Trans Sys Cvrs SS: HEPA Filters	AC: HEPA Filter Cntrls (Source Term) AC: Trans Sys Cvrs	These controls address this hazardous condition by inspection of HEPA filters and cover block status.
XS-03-TEMP05	Release of radioactive aerosols from DCRT headspace due to positive pressure	Excessive agitation-pumping causes positive pressure and generates aerosols	None	AC: HEPA Filter Cntrls (Filter Efficiency 244-S, TX, and A only)	SC: Trans Sys Cvrs SS: HEPA Filters	AC: HEPA Filter Cntrls (Source Term) AC: Trans Sys Cvrs	These controls address this hazardous condition by inspection of HEPA filters and cover block status.
XS-03-TEMP06	Release of toxic vapors from DCRT headspace due to positive pressure in DCRT	Excessive agitation-pumping causes positive pressure	None	AC: HEPA Filter Cntrls (Filter Efficiency 244-S, TX, and A only)	SC: Trans Sys Cvrs SS: HEPA Filters	AC: HEPA Filter Cntrls (Source Term) AC: Trans Sys Cvrs	These controls address this hazardous condition by inspection of HEPA filters and cover block status.
XS-03-TEMP07	Release of radioactive aerosols from DCRT headspace due to positive pressure	Loss of ventilation flow due to HEPA filter blockage in cold weather causes positive pressure in tank	None	AC: HEPA Filter Cntrls (Filter Efficiency 244-S, TX, and A only)	SC: Trans Sys Cvrs SS: HEPA Filters	AC: HEPA Filter Cntrls (Source Term) AC: Trans Sys Cvrs	These controls address this hazardous condition by inspection of HEPA filters and cover block status.
XS-03-TEMP08	Release of radioactive aerosols from DCRT headspace due to positive pressure	Loss of ventilation flow plus high heat waste causes positive pressure in tank	None	AC: HEPA Filter Cntrls (Filter Efficiency 244-S, TX, and A only)	SC: Trans Sys Cvrs SS: HEPA Filters	AC: HEPA Filter Cntrls (Source Term) AC: Trans Sys Cvrs	These controls address this hazardous condition by inspection of HEPA filters and cover block status.
XS-06-FLOW06	Release of radioactive aerosols from DCRT annulus due to a spill of radioactive liquid	Overfilling DCRT due to a misrouting causes spill into DCRT annulus	None	AC: Trans Cntrls (Leak Prevention/ Detect/Cntrl)	SC: Trans Leak Detect Syss SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Cntrls (Leak Prevention/ Detect/Cntrl) AC: Trans Pump Admin Lock Cntrls	These controls address this hazardous condition by indicating leak and minimizing exposure.
XS-12-FLOW01	Release of toxic gas from diversion box due to accumulation of toxic vapors from catch tank	Chemical reaction of catch tank material with backflow of vapors via diversion box drain line	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Health & Safety Plan.

Table 5.4-2. Safety Structures, Systems, and Components and Technical Safety Requirements for Potential S1 Consequences with F3 Frequency. (47 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo
XS-12-FLOW04	Release of toxic gas from diversion box due to accumulation of toxic vapors from catch tank	Radiolysis of catch tank material with backflow of vapors via diversion box drain line	None	None	None	None	No applicable SSCs or TSRs - Facility worker exposure controlled by Health & Safety Plan.
XS-12-FLOW06	Release of radioactive waste to the soil from diversion box drain due to a spill of radioactive liquid into 241-U-152 diversion box	Leak of diversion box drain line upstream of catch tank	None	AC: Trans Cntrls (Leak Prevention and Mis-routing) AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs SC: Trans Leak Detect Syss SS: Salt Well Flow Totalizer SS: Tank Level Detect Sys	LCO: Trans Sys Cvrs LCO: Trans Leak Detect Syss AC: Trans Cntrls (Mis-rout) AC: Trans Pump Admin Lock Cntrls AC: Trans Sys Cvr Removal Cntrls AC: Trans Cntrls (Leak Detect/Cntrl) AC: Emergency Prep (Significant Release)	These are applicable controls from the Subsurface Leak Resulting in Pool accident analysis. These controls also address this hazardous condition for worker risk by indicating leak and minimizing releases.
XS-26-PRES01A 102AW-02-PRES	Release of radioactive aerosols from Tank 241-SY-102 due to positive pressure	Blockage of exhaust path causes pressure in tank	SC: DST/AWF Ventilation	LCO: DST and AWF Tank Ventilation Syss AC: Flammability Cntrls (Pressurization)	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls (Tracking)	These controls address this hazardous condition by monitoring ventilation operation and cover block status.
XS-26-PRES02A 102AW-02-PRES	Release of radioactive aerosols from Tank 241-SY-102 due to positive pressure	Failure of ventilation fans causes pressure in tank	SC: DST/AWF Ventilation	LCO: DST and AWF Tank Ventilation Syss AC: Flammability Cntrls (Pressurization)	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls (Tracking)	These controls address this hazardous condition by monitoring ventilation operation and cover block status.
XS-26-PRES03	Release of radioactive aerosols from Tank 241-SY-102 due to positive pressure	Use of hot water to decontaminate equipment in tank atmosphere - generate aerosols and pressurizes the tank	SC: DST/AWF Ventilation	LCO: DST and AWF Tank Ventilation Syss AC: Flammability Cntrls (Pressurization)	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls (Tracking)	These controls address this hazardous condition by monitoring ventilation operation and cover block status.
XS-26-PRES03 102AW-02-PRES	Release of radioactive aerosols from Tank 241-SY-102 due to positive pressure	Loss of power to ventilation system causes positive pressure in tank	SC: DST/AWF Ventilation	LCO: DST and AWF Tank Ventilation Syss AC: Flammability Cntrls (Pressurization)	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls (Tracking)	These controls address this hazardous condition by monitoring ventilation operation and cover block status.

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Env Cons
CP-MSP-05	Release of radioactive or toxic material to atmosphere from waste tank due to flammable gas deflagration	Human error AND Flammable gas is present in tank AND Mechanical failure of the pipe and probe (ignition source)	SC: SST Ventilation SC: DCRT Level Dip Tube Flow SC: TK-002 244-AR Level Dip Tube Flow	LCO: SST Ventilation Syss - Active LCO: SST Ventilation Syss - Passive LCO: DCRT Ventilation Syss LCO: 244-AR TK-002 Ventilation Sys AC: Flammable Gas Mon Cntrls AC: Excavation Cntrls	None required	None required	Controls based on BIO Appendix E and Spray Leak From Underground Waste Transfer Lines.	E3
CP-MSP-06	Release of radioactive or toxic material to atmosphere due to flammable gas deflagration caused by puncture and ignition of flammable gas in transfer line which propagates to the waste tank	Human error AND Flammable gas is present in transfer pipe AND Spark from probe tip (ignition source)	SC: SST Ventilation SC: DCRT Level Dip Tube Flow SC: TK-002 244-AR Level Dip Tube Flow	LCO: SST Ventilation Syss - Active LCO: SST Ventilation Syss - Passive LCO: DCRT Ventilation Syss LCO: 244-AR TK-002 Ventilation Sys AC: Flammable Gas Mon Cntrls AC: Excavation Cntrls	None required	None required	Controls based on BIO Appendix E and Spray Leak from Underground Waste Transfer Lines.	E3
CP-MSP-07	Release of radioactive or toxic material to soil (plume) remaining subsurface from Miscellaneous Inactive Storage Facility (MISF) due to puncture of tank	Human error	None	AC: Excavation Cntrls	None	None	Controls based on accident analysis (Spray Leak From Underground Waste Transfer Lines).	E3
CP-RMV-03	Release of radioactive or toxic material from transfer line through the push pipe during removal activities	Human error	None required	AC: Excavation Cntrls	None required	None required	Controls based on accident analysis (Spray Leak From Underground Waste Transfer Lines).	E3
CP-SET-04	Release of radioactive or toxic material from waste tank due to dome collapse	Excessive weight on tank dome (static load of platform)	None required	AC: Dome Loading Cntrls (Excessive Loads)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	E3

Table 5.4-3. Safety Structures, Systems, and Components and Technical Safety Requirements for Potentially Severe (E3 and E2) Environmental Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Env Cons
CP-SET-05	Release of radioactive or toxic material from waste tank due to dome collapse caused by load drop	Mechanical failure of equipment causes load drop	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	E3
CP-SET-06	Release of radioactive or toxic material from waste tank due to dome collapse caused by load drop	Human error causes load drop	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	E3
CP-SSP-01	Release of radioactive or toxic material to soil surface (pool) from transfer line due to puncture of line during transfer	Human error caused puncture to transfer line during push operations.	None required	AC: Excavation Cntrls	None required	None required	Controls based on accident analysis (Spray Leak From Underground Waste Transfer Lines).	E3
CP-SSP-02	Release of radioactive or toxic material to soil (plume) remaining subsurface from transfer line due to puncture of line during transfer	Human error caused puncture to transfer line during push operations	None	AC: Excavation Cntrls	SC: Pipe Encasements SC: Trans Leak Detect Syss SS: Tank Level Detect Syss SS: Salt Well Flow Totalizer	LCO: Trans Leak Detect Syss AC: Trans Cntrls AC: Emergency Prep (Significant Release) AC: Excavation Cntrls	Controls based on accident analysis (Spray Leak From Underground Waste Transfer Lines).	E3
CP-SSP-04	Release of radioactive or toxic material to soil (plume) remaining subsurface from waste tank due to puncture of tank	Human error - Undetected deflection of drill string pipe causes breach of tank	None	None	SC: Primary Tank Leak Detect Syss SS: Tank Level Detect	AC: Emergency Prep (Significant Release)	Controls based on accident analysis (Subsurface Leak Remaining Subsurface).	E3
CP-SSP-05	Release of radioactive or toxic material to soil (plume) remaining subsurface from MISF due to puncture of tank	Human error	None	AC: Excavation Cntrls	None	None	Controls based on accident analysis (Spray Leak From Underground Waste Transfer Lines).	E3
CP-SSP-16	Release of radioactive or toxic material to soil surface (pool) from transfer line due to puncture of line during transfer	Human error AND Mechanical failure of push pipe integrity inside the transfer line	None required	AC: Excavation Cntrls	None required	None required	Controls based on accident analysis (Spray Leak From Underground Waste Transfer Lines).	E3

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Env Cons
CRN-03	Release of radioactive and/or toxic materials from tank due to dome collapse	Human error results in excessive weight on dome	None required	AC: Dome Loading Cntrls (Excessive Loads)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	E3
CRN-04	Release of radioactive and/or toxic materials from tank due to dome collapse	Crane or rigging failures drop load resulting in large impact to dome	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	E3
CRN-11	Radioactive or toxic material release from tank due to boom failure and tank/ equipment damage and dome collapse	Human error: improper load assembly, rigging, crane overloaded	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	E3
CRN-12	Radioactive or toxic material release from tank due to boom failure and tank/ equipment damage and dome collapse	Mechanical failure: corrosion, faulty materials	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	E3
CRN-13-a	Release of radioactive or toxic material from tank/equipment damage and dome collapse due to boom failure	High wind	None required	AC: Dome Loading Cntrls (High Wind)	None required	None required	Controls base on accident analysis (Natural Phenomena - High Wind).	E3
CRN-13-b	Release of radioactive or toxic material from tank/equipment damage and dome collapse due to boom failure	Seismic event	None required	None required	None required	AC: Emergency Prep (Seismic)	Controls based on accident analysis (Natural Phenomena - Seismic).	E3
CRN-21	Release of radioactive or toxic materials from tank due to loss of vertical load control, dropping crane load into tank, onto tank bottom (subsurface leak)	Human error: improper load assembly, rigging, positioning error	None	AC: Dome Loading Cntrls (Lifting Cntrls)	None	None	These are applicable controls from the Tank Failure Due to Excessive Loads accident analysis.	E3

Table 5.4-3. Safety Structures, Systems, and Components and Technical Safety Requirements for Potentially Severe (E3 and E2) Environmental Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Env Cons
CRN-22	Release of radioactive or toxic materials from tank due to loss of vertical load control, dropping crane load into tank, onto tank bottom (subsurface leak)	Mechanical failure: corrosion, faulty materials, hydraulics	None	AC: Dome Loading Cntrls (Lifting Cntrls)	None	None	These are applicable controls from the Tank Failure Due to Excessive Loads accident analysis.	E3
CRN-23	Release of radioactive or toxic materials from tank due to loss of vertical load control, dropping crane load into tank, onto tank bottom (subsurface leak)	High wind or seismic event	None required	AC: Dome Loading Cntrls (High Wind)	None required	AC: Emergency Prep (Seismic)	Controls base on accident analyses (Natural Phenomena - High Wind; and Natural Phenomena - Seismic).	E3
EE-01	Release of radioactive and toxic materials from tanks due to external force and fire	Aircraft crash	None required	None required	None required	None required	No controls required based on low accident frequency.	E3
EE-04-a	Release of radioactive and hazardous materials from SST tank due to external fires	Vehicle accident involving propane, diesel or gasoline delivery	None required	AC: Ign Cntrls (Speed Limits)	None required	AC: Emergency Prep (In-tank Fuel Fire)	Controls based on accident analysis (In-Tank Fuel Fire/ Deflagration).	E3
EE-04-b	Release of radioactive and hazardous materials from DST tank due to external fires	Vehicle accident involving propane, diesel or gasoline delivery	None required	AC: Ign Cntrls (Speed Limits)	None required	AC: Emergency Prep (In-tank Fuel Fire)	Controls based on accident analysis (In-Tank Fuel Fire/ Deflagration).	E3
EE-05-a	Release of radioactive or hazardous materials from SST tank due to external fires	Run-away vehicle or truck shears off one or more risers, ruptures gasoline tank	None required	AC: Ign Cntrls (Vehicle)	None required	AC: Emergency Prep (In-tank Fuel Fire)	Controls based on accident analysis (In-Tank Fuel Fire/ Deflagration).	E3
EE-05-b	Release of radioactive or hazardous materials from DST tank due to external fires	Run-away vehicle or truck shears off one or more risers, ruptures gasoline tank	None required	AC: Ign Cntrls (Vehicle)	None required	AC: Emergency Prep (In-tank Fuel Fire)	Controls based on accident analysis (In-Tank Fuel Fire/ Deflagration).	E3

Table 5.4-3. Safety Structures, Systems, and Components and Technical Safety Requirements for Potentially Severe (E3 and E2) Environmental Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Env Cons
EE-10	Release of radioactive and hazardous materials from tanks due to loss of tank integrity	Water line breaks, saturates subsurface, and hydrostatic head causes tank to float	SS: Service Water Flow Totalizer	None	SC: Primary Tank Leak Detect Syss SS: Tank Level Detect Syss	LCO: Primary Tank Leak Detect Syss AC: Emergency Prep (Significant Release)	These are applicable controls from the Surface Leak Resulting in Pool accident analysis. Tank floating from sub-surface hydrostatic head considered incredible.	E3
I-222S-1-CMP-E	Release of radioactive aerosols to the atmosphere from 244-S or receiver tank due to over pressurization of tank caused by organic fire	Human error - upset of 222-S Lab operations	None required	AC: Ign Cntrls (Organic Solvent) AC: Trans Cntrls (Organic Solvent)	None required	AC: HEPA Filter Cntrl (Source Term) AC: Emergency Prep Program (Organic Solvent)	Controls based on accident analysis (Organic Solvent Fire).	E3
I-242A-1-FLW-A	Release of radioactive material from Feed Tank 241-AW-102 due to fire/ explosion caused by igniting hydrogen gas when pump is damaged and possibly becomes an ignition source from dead heading	Valves fail to regulate (closed position) which fails pump and creates ignition source, sufficient hydrogen accumulation for fire/explosion.	SC: Primary Tank Leak Detect Syss SC: DST/AWF Ventilation	LCO: DST and AWF Tank Ventilation Syss LCO: Primary Tank Leak Detect Syss AC: Flammability Cntrls AC: Ign Cntrls AC: Flammable Gas Mon Cntrls	None required	None required	Controls based on BIO Appendix E.	E3
I-242A-1-FLW-B	Release of radioactive material from Feed Tank 241-AW-102 due to fire/ explosion caused by igniting hydrogen gas when pump is damaged and possibly becomes an ignition source	Feed pump fails and causes ignition source, sufficient hydrogen accumulation for fire/explosion	SC: Primary Tank Leak Detect Syss SC: DST/AWF Ventilation	LCO: DST and AWF Tank Ventilation Syss LCO: Primary Tank Leak Detect Syss AC: Flammability Cntrls AC: Ign Cntrls AC: Flammable Gas Mon Cntrls	None required	None required	Controls based on BIO Appendix E.	E3

I-242A-1-FLW-C	Release of radioactive material from Feed Tank 241-AW-102 due to fire/explosion caused by igniting hydrogen gas when pump is damaged and possibly becomes an ignition source from dead heading	Plugged line which fails pump and causes ignition source, sufficient hydrogen accumulation for fire/explosion	SC: Primary Tank Leak Detect Syss SC: DST/AWF Ventilation	LCO: DST and AWF Tank Ventilation Syss LCO: Primary Tank Leak Detect Syss AC: Flammability Cntrls AC: Ign Cntrls AC: Flammable Gas Mon Cntrls	None required	None required	Controls based on BIO Appendix E.	E3
I-242A-1-FLW-D	Release of radioactive material from Feed Tank 241-AW-102 due to fire/explosion caused by igniting hydrogen gas when pump is damaged and possibly becomes an ignition source	Pump plugged which fails pump and causes ignition source, sufficient hydrogen accumulation for fire/explosion	SC: Primary Tank Leak Detect Syss SC: DST/AWF Ventilation	LCO: DST and AWF Tank Ventilation Syss LCO: Primary Tank Leak Detect Syss AC: Flammability Cntrls AC: Ign Cntrls AC: Flammable Gas Mon Cntrls	None required	None required	Controls based on BIO Appendix E.	E3
I-242A-1-FLW-E	Release of radioactive material from Feed Tank 241-AW-102 due to fire/explosion caused by igniting hydrogen gas when pump is damaged and possibly becomes an ignition source from pump cavitation	Empty feed tank which fails pump and causes ignition source, sufficient hydrogen accumulation for fire/explosion	SC: Primary Tank Leak Detect Syss SC: DST/AWF Ventilation	LCO: DST and AWF Tank Ventilation Syss LCO: Primary Tank Leak Detect Syss AC: Flammability Cntrls AC: Ign Cntrls AC: Flammable Gas Mon Cntrls	None required	None required	Controls based on BIO Appendix E.	E3
I-242A-2-CMP-B	Release to the atmosphere through unsealed cracks in the cover blocks due to over pressurization of the receiver tank	Steam block valves inadvertently opened or left open	None required	None required	None required	AC: HEPA Filter Cntrls (Source Term)	Controls based on accident analysis (Steam Intrusion from Interfacing Syss).	E3
I-242A-4-TMP-A	Release of radioactive material from Tank 241-AW-102 caused by ignition of organics in Tank C-100 which pressurizes the drain line and propagates the fire down the line to Feed Tank 241-AW-102	Faulty control of vacuum to CA-1 vessel causing pot to boil with organic layer available	None required	None required	None required	None required	No controls required based on low accident frequency.	E3

Table 5.4-3. Safety Structures, Systems, and Components and Technical Safety Requirements for Potentially Severe (E3 and E2) Environmental Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Env Cons
I-242A-6-CMP-A	Release (steam) of aerosols to the atmosphere through unsealed cracks in the cover blocks due to over pressurization of the receiver tank	Human error - steam block valve inadvertently left opened	None required	None required	None required	AC: HEPA Filter Cntrls (Source Term)	Controls based on accident analysis (Steam Intrusion from Interfacing Syss).	E3
I-BPLANT-1-CMP-E	Release of tank waste due to fire in receiver tank from transferring organics from B Plant	Human error - tank containing organics in B Plant rupture and spills organics to the drains which eventually end up in Tank 24-1 and an inadvertent transfer to tank farms	None required	AC: Ign Cntrls (Organic Solvent) AC: Trans Cntrls (Organic Solvent)	None required	AC: HEPA Filter Cntrl (Source Term) AC: Emergency Prep Program (Organic Solvent)	Controls based on accident analysis (Organic Solvent Fire).	E3
I-PFP-1-CMP-E	Release of high level waste from receiver tank due to fire from organics transferred from PFP	Excess organic material added to waste results in fire	None required	AC: Ign Cntrls (Organic Solvent) AC: Trans Cntrls (Organic Solvent)	None required	AC: HEPA Filter Cntrl (Source Term) AC: Emergency Prep Program (Organic Solvent)	Controls based on accident analysis (Organic Solvent Fire).	E3
ITK-07	Radioactive and/or hazardous material release from tank below grade (non-fire, non-explosion) due to intrusive activity	Dropped equipment in tank from human error or equipment failures (also see crane operations) Penetration of tank with linear-force, high pressure, or rotational equipment from human error or equipment failure	None	AC: Dome Loading Cntrls (Lifting Cntrls)	None	None	These are applicable controls from the Tank Failure Due to Excessive Loads accident analysis. This control also addresses this hazardous condition for worker risk by preventing equipment drop.	E3
ITK-FR-04	Release of radioactive aerosols from tank due to tank collapse	Equipment becomes lodged in riser, efforts to remove pull riser out of tank causing loss of structural integrity leading to tank collapse	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	E3

Table 5.4-3. Safety Structures, Systems, and Components and Technical Safety Requirements for Potentially Severe (E3 and E2) Environmental Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Env Cons
ITK-FR-19	Release of radioactive aerosols from tank due to dome collapse	Hydraulic jacks on assembly stand are operated while assembly is bolted to flange tearing out riser and destroying tank integrity leading to dome collapse	None required	None required	None required	None required	No controls required based on low accident frequency.	E3
LDUA 1-25	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of flammable gas	Fire (electrical, lighting)	SC: SST Ventilation	LCO: SST Ventilation Syss - Active LCO: SST Ventilation Syss - Passive AC: Ign Cntrls AC: Flammable Gas Mon Cntrls	None required	None required	Controls based on BIO Appendix E.	E3
LDUA 1-32	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of flammable gas	During planned intrusive activities, sampling triggers GRE	SC: SST Ventilation	LCO: SST Ventilation Syss - Active LCO: SST Ventilation Syss - Passive AC: Ign Cntrls AC: Flammable Gas Mon Cntrls	None required	None required	Controls based on BIO Appendix E.	E3
LDUA 1-33	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of flammable gas	Non-arm end effectors (OVS, OSVS) dropped down riser	SC: SST Ventilation	LCO: SST Ventilation Syss - Active LCO: SST Ventilation Syss - Passive AC: Flammable Gas Mon Cntrls	None required	None Required	Controls based on BIO Appendix E.	E3
LDUA 1-33A	Release of liquid waste to the soil due to the dropping of non-arm end effector down riser which penetrates tank bottom	Non-arm end effectors (OVS, OSVS) dropped down riser	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	This control addresses the hazardous condition by preventing load drop.	E3
LDUA 2-2	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of hydraulic fluid	Structural failure of hydraulic system	None required	AC: Ign Cntrls	None required	AC: Emergency Prep	Controls based on BIO Appendix E.	E3

Table 5.4-3. Safety Structures, Systems, and Components and Technical Safety Requirements for Potentially Severe (E3 and E2) Environmental Consequences. (107 Sheets)

CRN-13-IC	Release of radioactive and/or toxic materials from facility due to containment top collapse damage by boom failure	High wind or seismic event	None required	AC: Dome Loading Cntrls (High Wind)	None required	AC: Emergency Prep (Seismic)	Controls base on accident analyses (Natural Phenomena - High Wind; and Natural Phenomena - Seismic).	E2
CRN-21-IA	Release of radioactive or toxic materials from underground facility bottom due to loss of vertical load control, dropping crane load into facility (subsurface leak)	Human error: improper load assembly, rigging, positioning error	None	AC: Dome Loading Cntrl	None	None	These are applicable controls from the Tank Failure Due to Excessive Loads accident analysis.	E2
CRN-21-IB	Release of radioactive or toxic materials from aboveground facility bottom due to loss of vertical load control, dropping crane load into facility (surface pool)	Human error: improper load assembly, rigging, positioning error	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	E2
CRN-22-IA	Release of radioactive or toxic materials from facility bottom due to loss of vertical load control, dropping crane load into facility	Mechanical failure: corrosion, faulty materials, hydraulics	None	AC: Dome Loading Cntrl	None	None	These are applicable controls from the Tank Failure Due to Excessive Loads accident analysis.	E2
CRN-22-IB	Release of radioactive or toxic materials from aboveground facility bottom due to loss of vertical load control, dropping crane load into facility (surface pool)	Mechanical failure: corrosion, faulty materials, hydraulics	None required	AC: Dome Loading Cntrls (Lifting Cntrls)	None required	None required	Controls based on accident analysis (Tank Failure Due to Excessive Loads).	E2

Table 5.4-3. Safety Structures, Systems, and Components and Technical Safety Requirements for Potentially Severe (E3 and E2) Environmental Consequences. (107 Sheets)

ID	Hazardous Condition	Cause	Preventive SSCs	Preventive TSRs	Mitigative SSCs	Mitigative TSRs	Memo	Env Cons
CRN-23-IB	Release of radioactive or toxic materials from aboveground facility bottom due to loss of vertical load control, dropping crane load into facility	High wind or seismic event	None required	None required	None required	None required	No controls required based on accident analysis (Above Ground Structure Failure).	E2
DCN-04-I	Decontamination personnel are contaminated, release of aerosol outside immediate area from equipment being decontaminated due to wind	Wind/tornado	None	None	None	None	There are no applicable controls from the Natural Phenomena - High Wind accident analysis.	E2
EE-11	Release of radioactive and hazardous materials from tank due to overfilling	Water line breaks and overfills tank	SS: Service Water Flow Totalizer	AC: Tank Service Water Intrusion Mon Program	SS: Service Water Flow Totalizer	AC: Tank Service Water Intrusion Mon Program	Controls based on accident analysis (Surface Leak Resulting in Pool).	E2
EE-16	Release of radioactive and hazardous material from transfer line spray leak due to excavation error	Excavation into waste transfer line during a transfer	None required	AC: Excavation Cntrls	None required	None required	Controls based on accident analysis (Spray Leak From Underground Waste Transfer Lines).	E2
I-222S-1-CMP-C	Release (potential spray leak) of 222-S lab waste to atmosphere in diversion box or 244-S Pump Pit due to increased corrosion from failure to add sodium hydroxide	Human error - failure to add sodium hydroxide	None required	AC: Trans Cntrls (Waste Compatibility) AC: Trans Pump Admin Lock Cntrls	SC: Trans Sys Cvrs	LCO: Trans Sys Cvrs AC: Trans Sys Cvr Removal Cntrls	Controls based on accident analysis (Spray Leak in Structure or from Overground Waste Transfer Lines; and Mixing of Incompatible Material Tank Pressurization).	E2
I-222S-1-LVL-A	Release (steam) of aerosols and entrained particulates to atmosphere through ventilation due to over pressurization of 244-S DCRT caused by sending just steam to tank farm	Human error - failing to shut off steam after Tank 219-S-102 is empty	None required	None required	None required	AC: HEPA Filter Cntrls (Source Term)	Controls based on accident analysis (Steam Intrusion from Interfacing Syss).	E2

LIST OF TERMS

AC	Administrative Control
AWF	Aging Waste Facility
BIO	Basis for Interim Operation
CAM	continuous air monitor
CPS	criticality prevention specification
CSER	criticality safety evaluation report
DCRT	double-contained receiver tank
DOE	U.S. Department of Energy
DST	double-shell tank
HASP	Health and Safety Plan
HEGA	high-efficiency gas adsorber
HEME	high-efficiency mist eliminator
HEPA	high-efficiency particulate air (filter)
JCO	Justification for Continued Operation
LANL	Los Alamos National Laboratory
LCO	Limiting Condition for Operation
LCS	Limiting Control Setting
LFL	Lower Flammability Limit
MISF	miscellaneous inactive storage facility
NFPA	National Fire Protection Association
OGT	overground transfer (line)
PRV	pressure relief valve
RCSTS	Replacement Cross-Site Transfer System
RL	U.S. Department of Energy, Richland Operations Office
SARP	Safety Analysis Report for Packaging
SC	Safety-Class
SEP	safety evaluation for packaging
SL	Safety Limit
SR	surveillance requirement
SS	Safety-Significant
SSC	structure, system, and component
SST	single-shell tank
TSR	Technical Safety Requirement
TWRS	Tank Waste Remediation System
U.S. DOT	U.S. Department of Transportation
WRSS	Waste Retrieval Sluicing System

6.0 OPERATIONAL CONTROLS

This document defines the operating envelope for those Tank Waste Remediation System (TWRS) facilities within its scope (Chapter 1.0, "Introduction"). Operational controls are detailed in Chapter 5.0, "Safety Analysis" and summarized in this chapter. Supplemental operational control information specific to the projects is included in the designated addenda. The safety analysis and controls for the Waste Retrieval Sluicing System (WRSS) operations are contained in Addendum 1, "Tank 241-C-106 Sluicing Safety Analysis." The safety analysis and controls for the replacement cross-site transfer system are contained in Addendum 2, "Safety Analysis for the Replacement Cross-Site Transfer System" and summarized in Table 6-1. The safety analysis and controls for the 241-AZ-702 ventilation system are contained in Addendum 3, "702-AZ Ventilation System (241-AZ-702) Safety Analysis" and summarized in Table 6-1. The safety analysis and controls for the 241-AZ-101 mixer pump test are contained in Addendum 4, "Safety Analysis for Tank 241-AZ-101 Mixer Pump Test."

This chapter provides the operating restrictions and administrative controls that are necessary to preserve the validity of the safety analysis assumptions and to ensure that TWRS is operated within the required conditions bounded by the analysis. The controls discussed in this chapter are implemented through HNF-SD-WM-TSR-006, *Tank Waste Remediation System Technical Safety Requirements*. HNF-SD-WM-TSR-006 was prepared using the guidance in DOE 5480.22, *Technical Safety Requirements*. The controls are also implemented through other non-TSR control documents (e.g., HNF-SD-WM-HSP-002, *Tank Farms Health and Safety Plan* [HASP]).

6.1 BASIS FOR INTERIM OPERATION CONTROLS

6.1.1 Scope of Controls

Consistent with DOE 5480.23, *Nuclear Safety Analysis Reports* and the DOE-STD-3009-94, *Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports*, the controls identified in this Basis for Interim Operation (BIO) address hazards for the offsite public, onsite worker, and facility worker. The hazards address both radiological and toxicological sources.

Controls designated to prevent or mitigate radiological consequences that exceed both the radiological and toxicological risk guidelines are evaluated to ensure that the controls also protect against toxicological hazards. If a radiological-based control does not also bring toxicological consequences within risk guidelines, a separate control is provided to mitigate or prevent those toxicological consequences. Controls for toxicological hazards where the consequences do not exceed risk guidelines are implemented through the HASP.

6.1.2 Control Selection Process

The hazard analysis results, together with the accident analysis results, were used to identify Safety-Class and Safety-Significant structures, systems and components, TSRs and other controls required to protect the offsite public, onsite worker, and facility worker. The control selection process is discussed in more detail in Chapter 5.0.

The BIO specifically considers the impact of identified hazards upon the facility worker and identifies those controls necessary to protect a facility worker from life threatening hazards or hazards that could result in serious injury. The controls identified to protect the offsite public, onsite worker, and facility worker also provide protection against most of the hazardous conditions that have significant environmental consequences. When additional controls were required they were selected in accordance with the discussion in Chapter 5.0. In addition, this process also identified controls that provided significant Defense-in-Depth.

6.1.3 Specific Basis for Interim Operation Controls

The operational controls selected for each accident analysis described in Chapter 5.0 are presented in Table 6-1. Additionally, Table 6-1 includes controls identified in Addenda 2 and 3. This table identifies the selected TSR control and its derivation basis. The TSR document contains the specific details of the controls. Following is a discussion of the sections included in Table 6-1.

The "Analyzed Accident/BIO Section Reference" column contains the title of the candidate accidents and a cross-reference to the applicable section from Chapter 5.0 which contains the discussion of the accident. A list of the representative hazards associated with the candidate accidents is provided in the tables in Section 5.4, "Engineered and Administrative Controls."

The "Safety Structures, Systems, and Components" column contains a composite list of the Safety-Class and Safety-Significant structures, systems, and components associated with each candidate accident.

The "Technical Safety Requirement" column lists the specific section in the TSR (e.g., LCO 3.1.1 Transfer System Covers and Entry Doors) where the controls selected for the candidate accident are included. A brief summary of the key program elements for the Administrative Controls (ACs) is included. The TSR document contains more details on the specific controls. Table 5.4-1 must be consulted to identify the controls selected for each representative hazard. The numerical parameters included in this column are in English units since these are the units used by operations personnel.

The "Derivation Basis" column is a brief statement of why the control was selected and what function the control is performing or providing. In addition, controls that are not specifically included in the TSR are discussed in this section.

	Description	SC	SS		
Nuclear Criticality (5.3.2.1)	None required	None	None	SL: None required LCS: None required LCO: None required AC: 5.7 Nuclear Criticality Safety - Establish CPSs based on CSERs - For transfers into the tank farm (excluding 242-A Evaporator and caustic/water additions) limits on pH ≥ 8, neutron absorber to plutonium ratio > subcritical mass ratio, and plutonium concentration < 0.04 g/L averaged over the entire volume of the transferred waste - Independent verification of documented results - Recovery actions if limits exceeded - Criticality training program - MISF activities prohibited until waste characterized (gas monitoring and sampling allowed) - CSERs for all cross-site slurry transfers of tank wastes from tank to tank	AC 5.7 PREVENTIVE: Implementation of the controls identified in the Nuclear Criticality Safety program protects the assumptions in the accident analysis to prevent a criticality from occurring. The controls maintain k_{eff} <0.935 which ensures subcritical storage of waste in TWRS. This implements double contingency principles and prevents the initiation of a self-sustaining nuclear chain reaction (criticality). Criticality limits and controls are documented in CSERs and implemented in CPSs through procedures. Criticality safety training is provided and procedures identify the recovery actions in the event the CPS requirements are not met. For waste transfers into the tank farm, controls to prevent criticality are established on (1) pH ≥ 8, (2) plutonium concentration <0.04 g/L averaged over the entire volume of the waste transferred, (3) limits on neutron absorber to plutonium mass ratio are > the subcritical mass ratios. Compliance with the requirements may be demonstrated by sample analysis or calculation and demonstrated compliance is documented. Independent verification of documentation of these controls is performed. These controls do not restrict water and caustic additions to the tank farm and are not required for transfers within the tank farm but are only for transfers from outside the tank farm into the tank farm. For waste transfers where the plutonium concentration is ≤ 0.001 g/l the absorber to plutonium ratio is not required. This allowance is because most of the plutonium will remain in solution since the concentration is less than the plutonium solubility limit of 0.002 g/l. Restrictions on MISF activities where characterization of the waste has not been performed prevents a criticality. Gas monitoring and sampling are permitted. Transfers via the RCSTS which will intentionally transfer high solids contents will require characterization of the waste, and preparation of a CSER and CPS (if required) prior to initiating the transfer.

Analyzed Accident/ BIO Section Reference	Safety Structures, Systems, and Components			Technical Safety Requirement	Derivation Basis
	Description	SC	SS		
HEPA Filter Failure-Exposure to High Temperature or Pressure (5.3.2.2)	Ventilation CAM interlock systems		X	SL: None required LCS: None required LCO: 3.1.4 Ventilation Stack CAM Interlock Systems AC: 5.18 HEPA Filter Controls - Periodic radiation surveillance - Replacement based on accumulation - Aerosol test upon installation (AWF 241-AZ-702) - Periodic aerosol test (AWF-241-AZ-702)	LCO 3.1.4 MITIGATIVE: The ventilation CAM interlock detects increasing radiological effluent releases and stops the ventilation exhaust fan on DSTs, AWF tanks, and actively ventilated SSTs (C and SX tank farms) within 10 minutes. Stopping the exhaust fan protects against the continued unfiltered release of radioactive and toxic materials following the breach of the filter. AC 5.18 MITIGATIVE: HEPA filter and pre-filter monitoring and replacement ($\leq$ 200 mrem/hr), HEME (for AWF tanks using 241-AZ-702) monitoring and replacement ($\leq$ 800 mrem/hr), and HEGA filter (for AWF tanks using 241-AZ-702) replacement protect against exceeding the source term assumptions in the analysis by limiting the accumulation on the filter and thereby limiting inventory available for release. Efficiency testing of the HEPA filter upstream of the HEGA filter (for AWF tanks using 241-AZ-702) protects the HEGA filter source term assumption in the analysis.
Fire in Contaminated Area (5.3.2.3)	None required	None	None	SL: None required LCS: None required LCO: None required AC: 5.10 Ignition Controls - Vehicle fuel system protection required within tank farm boundary - Physical barriers around tank farm aboveground structures outside the tank farm boundary. Vehicles with fuel system protection can access inside the barrier - Speed limit controls AC: 5.14 Emergency Preparedness - Response procedures	AC 5.10 PREVENTIVE: Vehicle access controls which prohibit vehicles without fuel system protection from entering the tank farms and physical barriers (i.e., chain-link fencing, metal interlocking rail systems, concrete or concrete filled piping posts, concrete barriers, or T-posts connected with chain) around tank farm aboveground structures outside the tank farms prevent the rupture of a vehicle fuel system which may result in a fire in a contaminated area (e.g., open pit). Vehicles with protected fuel systems are allowed access inside the barriers. Vehicle fuel system protection ensures the integrity of the fuel systems is maintained. Speed limit controls minimize the potential of a vehicle accident. AC 5.14 MITIGATIVE: In the event that a fire occurs, emergency response procedures mitigate the consequences by providing direction for fire response and recovery activities.
Evaporator Dump (5.3.2.4)	None required	None	None	SL: None required LCS: None required LCO: None required AC: None required	The unmitigated offsite and onsite radiological and toxicological dose consequences are below the risk guidelines so no controls are required to prevent or mitigate the accident scenario or protect the offsite public, onsite worker or facility worker.

Table 6-1. Hazard and Accident Analyses; Safety Structures, Systems, and Components; and Technical Safety Requirement Cross Reference. (25 sheets)

Analyzed Accident/ BIO Section Reference	Safety Structures, Systems, and Components			Technical Safety Requirement	Derivation Basis
	Description	SC	SS		
Steam Intrusion From Interfacing Systems (5.3.2.5)	None Required	None	None	SL: None required LCS: None required LCO: None required AC: 5.18 HEPA Filter Controls - Periodic radiation surveillance - Replacement Based on accumulation - Aerosol test upon installation (AWF 241-AZ-702) - Periodic aerosol test (AWF 241-AZ-702)	AC 5.18 MITIGATIVE: HEPA filter and pre-filter monitoring and replacement (≤ 200 mrem/hr), HEME (for AWF tanks using 241-AZ-702) monitoring and replacement (≤ 800 mrem/hr), and HEGA filter (for AWF tanks using 241-AZ-702) replacement protect against exceeding the source term assumptions in the analysis by limiting inventory available for release. Efficiency testing of the HEPA filter upstream of the HEGA filter (for AWF tanks using 241-AZ-702) protects the HEGA filter source term assumption in the analysis.
Leak from Railcar/ Tank Trailer (5.3.2.6)	None required	None	None	SL: None required LCS: None required LCO: None required AC: 5.8 Source Inventory Controls - Source term inventory limits for railcars and tank trailers shall comply with the safety analysis for packaging. Control also ensures nonflammable and thermally stable	AC 5.8 MITIGATIVE Requirements for waste transported by railcar are established in WHC-SD-RE-SAP-013, Safety Analysis Report for Packaging, Railroad Liquid Waste Tank Cars and for waste transported by tank trailer in WHC-SD-TP-SEP-011, Safety Evaluation for Packaging for the 222-S Laboratory Cargo Tank, 49 CFR Parts 173.403, 173.425, and 173.435. Control of radioactive and chemical concentrations, volumes, nonflammability and thermal stability to meet requirements in the existing SARP and SEP protects source term assumptions in the analysis. Although this control does not prevent a leak from occurring, the limits do prevent a release from exceeding risk evaluation guidelines in the event of a leak.

Table 6-1. Hazard and Accident Analyses; Safety Structures, Systems, and Components; and Technical Safety Requirement Cross Reference. (25 sheets)

Analyzed Accident/ BIO Section Reference	Safety Structures, Systems, and Components			Technical Safety Requirement	Derivation Basis
	Description	SC	SS		
Subsurface Leak Remaining Subsurface (5.3.2.7)	Transfer leak detection systems Pipe encasements Tank level detection systems Salt well flow totalizers		X X X X	SL: None required LCS: None required LCO: 3.1.3 Transfer Leak Detection Systems AC: 5.12 Transfer Controls - Material Balance - Single-walled direct buried/ bermed line surveillance during waste transfers (once per 12 hours for salt well pumping and once per 30 minutes for submersible pumping) - Configuration management - Independent route verification during transfer setup - Monitor interconnected tanks for level increase - Double valve isolation on interconnected lines - Aboveground labeling of single-walled direct buried/ bermed pipe locations (also AC 5.17) AC: 5.20 Transfer pump administrative lock controls	LCO 3.1.3 MITIGATIVE: Waste transfer leakage detection systems provide for collection and detection of leakage in the waste transfer piping systems and associated structures. Upon detection, actions can be taken to minimize and terminate a leak. These controls provide facility worker protection. AC 5.12 PREVENTIVE/MITIGATIVE: Performing a material balance during waste transfers identifies discrepancies in the amount of material transferred which indicates a potential leak or misrouting. Single-walled direct buried/bermed piping does not have an installed leakage detection system. Labeling the location of the piping and performing monitoring of the piping used during a transfer facilitates detection of a high radiation area caused by a subsurface leak such that action can be taken to minimize and terminate the leak. The independent verification of the selected transfer path, double valve isolation on interconnected lines, and configuration management of the alignment of the jumpers and valves used in the transfer help to prevent a misroute. Monitoring the tanks interconnected to the transfer route helps to detect any misroutes or leakage. AC 5.20 PREVENTIVE: Placing an administrative lock on an active transfer pump that is physically connected to a waste transfer system, minimizes the potential for an inadvertent pump start that could result in the unplanned transfer of waste. ENCASEMENTS MITIGATIVE: Concrete encasements and pipe-in-pipe encasements contain leakage from the primary pipe which minimizes the release of waste to the soil and directs the leakage to a collection point for detection and subsequent action.
Unplanned Excavation/Drilling in Crib/Ditch/Pond (5.3.2.8)	None required	None	None	SL: None required LCS: None required LCO: None required AC: None required	The unmitigated offsite and onsite radiological and toxicological dose consequences are below the risk guidelines so no controls are required to prevent or mitigate the accident scenario or protect the offsite public, onsite worker or facility worker.

Table 6-1. Hazard and Accident Analyses; Safety Structures, Systems, and Components; and Technical Safety Requirement Cross Reference. (25 sheets)

Analyzed Accident/ BIO Section Reference	Safety Structures, Systems, and Components			Technical Safety Requirement	Derivation Basis
	Description	SC	SS		
Caustic Spray Leak (5.3.2.9)	None required	None	None	SL: None required LCS: None required LCO: None required AC: 5.23 Caustic Transfer Controls - Sleeving around delivery piping - Pipeline transfer pressure ≤ 125 psig - Schedule 10 or heavier thickness for steel pipe	AC 5.23 PREVENTIVE/MITIGATIVE: TSR controls are established for polyethylene (or similar) sleeving around delivery piping, limitations of the caustic delivery system pressure to ≤ 125 psi, and use of Schedule 10 as a minimum thickness for caustic delivery if steel pipe is used.
Sodium Fire (5.3.2.10)	2727 W Building		X	SL: None required LCS: None required LCO: None required AC: None required	The unmitigated offsite and onsite radiological and toxicological dose consequences are below the risk guidelines so no controls are required to prevent or mitigate the accident scenario or protect the offsite public, onsite worker or facility worker. However an additional control was selected. 2727-W BUILDING PREVENTIVE: The 2727-W Building structure design prevents the sodium fire from occurring. The building protects the contents of the building from a vehicle crash that could lead to a fire. The building structure also protects the source term in the building from dispersal caused by high winds.
Mixing of Incompatible Material—Toxic Vapor Generation (5.3.2.11)	None required	None	None	SL: None required LCS: None required LCO: None required AC: None required	The unmitigated offsite and onsite radiological and toxicological dose consequences are below the risk guidelines so no controls are required to prevent or mitigate the accident scenario or protect the offsite public, onsite worker or facility worker.
Mixing of Incompatible Material—Tank Pressurization (5.3.2.12)	HEPA filters (one stage required on 244-S, 244-TX, and 244-A)		X	SL: None required LCS: None required LCO: None required AC: 5.12 Transfer Controls - Compatibility evaluation for pH ≥ 8 before transfer into tank farm (excluding water transfers and caustic additions) AC: 5.18 HEPA Filter Controls - Aerosol test upon installation - Periodic aerosol test	AC 5.12 PREVENTIVE: Transfer controls that evaluate planned transfers from Process Facilities to DCRTs 244S, 244TX, and 244A to verify only transfer of compatible material, prevents an energetic chemical reaction from occurring that will release waste through the operating ventilation system. These controls are also for large transfers into DSTs via a tank truck and 204-AR. (AC 5.7 also has pH controls). AC 5.18 MITIGATIVE: A conservative assumption in the analysis is the ventilation system continues to operate. Requiring one stage of HEPA filters be installed on DCRTs 244-S, 244-TX and 244-A with a demonstrated efficiency mitigates the consequences of a release to protect the onsite worker and facility worker.

Table 6-1. Hazard and Accident Analyses; Safety Structures, Systems, and Components; and Technical Safety Requirement Cross Reference. (25 sheets)

Analyzed Accident/ BIO Section Reference	Safety Structures, Systems, and Components			Technical Safety Requirement	Derivation Basis
	Description	SC	SS		
Tank Failure Due to Excessive Loads (5.3.2.13)	None required	None	None	SL: None required LCS: None required LCO: None required AC: 5.16 Dome Loading Controls - Limits on load height - Hanford Site Hoisting and Rigging Manual for critical lifts - Uniform and Concentrated load limits	AC 5.16 PREVENTIVE: Limiting the height that a load can be lifted to ≤ 20 ft prevents the force of a dropped load from damaging a waste retaining structure which can result in the release of radioactive or toxic material. This control reduces the frequency of occurrence for the event. The Hanford Site Hoisting and Rigging Manual, DOE-RL-92-36, provides requirements for lifts in the tank farm. This control specifically applies to hoisting operations that could either affect (1) facilities with radionuclide inventories greater than Hazard Category 2 threshold inventories in DOE-STD-1027-92 or (2) safety SSCs. The manual ensures lift controls are in place for loads to minimize the potential for a load damaging a waste retaining structure that can result in an uncontrolled release. Controls for uniform and concentrated loads protects against excessive concentrated or uniform loads over the tank dome thereby preventing a potential tank failure. The controls either limit the load to that existing or specify a soil depth for uniform loads or a weight limit in tons for a concentrated load. Tank failure caused by vacuum or degradation is bounded by tank failure caused by excessive loads. Therefore the controls previously identified to prevent tank failure caused by excessive loads are adequate to prevent a tank failure caused by vacuum or degradation.

	Description	SC	SS		
Flammable Gas Deflagrations (continued) (5.3.2.14)	Tank 241-SY-101 ammonia detection systems Tank 241-SY-101 temperature monitoring systems	X X		AC: 5.11 Flammable Gas Monitoring Controls - Manned work activity - Unmanned operations AC: 5.17 Excavation Controls AC: 5.18 HEPA Filter Controls - Periodic radiation surveillance - Replacement based on accumulation - Aerosol test upon installation (AWF 241-AZ-702) - Periodic aerosol test (AWF 241-AZ-702)	LCO 3.2.6 MITIGATIVE: The primary tank leak detection system (conductivity probes or CAMs) provides indication of leakage in the annulus so action can be taken to prevent the steady state flammable gas accumulation from reaching the LFL. AC 5.9 PREVENTIVE: Tank 241-SY-101 controls are in accordance with LANL requirements to control the potential for flammable gas deflagrations. AC 5.10 PREVENTIVE: Limiting the available ignition sources reduces the potential of a deflagration if the concentration of flammable gas was at the LFL. Controls prevent local waste heatup which could lead to dryout and potential ignition of an organic salt-nitrate reaction, organic solvent fire, or flammable gas deflagration. AC 5.11 PREVENTIVE: Flammable gas monitoring before and during manned work activities ensures that flammable conditions are not present in the work space caused by steady state accumulation of flammable gas or as a result of a recent gas release event. For unmanned operations, ignition source controls generally provide sufficient protection. However continued monitoring is required for global waste disturbing operations in passively ventilated tanks if LFL is ≥ 25%. AC 5.17 EXCAVATION CONTROLS: Controls prevent ignition of flammable gases by reducing the likelihood of inadvertently intruding any structure potentially containing flammable gas. AC 5.18 MITIGATIVE: HEPA filter and pre-filter monitoring and replacement (≤ 200 mrem/h), HEME (for AWF tanks using 241-AZ-702) monitoring and replacement (≤ 800 mrem/h), and HEGA filter (for AWF tanks using 241-AZ-702) replacement protect against exceeding the source term assumptions in the analysis by limiting the accumulation on the filter and thereby limiting inventory available for release.

Table 6-1. Hazard and Accident Analyses; Safety Structures, Systems, and Components; and Technical Safety Requirement Cross Reference. (25 sheets)

Analyzed Accident/ BIO Section Reference	Safety Structures, Systems, and Components			Technical Safety Requirement	Derivation Basis
	Description	SC	SS		
Flammable Gas Deflagrations (continued) (5.3.2.14)					Efficiency testing of the HEPA filter upstream of the HEGA filter (for AWF tanks using 241-AZ-702) protects the HEGA filter source term assumption in the analysis.
Organic Solvent Fire (5.3.2.15)	None required	None	None	SL: None required LCS: None required LCO: None required AC: 5.10 Ignition Controls - Stop all intrusive work when lightning is detected within 50 mi - Secure elevated equipment in lowest position when lightning is detected within 50 mi - Barrier for hot metal is required for flame cutting - Vehicle fuel system protection required within tank farm boundary - Physical barriers around tank farm aboveground structures outside the tank farm boundary. Vehicles with fuel system protection can access inside the barrier - Speed limit controls - Rotary Mode Core Sampling is permitted only per approved Authorization Basis AC: 5.12 Transfer Controls - Evaluate organic solvent transfers to ensure final state of receiving tank remains within BIO safety envelope AC: 5.14 Emergency Preparedness - Response procedures AC: 5.18 HEPA Filter Controls - Periodic radiation surveillance - Replacement based on accumulation - Aerosol test upon installation (AWF 241-AZ-702) - Periodic aerosol test (AWF 241-AZ-702)	AC 5.10 PREVENTIVE: Ignition controls minimize initiators (lightning, hot metal barrier, vehicle fuel fire) with sufficient energy to ignite an organic solvent fire. Stopping tank activities and securing elevated equipment (e.g., cranes) in a low position when lightning has been identified within 50 mi, minimizes the potential for a lightning strike to occur that could ignite the organic solvents. If flame cutting is performed in a location where debris from the cutting could fall on the waste surface of an organic solvent tank, a device that catches and contains hot metal debris shall be inserted between the cutting operation and waste surface to prevent a hot metal piece from falling in the waste surface and igniting a fire. Vehicle access controls which prohibit vehicles without fuel system protection from entering the tank farms and physical barriers (i.e., chain-link fencing, metal interlocking rail systems, concrete or concrete filled piping posts, concrete barriers, or T-posts connected with chain) around tank farm aboveground structures outside the tank farms prevent the rupture of a vehicle fuel system which may result in a fire in an organic solvent tank. Vehicles with protected fuel systems are allowed access inside the barriers. Vehicle fuel system protection ensures the integrity of the fuel systems is maintained. Speed limit controls minimize the potential of a vehicle accident. Rotary mode core sampling controls are only permitted in accordance with other approved Authorization Basis (e.g., WHC-SD-WM-SAD-035). Controls prevent local waste heatup which could lead to dryout and potential ignition of an organic salt-nitrate reaction, organic solvent fire, or flammable gas deflagration. AC 5.12 PREVENTIVE: Transfer controls to evaluate organic solvent transfers, restricts transfers to nonorganic tanks unless necessary. This prevents the organic solvent fire potential being applicable to new tanks.

	Description	SC	SS		
Organic Salt-Nitrate Reaction (5.3.2.17)	Temperature monitoring systems		X	SL: Waste temperature LCS/LCO:3.3.1 SST Waste Temperature Controls LCS/LCO:3.3.2 DST and AWF Tank Waste Temperature Controls AC: 5.10 Ignition Controls - Stop all intrusive work when lightning is detected within 50 mi - Secure elevated equipment in lowest position when lightning is detected within 50 mi - Barrier for hot metal/slag is required for flame cutting - Vehicle fuel system protection required within tank farm boundary - Physical barriers around tank farm aboveground structures outside the tank farm boundary; vehicles with fuel system protection can access inside the barrier - Speed limit controls - Rotary Mode Core Sampling is permitted only per approved Authorization Basis - Use of catch device when involved with intrusive activities and high heat source (e.g., for hot lighting filaments) - All flammable gas ignition controls in respective tank is in flammable gas topography AC: 5.14 Emergency Preparedness - Response procedures AC: 5.15 Moisture Controls - Interim stabilization (supernate and salt well pumping controls) - Moisture monitoring - SST ventilation system changes - Emergency pumping	LCO 3.3.1 PREVENTIVE: The temperature monitoring system provides information on waste temperature so that actions can be taken to prevent exceeding temperatures at which an organic salt-nitrate reaction can occur. In SSTs the waste temperatures shall be <205 °F which protects the tank bump accident analysis assumption of ≤ 220 °F and accounts for instrument uncertainty and surveillance intervals. LCO 3.3.2 PREVENTIVE: The temperature monitoring system provides information on waste temperature so that actions can be taken to prevent exceeding temperatures at which an organic salt-nitrate reaction can occur. In DSTs and AWF tanks the waste temperature for any level in the waste shall be ≤ 195 °F OR from the surface to 15 ft below the surface the temperature shall be ≤ 195 °F and shall be ≤ 215 °F for waste from the bottom of the tank to 15 ft below the waste surface. The TSR waste temperature limits protect the tank bump accident analysis temperature assumptions of ≤ 220 °F and ≤ 240 °F and accounts for instrument uncertainty and surveillance intervals. AC 5.10 PREVENTIVE: Ignition controls minimize initiators (lightning, hot metal/slag barrier, vehicle fuel fire, top hats, rotary mode core sampling restrictions) with sufficient energy to ignite an organic salt-nitrate reaction with sufficient energy to ignite an organic salt-nitrate reaction. Stopping tank activities and securing elevated equipment (e.g., cranes) in a low position when lightning has been identified within 50 mi, minimizes the potential for a lightning strike to occur that could ignite the organic salt-nitrate reaction. If flame cutting is performed in a location where debris from the cutting could fall on the waste surface of an organic salt-nitrate tank or if there are high heat sources around the waste (light filament), a device that catches and contains hot metal debris shall be inserted between the activity and waste surface to prevent a hot metal piece from falling in the waste surface and igniting a fire. AC 5.14 MITIGATIVE: In the event that a fire occurs, emergency response procedures mitigate the consequences by providing direction for fire response and recovery activities.

Table 6-1. Hazard and Accident Analyses; Safety Structures, Systems, and Components; and Technical Safety Requirement Cross Reference. (25 sheets)

	Description	SC	SS		
Organic Salt-Nitrate Reaction (continued) (5.3.2.17)				AC: 5.18 HEPA Filter Controls - Periodic radiation surveillance - Replacement based on accumulation - Aerosol test upon installation (AWF 241-AZ-702) - Periodic aerosol test (AWF 241-AZ-702) AC: 5.19 Process Instrumentation and measuring and test equipment	AC 5.15 PREVENTIVE: Moisture controls ensure that tanks which are moist tanks continue to have liquid levels near the top of the waste. Also evaluation of any changes in SST ventilation system design or operation that may cause increased tank moisture loss minimizes the potential for organic salt-nitrate reaction. Salt well pumping is prohibited unless post pumped condition of remaining waste meets the preliminary safety criteria for organic salt-nitrate reactions. Emergency pumping for leaks shall be limited to pumping supernate above the level of the solid waste. AC 5.18 MITIGATIVE: HEPA filter and pre-filter monitoring and replacement (≤ 200 mrem/hr), HEME (for AWF tanks using 241-AZ-702) monitoring and replacement (≤ 800 mrem/hr), and HEGA filter (for AWF tanks using 241-AZ-702) replacement protect against exceeding the source term assumptions in the analysis by limiting the accumulation on the filter and thereby limiting inventory available for release. Efficiency testing of the HEPA filter upstream of the HEGA filter (for AWF tanks using 241-AZ-702) protects the HEGA filter source term assumptions in the analysis. AC 5.19 PREVENTIVE: The process instrumentation and measuring and test equipment controls provide requirements for the instrumentation used to monitor the temperature in accordance with LCO 3.3.1 and LCO 3.3.2.

Surface Leak Resulting in Pool (5.3.2.18)	Transfer leak detection systems	X		SL: None required LCS: None required LCO: 3.1.1 Transfer System Covers and Entry Doors LCO: 3.1.2 Service Water Pressure Detection Systems LCO: 3.1.3 Transfer Leak Detection Systems LCO: 3.1.5 Replacement Cross-Site Transfer System PRV and Rupture Disk (Reserved) LCO: 3.2.6 Primary Tank Leak Detection Systems AC: 5.12 Transfer Controls - Material balance - Monitor interconnected tanks for level increase - Double valve isolation on interconnected lines - Configuration management - Independent route verification during transfer setup - Use of concrete shielding system or vehicle restrictions around OGT lines - Jumper leak testing - Caps/blanks on open nozzles - Pit floor drains open on cross-site transfer route	LCO 3.1.1 MITIGATIVE: Covers and entry doors for transfer-associated structures mitigate releases of hazardous material when transferring waste by stopping a leak from aerosolizing outside the transfer-associated structures. LCO 3.1.2 PREVENTIVE: Flushing system pressure switches and associated interlocks with waste transfer pumps or alarm response are used to stop inadvertent waste flow into flushing systems in transfer-associated structures that do not have covers. This prevents potential leaks from developing outside the transfer path. The pressure switches and associated interlocks or alarm response also prevent radioactive material from contaminating the service water supply system or the RCSTS water flush tank. LCO 3.1.3 MITIGATIVE: The leak detection systems detect leaks from the primary waste transfer system piping and either automatically stops the waste transfer or provides an alarm to initiate operator action. Stopping the transfer when a leak is detected minimizes the potential consequences from a continued leak. LCO 3.1.5 PREVENTIVE: (Reserved) The RCSTS pressure relief valves and rupture disks located in 244-A provide protection from overpressurization for the tank farm transfer systems downstream of the RCSTS. (Note: LCO 3.1.5 will be added to the TSR document after RL approval for transfers through line WT-SLL-3160 is granted).

Surface Leak Resulting in Pool (continued) (5.3.2.18)	Salt well flow totalizers		X	AC: 5.13 Encasement Seal Loop Controls - Encasement drain line valve not closed AC: 5.18 HEPA Filter Controls - Periodic radiation surveillance - Replacement based on accumulation AC: 5.14 Emergency Preparedness - Response procedures AC: 5.20 Transfer pump administrative lock controls AC: 5.21 Tank service water intrusion monitoring program AC: 5.22 Transfer system cover removal controls Transfer System Supplemental Cover JCO (Wagoner 1998 and HNF-2296)	LCO 3.2.6 MITIGATIVE: The primary tank leak detection system detects leakage in the annulus of the DSTs so action can be taken to terminate the leakage before it overflows and forms a surface pool. AC 5.12 MITIGATIVE: Performing a material balance during waste transfers identifies discrepancies in the amount of material transferred which indicates a potential leak or misrouting. The independent verification of the selected transfer path and configuration management of the alignment of the jumpers and valves used in the transfer help to prevent a misroute. Monitoring the tanks interconnected to the transfer route helps to detect any misroutes or leakage. Use of the concrete shielding system or vehicle restrictions around the OGT lines are used to protect the OGT lines from external events such as a vehicle accident that may damage the transfer line and result in a leak. Double valve isolation on lines interconnecting with the transfer route when a transfer cover is off or entry door is open, provides compensatory protection to prevent a leak in this area when the cover or entry door which mitigates the leak is unavailable. The leak test when jumpers are installed ensures proper installation to prevent a misalignment of the jumper or prevent the jumper from falling off during a transfer resulting in a leak. Ensuring either a cap or blank is installed on open nozzles and that the pit floor drains are open on the cross-site transfer route prevents an overflow which may be associated with a misrouting. TRANSFER SYSTEM SUPPLEMENTAL COVER JCO: Transfer system supplemental cover controls ensure that pits physically connected to the transfer route are covered during transfer.

Table 6-1. Hazard and Accident Analyses; Safety Structures, Systems, and Components; and Technical Safety Requirement Cross Reference. (25 sheets)

Analyzed Accident/ BIO Section Reference	Safety Structures, Systems, and Components			Technical Safety Requirement	Derivation Basis
	Description	SC	SS		
Surface Leak Resulting in Pool (continued) (5.3.2.18)					AC 5.13 MITIGATIVE: Verifying that there is an open drain path to the pit prevents the encasement pipe from pressurizing and filling with waste should the primary line leak because it allows encasement drainage. Also it ensures that leakage from the primary pipe drain back to a pit where leakage can be detected by the transfer system leak detection system. AC 5.14 MITIGATIVE: In the event that a leak occurs, emergency response procedures provide direction to minimize the consequences of the leak and to implement recovery activities. AC 5.18 MITIGATIVE: HEPA filter monitoring and replacement ($\leq$ 200 mrem/hr) for the RCSTS protects against exceeding the source term assumption in the analysis by limiting the accumulation on the filter and thereby limiting inventory available for release. Requiring the RCSTS inlet air HEPA filter system in diversion box 6241-A and vent station 6241-V to have a demonstrated efficiency mitigates the consequences of a release, protecting the onsite worker and facility worker. AC 5.20 PREVENTIVE: Placing an administrative lock on an active transfer pump that is physically connected to a waste transfer system, minimizes the potential for an inadvertent pump start that could result in the unplanned transfer of waste. AC 5.21 MITIGATIVE: The tank service water intrusion monitoring program is used to provide indication of service water leaks having the potential to cause tank intrusion. Service water flow totalizer monitoring or the tank level detection system provides alternate means of indicating service water intrusion. AC 5.22 MITIGATIVE: The transfer system cover removal controls provide compensatory measures for cover removal during waste transfers.

Table 6-1. Hazard and Accident Analyses; Safety Structures, Systems, and Components; and Technical Safety Requirement Cross Reference. (25 sheets)

	Description	SC	SS		
Surface Leak Resulting in Pool (continued) (5.3.2.18)					ENCASEMENTS MITIGATIVE: OGT concrete encasements and pipe-in-pipe encasements direct leakage from the primary pipe to a collection point for detection and subsequent action which minimizes the release of waste to the atmosphere.
Subsurface Leak Resulting in Pool (5.3.2.19)	Pipe encasements Tank level detection systems Salt well flow totalizers RCSTS Pressure relief valve (244-A lift station) RCSTS Rupture Disk (244-A lift station) RCSTS Transfer Leak Detection Systems	X X X X	 X X 	SL: None required LCS: None required LCO: 3.1.3 Transfer Leak Detection Systems LCO: 3.1.5 Replacement Cross-Site Transfer System PRV and Rupture Disk (Reserved) AC: 5.12 Transfer Controls - Material Balance - Single-walled direct buried/ bermed line surveillance during waste transfers (once per 12 hours for salt well pumping and once per 30 minutes for submersible pumping) - Configuration management - Independent route verification during transfer setup - Monitor interconnected tanks for level increase - Double valve isolation on interconnected lines AC: 5.13 Encasement Seal Loop Controls - Valve not closed AC: 5.14 Emergency Preparedness - Response procedures	LCO 3.1.3 MITIGATIVE The safety functions of the RCSTS transfer leak detection system are to detect the presence of waste transfer system leaks in the waste transfer associated structures, and to either provide an alarm to initiate operator action or provide an interlock to shut down transfer pump operation, thus limiting the amount of waste leaked and decreasing the consequences of the subsurface leak. LCO 3.1.5 PREVENTIVE: (Reserved) The RCSTS pressure relief valves and rupture disks located in 244-A provide protection from overpressurization for the tank farm transfer systems downstream of the RCSTS. (Note: LCO 3.1.5 will be added to the TSR document after RL approval for transfers through line WT-SLL-3160 is granted). AC 5.12 MITIGATIVE: The transfer control program detects leaks so action can be taken to minimize the potential consequences from a continued leak. Performing a material balance during waste transfers identifies discrepancies in the amount of material transferred which indicates a potential leak or misrouting. Single-walled direct buried/bermed piping does not have an installed leakage detection system. Performing monitoring of the piping used during a transfer facilitates detection of a high radiation area caused by a subsurface leak such that action can be taken to minimize and terminate the leak. Independent verification of the transfer path, double valve isolation on interconnected lines, and configuration management of the alignment of the jumpers and valves used in the transfer helps to prevent a misroute. Monitoring the tanks interconnected to the transfer route helps to detect any misroutes or leakage. AC 5.13 MITIGATIVE: Verifying the encasement drain line valve (i.e., encasement pneumatic test valve) is not closed prevents the encasement pipe from pressurizing and filling with waste should the primary line leak because it allows encasement drainage.

Spray Leak in Structure or from Overground Waste Transfer Line (5.3.2.20)	Transfer system covers	X		SL: None required LCS: None required LCO: 3.1.1 Transfer System Covers and Entry Doors LCO: 3.1.2 Service Water Pressure Detection Systems LCO: 3.1.4 Ventilation Stack CAM Interlock Systems LCO 3.1.5 Replacement Cross-Site Transfer System PRV and Rupture Disk (Reserved) AC: 5.12 Transfer Controls - Double valve isolation on interconnected lines - Configuration management - Independent route verification during transfer setup - Use of concrete shielding system or vehicle restrictions around OGT lines - Verify that the west exterior rollup door and the west exterior personnel access door are closed during waste transfers physically connected to the 204-AR Waste Unloading Facility	LCO 3.1.1 MITIGATIVE: Covers and entry doors for transfer-associated structures mitigate spray leak events when transferring waste by stopping a leak from aerosolizing outside the transfer-associated structures. LCO 3.1.2 PREVENTIVE: Flushing system pressure switches and associated interlocks with waste transfer pumps or alarm response are used to stop inadvertent waste flow into flushing systems in transfer-associated structures that do not have covers. This prevents potential leaks from developing outside the transfer path. The pressure switches and associated interlocks or alarm response also prevent radiological material from contaminating the service water supply system or the RCSTS water flush tank. LCO 3.1.4 MITIGATIVE: The ventilation CAM interlock detects increasing radiological effluent releases and stops the ventilation exhaust fan on DSTs, AWF tanks, actively ventilated SSTs (C and SX tank farms), DCRTs, and 204-AR Building. Stopping the exhaust fan protects against the continued unfiltered release of radiological and toxicological materials following the breach of the filter. LCO 3.1.5 PREVENTIVE: (Reserved) The RCSTS pressure relief valves and rupture disks located in 244-A provide protection from overpressurization for the tank farm transfer systems downstream of the RCSTS. (Note: LCO 3.1.5 will be added to the TSR document after RL approval for transfers through line WT-SLL-3160 is granted). AC 5.12 PREVENTIVE/MITIGATIVE: The independent verification of the selected transfer path and configuration management of the alignment of the jumpers and valves used in the transfer help to prevent a misroute. Monitoring the tanks interconnected to the transfer route helps to detect any misroutes or leakage. Spray Leak in Structure or from Overground Waste Transfer Line (continued) (5.3.2.20)	RCSTS Entry doors (diversion box and vent station) RCSTS Diversion box and vent station emergency pumpout line, air sample line, liner washdown system, and exhauster hookup RCSTS Inlet air HEPA filter system (one stage on 6241-A and 6241-V)	X X	 X	AC: 5.13 Encasement Seal Loop Controls - Encasement drain line valve not closed AC: 5.18 HEPA Filter Controls - Periodic radiation surveillance - Replacement based on accumulation AC: 5.20 Transfer pump administrative lock controls AC: 5.22 Transfer system cover removal controls	Double valve isolation on lines interconnecting with the transfer route when a transfer cover is off, provides compensatory protection to prevent a leak in this area when the cover which mitigates the leak is unavailable. Ensuring that the west exterior rollup door and west exterior personnel access door are closed during waste transfers physically connected to the 204-AR Waste Unloading Facility mitigates potential spray leaks inside the unloading area of the building. AC 5.13 PREVENTIVE: With the encasement seal loop valve not closed, it protects from pressurizing the encasement sufficiently to cause a spray leak. By the valve being at least partially open, the encasement can drain to a location where leakage can be detected. AC 5.18 MITIGATIVE HEPA filter monitoring and replacement ($\leq$ 200 mrem/hr) for the RCSTS protects against exceeding the source term assumption in the analysis by limiting the accumulation on the filter and thereby limiting inventory available for release. Requiring the RCSTS inlet air HEPA filter system in diversion box 6241-A and vent station 6241-V to have a demonstrated efficiency mitigates the consequences of a release, protecting the onsite worker and facility worker. AC 5.20 PREVENTIVE: Placing an administrative lock on an active transfer pump that is physically connected to a waste transfer system, minimizes the potential for an inadvertent pump start that could result in the unplanned transfer of waste. AC 5.22 MITIGATIVE: The transfer system cover removal controls provide compensatory measures for cover removal during waste transfers.

Table 6-1. Hazard and Accident Analyses; Safety Structures, Systems, and Components; and Technical Safety Requirement Cross Reference. (25 sheets)

Analyzed Accident/ BIO Section Reference	Safety Structures, Systems, and Components			Technical Safety Requirement	Derivation Basis
	Description	SC	SS		
Spray Leak from Underground Waste Transfer Lines (5.3.2.21)	None required	None	None	SL: None required LCS: None required LCO: None required AC: 5.17 Excavation Controls - Excavation permit including composite map, radiological evaluation, physical marking of the ground surface, activity approval, hand-digging limitations - Coordination of transfers with excavations and emergency response procedures - Aboveground labeling of buried active waste transfer lines outside the tank farm fences (also AC 5.12) - Restrictions on transfers through uncovered/excavated piping (prohibited or compensatory measures) - Waste transfers shall not be conducted in transfer lines located within approximately 15 ft of ongoing excavation activities	AC 5.17 PREVENTIVE/MITIGATIVE: The excavation controls provide requirements to prevent the excavation accident and also mitigate the accident if leakage is detected. Where active waste transfers can occur, the requirement for an excavation permit and coordination of the excavation activities minimizes the potential that an excavation activity which can damage the waste transfer line will occur in the vicinity of an ongoing waste transfer. The composite map for the excavation site, physically marking the ground surface, allowances for hand-digging only, and obtaining approval for the excavation activity ensures excavations are not inadvertently performed near active waste transfer lines. If an excavation activity damages a waste transfer line then the established communication system and emergency procedures provide the necessary notification and guidance to terminate the transfer, reduce potential exposure, and implement restoration activities. The requirement to monitor the waste transfer route verifies that no excavation activities are being conducted in the vicinity of active transfers. Aboveground labeling of the waste transfer line outside the tank farm fence provides visible indications of the waste transfer pipe location to prevent excavations that can damage the piping. Restriction on transfers through uncovered or excavated piping either prohibit the transfer or establish compensatory measures to minimize a potential release directly to atmosphere and to minimize worker radiation doses.

Table 6-1. Hazard and Accident Analyses; Safety Structures, Systems, and Components; and Technical Safety Requirement Cross Reference. (25 sheets)

Analyzed Accident/ BIO Section Reference	Safety Structures, Systems, and Components			Technical Safety Requirement	Derivation Basis
	Description	SC	SS		
Tank Bump (5.3.2.22)	Temperature monitoring systems Tank level detection systems		X X	SL: None required LCS: None required LCO: 3.3.1 SST Waste Temperature Controls LCO: 3.3.2 DST and AWF Tank Waste Temperature Controls AC: 5.12 Transfer Controls - Ensure final tank state within analyzed topography AC: 5.19 Process instrumentation and measuring and test equipment - Identification and calibrate	LCO 3.3.1 PREVENTIVE: The temperature monitoring system provides information on waste temperature so that actions can be taken to prevent exceeding temperatures at which a tank bump (or steam release event) can occur. In SSTs the waste temperatures shall be ≤ 205 °F which protects the accident analysis assumption of ≤ 220 °F and accounts for instrument uncertainty and surveillance intervals. Control also protects against a postulated "chemical runaway" accident (Organic Salt-Nitrate Reaction) LCO 3.3.2 PREVENTIVE: The temperature monitoring system provides information on waste temperature so that actions can be taken to prevent exceeding temperatures at which tank bump (or steam release event) can occur. In DSTs and AWF tanks the waste temperature for all level in the waste shall be ≤ 195 °F OR from the surface to 15 ft below the surface the temperature shall be ≤ 195 °F and shall be ≤ 215 °F for waste from the bottom of the tank to 15 ft below the waste surface. The TSR waste temperature limits protect the accident analysis temperature assumptions of ≤ 220 °F and ≤ 240 °F and accounts for instrument uncertainty and surveillance intervals. Control also protects against a postulated "chemical runaway" accident (Organic Salt-Nitrate Reaction) AC 5.12 PREVENTIVE: Transfer controls provide waste compatibility evaluations to ensure that controls are applied to the final state of pumped and receiving tanks prior to transfers. AC 5.19 PREVENTIVE: The process instrumentation and measuring and test equipment controls provide requirements for the instrumentation used to monitor the temperature in accordance with LCO 3.3.1 and LCO 3.3.2 and the level in LCO 3.3.2.

Analyzed Accident/ BIO Section Reference	Safety Structures, Systems, and Components			Technical Safety Requirement	Derivation Basis
	Description	SC	SS		
Natural Phenomena - High Wind (5.3.2.23.1a) a. Waste Transport Vehicle Accident	None required	None	None	SL: None required LCS: None required LCO: None required AC: None Required	The packaging and transporting of waste is designed and licensed to meet requirements established by the US DOT. Part of these requirements are satisfied by the submittal of safety analyses that identify hazards and corresponding controls. Since the hazards associated with the transportation of waste were adequately addressed in existing safety analyses, they are considered outside the scope of the TWRS analyses. Where hazards are associated with an interface between a transport vehicle and a TWRS facility, these hazardous conditions have been addressed in the accident analysis (e.g., Leak from Railcar/Tank Trailer).
Natural Phenomena – High Wind (5.3.2.23.1b) b. Load Drop	None required	None	None	SL: None required LCS: None required LCO: None required AC: 5.16 Dome Loading Controls - Hanford Site Hoisting and Rigging Manual for critical lift	AC 5.16 PREVENTIVE: The Hanford Site Hoisting and Rigging Manual provides requirements for lifts in the tank farm which considers wind speed before starting a lift and prohibits lifts if weather conditions are adverse to safe load-handling operations. The manual also requires securing of the crane in accordance with manufacturer's recommendations when a local weather storm warning exists. This control specifically applies to hoisting operations that could either affect (1) facilities with radionuclide inventories greater than Hazard Category 2 threshold inventories in DOE-STD-1027-92 or (2) safety SSCs. The manual ensures lift controls are in place during high winds to minimize the potential for a load damaging a waste retaining structure that can result in an uncontrolled release.
Natural Phenomena - High Wind (5.3.2.23.1c) c. Aboveground Structure Failure	None required	None	None	SL: None required LCS: None required LCO: None required AC: None required	The unmitigated offsite and onsite radiological and toxicological dose consequences are below the risk guidelines so no controls are required to prevent or mitigate the accident scenario or protect the offsite public, onsite worker or facility worker.

Table 6-1. Hazard and Accident Analyses; Safety Structures, Systems, and Components; and Technical Safety Requirement Cross Reference. (25 sheets)

Analyzed Accident/ BIO Section Reference	Safety Structures, Systems, and Components			Technical Safety Requirement	Derivation Basis
	Description	SC	SS		
Natural Phenomena - Lightning (5.3.2.23.2)	None required	None	None	SL: None required LCS: None required LCO: None required AC: 5.10 Ignition Controls - Restrictions on intrusive activities for flammable gas tanks with lightning activity in 50 mi - Restrictions on intrusive activities for organic solvent tanks with lightning activity in 50 mi - Restrictions on intrusive activities for organic nitrate tanks with lightning activity in 50 mi - Secure elevated equipment in the lowest position with lightning activity in 50 mi	AC 5.10 PREVENTIVE: Restricting operations and activities in intrusive regions of flammable gas tanks and organic solvent and organic salt-nitrate tanks when lightning has been identified within 50 mi, ensures that activities resulting in gas releases are minimized. This minimizes the fuel source when a lightning ignition source is in the vicinity to prevent a deflagration, fire, or reaction. Also lowering equipment elevated by the crane and lowering the crane boom minimizes the location of a lightning strike being conducted to the fuel element in the tanks.
Natural Phenomena - Seismic (5.3.2.23.3)	None required	None	None	SL: None required LCS: None required LCO: None required AC: 5.14 Emergency Preparedness - Response procedures	AC 5.14 MITIGATIVE: Establishing response requirements for a seismic event that addresses as applicable; facility inspections, transfer termination, intrusive activity termination, ventilation system evaluation, site evacuation, restoration of services, etc. serve to mitigate the potential consequences of a seismic event by placing TWRS in the safest condition, protecting onsite and offsite personnel, and implementing restoration activities. These controls manage the risk of uncontrolled releases of radiological and toxicological material that may be caused by the earthquake and limit direct risk to the facility worker.
General Control (none)	None required	None	None	SL: None required LCS: None required LCO: None required AC: 5.12 Transfer Controls - Transfers into SSTs prohibited except for flushing	AC 5.12 PREVENTIVE: A basic assumption in the analysis is that transfers into SSTs are not permitted (exclusive of flushing). This general control is included in the transfer controls.

7.0 CONCLUSIONS

The Tank Waste Remediation System Basis for Interim Operation (BIO), HNF-SD-WM-BIO-001 and associated Technical Safety Requirement (TSR) document provide the basis and controls for Tank Waste Remediation System (TWRS) facility operations until approval of the Final Safety Analysis Report and associated TSR document complying with the requirements of DOE 5480.23, *Nuclear Safety Analysis Reports*, and DOE 5480.22, *Technical Safety Requirements*. The BIO supports the conclusion that authorized TWRS facility operations can be conducted safely and provides a sound basis for conducting effective Unreviewed Safety Question (USQ) evaluations to ensure continued safe operations.

Addendum 1, "Tank 241-C-106 Sluicing Safety Analysis," to this BIO and the TSR document provide the interim safety basis for Waste Retrieval Sluicing System (WRSS) operations. Addendum 1 supports the conclusion that WRSS operations can be performed safely and provides the basis for conducting USQ evaluations related to project activities and facilities.

Addendum 2, "Replacement Cross-site Transfer System Safety Analysis," to this BIO and the TSR document provide the interim safety basis for replacement cross-site transfer system operations. Addendum 2 supports the conclusion that replacement cross-site transfer system operations can be performed safely and provides the basis for conducting USQ evaluations related to the replacement cross-site transfer system.

Addendum 3, "702-AZ Ventilation System (241-AZ-702) Safety Analysis," to this BIO and the TSR document provide the interim safety basis for the 702-AZ ventilation system. Addendum 3 supports the conclusion that the 702-AZ ventilation system can be operated safely and provides the basis for conducting USQ evaluations related to the 702-AZ ventilation system.

Addendum 4 to this BIO and its related TSR revisions provide the safety basis for the 241-AZ-101 mixer pump test. Addendum 4 supports the conclusion that the 241-AZ-101 mixer pump test can be operated safely and provides the basis for conducting USQ evaluations related to the 241-AZ-101 mixer pump test.

7.1 GENERAL AND SPECIFIC CONCLUSIONS

Based on this BIO, the following conclusions can be made:

- Separate Authorization Basis documents continue to exist for some TWRS facilities, activities, and projects.
- This BIO provides an acceptable description of Hanford Site characteristics and TWRS facilities and operations within the scope of this BIO (Chapter 2.0, "Facility Description," Appendices B and C, Addendum 1 for WRSS operations, Addendum 2 for the replacement cross-site transfer system, and Addendum 3 for the 702-AZ ventilation system, and Addendum 4 for the 241-AZ-101 mixer pump test).

- Over 1,090 occurrence reports and off-normal events from January 1972-May 1998 were reviewed to determine the degree of significance of reported abnormal occurrences. None of the tank farm occurrences met the criteria for significant consequences, serious consequences, or very serious consequences.

  These occurrence reports were used in the identification and evaluation of hazardous conditions for TWRS facilities and operations (Chapter 3.0, "Relevant Operational History").

- The safety management programs, applicable requirements, and implementing documents that support TWRS operations provide the administrative framework for safety operation of TWRS facilities. These safety management programs ensure the safe storage of radioactive and hazardous materials; protection of facility workers from exposure to radioactive and hazardous materials and industrial hazards; and protection of the public, onsite workers, and the environment from releases of radioactive and hazardous materials (Chapter 4.0, "Safety Management").

- The hazard classification, performed in accordance with DOE-STD-1027-92, *Hazard Categorization and Accident Analysis Techniques for Compliance with DOE Order 5480.23, Nuclear Safety Analysis Reports*, determined that all of the double-shell tanks, Aging Waste Facility (AWF) tanks, single-shell tanks, associated waste transfer systems, and WRSS are Hazard Category 2. The associated waste transfer systems include the 204-AR Waste Unloading Facility and the 244-AR Vault. Several TWRS facilities are independent segments and are classified as Hazard Category 3 or as a Radiological Facility (Section 5.1, "Introduction," and Addendum 1).

- Hazard analyses representative of TWRS facilities were performed consistent with the guidance in DOE-STD-3009-94, *Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports*. The hazard analyses provide systematic and comprehensive identification and evaluation of hazardous conditions at TWRS facilities, WRSS, and from TWRS operations. Based on the hazard analysis, 29 representative accidents are selected for further quantitative analysis (Section 5.2, "Requirements," Addendum 1, Addendum 2, Addendum 3, and Addendum 4).

- Accident analyses were performed for representative accidents consistent with the guidance in DOE-STD-3009-94.

- Decisions on classifying structures, systems, and components as Safety-Class and Safety-Significant, selecting required TSRs, identifying Defense-in-Depth controls, and identifying additional controls specifically for environmental protection were developed with a disciplined methodology and process using established control decision criteria. Safety structures, systems, and components, TSRs, and Defense-in-Depth controls for the protection of the public and onsite worker were based on the hazard and accident analyses. Controls for the protection of the facility worker and the

environment were selected primarily based on the qualitative hazard analysis. The selected controls were applied to all hazardous conditions identified for TWRS facilities and operations. The controls identified provide a necessary and sufficient set that establish a safety envelop within which TWRS operation can be safely performed (Chapters 5.0, "Safety Analysis," and 6.0, "Operational Controls," and Addendum 1, Addendum 2, Addendum 3, and Addendum 4).

For several postulated accidents the conservatively estimated frequency and calculated consequences of the accident exceed the risk guidelines established by the U.S. Department of Energy for TWRS (e.g., organic salt-nitrate reactions, flammable gas deflagrations, seismic induced accidents). Although the interim risk from these accident are judged acceptable, actions are required to reduce the long-term risk from continued waste storage management. Table 7-1 is a list of items that should be given consideration to further reduce risk.

7.2 SUMMARY CONCLUSIONS

In summary, this BIO and the associated TSRs draw the following conclusions.

- The accidents analyzed to date confirm known vulnerabilities.
- The selected structures, systems, and components and controls (TSRs, health and safety plan, and implementing procedures) provide prevention and mitigation measures to address these vulnerabilities when implemented.
- The analyses show that these measures provide reasonable assurance that continued facility operations can be conducted safely.
- Several postulated accidents are shown to be significantly above the risk guidelines based on bounding analyses. Existing and available controls selected provide immediate, near term protection, while options for measures to further reduce risk are evaluated.

Collectively, these conclusions find that the TWRS facilities can be operated safely following the requirements of this BIO until the BIO is replaced by a fully compliant Final Safety Analysis Report. Continuing safety analysis for the Final Safety Analysis Report will further improve understanding of the risk of TWRS and refine these interim controls. Action on considerations identified in this BIO to further reduce risk are also required to address the long-term risk associated with continued storage.

Table 7-1. Listing of Considerations to Further Reduce Risk. (4 sheets)

Number	Consideration
1	Implementing a comprehensive inspection program for DSTs (including AWF tanks), SSTs, DCRTs, catch tanks, and waste transfer piping to identify areas require preventive maintenance or that have a high likelihood of failure
2	Accelerating the interim stabilization of SST farms will reduce significantly the need for heavy load lifting, thereby reducing the time at risk (Tank Failure Due to Excessive Loads)
3	Retrieval of waste from Tank 241-C-106 to address the most significant SST with high heat waste (Tank Bump)
4	Acceleration of the retrieval of other SSTs where an analysis of the tank heat load indicates the tank contents could approach the saturation temperature in the absence of active ventilation (Tank Bump)
5	Completion of the upgrades to provide grounding, bonding, and air terminals to reduce the possibility of lightning-initiated ignition (Natural Phenomena - Lightning)
6	Installation of additional lightning protection systems (e.g., catenary network) for waste tanks that pose significant long-term risks caused by lightning-initiated accidents (Natural Phenomena - Lightning)
7	Provide a seismic monitor notification and alarm capability in the 200 Areas to alert personnel in case of a seismic event so emergency actions can be initiated as quickly as possible (Natural Phenomena - Seismic)
8	Provide an automatic shut down of waste transfer pumps following a seismic event (Natural Phenomena - Seismic)
9	Perform a comprehensive seismic vulnerability study that considers the process operating history of the tank farm facilities to provide recommendations that address identified vulnerabilities (Natural Phenomena - Seismic)
10	Completion of the upgrades to provide grounding, bonding, and air terminals to reduce the possibility of lightning-initiated ignition (Organic Solvent Fire)
11	Completion of the tank vapor space sampling program for all tanks to predict the presence of significant quantities of organic solvents (Organic Solvent Fire)
12	Reduction in the organic solvent inventory in tanks (Organic Solvent Fire)

Table 7-1. Listing of Considerations to Further Reduce Risk. (4 sheets)

Number	Consideration
13	Spray leaks are currently modeled conservatively because of large uncertainties in the phenomena of leak size, orientation, crack plugging, aerosol loading, and deposition. Crack plugging by solids carried in the waste could be investigated with some simple experiments. This would potentially limit the duration of the spray leak and significantly reduce the inventory released. More detailed computer modeling of the generation, agglomeration, deposition, and leakage of aerosols from an enclosed pit or compartment would likely reduce the dose from the mitigated spray leaks (from pits and compartments) (Spray Leak in Structures or from Overground Transfer Lines).
14	Installation and operation of high-efficiency particulate air filter ventilation systems on process pits, diversion boxes, vault pits, and cleanout boxes; and installing and operating radiation monitors in process pits, diversion boxes, vault pits, and cleanout boxes to detect waste leaks (Spray Leak in Structures or from Overground Transfer Lines)
15	Accelerating the elimination of steam jets and the blanking or removal of steam lines that potentially tie into waste tanks (Steam Intrusion from Interfacing Systems)
16	Ventilation Upgrades—Making modifications to allow direct measurement of the flow rate through each individual actively ventilated tank would provide better assurance that flammable gases are not accumulating as a result of continuous releases. DCRT design modifications to provide an inlet flow path to each tank and to allow measurement of the flow rate through each DCRT would provide assurance that flammable gases are not accumulating in DCRTs (Flammable Gas Deflagrations).
17	Monitoring Upgrades—Adding monitors (e.g., flammable gas, level) with alarms to tanks (a) which either exhibit gas release, level change, or other parameters that would be valuable in better defining the hazard, or (b) where intrusive work is planned, would allow detection of changes in parameters such as flammable gas concentrations (Flammable Gas Deflagrations).
18	Ignition Controls—Verifying that tank ventilation systems, instrumentation, and equipment for intrusive activities meet industry standards (e.g., National Fire Protection Association, American Petroleum Institute) requirements for hazardous location equipment would eliminate potential hazards. Upgrade equipment that does not meet these requirements or justify that the design is equivalent to the industry standard requirements (Flammable Gas Deflagrations).

Table 7-1. Listing of Considerations to Further Reduce Risk. (4 sheets)

Number	Consideration
19	Other Controls—Installation and operation of mixer pumps in tanks with the potential for gas release events would reduce the time at risk for these large releases by converting the releases into manageable continuous releases. Provisions of a sample port on the ventilation inlet duct would facilitate sampling on loss of ventilation (Flammable Gas Deflagrations).
20	Continuing research on flammable gas generation and retention phenomena in tank waste (Flammable Gas Deflagrations)
21	Augmenting the characterization and testing to reduce the actual chemical compositions making up total organic carbon would reduce conservatisms in modeling reaction energetics (Organic Salt-Nitrate Reaction).
22	Investigating the efficiency of removing soluble organic species that could cause propagating reactions by salt well pumping or washing with sodium hydroxide solution (Organic Salt-Nitrate Reaction)
23	Installing and operating a spray system with high organic concentrations to ensure adequate moisture in the waste (Organic Salt-Nitrate Reaction)
24	Completing the upgrades to provide grounding, bonding, and air terminals to reduce the possibility of lightning-initiated accidents (Organic Salt-Nitrate Reaction)
25	Provide a seismic monitor notification and alarm capability in the 200 Areas to alert personnel in case of a seismic event so emergency actions can be initiated as quickly as possible (Natural Phenomena - Seismic)
26	Eliminate or mitigate gas release events by accelerating tank waste retrieval (Natural Phenomena - Seismic)
27	Source Term—The radioactive inventory estimates for the high-level waste tanks are currently divided into three groups of tanks: DST, AWF tank, and SST; with the isotopic inventories represented by the maximum sample value within the group. Except for the AWF, this is a recognized conservatism necessary because sampling and analysis data presently cannot provide discrete source terms for all individual tanks with adequate statistical confidence to support a safety basis. With more complete data of the high-level waste tank inventory, the DSTs and SSTs could be parceled into more groups with only a few tanks having to be represented by the current conservative inventory estimates. Orders of magnitude reductions could be achieved for some DSTs and some SSTs. It is important that little reduction in the inventory estimates is achievable for some tanks because the sample data represents the actual tank contents (General Accident Analysis).

Table 7-1. Listing of Considerations to Further Reduce Risk. (4 sheets)

Number	Consideration
28	Toxicological Methodology—The current toxicological exposure methodology is based on a sum-of-fractions which represents the best approach currently available. Potential risk reductions could be achieved by developing a method which, while still conservative, does not rely on a simple sum of exposure concentrations divided by the respective concentration limits. Additional risk reductions could also be achieved by revising the toxic risk guidelines, which are based on routine occupational exposures at the lowest limits, to less conservative limits (General Accident Analysis).
29	Atmospheric Dispersion Modeling—The accident analysis modeling of atmospheric dispersion neglects agglomeration and deposition of particulate material. The radioactive components and some of the toxicological components are carried by aerosols. More detailed computer modeling of the agglomeration and deposition of the combustion aerosols could reduce the consequences of several accidents (e.g., organic salt-nitrate reaction, organic solvent) (General Accident Analysis).
30	Emergency Response Actions—Calculating radiological and toxicological exposures to the maximum offsite and onsite individuals takes no credit for emergency response actions (evacuation, sheltering) or personnel self-evacuations based on observed or sensed conditions. If further assessment of postulated accidents identifies means of detecting the event and if a demonstrated ability to take emergency response actions can be shown, the exposure times to the maximum offsite and onsite individual may be reduced. Accident detection could require classification of additional safety SSCs, new TSRs, or consideration for adding new monitoring systems (General Accident Analysis).

AWF = Aging Waste Facility.
DCRT = double-contained receiver tank.
DST = double-shell tank.
SSC = structure, system, and component.
SST = single-shell tank.
TSR = Technical Safety Requirement.

This document was too large to scan as a single document; therefore, it has been divided into smaller sections.

APPENDIX A
BASIS FOR INTERIM OPERATION DEVELOPMENT PROCESS

This appendix describes the Tank Waste Remediation System Basis for Interim Operation (BIO) development process including a chronology of review and approval steps. Figure A-1 presents an overview of the BIO development process. This appendix also describes summary of changes to the BIO subsequent to its initial release and implementation.

Development Process

1. The first step in the preparation of the BIO was the identification of the facilities included in the scope of this document. For each facility identified, the hazardous material and energy sources was compiled. Hazards evaluations were then performed to identify all hazardous conditions (i.e., accidents) associated with the facilities and their operations. Using the qualitative results of the hazard evaluations, each hazardous condition was then placed into a frequency and consequence bin. The results of these activities are documented in WHC-SD-WM-TI-759, *Hazard Evaluations for the Tank Waste Remediation Systems Final Safety Analysis Report*.

2. The hazardous conditions with significant offsite and onsite consequences were grouped into 29 representative accidents for detailed quantitative analysis. For those hazardous conditions which affected only the facility worker or the environment, additional controls were selected based on the qualitative hazard evaluation. The results of these activities are documented in Appendix D, "Hazardous Analysis Results Report."

3. The next step of the process was to perform the quantitative accident analyses for the representative accidents and determine the controls required to prevent or mitigate unacceptable consequences. The analyses were documented in calculation notes (see Section 5.0, "Safety Analysis," for applicable references). During the process, control decision meetings were held to identify the initial set of controls. These decisions were recorded in Control Decision Records that are archived in the Final Safety Analysis Report project files. These control decisions subsequently went through many reviews and revisions.

4. The next step of the process was to develop the parameters that govern the safety functions of the safety structures, systems, and components (SSCs). These parameters are those necessary to develop the Technical Safety Requirements (TSRs) (see step 5). The parameters were developed on the facility, system, or component level, on the basis of the TSR development needs. The operating parameters of the safety SSCs are documented in HNF-SD-WM-SEL-040, *TWRS Facility Safety Equipment List*.

5. The next step was the preparation of the administrative controls, safety limits, limiting control settings, limiting conditions of

operation, surveillance requirements and design features required to implement and maintain the controls selected in step 3. These activities are documented in HNF-SD-WM-TSR-006, *Tank Waste Remediation System Technical Safety Requirements*, and in WHC-SD-WM-HSP-002, *Tank Farms Health and Safety Plan (HASP)*.

6. The BIO document (Revision E of HNF-SD-WM-BIO-001) was submitted for Tier II review to the U.S. Department of Energy, Richland Operations Office (RL) by the former Tank Waste Remediation System Management and Operation Contractor, Westinghouse Hanford Company (WHC), on September 30, 1996 (Bacon 1996). The TSRs (Revision E of HNF-SD-WM-TSR-006) were submitted to RL for Tier II review by the Project Hanford Management Contract (PHMC) on October 15, 1996 (Hall 1996). (The draft TWRS Final Safety Analysis Report [FSAR] and draft FSAR TSRs [Revision I of HNF-SD-WM-TSR-006] were submitted to RL on November 15, 1996. The hazard and accident analysis and TSRs in the BIO and FSAR are consistent.)

7. The next step in the BIO and TSR development process was the RL's Tier II and Tier III review and comment of the subject documents. A Safety Evaluation Report (SER) was issued by RL on December 12, 1996, with direction to incorporate RL comments prior to their final submittal (Wagoner 1996).

8. RL directed PHMC to form a joint RL-Contractor Integrated Control Decision Team (ICDT) to evaluate the TWRS FSAR accident scenarios that were identified to be above the risk evaluation guidelines. The ICDT reviewed accidents which have analyzed consequences above the risk evaluation guidelines and examined controls and options for managing risk in the future. The ICDT meeting proceedings are documented in DOE/RL-97-26, *U.S. Department of Energy (DOE), Richland Operations Office (RL) Tank Waste Remediation System (TWRS) Final Safety Analysis Report (FSAR) Integrated Control Decision Team (ICDT) Meetings, January 22-31, 1997*.

9. A control verification process was developed and all TSR controls were evaluated per RL direction (Wagoner 1996). The TSR verification report was submitted to RL on February 6, 1997 (Funderburke 1997). RL approved the TSR verification report on March 5, 1997 (Sohn 1997).

10. Revised BIO (Revision F of HNF-SD-WM-BIO-001) was submitted to RL for approval on February 6, 1997 (Hall 1997a).

11. The Justification for Continued Operation (JCO) for the tank farms flammable gas Unreviewed Safety Question (HNF-SD-WM-JCO-007, *Flammable Gas/Slurry Growth Unreviewed Safety Question: Justification for Continued Operation for the Tank Farms at the Hanford Site*, Revision 1) was submitted for RL approval on February 21, 1997 (Hatch 1997a). The HNF-SD-WM-JCO-007 document has been incorporated into the BIO as Appendix E and the flammable gas JCO controls have been incorporated into the TSRs per RL direction (Wagoner 1997a).

12. A BIO Compliance Implementation Plan was developed to address the activities required to fully implement the controls described in the BIO and TSRs. These activities included revising operating procedures, performing training, making minor hardware modifications, etc. The Implementation Plan was submitted to RL on April 1, 1997 (Hatch 1997b; Hall 1997b).

13. Revised TSRs (Revision J of HNF-SD-WM-TSR-006) based on the TSR verification process discussed in step 10 and associated BIO page changes (Revision G of the HNF-SD-WM-BIO-001) were submitted to RL on April 1, 1997, for approval (Hatch 1997b; Hall 1997b).

14. RL provided comments on the BIO Compliance Implementation Plan on May 7, 1997, and delegated approval authority for the Compliance Implementation Plan to the Fluor Daniel Hanford Company (FDH) in concert with the provisions of the PHM Contract (Kinzer 1997).

15. The BIO, TSR, and JCO were approved by RL with directed changes on May 30, 1997 (Wagoner 1997a). A 90-day implementation phase was initiated to accomplish readiness to transition to the BIO Authorization Basis.

16. PHMC declared readiness to transition from the Interim Safety Basis Authorization Basis to the BIO Authorization Basis on August 27, 1997 (Hall 1997c).

17. RL Authorized PHMC to transition to the BIO and the associated TSRs on September 12, 1997 (Wagoner 1997d).

18. TWRS transitioned to the BIO Authorization Basis effective 6:00 a.m. September 29, 1997.

Summary of Changes

The TWRS BIO is a living document and is revised, as required, in accordance with the HNF-IP-0842, Volume IV, Section 5.4, "Unreviewed Safety Questions," procedure. The following is a summary of changes to the BIO since its initial release in July 1997 and implementation in September 1997:

- Changes to incorporate application of selected BIO flammable gas controls for Rotary Mode Core Sampling operations (Wagoner 1997b).
- Changes to redesignate Tank 241-BY-103 from Facility Group 2 to Facility Group 3 tank (Wagoner 1997c).
- Incorporate safety analysis for the Waste Retrieval Sluicing System operations as Addendum 1 (Wagoner 1997e).
- Incorporate safety analysis for 241-AZ-702 Ventilation System as Addendum 3 (Wagoner 1997f).
- Changes to incorporate flammable gas monitoring success criteria for flow validation of 241-AZ-702 Ventilation System (Wagoner 1997g).

- Corrected references to documents that were necessary for control implementation, and were not traceable as referenced. These changes are covered by USQ Screening TF-97-0988.

- Incorporate safety analysis for the Replacement Cross-Site Transfer System as Addendum 2 (Wagoner 1997h and Wagoner 1998a).

- Changes to Addendum 3 to correct applicability statements regarding organic salt-nitrate reaction analysis and clarification of references for the fire hazard analysis described in the addendum. These changes were evaluated in USQ screening TF-98-0266.

- Incorporate safety analysis for the mixer pump process test in Tank 241-AZ-101 as Addendum 4 (Wagoner 1998d)

- Changes to Addendum 1 and BIO main text to incorporate reanalysis of the 241-AZ-702, 241-A-702, 296-C-006, and 296-P-16 ventilation systems (Wagoner 1998e).

- Incorporate safety analysis for salt well pumping of single-shell tanks (Wagoner 1998c and Wagoner 1998f).

B2.0 FACILITY DESCRIPTION

B2.1 INTRODUCTION

In this chapter, the Tank Waste Remediation System (TWRS) tank farm facilities and operations are described to support assumptions used in Chapter 5.0, "Safety Analysis." The structures, systems, and components described are necessary to the TWRS mission and provide the means to safely store, treat, and manage tank farm wastes. The design, siting, and operation of these structures, systems, and components, in conjunction with the institutional and safety programs discussed in Chapter 4.0, "Safety Management," provide layers of physical and administrative protection to prevent or mitigate unwanted releases of radioactive or hazardous materials. Those systems that are directly relied upon to protect the facility worker, the onsite worker, or offsite individuals are identified in Chapter 6.0, "Operational Controls." The structures, systems, and components (i.e., Defense-in-Depth, Safety-Class, and Safety-Significant) are discussed further in Chapters 5.0 and 6.0.

As shown in Figures B2-1 and B2-2, the TWRS facilities are located in the 200 East, 200 West, and 600 Areas of the Hanford Site. The TWRS facilities comprise the single-shell tank (SST) farms, the double-shell tank (DST) farms, and associated support facilities, systems, and transfer equipment. All SSTs are no longer receiving waste and are considered out of service. The DSTs, however, may receive liquid waste from processing activities or other tanks and are considered in service. Even though all SSTs at TWRS are not currently receiving waste, waste storage in the tanks and waste transfer out of the tanks will continue until final waste disposal plans are approved. The TWRS facilities within the scope of the Basis for Interim Operation (BIO) is identified in Chapter 1.0, "Introduction."

The TWRS mission as described in HNF-SD-WM-MAR-008, *TWRS Mission Analysis Report*, includes waste storage management, retrieval, pretreatment, immobilization, interim storage and disposal, and tank closure operations. The TWRS Authorization Basis addresses the "manage tank waste" function, which is limited to the storage of waste before retrieval for processing; waste characterization; transfer of liquid wastes to resolve significant safety issues, optimize tank space, volume reduction, interim stabilization, or emergency pumping; and out-of-tank concentration (e.g., 242-A Evaporator) of tank waste to support tank space usage. In addition, this function also includes the treatment or preparation of liquid, airborne, and solid wastes before releasing to the environment or other onsite waste handling facilities and monitoring liquids released intentionally (e.g., discharges to cribs) or inadvertently (e.g., leaking SSTs) to the soil column.

The BIO addresses the operations or processes, with the exception of out-of-tank waste concentration, and the equipment (e.g., temperature monitors, liquid level indicators, samplers), systems (e.g., waste transfer piping, maintenance programs, conduct of operations), or facilities (e.g., DSTs, SSTs, waste handling facilities) required to support the "manage tank waste" function.

The specific facilities and projects that are excluded from the current BIO are listed in Tables B2-1 and B2-2, respectively. Projects currently excluded will be incorporated into the BIO during future annual revisions as appropriate.

Section B2.3, "Facility Overview" includes an overview of the facilities and operations discussed in this chapter, and more detail on the structures is given in Section B2.4, "Facility Structures." Requirements that are relevant to this chapter are listed in Section B2.2, "Requirements." Sections B2.5 through B2.9 contain details of the operations, support systems, and equipment at each of these facilities, including the following:

- **Current TWRS Operations**—tank waste storage and waste transfers
- **Safety Support Systems**—fire protection, radiation and toxicological monitoring, and effluent monitoring
- **Utility Distribution Systems**—electrical supply systems, process and sanitary water, and compressed air.

B2.2 REQUIREMENTS

The design codes, standards, regulations, and U.S. Department of Energy orders relevant to this chapter and required for establishing the Authorization Basis for TWRS facilities are as follows:

- DOE 5480.7A, *Fire Protection* (1993)[1]
- DOE 5480.28, *Natural Phenomena Hazard Mitigation* (1993)[1]
- DOE 5820.2A, *Radioactive Waste Management* (1988)
- DOE 6430.1A, *General Design Criteria* (1989)[1]
- DOE-STD-1020-94, *Natural Phenomena Hazards Design and Evaluation Criteria for Department of Energy Facilities* (Change 1)
- DOE-STD-1021-93, *Natural Phenomena Hazards Performance Categorization Guidelines for Structures, Systems, and Components* (Change 1)
- DOE-STD-1022-94, *Natural Phenomena Hazards Characterization Criteria* (Change 1)
- DOE-STD-1023-95, *Natural Phenomena Hazards Assessment Criteria* (Change 1).

[1]Although DOE 5480.7A, 5480.28, and 6430.1A have been rescinded, the contractor is obligated by the existing contract to meet the requirements stated in these orders.

Before the current design requirements were issued, facilities were designed and constructed in accordance with the functional and safety requirements documented in project functional design criteria, specifications, and drawings (WHC-SD-TWR-RPT-002, *Structural Integrity and Potential Failure Modes of the Hanford High-Level Waste Tanks*).

B2.3 FACILITY OVERVIEW

The TWRS tank farm facilities provide the physical means for moving radioactive liquid wastes between processing and storage facilities. In this section, an overview of tank farm facilities configuration is given (Figures B2-3 and B2-4), the current mission of the TWRS facilities is defined, and the operations performed in the facilities are briefly described.

B2.3.1 Current Mission of TWRS Facilities and Operations Supporting that Mission

The TWRS mission as described in WHC-SD-WM-MAR-008 includes storage management, retrieval, pretreatment, immobilization, interim storage and disposal, and tank closure operations. The BIO addresses the tank farm facilities and operations that support the "manage tank waste" function. Tank farm facilities necessary for managing the tank waste are the SST and DST farms and the tank farm supporting facilities (e.g., catch tanks, DCRTs, and transfer lines). Necessary operations are in-tank waste storage, tank-to-tank transfers, waste characterization, and waste concentration.

B2.3.2 Brief History of TWRS Operations

The TWRS project was established in 1991 to integrate all aspects of the treatment and management of the high-level radioactive wastes in 177 underground storage tanks in the 200 East and 200 West Areas. All aspects of operations, safety, corrective actions, characterization, projects, and disposal are included. The contractor is responsible for managing and operating the waste tanks.

B2.3.2.1 Development of SST and DST Farms. The production of defense-related materials at the Hanford Site generated large quantities of solid and liquid radioactive mixed waste. Chemical processing of irradiated uranium fuels generated alkaline slurries containing heavy metals, organic solvents, inorganic salts, uranium, plutonium, and mixed fission products. Cooling water, condensates, and other low-level wastes from processing operations were discharged to the ground. High-level wastes were placed in the large, steel-lined, underground SSTs for temporary storage. Over time, the design of the high-level waste tanks has gradually improved and been modified, and more tanks have been built to store an increasing volume of waste.

The underground waste storage tanks are grouped into "farms" and are buried approximately 3 m (10 ft) belowground near the center of the Hanford Site in the 200 East and 200 West Areas. The tanks were buried at

this depth to shield facility workers and the public from the radioactive wastes and also to prevent or mitigate the consequences of releases of radioactive materials.

Many of the tank farm facilities have been used beyond their intended design life. Continued safe operations are ensured by comprehensive maintenance and surveillance programs. These programs and other programmatic features that support TWRS operations are discussed in Chapter 4.0.

Certain tanks within the tank farms present unique safety hazards because of past in-facility or in-tank operations. These tanks are identified as "watch list" tanks. These "watch list" tanks are categorized on the basis of the unique safety hazard presented by the content of the waste in the tank. The "watch list" tank categories are as follows.

- **Hydrogen/Flammable Gas Tanks**—Suspected to have a significant potential for hydrogen/flammable gas generation, entrapment, and episodic release. The presence of a flammable gas mixture and an ignition source would increase the risk of a release of radioactive material to the environment.

- **Organic Salt Tanks**—Contain organic carbon. High concentrations of organic compounds/chemicals could support an exothermic reaction at elevated temperatures (WHC-EP-0681, *Interim Criteria for Organic Watch List Tanks at the Hanford Site*). Under certain scenarios involving overheating of the tank, such a mixture of organic solids could react rapidly, possibly damaging the tank and allowing a release of radioactive material.

- **High Heat Tanks**—Contain heat-generating, cesium and strontium-rich sludge and require the maintenance of drainable liquid in the tanks to promote cooling. Water is periodically added to the tanks to maintain liquid levels. The tanks are cooled by evaporation in conjunction with active ventilation.

The underground waste storage tanks are briefly described in the following paragraphs. The latest tank summary data for the SSTs and DSTs is provided in HNF-EP-0182, *Tank Farm Surveillance and Waste Status Summary Report for Month Ending March 31, 1998*. (This was the current version as of the time of BIO annual update. The report is published each month.) HNF-EP-0182 includes descriptions of currently stored waste, tank watch list designations, and waste volumes by type of waste (i.e., supernatant, interstitial liquids, sludge, and salt cake). For the SSTs, the status of interim stabilization and intrusion-prevention efforts is included.

B2.3.2.1.1 Single-Shell Tank Farms. Twelve SST farms containing 149 tanks were constructed between 1943 and 1964 and grouped into farms consisting of 4 to 18 tanks. The farms were divided equally between the 200 East and the 200 West Areas and assigned letter identifiers consistent with the area designations. Tank farms beginning with letters A to N are located in 200 East, with the last half of the alphabet located in 200 West. The original SST design was a reinforced concrete shell and dome with mild carbon steel lining the bottom and walls. Over time, while the basic design remained essentially the same, the depth of the steel liner within the

concrete shell was increased with corresponding increases in operating depth and storage capacity. Minor design improvements, however, were made in the tank bottoms.

The first tanks, built concurrently with the bismuth-phosphate processing plants (B Plant and T Plant), were designed with 5.5 m (18 ft) liners and operating volumes of 2 million L (530,000 gal).[2] The next tanks were built first with 7.3 m (24 ft) liners and operating volumes of 2.9 million L (758,000 gal) and finally with liner heights of 9.8 m (32 ft) and operating capacities of 3.8 million L (1 million gal).

No process wastes have been added to the 149 SSTs since November 1980; therefore, these tanks are considered out of service. The SST farms are described in detail in Section B2.4.

No tank leaks were reported at the Hanford Site before the early 1950s; however, some pipes and fittings made from materials other than stainless steel did leak as early as 1945 (WHC-MR-0293, *Legend and Legacy: Fifty Years of Defense Production at the Hanford Site*). The first large, confirmed tank leak, 208,000 L (55,000 gal), occurred in 1956 at Tank 241-U-104. The largest known leak from a Hanford Site SST occurred in 1973 when 435,000 L (115,000 gal) escaped from Tank 241-T-106.

In a November 1963 incident, Tank 241-A-105, which had received PUREX high-level waste for about three years, underwent a steam pressurization event below the tank liner bottom. The event ripped the liner and formed an irregular bulge about 15 m (50 ft) in diameter by 2 m (8 ft) high in the tank liner bottom. Following this incident, the tank was immediately taken out of service; and was interim stabilized in July 1979 and finally interim isolated in October 1985. For 10 years following the incident, the contents were kept cool by using an exhauster and by sprinkling a small amount of water on the sludge. Nothing could safely remove the sludge trapped under the ruptured liner, but the tank was substantially emptied in 1977, and a hole was chemically milled at the top of the bulge (in 1977) to allow potential radiolytic hydrogen to escape. Temperatures below the tank are monitored via probes in lateral wells.

Currently, 67 SSTs are assumed to be leaking on the basis of tank surveillance data that indicates a loss of liquid attributed to a breach of tank integrity (HNF-EP-0182).

Both active and passive ventilation systems are used to contain SST airborne particulates. Active ventilation systems (exhausters) are used in the SST farms when the heat load is greater than 11,700 W (40,000 Btu/h) or when studies predict a peak waste temperature greater than operating specifications. The only two SST farms that contain actively ventilated tanks are 241-C and 241-SX. All other SST farms contain tanks that are passively vented to the atmosphere through breather filters.

---

[2]The tanks were built using English units. Most of the conversions in this chapter are from English to metric units.

B2.3.2.1.2 Double-Shell Tanks. As a result of leakage at the SST farms, construction of DSTs started in the late 1960s; these tanks had double steel shells and improved leak detection. Between 1968 and 1986, 28 DSTs were built and situated in 6 tank farms each with 2 to 8 tanks. Five of the tank farms are located in the 200 East Area, and one tank farm is located in the 200 West Area. All DSTs are similar in design and each has a capacity of approximately 3.8 million L (1 million gal). Slight design improvements in the tanks and ancillary equipment were made over the years to accommodate variations in waste composition.

The DSTs were constructed to provide intermediate storage for high-level radioactive waste, including waste capable of boiling due to radioactive decay (aging waste) and waste not capable of boiling (non-aging waste). Waste requiring intermediate storage has come from Hanford Site processing facilities.

Designed to minimize the potential for leakage of radioactive liquids to the environment, each DST consists of a carbon steel primary tank and a carbon steel secondary tank within a protective reinforced concrete shell. The protective concrete shell is designed to sustain soil loads and to tolerate the temperature gradients caused by the heat generated by the contained radioactive waste.

The primary tank contains waste, is freestanding, and stands on an insulated concrete pad. During construction, the insulated pad protected the structural concrete foundation from excessive temperatures during annealing or stress relief treatment of the primary tank. Annealing reduces high-stress points at metal joints to reduce joint susceptibility to corrosion and cracking. The insulating pad is also cast with air distribution and drain grids to provide for leak detection, to maintain a uniform tank bottom temperature, facilitate heat removal, and to eliminate pockets of water condensation.

The insulating pad rests on the secondary tank, which is 1.5 m (5 ft) larger in diameter than the primary tank, creating an air space, or annulus, separating the two steel tank walls. The secondary tank serves as a confinement barrier in case of primary tank leakage.

The DSTs are actively vented (with fan-driven ventilation systems) to the environment. The primary ventilation system removes vapors from the primary tank and cools the waste by convective heat transfer and by the evaporation of moisture. The annulus ventilation system can be used to cool the primary tank, remove moisture accumulation in the annular space, and help detect radioactive leakage. The annular space of each DST is monitored for leaks. To date, none of the Hanford Site DSTs have leaked.

Tank summary data is given in Table B2-3. The DST farms are described in detail in Section B2.4.

B2.3.2.1.3 Ancillary Systems, Facilities, and Equipment. The ancillary systems, facilities, and equipment supporting operations in the SST and DST farms include underground waste transfer pipelines, valves, diversion boxes, jumper connectors, waste transfer pumps, DCRTs, catch tanks, process pits, the 204-AR Waste Unloading Facility, and the 244-AR Vault Facility. These

ancillary systems, facilities, equipment, and other miscellaneous facilities under the control of TWRS are discussed in Section B2.4.

B2.3.2.2 Waste Inventory Generation and Description. Most wastes stored in the Hanford Site underground waste tanks are radioactive slurries generated by reprocessing of irradiated uranium fuel by means of one of the following processes (WHC-MR-0132, *A History of the 200 Area Tank Farms*):

- Bismuth phosphate ($BiPO_4$)
- Reduction oxidation (REDOX)
- Plutonium uranium extraction (PUREX)
- Uranium recovery
- Waste fractionization.

Typical chemical compounds in the wastes produced by each of the processes are listed in Table B2-4. Smaller volumes of wastes were generated by research and development programs, laboratory processes, the "hot semi-works" (pilot plant) for REDOX process, the PUREX pilot (233-5), and Plutonium Finishing Plant operations (WHC-EP-0210, *Waste Characterization Plan for Hanford Site Single-Shell Tanks*).

Since 1944, more than 1,510 million L (400 million gal) of high-level radioactive waste have been generated by these operations and various others. More than 1,140 million L (300 million gal) were directed to the SSTs and DSTs. The remainder of the liquids were discharged to the soil in percolation or evaporating ponds, or by decanting decontaminated (i.e., very low radioactivity) dilute liquid wastes to the ground. Waste volume in the tanks has been reduced to approximately 208 million L (55 million gal) by evaporation, concentration, or both (either in the tanks or externally in evaporators).

All the fuel processing methods generated acidic waste streams. To neutralize the acid and minimize tank corrosion, sodium hydroxide or calcium carbonate was added before the waste was transferred to the tanks. Thus, the tanks contain moderately to strongly alkaline solutions with pH values up to 14. Further post-processing of some of the wastes has resulted in the addition of some organic compounds listed as hazardous (WHC-MR-0132), thereby creating some of the current safety concerns.

Waste stored in the tanks consists primarily of inorganic compounds, including sodium hydroxide; sodium salts of nitrate, nitrite, carbonate, aluminate, and phosphate; and hydrous oxides of aluminum, iron, and manganese. The radioactive components in the waste consist primarily of mixed long-lived fission product radionuclides and actinide elements.

Mixed waste in some underground waste storage tanks may contain heavy metals such as lead, chromium, and cadmium. Detectable amounts of organic

compounds are present. The small portion of waste that is organic (complexed waste) contains the chelating agents EDTA (ethylenediaminetetraacetic acid) and HEDTA (hydroxyethylethylenediaminetriacetic acid) or TBP (tri-butyl phosphate), which was used in fuel processing.

The tanks now contain a mixture of liquid, sludge, and salt cake waste types with both radioactive and chemically toxic hazardous constituents. Liquids exist as supernatant (liquid above solids) and interstitial liquid (liquid filling the void between solids) in the tanks. Sludge consists primarily of solids (hydrous metal oxides) precipitated by the neutralization of acid wastes. Salt cake, generally between the supernatant and sludge, consists of the various salts formed by the evaporation of water from the waste. These waste types do not necessarily exist as distinct layers but rather are intermingled to differing degrees. Some sludges and salt cake contain interstitial liquids and are relatively soft; others are drier and harder. HNF-EP-0182 contains the current volumes of each of these waste types for each waste tank.

B2.3.3 Interfacing Facilities

As discussed in Section B2.1, "Introduction" and identified in Figures B2-1 and B2-2, other facilities within the Hanford Site interface with TWRS facilities. These interfaces are controlled to ensure that these other facilities do not impact TWRS operations (e.g., radionuclide controls are placed on 242-A Evaporator slurry being transferred to 241-AW Tank Farm or TWRS solid waste being transferred to non-TWRS solid waste facilities). Major facilities that interface with the TWRS facilities and that are addressed in the BIO are identified in Table B2-5.

Typical facility interfaces for both liquid and solid waste transfers are shown in Figures B2-5 and B2-6. Specifically, these figures show facility or system physical boundaries: systems or structures belonging to the facility of origin (facility that generates the waste), the waste transfer system, and the facility destination (or facility that receives the waste). Although Figures B2-5 and B2-6 represent facility interfaces between TWRS facilities and other Hanford Site facilities, interfaces between TWRS facilities are similar.

The physical boundaries that are the TWRS interfaces for liquid waste transfers to a TWRS facility are shown in Figure B2-5 and identified in Table B2-5. For example, when PUREX was operational and transferring waste from the PUREX Facility (facility of origin) to the 241-AW Tank Farm (receiving facility), the PUREX Facility managed the transfer line to the 241-A-151 diversion box (junction); the waste transfer system managed the internals of diversion box 241-A-151 and the transfer line to valve pit 241-A-A or 241-A-B (junction); and the 241-AW Tank Farm managed the internals of valve pit 241-AW-A or 241-AW-B and the transfer line to the receiving tank.

The physical boundaries and the TWRS interfaces for liquid and solid waste transfers are shown in Figure B2-6 and identified in Table B2-5. The receiving facility can be another TWRS facility or another Hanford Site facility. For example, during transfers from a TWRS facility (facility of

origin) to solid waste facilities (receiving facility), TWRS is responsible for the waste packaging, a truck transport system is responsible for transportation, and solid waste facilities in the 200 West Area are responsible for waste handling and disposal. Liquid waste transfers between TWRS facilities are depicted in Figure B2-6.

B2.4 FACILITY STRUCTURES

TWRS is a complex of tank farm facilities primarily located in the 200 East and 200 West Areas (Figures B2-1 and B2-2); however, other TWRS facilities, including administrative buildings, retention basins, and transfer lines are located in areas adjacent to the 200 East and 200 West Areas. In addition, some administrative TWRS facilities are located in the nearby city of Richland.

This appendix provides a description of the structures, systems, and components (SSCs) as they were designed and constructed and the intended function of each SSC. The SSCs identified in this chapter provide the hazard and accident analysts a "laundry list" of potential mitigative or preventive barriers for selecting Safety-Class, Safety-Significant, and Defense-in-Depth items. The operability, as defined in the Technical Safety Requirements (TSRs), of many of the active systems within the TWRS facilities and described in the following has not been formally verified using operability tests. However, the TSRs provide the assurance that the selected Safety-Class and Safety-Significant SSCs are and remain operable in accordance with the TSRs. The configuration management program including the maintenance program assures operability of the Defense-in-Depth SSCs.

Field walkdowns were performed at the facility level (i.e., tank farm, building, or miscellaneous facility) to identify which structures currently exist and appear operable. The field walkdowns included an initial document review before the walkdown and a visual inspection of accessible portions of the operating systems. The members of the field walkdown team included system and/or facility cognizant engineers, design authorities, and operations personnel. The field walkdown activity independently verified all TWRS-owned structures or systems and the operability of the structures or systems. The procedure and results of the field walkdowns are documented in WHC-SD-WM-HIE-007, *Tank Waste Remediation FSAR Hazard Identification/Facility Configuration Verification Report*.

The initial document review involved the latest drawings, databases, supporting design documents, procedures, roundsheets, condition assessment reports, and operations specifications or requirements. The design data collected during the document review was visually verified during the walkdown for aboveground structures or systems. Verification of inaccessible portions of a facility or structure (e.g., contents within a valve pit or diversion box) was based on the document review.

System operability was evaluated during the walkdown. This evaluation was qualitative (yes or no) and did not assess system condition. Operability of systems that could not be verified visually were marked "assumed operable," "inoperable," or "unknown," based on the document review and the information provided by members of the field walkdown team.

The data collected during the facility walkdowns is provided in the facility, structure, or systems descriptions, which are described in this appendix.

The following discussion begins with a description of the common structures and systems of SSTs, followed by a description of the specific structures and systems associated with these SSTs. This SST discussion is followed by a comparable discussion of DSTs. The next sections describe other underground storage tanks, including catch tanks and DCRTs; the 204-AR Waste Unloading Facility; the 244-AR Vault; cribs, ditches, and ponds; and storage and handling areas for contaminated materials. Completing the facility description are sections on the waste transfer systems, instrumentation and monitoring systems, cathodic protection systems, interlock systems, and mixer pumps.

B2.4.1 Common Structures and Systems of Single-Shell Tanks

The primary function of an SST is to contain radioactive liquid waste over the lifetime of the facility. SST tanks were designed to contain waste within a reinforced concrete shell with an internal liner (structurally independent from the reinforced concrete tank) of mild carbon steel covering the bottom and sidewalls (Figures B2-7 and B2-8). These tanks are collectively referred to as 100 Series tanks. Of the 149 SSTs, 133 are 23 m (75 ft) in diameter with operating volumes of 2, 2.9, and 3.8 million L (530,000, 758,000, and 1 million gal). Sixteen smaller tanks (called receiver tanks) share the same design as the larger tanks, but are only 6.1 m (20 ft) in diameter and can hold 208,000 L (55,000 gal) each. These tanks are collectively referred to as 200 Series tanks. Table B2-6 provides more details on SST design. Earth cover over each tank provides shielding. Heat generated by radioactive decay is dissipated through the walls and bottom to the surrounding soil.

Most of the 100 Series tanks (2- and 2.9-million L [530,000- and 758,000-gal]) are arranged in "cascades" of three or four tanks in a farm; when the first tank was filled, waste was allowed to overflow into successive tanks through piping in the sidewalls. Each successive tank in the cascade is lower than the previous tank. Therefore, solids settled out in the first or higher tank, and the supernatant was stored in the last tank of the cascade or allowed to overflow to an adjacent crib. Much of the overflow piping between tanks in the various cascades has been removed or blanked. Currently, cascade lines provide an air flow path from a tank not actively ventilated to a tank that is actively ventilated (see 241-C Tank Farm description in Section B2.4.1.5.1).

The design of the common SST elements is discussed in more detail in the following sections. WHC-SD-TWR-RPT-002 provides the limited information available regarding standards or specifications followed during the design and construction of the SSTs.

B2.4.1.1 Concrete Shell. The concrete shell maintains the structural integrity of the steel liner by protecting it from soil loads and provides secondary confinement of the waste material. Each SST shell has a 0.3-m-

(1-ft-) thick concrete base slab, a 0.3-to-0.38-m- (1-to-1.25-ft-) doom roof, and a 0.3-m- (1-ft-) thick cylindrical wall that rests on a circular footing integral with the tank and base slab. The reinforced concrete shells of the larger SSTs, 23 m (75 ft), are cylindrical with domed roofs. The reinforced concrete walls, dome, and base of the shell support the tank surface live loads, static and dynamic soil loads, and hydrostatic and hydrodynamic loads.

The reinforced concrete shells of the 100 Series SSTs are vertical cylinders constructed of reinforced concrete. Each receiver SST shell has a 178-mm- (7-in.-) thick concrete base slab, a 0.3 m- (1-ft-) thick dome, and a 0.3-m- (1-ft-) thick cylindrical wall resting on a circular footing integral with the tank and base slab. The tanks are buried underground to provide radiation shielding.

B2.4.1.2 Steel Liner. All SSTs are constructed of ASTM A 283 Grade C mild steel (except those in the 241-AX Tank Farm, which are ASTM A 201 Grade C). The thickness of each liner varies from 6.4 mm (0.25 in.) to 9.53 mm (0.375 in.). For the 100 Series tanks, the steel liners extend up the tank wall to a height of 5.5, 7.3, and 9.8 m (18, 24, and 32 ft) for the 2, 2.9, and 3.8 million L (530,000; 758,000; and 1 million gal) tanks, respectively. For the smaller 200 Series tanks, the steel liner extends 7.6 m (25 ft) up the tank wall. Waste levels were managed at approximately 0.3 m (1 ft) below the top edge of the liner.

B2.4.1.3 Risers. Each SST has numerous dome risers, which are vertical pipes that penetrate the tank domes to various depths. Almost all the risers are either 102, 305, or 1,070 mm (4, 12, or 42 in.) in diameter. Located either in covered pits at or below ground level, dome risers primarily provide access to the tank interior for a variety of operating and monitoring equipment. This equipment can include periscopes; still and television cameras; ventilation air supply and exhaust ducts; and instruments used to measure or monitor temperature, pressure, specific gravity, liquid levels, dome-space gas levels and concentrations, and sludge (solid) levels. Some risers are reserved as spares. Dome risers are normally capped or covered to prevent uncontrolled intrusion (e.g., rain and personnel) and to prevent releases of radioactive materials. Additional details regarding SST risers can be found in WHC-SD-RE-TI-053, *Riser Configuration Document for Single-Shell Waste Tanks.*

B2.4.1.4 Process and Service Pits. Pumps, monitoring equipment, or transfer systems are typically contained in belowgrade concrete enclosures with removable reinforced concrete cover blocks (i.e., pits, caissons, diversion boxes). The type and number of pits associated with SSTs depend on the type of waste stored and the function of the SST. Therefore, not all pits listed here are present at each tank. Leak detection is provided in the process and service pits used during transfers.

Process pits of the following types handle process solutions.

- **Central pump pit**—located at the center of the SST dome. Waste is normally pumped out of the SST through this pit.
- **Sluice pits**—located over off-center tank risers. A sluice pit is used to route high-pressure liquids to the sluicer assembly.

- **Condenser pit**—located off-center. A condenser pit contains a condenser used to condense tank vapors.
- **Heel pit**—located off-center. A heel pit can be used for equipment installation.
- **Salt well pit**—located off-center. A salt well pit is used for installing salt well pumps and piping.
- **Valve pit**—allows waste to be diverted to pipelines by means of valves, jumpers (temporary piping systems), or both.

Other pits located adjacent to the SSTs in the tank farms do not handle process solutions and therefore are not considered process pits. These pits are as follows.

- **Flush pit**—provides conduit through which water is supplied to flush pipelines after a waste transfer.
- **Leak detection pit** (241-AX Tank Farm only)—provides primary tank leak detection capability.

B2.4.1.5 Ventilation Systems. Both active ventilation and passive ventilation are used for tank venting.

B2.4.1.5.1 Active Ventilation Systems. Air is drawn through a tank and its ventilation system, which may include permanent and temporarily installed systems, by a centrifugal exhaust fan. Air entering a tank is filtered to prevent particulate matter from entering the tank.

Exhaust duct work vents prefiltered air through high-efficiency particulate air (HEPA) filters and the exhaust blower, and then out the stack where the air is sampled for radioactive materials by a continuous air monitor (CAM) and record sampler. Both the inlet and exhaust filters will function as passive ventilation systems upon loss of the exhauster fans.

Each active ventilation system in use at the SST farms is described in the following paragraphs. An active ventilation system was initially installed on Tank 241-A-105, however this system is currently inactive (i.e., not operating) and will not be restarted. Active ventilation is installed on specific tanks within two SST farms (241-C and 241-SX). At these two farms, a centrifugal exhaust fan draws air through the underground tanks, primarily to minimize accumulation of flammable gas. Additionally, an active ventilation system provides a cooling function as a Defense-in-Depth measure. System specifications are given in Table B2-7.

241-C Tank Farm. A skid-mounted, portable exhauster with a centrifugal exhaust fan has been installed for permanent use at Tanks 241-C-105 and 241-C-106 (Figure B2-10). Because of the cascade effect, the blower also indirectly serves Tank 241-C-104. Tanks 241-C-105 and 241-C-106 have air inlet filters. The exhauster draws air from the underground tanks, primarily to cool the tank contents either by convective heat transfer from the waste or by evaporation of moisture. A dedicated system will be used during Tank 241-C-106 sluicing (refer to Addendum 1).

In the 241-C Tank Farm, air enters 0.5-m (1.5-ft) ports in the exhauster plenum and is drawn through an electric heating system and through HEPA filters. The air is then discharged to the atmosphere via a short stack. The discharged air is continuously sampled and monitored for radioactive materials. In addition to the HEPA filters, Tank 241-C-103 has a vapor mixing system designed to mix outside air with headspace gases.

241-SX Tank Farm. The 241-SX Primary Ventilation System cools the waste stored in various underground storage tanks using a stationary, pad-mounted exhauster (Figure B2-11). SSTs 241-SX-101 through 241-SX-112 and 241-SX-114 are ventilated by the exhaust system. Ducting from SSTs 241-SX-101 through 241-SX-106 is connected and routed underground to SST 241-SX-109. SSTs 241-SX-107 through 241-SX-112 and 241-SX-114 are actively ventilated for cooling and are equipped with inlet air filters that include balancing dampers. Air inlet filters in Tanks 241-SX-101 through 241-SX-106 are the same type of breather filter assemblies used for passively ventilated SSTs.

Filtered air is discharged to the atmosphere through exhaust blowers and a short stack. A sampling facility in the stack monitors the air being discharged for radioactive materials. SSTs 241-SX-113 and 241-SX-115 are passively ventilated through HEPA filters to the environment.

B2.4.1.5.2 Passive Ventilation Systems. Passive ventilation systems serve all SSTs except those in Tank Farms 241-C and 241-SX, which have active systems. Passive ventilation means that airflow through the tanks is dictated by differences in atmospheric conditions (e.g., temperature and atmospheric pressure) in and out of the tank.

A breather filter system (Figure B2-9) is used on all tanks with little or no activity or cooling requirements. Each breather filter consists of a housing that contains a HEPA filter, an outlet screen, and a small seal loop. Unmodified breather filters mount on a single spool piece attached to the tank riser. An isolation valve is normally open to permit air flow between the tank vapor space and outside atmosphere through the filter. Air flowing to and from the tank passes horizontally through the filter and then vertically through the downward-facing exit weather hood.

Seal loops installed in the exhaust lines are designed to maintain tank pressures near atmospheric. The seal loops are provided to relieve slight tank overpressurizations when the HEPA filter is plugged or isolated for maintenance. The seal loops are inspected weekly and refilled if required.

B2.4.2 Specific Structures and Systems of Single-Shell Tanks

In the following sections, each SST farm is discussed first for the 200 East Area and then for the 200 West Area. The tank farms within each area are discussed in order of construction from earliest to latest dates. Major systems, facilities, or structures within each tank farm are identified in WHC-SD-WM-HIE-007. In addition, this report provides an assessment of system status and operability.

B2.4.2.1 200 East Area Single-Shell Tanks. The following sections describe the six SST farms located in the 200 East Area.

B2.4.2.1.1 241-B Tank Farm. The 241-B Tank Farm, located north of B Plant on Baltimore Avenue, was built during 1943 and 1944 and was one of the first four tank farms at the Hanford Site. The tank farm includes twelve 23-m- (75-ft-) dia SSTs, each of which can hold 2 million L (530,000 gal). This volume corresponds to a liner height of 5.5 m (18 ft). The 241-B Tank Farm also has four receiver tanks, each 6.1 m (20 ft) in diameter and able to hold 208,000 L (55,000 gal). All 16 SSTs are passively ventilated through HEPA filters to the environment.

Originally, these tanks received waste from B Plant. Later, Tanks 241-B-102, 241-B-103, 241-B-106, 241-B-108, 241-B-109, and 241-B-112 were modified for use as receiver tanks for the In-Tank Solidification and Evaporator Program. Modifications included construction of pump pits, insulation and heat-tracing of transfer lines, and installation of temperature profile equipment. Systems, facilities, and structures associated with the 241-B Tank Farm are listed in WHC-SD-WM-HIE-007.

B2.4.2.1.2 241-C Tank Farm. The 241-C Tank Farm, located north of the PUREX Facility and just northwest of the 241-AN Tank Farm, was constructed during 1943 and 1944. The 241-C Tank Farm has twelve 2 million-L (530,000-gal) SSTs (241-C-101 to 241-C-112) measuring 23 m (75 ft) in diameter and four 208,000-L (55,000-gal) receiver tanks (241-C-201 to 241-C-204) measuring 6.1 m (20 ft) in diameter. The 23-m- (75-ft-) dia SSTs are arranged in four cascades of three tanks each. These tanks received waste from B Plant. SSTs 241-C-105 and 241-C-106 (and indirectly 241-C-104) are actively ventilated; these tanks are connected to a common operating exhaust system (Section B2.4.1.5.1). All other tanks within the 241-C Tank Farm are passively ventilated through HEPA filters to the environment. Systems, related facilities, or structures associated with the 241-C Tank Farm are listed in WHC-SD-WM-HIE-007.

B2.4.2.1.3 241-BX Tank Farm. SSTs in the 241-BX Tank Farm, located north of B Plant, were constructed during 1946 and 1947 according to the original tank design for 241-B Tank Farm. The twelve 2 million-L (530,000-gal) SSTs are arranged in four cascades of three tanks each. These tanks received waste from B Plant. None of the 241-BX SSTs are connected to an operating exhaust system. All are passively ventilated through HEPA filters to the environment. Systems, facilities, and structures associated with the 241-BX Tank Farm are listed in WHC-SD-WM-HIE-007.

B2.4.2.1.4 241-BY Tank Farm. The 241-BY Tank Farm, located north of B Plant, was built from 1948 to 1949 according to a modified 241-B Tank Farm design. Each of the 12 tanks can hold 2.9 million L (758,000 gal). This corresponds to a 7.3-m (24-ft) liner height, versus 5.5 m (18 ft) for the original design. These tanks received waste from B Plant and are passively ventilated through HEPA filters to the environment. Systems, facilities, and structures associated with the 241-BY Tank Farm are listed in WHC-SD-WM-HIE-007.

B2.4.2.1.5 241-A Tank Farm. The 241-A Tank Farm, located directly north of the 242-A Evaporator, was constructed during 1954 and 1955. Each of the

six SSTs can hold 3.8 million L (1 million gal). None of the SSTs in the 241-A Tank Farm have received waste since November 1980. Originally, these tanks received boiling waste from the PUREX Facility. All tanks within the 241-A Tank Farm are passively ventilated through HEPA filters to the environment (Section B2.4.1.5.2). Systems, related facilities, or structures associated with the 241-A Tank Farm are listed in WHC-SD-WM-HIE-007.

B2.4.2.1.6 241-AX Tank Farm. The 241-AX Tank Farm, located north of the 241-A Tank Farm and east of the 241-AY Tank Farm, was constructed during 1963 and 1964. This tank farm contains four SSTs, each with a capacity of 3.8 million L (1 million gal) and similar in basic construction to SSTs in the 241-A Tank Farm. These four SSTs are 23 m (75 ft) in diameter with 9.8-m- (32-ft-) high liners. In these tanks, a grid of drainage slots was added beneath the steel-lined bottoms. Any leakage through the tank liner enters drainage slots in the concrete pads and then flows to an adjacent leak-detection pit. These tanks received boiling waste from the PUREX Facility and are passively ventilated through HEPA filters to the environment. Systems, related facilities, and structures associated with the 241-AX Tank Farm are listed in WHC-SD-WM-HIE-007.

B2.4.2.2 200 West Area Single-Shell Tanks. The following sections describe the six SST farms located in the 200 West Area.

B2.4.2.2.1 241-T Tank Farm. The 241-T Tank Farm is located directly west of the T Plant. The 241-T Tank Farm was constructed from 1943 to 1944 and contains 16 SSTs. Twelve of the SSTs are 23 m (75 ft) in diameter, have 5.5-m- (18-ft-) high liners, and can hold 2 million L (530,000 gal). Four of the SSTs are 6.1-m- (20-ft-) dia receiver tanks that can hold 208,000 L (55,000 gal). The 23-m- (75-ft-) dia tanks are arranged in four cascades of three tanks each. The 241-T Tank Farm received bismuth phosphate wastes from T Plant. All the SSTs at this tank farm are passively ventilated through HEPA filters to the environment. Systems, facilities, and structures associated with the 241-T Tank Farm are listed in WHC-SD-WM-HIE-007.

B2.4.2.2.2 241-U Tank Farm. The 241-U Tank Farm, located directly west of U Plant, was constructed from 1943 to 1944. The 241-U Tank Farm contains 16 SSTs. Twelve of the SSTs can hold 2 million L (530,000 gal) and are 23 m (75 ft) in diameter with 5.5-m- (18-ft-) high liners. Four of the SSTs are 6.1-m- (20-ft-) dia receiver tanks that can hold 208,000 L (55,000 gal). SSTs in the 241-U Tank Farm received slurry from the 242-S Evaporator. These tanks are passively ventilated through HEPA filters to the environment. Systems, facilities, and structures associated with the 241-U Tank Farm are listed in WHC-SD-WM-HIE-007.

B2.4.2.2.3 241-TX Tank Farm. The 241-TX Tank Farm, located south of the 241-T Tank Farm, was constructed from 1947 to 1948 according to a modified 241-B Tank Farm design. The 18 SSTs in the 241-TX Tank Farm are essentially the same as the original B Tank Farm design except for increased capacity (from 2 million to 2.9 million L [530,000 to 758,000 gal]) achieved by increasing the liner height from 5.5 to 7.3 m (18 to 24 ft). The 241-TX Tank Farm received slurry from the 242-T Evaporator. The SSTs in the 241-TX Tank Farm are passively ventilated through HEPA filters to the environment. Systems, facilities, and structures associated with the 241-TX Tank Farm are listed in WHC-SD-WM-HIE-007.

B2.4.2.2.4 241-S Tank Farm. The 214-S Tank Farm is located on 13th Street, northwest of S Plant (the REDOX Plant), was constructed during 1950 and 1951 and consists of twelve 2.9 million-L (758,000-gal) SSTs. The SSTs were constructed according to the same design as the original 23-m-(75-ft-) dia SSTs, but with an increased liner height (from 5.5 to 7.3 m [18 to 24 ft]). The 241-S Tank Farm received several types of REDOX Plant wastes in all four cascades. These SSTs are passively ventilated through HEPA filters to the environment. Systems, related facilities, or structures associated with the 241-S Tank Farm are listed in WHC-SD-WM-HIE-007.

B2.4.2.2.5 241-TY Tank Farm. The 241-TY Tank Farm is located north of the 241-TX Tank Farm and was constructed during 1951 and 1952. All six SSTs can hold 2.9 million L (758,000 gal) and are of the same design as the tanks in the 241-TX Tank Farm. The 241-TY Tank Farm SSTs were used to settle and decant low-level wastes from T Plant and also to store the 242-T Evaporator feed. The 241-TY Tank Farm SSTs are passively ventilated through HEPA filters to the environment. Systems, facilities, and structures associated with the 241-TY Tank Farm are listed in WHC-SD-WM-HIE-007.

B2.4.2.2.6 241-SX Tank Farm. The 241-SX Tank Farm is located south of the 241-S Tank Farm and was constructed during 1953 and 1954. Each of the 15 SSTs in this tank farm can hold 3.8 million L (1 million gal). These were the first tanks designed to contain self-boiling waste. Only SSTs SX-113 and SX-115 are passively ventilated through HEPA filters to the environment. All other tanks within the 241-SX Tank Farm are actively ventilated to the environment as described in Section B2.4.1.5.1. Systems, related facilities, and structures associated with the 241-SX Tank Farm are listed in WHC-SD-WM-HIE-007.

B2.4.3 Common Structures and Systems of Double-Shell Tanks

Twenty-eight DSTs are located in six tank farms, five farms in 200 East Area and one farm in 200 West Area. As shown in Figures B2-12 and B2-13, DSTs consist of a carbon steel primary tank and a carbon steel secondary tank encased by a protective reinforced concrete shell. Dimensions for the tanks located in each of the six farms are given in Table B2-8.

The primary safety function of DSTs is to confine radioactive liquid waste over the lifetime of the facility. These confinement features are discussed in the following sections. The design codes and standards followed during construction of the tanks are provided in WHC-SD-TWR-RPT-002, and the design and operational parameters that are important to ensure continued operation of the tanks are summarized in Table B2-9.

B2.4.3.1 Primary Tank. The carbon steel primary tank is a free-standing, completely enclosed structure that contains and confines the waste. The primary tank measures 23 m (75 ft) in diameter and is 14.25 m (46.75 ft) high at the dome center. The nominal storage capacity is 3.8 million L (1 million gal) at a liquid level of 9.20 m (30.2 ft). The maximum storage capacity is 4.4 million L (1.16 million gal) at a liquid level of 10.7 m (35.2 ft).

A 25-mm- (1-in.-) thick steel plate 1.2 m (4 ft) in diameter is located at the center of the tank bottom. The plate gradually thins to 13 mm (0.5 in.) and extends to a curved, or formed, piece of the steel plate called the "knuckle" (where the tank bottom joins the tank wall). The knuckle plate is 22.2 mm (0.875 in.) thick.

The wall plates gradually thin from 22.2 mm (0.875 in.) at the knuckle to 19 mm (0.75 in.) to 15.9 mm (0.625 in.) to 13 mm (0.5 in.) and finally to 9.53 mm (0.375 in.). The wall meets the tank dome at the "haunch" junction. The haunch and most of the dome are formed of 9.53-mm- (0.375-in.-) thick steel plate. The exact dome center is a 13-mm- (0.5-in.-) thick circular plate 3.7 m (12 ft) in diameter.

Because high-stress points at weld joints are susceptible to corrosion and cracking, the primary tank was subjected in place to post-fabrication stress relief treatment.

B2.4.3.2 Concrete Support Pad. The primary tank sits on an 203-mm- (8-in.-) thick insulating concrete support pad located between the primary and secondary tank floors. During construction, the pad protected the external structural concrete foundation from excessive temperatures during the thermal stress relief of the primary shell. The pad was cast with air distribution and drain slots in a grid pattern. During regular tank operation, the pad establishes a uniform tank bottom temperature, provides a means of heat removal, provides a means of leak detection, and helps eliminate pockets of water condensation.

To provide cooling, air is drawn through the drain slots via the annulus ventilation system (Section B2.4.3.7, "Ventilation Systems"). The drain slots allow any leakage from the primary tank to drain into the annular space, where conductivity leak detection instrumentation is installed in annulus risers.

B2.4.3.3 Secondary Tank. The floor of the secondary tank (sometimes called a liner) lies beneath the insulating concrete pad and is built directly on top of the concrete foundation. This secondary tank is 1.5 m (5 ft) larger in diameter than the primary tank, which forms a 0.76-m- (2.5-ft-) wide annular space between the primary and secondary tanks. The secondary tank joins the primary tank dome at the upper haunch area, and these two tanks are enclosed in a reinforced concrete shell. The secondary tank provides a second confinement barrier for potential primary tank leaks, thus preventing uncontrolled releases of waste to the environment.

The secondary tank extends along the bottom, side, and upper haunch of the concrete shell. The secondary liner is roughly 12 m (40 ft) high and constructed of carbon steel plates varying in thickness from 9.53 mm (0.375 in.) to 13 mm (0.5 in.). The liner bottom is constructed of 9.53-mm (0.375-in.) steel plate. The secondary liner knuckle is made of a 13-mm (0.5-in.) steel plate that extends about 0.6 m (2 ft) from the floor and is welded to 9.53-mm (0.375-in.) wall plates. The secondary liner was not stress-relieved after construction and thus is not designed for long-term confinement of waste leaking from the primary tank.

Induced-draft ventilation of the annulus between the primary and secondary tank liners removes decay heat from the stored waste. Radiation

detectors in the annulus ventilation exhaust stream are provided to detect airborne radioactivity resulting from primary tank leakage.

B2.4.3.4 Concrete Shell. The exterior concrete shell is composed of a foundation, walls, and a dome that completely encloses the secondary tank and primary tank dome. This shell is designed to support soil loading, dead loads, live loads (equipment, personnel), and seismic loads. The 27-m- (89-ft-) dia, steel-reinforced shell rests on a separate structural concrete foundation. The 0.46-m- (1.5-ft-) thick shell concrete walls rest on steel slide plates supported by the tank foundation. The 0.38-m- (1.25-ft-) thick concrete dome and the walls contain a lattice of reinforcement bars and embedded J-bolts. The J-bolts are threaded into nuts welded to the steel tank walls and dome.

The structural concrete foundation, which is 27.23 m (89.33 ft) in diameter, evenly distributes all weight loads uniformly to the ground below. The circular center portion of the foundation is 1.8 m (6 ft) in diameter and 0.6 m (2 ft) thick. From the circular center portion, foundation thickness tapers to 0.3 m (1 ft) and expands again to 0.84 m (2.75 ft) at the outer edge.

The structural foundation contains drain lines and sumps to collect leakage from the secondary liner. The top of the concrete foundation contains slots to drain any liquid that might leak from the secondary tank (actually, a tertiary leak detection and collection system). Any liquid that reached the foundation would drain through the slots to a leak detection well.

B2.4.3.5 Risers. Each tank is equipped with riser pipes that penetrate the concrete dome and the top of the primary or secondary tank. The risers provide access to the primary tank and to the annulus space for waste transfer operations, equipment installation or use, and monitoring. Some risers are located in covered pits (e.g., central pump pits, annulus pump pits, and drain pits); others are located at specific predetermined locations at each tank.

Primary tank dome risers can be used to enable liquid and sludge sampling and also for instrument access to measure temperature and pressure, derive specific gravity, monitor liquid and sludge levels, and ventilate and pump the tank.

Annulus risers provide access for inspection and enable the introduction of liquid leak detection instruments, annulus pumps, periscopes, still and television cameras, ventilation air supply and exhaust ducts, and temperature monitors. Additional details regarding DST risers can be found in WHC-SD-RE-TI-093, *Double-Shell Underground Waste Storage Tank-Riser Survey*.

B2.4.3.6 Pits. Pits provide access from the surface to process piping and tank risers and are the points where jumpers (temporary piping systems), pumps, and other equipment are installed to establish waste transfer routings. Pump pits are constructed of reinforced concrete walls and floors located belowgrade and are provided with removable reinforced concrete cover blocks located approximately at grade elevation. Personnel are protected from radiation by the 508-mm- (20-in.-) thick cover blocks. The configuration of the piping in the pit is painted on the cover blocks to show the operator the

routing of the liquid waste and the valve positions. Leak detection is provided in all pits used during transfers.

Permanently installed pumps are used to remove liquid waste from primary tanks, and temporary pumps are used to remove liquid waste from annuli and leak detection pits. Spare pumps can be used for either purpose. However, pumps that become contaminated during a transfer operation in a particular pit may remain permanently in that pit.

B2.4.3.6.1 Central Pump Pits. Central pump pits, which are approximately centered on the tanks, have three purposes: (1) supernatant filling or removal, (2) slurry distribution, and (3) mixer pump installation. Central pump pits typically measure approximately 2.1 m (7 ft) square by 2.51 m (8.25 ft) deep. A typical central pump or distributor pit is illustrated in Figure B2-14.

Supernatant filling is accomplished through piping or jumpers (temporary piping systems) connected to a riser. For supernatant removal, central pump pits are designed to hold a deep-well turbine pump and piping or jumpers. In tanks without pumps, dummy pump heads are installed on the pump flange to support the supernatant pump-out (and fill) jumper. Central pump pits for receiver tanks that store slurry are equipped with slurry distributors (Figure B2-15).

During filling operations, a slurry distributor disperses the slurry evenly within the tank. The pump pit cover block is marked with a distributor-indexing diagram so that the distributor may be set at any given position from an established zero-degree reference point. The zero-degree position for the distributor points directly at the level instrument assembly. Two "Do Not Slurry" zones appear on each slurry distributor indexing diagram. One zone, at the indicated zero-degree position, protects the level instrument; the other zone prevents slurry from being sprayed directly under the tank ventilation outlet.

A central pump pit on Tank SY-101 houses the mixer pump that mixes tank contents.

B2.4.3.6.2 Annulus Pump Pits. Annulus pump pits, located over annulus risers, provide a means for pumping out any liquids that may accumulate in the annular space from a primary tank leak. A typical annulus pump pit is shown in Figure B2-16.

Annulus pump pits typically measure approximately 2.1 m (7 ft) square by 3.53 m (11.58 ft) deep with 0.3-m- (1-ft-) thick concrete walls. Annulus pump pits are covered with a 0.51-m- (20-in.-) thick concrete cover block. A shielding plug on a small leak detector assembly access hole in the cover block may be removed for observation purposes. The entire cover block, however, must be removed to obtain access to the leak detector.

In most instances, deep-well vertical turbine pumps will be installed as needed in annulus pump pits. The pump is lowered into position after a blind flange is removed. A rigid jumper assembly connects the pump outlet to a 51-mm (2-in.) process waste line enclosed in a 102-mm (4-in.) encasement. The encasement slopes to drain the encasement pipe toward the annulus pump pit.

The process waste line terminates at the central pump pit of the tank. The waste may then be pumped to a suitable tank through the existing transfer piping.

B2.4.3.6.3 Feed Pump Pits. Feed pump pits are located off center on Tanks 241-AW-102, 241-AP-102, and 241-SY-102 to provide a means of pumping the tank contents to a processing facility such as the 242-A Evaporator. Feed pump pits typically measure approximately 2.1 m (7 ft) square by 2.51 m (8.25 ft) deep with 0.3-m- (1-ft-) thick reinforced concrete walls and 0.51-m- (20-in.-) thick concrete cover blocks. A typical feed pump pit is shown in Figure B2-17.

B2.4.3.6.4 Leak Detection Pits. Leak detection pits installed in all DST farms house level indicators and leak-monitoring instruments and collect liquid from the drainage grid at the top of the concrete foundation (upon which the secondary liner bottom rests). Each pit is fabricated as two parts: (1) a leak detection well and pump pit and (2) a 152-mm- (6-in.-) dia radiation detection pit with dry well (Figure B2-18). A leak detection pit is normally located adjacent to each tank annulus. The 241-AP Tank Farm, however, only has two pits; each pit collects drainage from four tanks.

The leak detection pit (including the adjacent radiation detection pit) may be ventilated through a 51-mm- (2-in.-) dia ventilation line connected to the tank annulus ventilation system by opening an in-line ball valve with a T-handle. The T-handle extends about 0.9 m (3 ft) abovegrade, near the leak detection pump pit. Ventilation is unnecessary, however, unless the leak detection pits are contaminated.

Leak detection well and pump pits are 2.1 m (7 ft) square by 3.23 m (10.58 ft) deep with 0.3-m- (1-ft-) thick concrete floors and walls. A 0.51-m- (20-in.-) thick concrete cover block fits over the well and pump pit. The leak detection well floor is typically 19.15 m (62.83 ft) belowgrade. Below the top of the cover block at approximately 18 m (58 ft), a 152-mm (6-in.) encased drainpipe connects the leak detection well to the tank foundation for liquid collection. Depending upon the tank farm, the liquid can be pumped back into the primary tank, which is approximately 3.7 m (12 ft) from the pit, or through process piping to a designated receiver tank.

The radiation dry well (through which radiation detection probes are inserted as part of the leak detection system) is 152 mm (6 in.) in diameter and terminates adjacent to the bottom of the leak detection well. The radiation dry well is accessed through a pit adjacent to the pump pit. This access pit is 1.17 m (3.83 ft) long by 0.71 m (2.33 ft) wide by 0.69 m (2.25 ft) deep and is covered with a steel or sheet metal cover that is removed by using retractable lifting bails. The radiation well access pit drains into the leak detection pump pit, which then drains to the leak detection well.

B2.4.3.6.5 Drain Pits. Drain pits are located over an off-center primary tank riser on Tanks 241-AW-102 and 241-SY-102 to provide a means for returning fluids to the tank. Drain pits typically measure approximately 2.4 by 2.1 m (8 by 7 ft) by 3.53 m (11.58 ft) deep with 0.3-m- (1-ft-) thick walls and are covered with a 0.51-m- (20-in.-) thick concrete cover block. A typical drain pit is shown in Figure B2-19.

B2.4.3.6.6 Sluice Pits. A sluice pit is a reinforced concrete pit through which high-pressure liquids are routed to the sluicer assembly. Sluice pits are typically 4.3 m square by 3.84 m deep (14 ft square by 12.6 ft deep). These pits are located over off-center primary tank risers on DSTs 241-AY-102, 241-AY-101, 241-AZ-101, and 241-AZ-102. The pits provide a means of injecting a high-pressure liquid stream directly into the sludge so that the sludge may be broken up, removed, and transferred to another tank.

In 241-AY Tank Farm, Tank 241-AY-101 has four sluice pits and Tank 241-AY-102 has three sluice pits. 241-AZ Tank Farm is equipped with two sluice pits per tank and a central sluice transfer diversion box, 241-AZ-152.

B2.4.3.7 Ventilation Systems. All DST ventilation systems consist of both a primary ventilation system and an annulus ventilation system. The combined annulus and primary tank ventilation systems for the AN, AP, AW, and SY tank farms can remove up to 29,000 W (100,000 Btu/h). The 241-A-702 Ventilation System for the AY and AZ tank farms has three large condensers in the 241-A-401 Building, each designed for removing up to 5,860,000 W (20,000,000 Btu/h). The 241-AZ-702 Ventilation System is the new ventilation system for the AZ and AY tank farms and it replaces the 241-A-702 Ventilation System. See Addendum 3 for the facility description and system operation details for 241-AZ-702. The 241-A-702 Ventilation System has been isolated. The main functions of primary ventilation are as follows.

- Remove radioactive decay heat from the primary tank by removing water vapors from the tank headspace.
- Confine stored materials by maintaining vacuum conditions within the tank. The primary method of contamination control for the DSTs is confinement.
- Provide deentrainment of liquid droplets from condensed water vapor.
- Remove radioactive particulate materials from gaseous effluent.
- Control gaseous emissions with dilution air.

The primary tank ventilation system filters and removes moisture from tank exhaust vapor before the vapor is discharged to the atmosphere. The primary tank ventilation system maintains a negative pressure on the tanks. Confinement of airborne radioactive materials is thus ensured. The primary tank ventilation system can handle offgas with as much as 100% humidity. A breakdown of the primary ventilation system airflow rates for DST farms is provided in Table B2-10.

The annulus ventilation system can be used for both cooling and leak detection.

Instrumentation for both primary and annulus ventilation systems is abovegrade and is located at the exhaust unit or in the instrument building. All primary ventilation, instrumentation, duct work drains, and seal pots are protected from freezing weather. Shielding is provided for the demister, preheater, and filter assembly of each primary tank system.

B2.4.3.7.1 241-AY and 241-AZ (Aging Waste Facility) Tank Farm Ventilation Systems.

B2.4.3.7.1.1 241-AZ-702 Primary Ventilation System. See Addendum 3 for description of the primary tank ventilation system for the Aging Waste Facility.

B2.4.3.7.1.2 241-A-702 Primary Ventilation System. The 241-A-702 Primary Ventilation System (Figure B2-20) has been isolated. This system previously provided primary tank ventilation for the four aging waste facility (AWF) tanks (241-AY-101, 241-AY-102, 241-AZ-101, and 241-AZ-102) and for the 241-AX-152 diverter station. Several other miscellaneous structures (e.g., the 241-AZ-151 and 241-AZ-154 catch tanks) were ventilated indirectly through waste transfer lines. A backup ventilation system (Figure B2-20) was available when necessary. Table B2-10 provides summary information on the AWF ventilation systems.

The primary ventilation system was designed specifically for PUREX-generated aging waste (or boiling waste), which is exceptionally "hot," both thermally and radiologically.

The headspace in the AWF tanks contains water vapor and entrained radioactive particulate matter generated by the stored waste. These vapors mix with air from operating air lift circulators, instrument air purges, and direct atmospheric inleakage through pit cover blocks and risers. Vapor can also be generated by radiolytic heat converting water to steam and by natural convection currents from thermal gradients. In addition to providing a confinement function, this system maintained the temperature of the liquid in the tanks by removing heat released through such vaporization processes.

241-A-702 Ventilation System Operation. Air is introduced into an AWF tank headspace through air lift circulators and air purge instruments. Also, outside air is drawn into the tank through pit cover blocks and risers due to the vacuum created by the exhaust blower. Two 1,899 L/s (4,000-cfm) exhausters (blowers) operate one at a time to draw the gases through an extensive particle and condensate removal system before discharging the gases to the atmosphere. Vapor is exhausted through a single 508-mm- (20-in.-) dia duct on each AWF tank and continues through individual tank-seal loops to a common 610-mm (24-in.) vent header.

The vapor stream proceeds through a section of 0.46-m- (1.5-ft-) dia steel pipe before passing through the 0.6-m- (2-ft-) dia seal loop to the K1-5-1 deentrainer. After passing through the K1-5-1 deentrainer, the vapor stream continues along the vent header through the vent header extension seal loop and enters the hot-pipe gallery of the 241-A-401 Surface Condenser Building. Three condensers (two in operation at a time) for removing moisture from the exhaust system are located in this building. The offgases from the three surface condensers are vented through a second deentrainer (K1-5-2A) before entering the 241-A-702 Ventilation Building.

The vapor stream then continues into the K1-3-1 steam heater housing (not in service) before reaching the filter banks. The ventilation ducts routed from the K1-3-1 steam heater housing extend through the floor of the filter side of 241-A-702 and exit through a wall on the blower side of

241-A-702 Building into a common 0.2 m^2 (2 ft^2) plenum that feeds one of the two 241-A-702 exhaust blowers. Twelve HEPA filters, in six banks, simultaneously filter the exhaust air flowing through the 241-A-702 Primary Ventilation System.

After filtration, the vapor stream from each set of filters enters a plenum and then passes through one of two 0.41-m- (1.33-ft-) dia stainless steel ducts, depending upon which blower is operating. Vapor is discharged by the blower into the atmosphere via the 0.46-m- (1.5-ft-) dia stainless steel exhaust stack. To control the volume of air being drawn off the tanks, a portion of the exhaust vapor is recirculated from the stack to the plenum through a manually controlled butterfly valve. This modification eliminated the need to replace (downsize) the blowers when two SST farms (241-A and 241-AX) were removed from the system. A CAM monitors effluent radioactivity levels, and a record sampler collects representative samples before the vapor stream is discharged to the atmosphere.

Two 203-mm (8-in.) cross-tie valves are located in a caisson near each tank. The primary purpose of these cross-ties is to allow the primary ventilation system to ventilate the annuli of the tanks. The vent system transfer can be performed by opening the two manual cross-tie valves in the caisson located near the desired tank. These valves connect the primary ventilation piping to the associated annulus downstream of each primary tank.

The 241-A-702 Backup Ventilation System confines radioactivity when the 241-A-702 system is shut down, for example, when K1-1-1 and K1-1-2 exhaust fans are shut down. Manual shutdown of 241-A-702 Primary Ventilation System caused by a verified exhaust high-radiation alarm will also require operation of the backup exhauster (Figure B2-20).

Additionally, should both 241-A-702 primary blowers fail to provide the required 0.37 kPa (1.5-in. water gauge [WG]) vacuum (as measured by the K1-5-1 deentrainer inlet vacuum gauge) for the AWF tanks, the backup exhauster has a sequencing system designed to start automatically.

During backup exhauster operation, vapor is drawn through the butterfly valve and into the plenum of the exhauster system by a centrifugal exhaust blower. The vapor continues through a heater, which is capable of raising the temperature of saturated vapor. The heated vapor stream passes through two banks of four HEPA filters each and then out the stack, which is equipped with a CAM.

B2.4.3.7.1.3 241-AZ and 241-AY (Aging Waste Facility) Annulus Ventilation Systems. Each of the 241-AY AWF tanks has its own annulus ventilation system. The 241-AZ Annulus Ventilation System is similar in function and design except that AZ tanks are served by a common annulus ventilation system and share an annulus exhauster. To prevent contamination of the annulus should a leak path develop between the annulus and the primary tank headspace, the controls maintain a positive pressure in the annulus with respect to the primary tank headspace pressure. The following describes the 241-AY Annulus Ventilation System, which is depicted in Figure B2-21.

The exhaust fan draws outside air into each ventilation unit through louver inlets. To prevent frost damage to the supply filters, radiant heaters

are mounted inside each louver inlet. The air is then filtered through banks of HEPA filters. The filtered air continues through a supply air heater before entering the annulus. The air then passes through a manual butterfly valve and into the annular space via underground duct work. The air is distributed between the side of the annulus and a central air distribution chamber below the primary tank. An exception to this configuration is the system on Tank 241-AY-102, which has been modified to distribute air only to the central air distribution chamber below the tank (refer to Addendum 1). Exhaust air is then drawn out of the annulus through ducts that merge into a common underground duct, called the vent header. One vent header from each tank rises aboveground to a separate HEPA filter housing for each tank. As the air exits the header, a vacuum pump extracts an air sample and feeds it to a CAM. The exhaust air continues through an automatically controlled electric heater. The air then passes through another manual butterfly valve and through two filter housings, each containing four HEPA filters. The HEPA filters are aerosol tested annually to ensure that 99.95% efficiency is maintained. Filtered air exits the ventilation system through the exhaust blower and stack and is released to the environment.

B2.4.3.7.2 241-AN, 241-AP, 241-AW, and 241-SY Tank Farm Ventilation Systems. The primary ventilation systems for DST farms 241-AN, 241-AP, and 241-AW are essentially identical (Figure B2-22). The only differences among these systems are in blower capacities and resulting tank airflow rates and in the efficiency rating of prefilters. The primary tank ventilation system filters and removes moisture from tank exhaust vapor before the vapor is discharged to the atmosphere. The primary ventilation system for 241-SY Tank Farm is slightly different from that of the other three tank farms and is addressed following the main ventilation discussion. In the discussion of the annulus ventilation system, the systems for 241-AN and 241-AW tank farms are discussed together because they are very similar; the annulus ventilation systems for the 241-AP and 241-SY tank farms are then discussed in turn.

Primary Tank Ventilation System. The primary ventilation system for all four tank farms is a dual system. Under normal operating conditions, only one of the dual systems operates at a time. The other unit provides backup support in case of equipment failure or HEPA filter changes.

Outside air is drawn into the tank through inlet filters, or pit cover blocks, or risers due to the vacuum created by the exhaust blower. Also, air is introduced into the tank headspace through operating air lift circulators (241-AW-102) and air purge instruments. Air is drawn out of the tank through a 305-mm- (12-in.-) dia duct and into a belowgrade exhaust header. Primary tank exhaust ducts have air volume control butterfly valves located in vent pits. After leaving the ventilation pits, exhaust ducts combine into one 406-mm- (16-in.-) dia duct. The exhaust header terminates at the primary K1 exhauster unit located on the primary ventilation pad.

At the primary ventilation pad, the air initially passes through a demister consisting of a wire-mesh pad that separates heavy moisture particles from the airstream and then through one of two motor-operated valves. Valve positions are controlled automatically by differential pressure switches that measure differential pressure across the blowers. The air then passes through an electric heater, which vaporizes the remaining moisture.

The dry, heated air is prefiltered to remove particulates. Next, two HEPA filters mounted in series remove particulates as small as 0.3 μ with at least 99.95% efficiency. Smaller particles can be trapped by the filter, but the filter is not rated for any particle smaller than 0.3 μ. Two differential pressure indicators across the HEPA filters monitor operating conditions. Low differential pressure indicates low air flow or a failed filter. High differential pressure indicates blockage caused by accumulated solids or possibly ice formation on the filters.

After passing through the filters, the air is drawn through a K1 blower and exhausted out the K1 stack. A CAM monitors effluent radioactivity levels and a record sampler collects representative samples before the air is discharged to the atmosphere. If an exhaust fan in the operating system fails, the backup ventilation system blower starts automatically. Under normal operating conditions, one of the K1 demisters is valved in and the opposite demister is valved out.

The 241-SY Ventilation System is entirely abovegrade. All 241-SY DSTs receive air through dual HEPA filter inlets. The airflow exhausted from each tank to the primary ventilation system is combined into a 0.3-m- (1-ft-) dia duct and then routed to either the normal exhauster train or the backup portable exhauster train. The normal exhauster train consists of a demister, a prefilter, two HEPA filter housings, a fan, a flow meter, and an exhaust stack. The normal exhauster fan is designed to handle an airflow rate of 330 L/s (700 cfm). The backup exhauster train also consists of a demister, a prefilter, two HEPA filter housings, a fan, and an exhaust stack. The backup exhauster is designed to handle an airflow rate of 472 L/s (1,000 cfm) and must be started manually.

Annulus Ventilation System. The annulus ventilation systems for DST farms 241-AN and 241-AW are very similar (Figure B2-23). The air intake to the annulus of each tank is designed for 378 L/s (800 cfm), and the air is routed through a 35%-efficiency prefilter and a nontestable, self-contained HEPA filter before being supplied to the annulus air distribution channels of each tank. The airflow exhausted from the annulus of each tank is combined and then routed through the two exhaust trains, each of which consists of a demister, an electric heater, two HEPA filter housings, and a fan, before being exhausted from a stack to the atmosphere. The annulus ventilation systems for DST farms 241-AN and 241-AW are designed to handle approximately total airflow rates of 2,891 L/s (6,125 cfm) and 2,478 L/s (5,250 cfm), respectively.

The 241-AP Annulus Ventilation System is similar to that of 241-AN with some differences (Figure B2-23). For example, the air intake to the annulus of each tank has a capacity of 507 L/s (1,075 cfm) as compared with 401 L/s (850 cfm) for the 241-AN system. To prevent ice formation on the filters, the 241-AP annulus air intake includes a heater to warm the incoming air. The air then passes through a 35%-efficiency prefilter and a HEPA filter before being supplied to the annulus air distribution channels of each tank. The airflow exhausted from the annulus of each tank is combined and then routed through one of two exhaust trains before being exhausted from a stack to the atmosphere. Each train consists of an electric heater, two HEPA filter housings, and a blower. The blower is designed to provide a total airflow rate of 4,060 L/s (8,600 cfm) through the annulus system.

The entire annulus ventilation system for the 241-SY Tank Farm is abovegrade. Air intakes to the annulus of each tank are designed for a total of 94.4 L/s (200 cfm). Intake air originates from four intake stations per tank. Each station consists of two cylindrical filter housings. These intakes are routed to the air distribution channels of each tank. Another intake, which has a single cylindrical filter housing, is routed directly into the annulus vent space. This additional intake is typically isolated from the tank annulus. The airflow exhausted from the annulus of each tank is combined and then routed through a single exhaust train before being exhausted from a stack to the atmosphere. The exhaust train consists of a moisture eliminator, a prefilter, two HEPA filter housings, and a blower. The blower is designed to provide a total airflow rate of 354 L/s (750 cfm) through the annulus system.

B2.4.4 Specific Structures and Systems of Double-Shell Tanks

In the following sections, each of the DST farms is discussed in order of construction date from earliest to latest. All DSTs are actively ventilated, and tank design is summarized in Table B2-9. The codes and standards used to design and construct the DSTs are provided in WHC-SD-TWR-RPT-002. Major systems, facilities, or structures within the tank farm, as well as system status and operability, are identified in WHC-SD-WM-HIE-007.

B2.4.4.1 200 East Area Double-Shell Tanks. The following sections describe the five tank farms located in 200 East Area.

B2.4.4.1.1 241-AY and 241-AZ Tank Farms (Aging Waste Facility). The AWF, located northeast of the PUREX Facility, was constructed between 1968 and 1977. The AWF tank farms (241-AY and 241-AZ) consist of four tanks (241-AY-101, 241-AY-102, 241-AZ-101, and 241-AZ-102) each of which can hold 3.8 million L (1 million gal). The tanks, with the exception of 241-AY-102, received aging waste from the PUREX Facility. All tanks have received other process wastes.

The two 241-AY tanks are located southwest of the 241-AZ tanks on the western fringe of the 241-A Tank Farm. The two 241-AZ tanks are located in the northernmost fringe of the 241-A Tank Farm. Instrument buildings, located between the tanks of the 241-AY and 241-AZ Tank Farms, house process control piping and instrumentation. Various process pits and caissons contain the valves, meters, transmitters, and connectors required for waste transfer and tank control. Local exhausters (two in the 241-AY Tank Farm and one in the 241-AZ Tank Farm) maintain a negative pressure on the AWF tank annular spaces. The systems and supporting structures within the AWF complex are listed in WHC-SD-WM-HIE-007.

The tank design used in the AWF tank farms reflects a departure from the basic design used in all previous tanks. This design features a heat-treated, stress-relieved primary steel liner and a nonstress-relieved outer steel liner, both inside a reinforced concrete shell.

The AWF tanks are the only DSTs in which process pipelines penetrate the sides of the tanks. Special temperature and radiation shielding is required

because the tank farms received and handled PUREX process waste. A unique ventilation system capable of handling moist air is also required. Each 241-AY tank has its own annulus ventilation systems. The 241-AZ tanks share a common annulus ventilation system.

The AWF tanks also differ from other DSTs, such as others in 200 East Area, by the addition of systems that allowed the tanks to receive and store high heat-generating wastes. These additional systems consist of air lift circulators (currently operating in 102-AZ), steam coils (currently inactive), and exhaust condensers. An AWF tank with air lift circulators and steam coils is depicted in Figure B2-24.

To prevent temperature excursions caused by excessive settling of heat-generating fission products, air lift circulators in each tank gently agitate the tank contents by forcing air into the liquid waste except for Tank 241-AY-102 for WRSS (Addendum 1). Each AWF tank is equipped with 22 air lift circulators. Circulator 1 is located at the tank center axis, circulators 2 through 8 are equally spaced around a radius of 4.4 m (14.5 ft), and circulators 9 through 22 are equally spaced around a radius of 8.2 m (27 ft). Air lift circulators 1, 9, 12, 16, and 19 are 5.2 m (17 ft) long and require a solution volume of about 2,460,000 L (650,000 gal) for total submergence. The remaining 17 circulators are 6.7 m (22 ft) long and require a solution volume of 3,220,000 L (850,000 gal) for total submergence. The air lift circulators installed in the AWF tanks are shown in Figure B2-24.

Steam coils have been installed in each of the AWF tanks but are currently not in use and steam has been blanked off. The coils were used initially to heat the tank contents and to either maintain a standby temperature or obtain a desired boil off rate. The coils are constructed of Schedule 40 carbon steel tubing; the diameter of the outer coil is about 1.0 m (40 in.). The overall length of the coil assembly is 17 m (55 ft) in the 241-AY tanks and 16.56 m (54.33 ft) in the 241-AZ tanks. The coil portion of the assembly is approximately 7 m (23 ft) long. A steam coil is shown in Figure B2-24.

The exhaust condenser system, which is part of the 241-AZ-702 Ventilation System, is described in Addendum 3 (Section B2.4.3.7.1.1).

B2.4.4.1.2 241-AW Tank Farm. The 241-AW Tank Farm, located south of the 242-A Evaporator and constructed from 1978 to 1980, comprises six 4.4 million-L (1.16 million-gal) DSTs. The farm, which stores low-heat radioactive liquid waste generated by the PUREX Facility, is an integrated facility that has dedicated ventilation equipment (Section B2.4.3.7.2).

Tank 241-AW-102 is the feed tank for the 242-A Evaporator and is used for all waste concentration operations. Any waste designated for concentration is pumped to feed Tank 241-AW-102 for transfer to the 242-A Evaporator. Tank 241-AW-101 was constructed as an alternative feed tank to the 242-A Evaporator.

In addition to the central pump pit, annulus pump pit, and leak detection pit, which are associated with all 241-AW tanks, Tank 241-AW-102 has a feed pump pit and drain pit. Tank 241-AW-102 also has two air lift circulators for mixing tank contents to provide a uniform feed to the 242-A Evaporator and a

dip tube assembly installed to read specific gravity. Cladding removal waste is initially stored in Tanks 241-AW-103 and 241-AW-105. Solvent extraction wash waste and miscellaneous sump waste are stored in Tank 241-AW-104. The systems and supporting structures for the 241-AW Tank Farm are listed in WHC-SD-WM-HIE-007.

B2.4.4.1.3 241-AN Tank Farm. The 241-AN Tank Farm, located north of the 241-AZ Tank Farm and constructed in 1980-1981, comprises seven 4.4 million-L (1.16 million-gal) DSTs. The tanks are essentially identical except that one tank (241-AN-101) has two additional concrete process pits, and another tank (241-AN-107) has 80 risers because of the 21 air lift circulator assemblies installed in the tank to gently agitate the waste. (The air lift circulators, however, are currently out of service.) The tanks are designed to store double-shell slurry produced at the 242-A Evaporator. (Double-shell slurry exceeds the sodium aluminate saturation boundary in the evaporator without exceeding the receiving tank composition limits.) The systems and supporting structures within the 241-AN Tank Farm are listed in WHC-SD-WM-HIE-007.

B2.4.4.1.4 241-AP Tank Farm. The 241-AP Tank Farm is the most recently constructed (1983 to 1986) and comprises eight DSTs and associated facilities located southeast of the 242-A Evaporator. Each tank can hold 4.4 million L (1.16 million gal). The 241-AP Tank Farm is designed to operate similarly to the 241-AW Tank Farm. Low-heat radioactive liquid wastes are transferred to or from the 241-AP Tank Farm via 241-AW Tank Farm facilities. The systems and supporting structures within the 241-AP Tank Farm are listed in WHC-SD-WM-HIE-007. Tank 241-AP-102 was identified as the Grout Treatment Facility feed tank and contains a mixer pump originally installed to support grout operations.

B2.4.4.2 200 West Area Double-Shell Tanks. Only one DST farm, 241-SY, is located in the 200 West Area. This tank farm was constructed from 1973 to 1976 and consists of three tanks, each of which can hold 4.4 million L (1.16 million gal). These tanks have received various wastes from various operations and facilities in the 200 East and 200 West Areas. Tank 241-SY-101 was used as a double-shell slurry holding tank for the 242-S Evaporator. A mixer pump and monitoring and control systems have been added. Tank 241-SY-102 receives waste generated by 200 West Area SSTs and other 200 West Area facilities (e.g., T Plant and 222-S Laboratory). This tank was the feed tank for the 242-S Evaporator and serves as a cross-site tie for transfers between the 200 East and 200 West Areas. Tank 241-SY-103 was used to store high-strontium concentrated liquor. The systems and supporting structures within the 241-SY Tank Farm are listed in WHC-SD-WM-HIE-007.

B2.4.5 Other Underground Waste Storage Tanks

The following sections discuss the catch tanks, DCRTs, and associated ventilation systems, and inactive miscellaneous underground storage tanks.

B2.4.5.1 Catch Tanks and Double-Contained Receiver Tanks. Catch tanks (discussed in Section B2.4.5.1.2) are buried, underground storage tanks that collect small amounts of waste drained from waste transfer systems and DST

equipment. A DCRT (discussed in Section B2.4.5.1.3), together with its related equipment, is an interim short-term storage facility for liquid waste and a valve pit for waste transfer operations. DCRTs are sometimes referred to as lift stations or catch stations.

B2.4.5.1.1 Ventilation Systems. The three types of ventilation systems in use at TWRS are active systems (i.e., with an exhaust fan), shared (i.e., connected via a line with an operating exhaust system), and passive (i.e., breather filter assembly). The following catch tanks have no HEPA filtration systems: 241-A-302-A, 241-TX-302-C, 241-U-301-B, 241-UX-302-A, and 241-ER-311.

Active Ventilation Systems. No active ventilation systems are associated with catch tanks. Thus, only those active systems associated with the DCRTs are discussed in the following paragraphs and summarized in Table B2-11.

- **244-A DCRT**—The ventilation system for the 244-A DCRT is installed vertically in the filter pit. Associated instrument readout and alarm panels are located in the 242-A Evaporator control room.

  The receiver tank, the pump and filter pits, and the tank vault annulus are vented through a single exhaust system. The filter pit contains tank and annulus air ventilation and filtering equipment. Outside air at 47.2 L/s (100 cfm) enters the DCRT annulus through an air intake equipped with an electric heater, prefilter (roughing filter), and single-stage HEPA filter.

  An exhaust fan provides ventilation air flow through the DCRT vault, receiver tank (or both vault and receiver tank) and filters. The vault and receiver air streams flow through one of two parallel HEPA filter banks in the filter pit, and then join into a single line. After passing through the filters and fan, the air stream is exhausted out a short stack to the atmosphere. Detectors equipped with sample probes and located in the exhaust stack continuously monitor and sample the exhaust air. The stack exhaust fan shuts off automatically if alpha or beta-gamma monitoring capabilities are lost.

  A pressure gauge on the intake exhaust duct measures the annulus air pressure relative to ambient atmospheric pressure. Differential pressure indicators installed in the HEPA filter banks provide pressure-drop data. High differential pressure across the prefilter and the first of two HEPA filters in each bank causes an alarm to sound in the 242-A Evaporator control room. Low differential pressure across the final HEPA filter in each bank automatically shuts down the exhaust fan and sounds a local alarm. A pressure indicator monitors air flow through the stack and stack sampler.

- **244-BX DCRT**—The ventilation system for 244-BX DCRT is similar (but not identical) to the 244-A Ventilation System. The ventilation system in 244-BX is installed horizontally in the filter pit with three banks of HEPA filters. Instrument readout and alarm panels are located in the 241-BY-254 Building.

At 244-BX, the air from the receiver tank and the vault is vented through a single exhaust system. Outside air is drawn through an air heater, a prefilter, and one HEPA filter at a flow rate of 59 L/s (125 cfm) into the annulus. Because no provision is made to provide filtered air to the tank, fresh air normally seeps in through risers and transfer lines.

An exhaust fan provides ventilation air flow through the DCRT vault, receiver tank (or both vault and receiver tank), and filters. The vault and receiver air streams flow through two of the three parallel HEPA filter banks in the filter pit, and then join into a single line. After passing through the filters and fan, the air stream is exhausted out a short stack to the atmosphere. Detectors equipped with sample probes and located in the exhaust stack continuously monitor and sample the exhaust air. The stack exhaust fan shuts off automatically if beta-gamma monitoring capabilities are lost.

A pressure gauge installed on the intake exhaust duct measures the annulus air pressure relative to ambient atmospheric pressure. Differential pressure indicators installed in the HEPA filter banks provide pressure drop data banks. High differential pressure across the prefilter and the first of two HEPA filters in each bank sound an alarm in the 241-BY-254 Building. Low differential pressure across the final HEPA filter in each bank automatically shuts down the exhaust fan and sounds a local alarm. A pressure indicator monitors air flow through the stack and stack sampler.

- **244-CR DCRT**—The ventilation system for 244-CR DCRT is similar to the ventilation system for 244-BX DCRT. Alarm panels are located in the 271-CR control room.

- **244-S DCRT**—The ventilation system for 244-S DCRT is identical to the ventilation system for 244-A DCRT (see the 244-A DCRT discussion). The 244-S DCRT instrument readout is located in the 244-S DCRT Instrument Building.

- **244-TX DCRT**—The ventilation system for 244-TX DCRT is identical to the ventilation system for 244-BX DCRT. Alarm panels are located in the 244-TX Building and 242-T Evaporator control room.

- **244-U DCRT**—The ventilation system in the 244-U DCRT is installed horizontally in the filter pit with three banks of HEPA filters. The instrument readout and alarm panels are located in the 244-U Instrument Building and the 241-U-271 Control Room.

  In this system, the air from the receiver tank and the vault is vented through a single exhaust system. The exhaust fan draws air from both the tank and the annulus on a common header at a flow rate of 59 to 118 L/s (125 to 250 cfm). The flow rate is measured by a self-averaging pitot-type device mounted in the stack. The relative air distribution drawn from the tank and annulus is regulated so that the tank pressure is slightly negative with respect to the annulus.

The DCRT vault, receiver tank, and filter pit exhaust air is drawn through a roughing filter, heater, and two of the three parallel HEPA filter banks in the filter pit. Detectors equipped with sample probes and located in the exhaust stack continuously monitor and sample the exhaust air after it is drawn through the filters. The stack exhaust fan shuts off automatically and isolates the DCRT vault from the filter banks if alpha or beta-gamma monitoring capabilities are lost.

A pressure gauge installed on the intake exhaust duct measures the annulus air pressure relative to ambient atmospheric pressure. Differential pressure indicators installed across the HEPA filter banks provide pressure-drop data. High differential pressure across the prefilter and the first of two HEPA filters in each bank sound an alarm in the 244-U Instrument Building and the 241-U-271 Control Room. Low differential pressure across the final HEPA filter in each bank automatically shuts down the exhaust fan and sounds a local alarm. A pressure indicator monitors air flow through the stack and stack sampler.

Shared Ventilation Systems. One catch tank has a shared ventilation system.

- **241-AX-152 Catch Tank**—The 241-AX-152 catch tank is connected to the 241-AZ-702 ventilation system (Section B2.4.3.7.1) via a ventilation line.

Passive Ventilation Systems. The ventilation systems for the following catch tanks and DCRTs consist of a breather filter similar to the breather filter assemblies on SSTs (described in Section B2.A.3.7, "Ventilation Systems"):

- 241-A-350 DCRT
- 241-A-417 catch tank
- 241-EW-151 DCRT
- 241-S-304 catch tank.

B2.4.5.1.2 Specific Systems and Structures of Catch Tanks. Catch tanks are underground storage tanks used to collect small amounts of waste drained from waste transfer systems and DST equipment. The four basic catch tank designs (Figures B2-25 and B2-26) are (1) direct buried, concrete; (2) direct buried, steel; (3) steel tanks contained in a vault or pit; and (4) concrete vaults with steel liner. The first three designs are shown in Figures B2-25 and B2-26. The catch tanks are ventilated by using a passive ventilation system. The active catch tanks and their dimensions and other attributes are listed in Tables B2-12, B2-13, and B2-14.

Catch tanks can be emptied to a DST via a diversion box through an underground pump-out line. In most instances, a submersible pump is installed in the catch tank to remove liquid; however, in some instances, steam and water jets are also used. When necessary, catch tanks are pumped out by using

aboveground lines and a tank truck. With the exception of 241-U-301-B, all catch tanks are connected to a diversion box via a permanent, underground pump-out line.

200 East Area Catch Tanks. The catch tanks located in the 200 East Area are described in the following paragraphs.

- **241-A-302A Catch Tank**—This 31,940-L (8,438-gal) catch tank is a horizontal cylindrical vessel. A pump pit is located above the tank, which is approximately 5.2 m (17 ft) belowgrade and rests on a sand bed. The catch tank is not actively ventilated. This catch tank is connected to diversion box 241-A-151 and can be pumped out via an encased line to the diversion box.

- **241-A-350 Catch Tank**—The 241-A-350 lift station is located southeast of Tank 241-A-106 in the 241-A Tank Farm. The lift station has a pump pit over a caisson, or vault that contains the catch Tank 241-A-350. The 2,940-L (776-gal) catch tank receives drainage from the 241-A-A and 241-A-B valve pits and, when needed, steam condensate from the 207-A basin. It also provides for routing 207-A basin waste (if out of specification) to Tank 241-AW-102. A waste transfer pump is contained within Tank 241-A-350. The sump within this lift station also contains one pump that pumps sump liquid back to Tank 241-A-350.

- **241-A-417 Catch Tank**—This 167,315-L (44,200-gal) catch tank is a cylindrical concrete vault with an all-welded steel liner that extends to within 127 mm (5 in.) of the vault roof. Above the catch tank are a rectangular pump pit and a rectangular valve pit. The vault/catch tank is approximately 4.3 m (14 ft) belowgrade.

- **241-AX-152 Catch Tank**—This 41,640-L (11,000-gal) catch tank, which is constructed of reinforced concrete and stainless steel-lined walls is approximately 5.2 m (17 ft) belowgrade. Above the catch tank are a rectangular pump pit and a rectangular diverter pit. This catch tank is connected to diverter station 241-AX-152 and equipped with a water jet for moving accumulated waste solutions to an underground storage tank.

- **241-AZ-151 Catch Tank**—This 45,046-L (11,900-gal) catch tank, which consists of a pump pit on top of a catch tank, is buried approximately 5.2 m (17 ft) belowgrade. The 241-AZ-151 catch tank is L-shaped. All inside surfaces of the catch tank are lined with ASTM A 569, 10-gauge steel. This catch tank is connected to diversion box 241-AZ-152.

- **241-AZ-154 Catch Tank** (out of service)—This 3,290-L (869-gal) catch tank consists of a pump pit equipped with a pump and located on top of a steel-lined, reinforced-concrete catch tank. The catch tank is 3.4 m (11 ft) belowgrade and is connected to 241-AZ-101 and 241-AZ-102.

- **241-ER-311 Catch Tank**—This 66,934-L (17,682-gal) catch tank consists of a horizontal, cylindrical carbon steel vessel; a steam jet box resting on the tank, and a pump pit above the tank. The catch tank is 6.1 m (20 ft) belowgrade and rests on a sand bed. The catch tank is connected to diversion boxes 241-ER-151 and 241-ER-152. Catch Tank 241-ER-311 can be pumped out by means of an unencased line buried directly in the soil (direct-buried line) to diversion box 241-ER-151.

200 West Area Catch Tanks. The catch tanks located in the 200 West Area are described in the following paragraphs.

- **241-S-304 Catch Tank**—This 23,850-L (6,300-gal) catch tank, which consists of a pump pit on top of a vertically positioned steel tank, is 7.9 m (26 ft) belowgrade. The catch tank is connected to diversion box 241-S-151.

- **241-TX-302C Catch Tank**—This 66,930-L (17,681-gal) catch tank, which consists of a horizontal, cylindrical vessel, a steam jet box resting on the tank, and a pump pit above the tank, is approximately 8.8 m (29 ft) belowgrade and rests on a sand bed. This catch tank is connected to the 241-TX-154 diversion box. Catch Tank 241-TX-302C can be pumped out via a direct-buried line to the diversion box.

- **241-U-301B Catch Tank**—The 241-U-301B structure consists of a 133,530-L (35,275-gal) catch tank and a pump pit directly above the catch tank, which is approximately 1.8 m (6 ft) belowgrade. The catch tank is an unlined, reinforced concrete tank connected to diversion boxes 241-U-151 and 241-U-152. This catch tank can be pumped out by means of a direct-buried line to the 244-U DCRT, or through an aboveground line and tank truck.

- **241-UX-302-A Catch Tank**—This 66,934-L (17,682-gal) catch tank is connected to diversion box 241-UX-154. A pump pit is located above the tank, which is approximately 6.1 m (20 ft) belowgrade and rests on a sand bed. The catch tank is not actively ventilated. Catch Tank 241-UX-302-A is located near the 241-UX-154 diversion box and can be pumped out via a direct-buried line to the diversion box.

600 Area Catch Tanks. The catch tank located in the 600 Area is described in the following paragraph.

- **241-EW-151 Catch Tank**—A 2,940-L (776-gal) catch tank is provided to collect liquids that might enter the cross-site transfer vent lines. The catch tank and sump-overflow to the cross-site transfer pipeline encasement and then drain to the catch tanks in 241-UX-154 and 241-ER-151. One transfer pump is provided in catch Tank 241-EW-151 so that liquids can be transferred from the catch tank.

B2.4.5.1.3 Specific Systems and Structures of Double-Contained Receiver Tanks. A DCRT, together with its related equipment, is a short-term storage facility for liquid waste and a valve pit for waste transfer operations. A DCRT typically consists of an underground concrete structure that contains a

filter pit, pump pit, and vault in which a catch tank is installed. The active DCRTs are depicted in Figures B2-27 and B2-28 and listed in Table B2-15.

200 East Area Double-Contained Receiver Tanks. The DCRTs located in the 200 East Area are described in the following paragraphs.

- **244-A DCRT**—The 244-A DCRT (Figure B2-27) is located west of the 241-AN Tank Farm. The 244-A DCRT is similar in design to the 244-S DCRT. The DCRT consists of an underground concrete structure that contains a filter pit, a pump pit, and a vault. The vertically mounted carbon steel receiver tank is located in a steel-lined vault and has a total capacity of 61,627 L (16,280 gal).

  The 244-A DCRT is located at a low point in the transfer system. A transfer pump is used to "lift" the transferred liquids. One waste transfer pump is located inside the receiver tank (TK-244-A). This DCRT is an intermediate facility between diversion box 241-ER-153 and valve pits 241-A-A and 241-A-B.

- **244-BX DCRT**—The 244-BX DCRT catch station is located east of Tank 241-BX-102 within the 241-BX Tank Farm. The rectangular 244-BX DCRT catch station is fabricated of reinforced concrete. The DCRT catch station consists of a tank vault, a pump pit, and a filter pit (Figure B2-27). An instrument building is adjacent to the catch station. The top of the vault is closed with cover blocks that are removed to allow access to the pump and filter pits.

  The 117,350-L (31,000-gal) receiver tank (TK-244-BX) is located in the tank vault. A waste transfer pump is located inside the receiver tank, and a pump can be located in the vault sump. This catch station is connected to the 241-B, 241-BX, and 241-BY Tank Farms.

- **244-CR DCRT**—The 244-CR vault is located south of the 241-C Tank Farm. The 56,781-L (15,000-gal), 347-type stainless steel receiver tank (244-CR-003) is used for short-term storage of salt well waste from the 241-C Tank Farm. The 244-CR vault is a two-level, multicell structure constructed belowgrade (Figure B2-27). The lower cell contains the process tanks and the upper cells contain piping and equipment. The vault structure is covered by concrete cover blocks that are removed to permit access to the piping and equipment cells. One waste transfer pump is located inside Tank 244-CR-003. Tanks 244-CR-001 (151,400 L [40,000 gal]), 244-CR-002 (56,781 L [15,000 gal]), and 244-CR-011 (151,400 L [40,000 gal]), which are internal to the vault, are inactive.

200 West Area Double-Contained Receiver Tanks. The DCRTs located in the 200 West Area are described in the following paragraphs and a summary list is provided in Table B2-15.

- **244-S DCRT**—The 244-S DCRT is located south of the 241-SY Tank Farm and east of 13th Street. The tank vault, which contains the 76,768-L (20,280-gal) 244-S receiver tank, mounted vertically, is

lined and separated from the pump pit above by a concrete slab perforated to permit piping and personnel access and supported on steel beams. Surface structures above the 244-S DCRT include an instrument building, an exhaust unit enclosure, an annulus unit enclosure, and an air intake structure.

Waste transfer pumps can be installed within the 244-S DCRT to remove waste from the receiver tank and vault sump. This tank is connected to the cross-site transfer system and to the 241-S, 241-SX, and 241-SY Tank Farms.

- **244-TX DCRT**—The 244-TX DCRT (Figure B2-27) is located north of the single-shell 241-TX Tank Farm. The rectangular 117,350-L (31,000-gal) 244-TX DCRT is fabricated of reinforced concrete and consists of a tank vault, a pump pit, and filter pit. The top of the vault is closed with cover blocks that are removed to allow access to the pump and filter pits. The horizontally mounted 244-TX receiver tank is fabricated of carbon steel and is located in the tank vault.

  Unlike other DCRTs, the 244-TX receiver tank is equipped with high-pressure turbine pumps to sluice and agitate the waste. These pumps keep solids suspended in the tank when plutonium-bearing waste from the Plutonium Finishing Plant is handled. In addition, three neutron monitors located beneath the tank detect plutonium buildup.

  Waste transfer pumps can be installed within the 244-TX DCRT to remove waste from the receiver tank and vault sump. Waste can be transferred from the 244-TX DCRT to the 241-SY Tank Farm via the 244-S DCRT. Waste within the 244-TX DCRT is routed through the 241-TX-152 diversion box to the 241-U-152, 241-U-151, and 241-S-151 diversion boxes. Piping enables direct routing of the waste from the 241-U-151 diversion box to the 244-S DCRT.

- **244-U DCRT**—The 117,350-L (31,000-gal) 244-U DCRT catch station (Figure B2-27) is located southeast of Tank 241-U-110 in the 241-U Tank Farm. The 244-U DCRT was constructed in 1978 and is currently being put into service to receive salt well interstitial liquid from tanks at the 241-U Tank Farm and catch Tank 241-U-301-B. The 244-U DCRT is located in a tank vault.

  Waste transfer pumps are provided in the receiver tank and the vault sump. Contents of 244-U DCRT can be routed to any of the 241-SY tanks through supernatant lines and valve pit 241-SY-B.

B2.4.5.2 Miscellaneous Inactive Storage Facilities. The miscellaneous inactive storage facilities (MISFs) may contain low- or high-level radioactive wastes or nonradioactive materials and may be located belowground or aboveground. The inactive miscellaneous underground storage facilities are typically tanks buried directly in the ground or contained with vaults. These tanks contain both radioactively contaminated (Section B2.4.5.2.1) and nonradioactively contaminated (Section B2.4.5.2.2) waste. The inactive miscellaneous aboveground storage facilities are typically tanks located on the surface or contained within inactive TWRS facilities. These tanks include

both radioactively contaminated and nonradioactively contaminated (Section B2.4.5.2.3) waste.

B2.4.5.2.1 Radioactively Contaminated Inactive Miscellaneous Underground Storage Tanks. A group of 63 small, <189,270 L (<50,000 gal), radioactively contaminated, inactive, and abandoned underground storage tanks are collectively termed the inactive miscellaneous underground storage tanks. These tanks are located throughout the 200 East and 200 West Areas, as shown in Figures B2-29 and B2-30.

Many of these abandoned tanks are buried directly in the ground; others are installed in underground vaults. Many of the tanks contain sludge and process materials. These inactive miscellaneous underground storage tanks were not designed, nor are they used, for high-level waste storage.

The tanks have been administratively divided between TWRS (36 tanks), the U.S. Department of Energy Environmental Restoration Project (24 tanks), the Plutonium Finishing Plant (1 tank), and T Plant (2 tanks) (WHC-SD-WM-PD-046, *Tank Waste Remediation System Inactive Miscellaneous Underground Storage Tanks Program Plan*, and WHC-EP-0861, *Status Report for Inactive Miscellaneous Underground Storage Tanks at Hanford Site 200 Areas*). Most of the tanks assigned to TWRS are considered ancillary components of the tank farm system.

Of the inactive miscellaneous underground storage tanks under TWRS control, 14 are located in the 200 East Area and 22 in the 200 West Area. All 36 tanks are listed in Table B2-16, together with their location and current status.

B2.4.5.2.2 Nonradioactively Contaminated Inactive Miscellaneous Underground Storage Tanks. Waste in the nonradioactively contaminated inactive underground storage tanks is not fully characterized. The nonradioactively contaminated tanks include, for example, chemical addition, fuel storage tanks, and septic tanks. Table B2-17 identifies active nonradioactively contaminated underground storage tanks. These active tanks and the contents are representative of nonradioactively contaminated inactive underground storage tanks.

B2.4.5.2.3 Radioactively and Nonradioactively Contaminated Inactive Miscellaneous Aboveground Storage Tanks. No radioactively contaminated inactive aboveground storage tanks have been identified (WHC-SD-WM-HIE-007). The inactive miscellaneous aboveground storage facilities are similar to tanks found in industry. Waste in the nonradioactively and radioactively contaminated aboveground tanks is not fully characterized. As documented in WHC-SD-WM-HIE-007, the nonradioactive aboveground tanks were used for chemical addition, fuel storage, sodium storage, and air receivers. These tanks are located in or in close proximity to a tank farm or located within inactive TWRS facilities.

B2.4.6 204-AR Waste Unloading Facility

The 204-AR Waste Unloading Facility, located south of the 244-AR Vault and west of the 241-AX Tank Farm, permits rail tank cars or tank trailers carrying liquid radioactive waste to be received into a fully enclosed,

heated, and ventilated building. This versatile facility not only allows tank cars and tank trailers to be pumped out to a designated 200 East Area tank farm, but also allows chemical adjustment and sluicing of tank cars to remove sludge.

Completed in 1981, the 204-AR Waste Unloading Facility (Figure B2-31) is a reinforced concrete structure approximately 20 m (64 ft) long by 12 m (40 ft) wide by 7.77 m (25.5 ft) high. The facility is divided into three major areas:

- Rail tank car unloading canyon (located on the first floor) containing transfer pumps, process piping, remotely operated valves, and a catch tank (located belowgrade)
- Mechanical equipment room (located on the first floor) containing chemical storage and makeup tanks, motor control center, ventilation system, and fire system
- Control room and personnel facilities (located on the second floor).

The air compressor is located in a small prefabricated steel building (Building 209-A) near the northwest corner of the facility. The following sections provide more details on the major areas of the 204-AR Waste Unloading Facility.

B2.4.6.1 First Floor. The first floor of the 204-AR Waste Unloading Facility is approximately 19 m (62 ft) long, 12 m (38 ft) wide, and 7.3 m (24 ft) high (Figure B2-32). The first floor is divided into two process areas: the railcar unloading canyon and the mechanical equipment room.

B2.4.6.1.1 Rail Tank Car Unloading Canyon. The shielded rail tank car unloading canyon is approximately 19 m (62 ft) long, 5.5 m (18 ft) wide, and 7.3 m (24 ft) high. The concrete shielding walls are approximately 0.6 m (2 ft) thick at the base and 0.3 m (1 ft) thick at the top. An additional concrete wall [approximately 5.5 m (18 ft) long by 3.7 m (12 ft) high] at the east end of the canyon shields personnel from the tank car during tank pumping activities. Three drains in the floor of the canyon are routed to the catch tank. Railcars or tank trailers enter the west end of the canyon through a roll-up door and a pair of hinged doors in an arrangement similar to an air lock.

Two radiation probes are located in the tank car unloading area, one on the balcony, and the other on the main floor. These probes, which warn of high radiation fields, are single-channel gamma monitoring units with local readouts as well as audible and visual alarms, both at the instrument and in the 204-AR control room.

Catch Tank. Tank TK-1 is a 5,678-L (1,500-gal), stainless steel catch tank for temporarily storing process solutions flowing through the floor drain system. The tank is located beneath the floor of the unloading area in a stainless steel-lined pit containing a sump. The pit is covered with a removable steel grating. The catch tank is equipped with liquid-level instrumentation, an overflow line that drains to the sump in the pit, inlet

connections for the drain lines and decontamination solution, and a pump-out line. The bottom of the catch tank slopes toward the pump-out line.

The catch tank is vented to the ventilation exhaust plenum through a deentrainer/heater and a single-stage HEPA filter. A hydraulically driven sluicer removes solids from the interior of the catch tank, thereby minimizing the accumulation of radionuclides.

Liquids from the catch tank are periodically pumped to the tank farm on a batch basis by either pump P1-A or P1-B. Any liquid in excess of tank capacity overflows into the pit. The catch tank is equipped with a high-liquid-level alarm that annunciates in the control room. The alarm is wired to close motor-operated valves to prevent process liquid from flowing into the catch tank. The sump in the pit has a leak detector and a pump-out line to the 241-A-A Valve Pit. The sump in the tank also collects liquids from the operating gallery (located in the second-floor balcony) and the mechanical equipment room.

Transfer Pumps P1-A and P1-B. Two identical, self-priming pumps, are located at the east end of the rail tank car unloading canyon. Pump design allows either pump to transfer liquids or boost raw water pressure. The P1-A pump normally pumps radioactive liquids from tank cars, tank trailers, the catch tank, and the sump liquids. The P1-B pump raises the raw water pressure to sluicing tank cars.

Either pump transfers waste from the 204-AR Waste Unloading Facility to a tank farm. A flow recorder/controller on the 204-AR control panel indicates and permits adjustments to the flow rate. An ultrasonic flowmeter measures the flow rate of the waste, and a diaphragm-operated valve in the transfer line controls the waste flow.

B2.4.6.1.2 Mechanical Equipment Room. The mechanical equipment room, located on the north side of the unloading canyon, is approximately 18 m (58 ft) long, 6.1 m (20 ft) wide, and 3 m (10 ft) high and has two floor drains connected to the catch tank. The chemical makeup system; motor control center; heating, ventilation, and air conditioning (HVAC) equipment; and fire protection equipment are located in this room.

Chemical Makeup System. When the composition of waste in the tank car or the catch tank does not meet tank farm acceptance specifications, chemical adjustment solutions are prepared in the chemical makeup system. The required volume of adjustment solution is metered into the tank car pump-out line during transfer.

An inline mixer system enables the receipt of liquid waste with a solution pH as low as 7. Inline chemical adjustment is the only method used for adjusting the contents of tank trailers. The inline mixer system provides a means for pumping out the low pH waste and mixing it with a required nitrite or caustic solution in the pump-out line to reduce the problem of precipitating solids. Two positive displacement metering pumps, P5-A and P5-B (in parallel), feed the necessary nitrite or caustic additive to the static mixing device. A pH probe system incorporated downstream from the mixer ensures that the liquid waste meets tank farm acceptance specifications.

The four storage/makeup tanks are used for various solutions:

- **Tank 2, Nitrite Solution (TK-2)**—This 1,893-L (500-gal) carbon steel tank is used to make up sodium nitrite solutions. TK-2 equipment includes drain and overflow lines to the catch tank, a steam heating coil, a weight factor liquid-level sensing system, a raw water supply line, a chemical addition port, and an agitator. Chemicals can be pumped into the tank car or catch tank by using pump P-3. Pumps P5-A and P5-B can pump chemicals from TK-2 into the 102-mm (4-in.) pump-out line.

- **Tank 3, Dilute Caustic Solution (TK-3)**—This 1,893-L (500-gal) stainless steel tank is used to make up dilute caustic solutions. TK-3 equipment includes drain and overflow lines to the catch tank, a steam heating coil, a weight factor liquid-level sensing system, a raw water supply line, a chemical addition port, and an agitator. Chemicals can be received from TK-5 by using pump P-4 and routed to the tank car or catch tank by using pump P-3. Pumps P5-A and P5-B can pump chemicals from TK-3 into the 102-mm (4-in.) pump-out line.

- **Tank 4, High pH Buffer Solution (TK-4)**—This 757-L (200-gal) stainless steel tank is used to make up a high pH buffer solution for pH probe calibration. TK-4 equipment includes drain and overflow lines to the catch tank, a weight factor liquid-level sensing system, a raw water supply line, a chemical addition port, and an agitator. Buffer solution is routed to the pH probe cavity by using either pump P5-A or pump P5-B.

- **Tank 5, 50% Caustic Solution (TK-5)**—This 6,814-L (1,800-gal) carbon steel tank receives 50% sodium hydroxide solution delivered by tank truck. The fill pipe for TK-5 penetrates the 204-AR Waste Unloading Facility wall and terminates outside the building next to a platform provided for the tank truck. A pump mounted on the tank truck transfers the caustic solution to TK-5. From TK-5, chemicals can be transferred either (1) to TK-2 by using pump P-4 or (2) directly to the catch tank or tank car by using pump P-3. Pumps can also be used to transfer liquid from TK-5 to the 102-mm (4-in.) pump-out line. TK-5 equipment includes drain and overflow lines to the catch tank, a steam heating coil, and a weight factor liquid-level sensing system.

Chemicals are added to TK-2, TK-3, and TK-4 in the mechanical equipment room.

Motor Control Center. The motor control center is located at the west end of the mechanical equipment room. Agitator controls for the chemical makeup system, pump controls, and power controls are mounted on the control panels.

Heating, Ventilation, and Air Conditioning Equipment. The HVAC equipment located in the mechanical equipment room includes the main exhaust duct work, exhaust fan, and final stage of HEPA filters. The duct work also houses the demisters, heaters, and exhaust dampers.

Fire Protection. Heat and smoke detectors, as well as a sprinkler system, are installed throughout the 204-AR Waste Unloading Facility. A fire alarm master control box, control panel, trouble control transmitter, and supervisory annunciator panel are located at the building exit that is at the southeast end of the facility. One inlet line supplies raw water for use in the mechanical equipment room and other similar demands. Another inlet line supplies raw water for use in the fire protection system for the facility, in the sluicing system for the tank car unloading canyon, and in pump shaft seals for the P-1A and P-1B pumps. A backflow preventer in each raw water supply line prevents accidental contamination of the raw water system.

B2.4.6.2 Second Floor. The second floor contains the control room and administrative areas. The administrative areas include a soiled clothes room and its airlock, toilets, and a locker room (Figure B2-32).

The control room, located on the east end of the second floor, is shielded from the rail tank car unloading canyon by approximately 0.3-m-(1-ft-) thick concrete shield walls that contain a lead glass window for viewing tank unloading operations. The control room contains a main control panel and an auxiliary panel. The main control panel contains instrumentation to monitor pump pressures, drain valve operations, leak detection, and radiation levels (204-AR stack, soiled clothes room, and rail car unloading canyon).

The auxiliary panel contains audible and visible alarms for the following process and monitoring variables:

- Radiation monitors—High radiation or monitor failure
- Catch tank level—High and low
- Leak detection—Catch tank sump level, transfer line
- Flow rates—Low flow to tank farms
- Door position—Outer and inner doors to canyon
- HEPA filter differential pressures.

B2.4.6.3 Ventilation Systems. Three ventilation systems within the 204-AR Waste Unloading Facility service the personnel area, the radiation zone, and the mechanical equipment room. The personnel area ventilation system operates at positive pressure. This system provides air to the control room, locker room, toilet, and soiled clothes room. Most of the air supplied to the control room is recirculated. The air not recirculated is exhausted through the soiled clothes room or the toilet exhaust systems.

The radiation zone exhaust system operates at a negative air pressure and draws air from the canyon area, soiled clothes room, and catch tank. The fan is located in the mechanical equipment room and discharges air through the roof ventilator. The canyon area exhaust air is filtered through parallel roughing and HEPA filter banks (Table B2-18), through a second or final HEPA filter bank located in the mechanical equipment room, and then through the main duct work before being exhausted to the environment through a stack.

The catch tank exhaust system consists of a moisture separator, heater, and HEPA filter and associated duct work. The catch tank duct work is connected to the main duct work just upstream of the final HEPA filter bank. The soiled clothes exhaust system duct work is also connected to the main exhaust duct work just upstream of the final HEPA filter bank. A water spray fire protection system suppresses fires upstream of the HEPA filters.

The mechanical equipment room is not connected to the radiation zone exhaust system. The mechanical equipment room exhaust system consists of a roof-mounted exhaust fan operated on a demand basis and only when the radiation zone exhaust system is operable.

B2.4.6.4 Radiation Monitoring Systems. The 204-AR Waste Unloading Facility is equipped with radiation monitoring systems for the radiological protection of personnel and the environment in accordance with WHC-SD-SQA-TA-20011, *Technical Assessment of the Workplace Air Sampling Requirements at the Tank Farm Facilities*. These systems may include record air samplers and CAMs.

Record air samplers collect particulate matter on filter paper at four 204-AR Waste Unloading Facility locations: the tank car unloading room balcony, soiled clothing room, control room, and exhaust stack.

CAMs monitor and record beta-gamma activity in the airflow through the tank car/tank trailer unloading area, soiled clothes room, mechanical equipment room, control room, and exhaust stack. Audible and visual alarms annunciate at the CAMs and in the 204-AR Control Room. A multipen recorder on the auxiliary panel in the 204-AR Control Room records CAM levels for the exhaust stack, unloading area, and soiled clothes room.

The exhaust stack monitoring system consists of a fixed record air sampler in addition to a CAM. The CAM measures particulate emissions from the stack through isokinetic probes mounted in the stack.

B2.4.7 244-AR Vault

The 244-AR Vault, located north and west of 241-A Tank Farm in the 200 East Area, was constructed in 1966. The vault was designed to remove, treat, and transfer PUREX Facility tank farm sludges to 221-B Plant for fission product removal; provide interim storage for PUREX Facility acid waste feed to 221-B Plant; and receive and distribute the neutralized high-level waste of 221-B Plant. The 244-AR Vault is being cleaned and readied for decontamination and decommissioning. Therefore, this facility description addresses only the following major structures and components:

- Canyon building and process cells
- Ventilation systems
- Control rooms.

B2.4.7.1 Canyon Building and Process Cells. The canyon building is a reinforced concrete structure with 0.5-m- (1.5-ft-) thick walls. The canyon building measures 29 m (94 ft) by 5.5 m (18 ft) internally and is 11 m (36 ft) high above the process cell concrete cover blocks on the canyon floor. The cover blocks, which separate the process cells from the canyon, are 1.5 m (5 ft) thick and have recessed lifting bails. The process cells house the process vessels and associated equipment. The canyon building also contains two shielded personnel access doors and a large, shielded motor-driven equipment access door that slides on a monorail. A metal wind-reduction facility is attached to the east end of the building for weather protection when the equipment-access doors are open.

Three process cells and a failed equipment storage cell are located below the canyon (Figures B2-33 and B2-34). Each of the three process cells contains sumps with an intercell sump overflow. Cells 1 and 2 have identical inside dimensions, 6.4 m (21 ft) square by 9.98 m (32.75 ft) deep. Cell 3 is 9.8 m (32 ft) long by 3.7 m (12 ft) wide by 6.4 m (21 ft) deep. The concrete cell walls are 0.6 m (2 ft) thick.

Cell 1 (Figure B2-34) is located between cell 2 and the failed equipment storage area at the east end of the vault. Each of the concrete cell walls is 0.6 m (2 ft) thick. Cell 1 contains Tank TK-244-AR-001, a sump jet, wall nozzles, permanent piping, instrumentation, and a cell spray system.

Tank TK-244-AR-001, the primary storage tank for neutralized current acid waste (high-level first-cycle solvent extraction waste from the PUREX Facility), is located in cell 1 of the 244-AR Vault and is constructed of 9.53-mm- (0.375-in.-) thick, Type 304L stainless steel plate. The flat-bottomed, 163,333-L (43,148-gal) tank is 6.1 m (20 ft) in diameter and 6.02 m (19.75 ft) high. The tank is equipped with upper and lower cooling coils, a transfer pump, a transfer jet, an agitator, spray rings, a purge air system, a sampler, vessel vent and chemical addition lines, instrumentation, and three spare tank nozzles.

Cell 2 (Figure B2-34) is located between cells 1 and 3 of the canyon building. Cell 2 contains Tank TK-244-AR-002, a sump jet, wall nozzles, permanent piping, instrumentation, a cell spray system, and radiation monitoring equipment.

Tank TK-244-AR-002 is constructed of 9.53-mm- (0.375-in.-) thick, Type 304L stainless steel plate. The flat-bottomed, 164,431-L (43,438-gal) tank is 6.1 m (20 ft) in diameter and 6.02 m (19.75 ft) high. The tank is equipped with upper and lower dual service (heating and cooling) coils, a transfer pump, a sluice pump, a transfer jet, an agitator, spray rings, a purge air system, a sampler, vessel vent and chemical addition lines, a radiation monitoring dry well, instrumentation, three spare tank nozzles, and a spare permanent piping line.

Cell 3 (Figure B2-34) is located on the west end of the canyon building and contains Tanks TK-244-AR-003 and TK-244-AR-004, a sump jet, wall nozzles, permanent piping, instrumentation, a cell spray system, and radiation monitoring equipment.

Tanks TK-244-AR-003 and TK-244-AR-004 are constructed of 13-mm- (0.5-in.-) thick, Type 18-8Cb, stainless steel plate. The slope-bottomed, 18,143-L (4,793-gal) tanks are 2.9 m (9.5 ft) in diameter and 2.7 m (9 ft) high. Each tank is equipped with a cooling coil, two transfer jets, a transfer pump, an agitator, a spray ring, a purge air system, a sampler, vessel ventilation and chemical addition lines, instrumentation, and three spare tank nozzles.

The failed equipment storage area is located next to cell 1 in the east end of the canyon building. This storage area contains three storage tubes, each constructed of 1.4-m- (4.5-ft-) dia, 12-gauge, corrugated, galvanized pipe, that extend 11 m (35 ft) below the failed equipment storage area cover blocks. Each of the storage tubes discharges to the cell 1 floor. The storage tubes are vented to cell 1 through 152-mm- (6-in.-) dia vent pipes located 6.7 m (22 ft) above the storage tube bottom. The storage tubes are covered with a 0.6-m- (2-ft-) thick reinforced concrete block.

B2.4.7.2 Ventilation Systems. Four ventilation systems service the 244-AR Vault Facility:

- Control room ventilation system, K-1
- Canyon intake ventilation system, K-2
- Canyon exhaust ventilation system, K-3
- Vessel ventilation system, K-4.

These systems are not currently operable and significant modifications or upgrades would be required to return these systems to service. The facility process area is passively ventilated to the building. A summary description of the 244-AR Vault ventilation systems, as designed, is provided in Table B2-19.

B2.4.7.3 Control Rooms. The control room contains controls or instrumentation required to operate the 244-AR Vault. The room is 10 m (34 ft) long, 6.86 m (22.5 ft) wide, and is divided into several localized equipment areas. These areas are the jet gang valve stations, steam control station, HVAC instrument panel, transmitter and converter racks, process instrument panels, hydrogen purge air control station, switch gear and motor control centers, and crane control room. (Steam lines to the steam control station are blanked; therefore, the station is out of service.)

B2.4.8 Cribs, Ditches, and Ponds

Those cribs currently owned or operated by TWRS are shown in Table B2-20. All cribs, ditches, and ponds used or operated by TWRS are identified graphically in Figure B2-35 and discussed in the following sections. These facilities are now inactive.

B2.4.8.1 Cribs. A crib is defined as a subsurface liquid distribution system. The primary function of a crib at TWRS was to dispose of liquid

effluents so that low-level radionuclides (if any) were absorbed and held in the soil beneath the crib.

Crib designs vary widely but the function of all designs is the same. A typical crib design is shown in Figure B2-36. Most cribs consist of gravel-filled trenches, 3.0 to 4.6 m (10 to 15 ft) deep, approximately 3 m (10 ft) wide at the bottom, with the sides sloping out toward the top. The bottom third to half of the crib is filled with coarse gravel to provide a large volume of pore space between the individual rocks.

For many cribs vapor barrier (typically plastic) on top of the gravel is covered by original soil material. Liquid-level risers are constructed into the gravel to allow measurement of effluent levels in the crib. Level readings are taken by using an insulated calibrated wire (zip cord) and a direct current meter, a sonic ullage gauge, or a liquid-level gauge.

B2.4.8.2 Ditches and Ponds. Wastewater generated from operating facilities within the exclusion areas of the 200 East and 200 West Areas can be discharged to B Pond, which consists of the following lobes: 216-B-3, 216-B-3A, and 216-B-3B, which are currently inactive, and 216-B-3C, which is currently active. A contingency pond (216-E-28) is located northwest of B Pond and east of 200 East Area and consists of three lobes. Each 216-E-28 lobe is equipped with liquid-level stakes, a flow control structure, and a flowmeter. Ditches (which are gravel-lined) and pipelines (used for transporting water to the ponds) may be equipped with valves for regulating or adjusting the flow.

B2.4.9 Storage and Handling Areas for Contaminated Equipment and Materials

Facilities or areas that have stored contaminated equipment and materials include the 209-E Complex, less than 90-day waste storage pads, vertical storage units, a low-level waste pad, the 213-W Building, and the 2727-W Sodium Storage Facility. The 209-E Complex is a staging area for contaminated equipment, mixed waste, and both regulated and nonregulated wastes awaiting final disposition.

The vertical storage units and the low-level waste pad supplement the temporary storage areas provided to support a short-term operation and are controlled by the radiation protection and hazardous materials programs (Chapter 4.0).

The vertical storage units (Section B2.4.9.2) are typically associated with a specific tank farm. The 213-W Building and the 2727-W Sodium Storage Facility (Sections B2.4.9.3 and B2.4.9.4) are used for material storage and handling activities.

B2.4.9.1 209-E Complex. The 209-E Complex, which is compliant with the *Resource Conservation and Recovery Act of 1976*, is located north of the PUREX Facility. The complex consists of an administrative building, the less than 90-day waste storage pad, and the low-level waste storage pad. The administrative building houses support personnel who operate the less than 90-day waste storage pad for mixed, low-level, and hazardous waste.

The less than 90-day waste storage pad consists of a hazardous-waste pad, a mixed-waste pad, and a low-level waste pad. The waste stored on these pads is generated by day-to-day maintenance and operations in the 200 East Area tank farms. The waste materials include solvents, oils, paints, and cleaning materials from the radiation zones. Other waste contributions are equipment or material contaminated through contact with the mixed waste stored in tank farms. The low-level waste pad stores low-level, radiologically contaminated solid waste. This pad is located northwest of the less than 90-day waste storage pad.

B2.4.9.2 Vertical Storage Units. The vertical storage units (most of which are located in the 200 West Area SST farms) were used in the past to store dry, radiologically contaminated equipment or soil. These facilities are now inactive. The vertical storage units are constructed of steel pipes, range from 0.3 to 0.6 m (1 to 2 ft) in diameter, and are approximately 1.8 to 2.1 m (6 to 7 ft) deep; however, some of the vertical storage units may be up to 7.3 m (24 ft) deep. Although most of the units are capped, no documentation is available to verify whether each has a bottom. The number and dimensions of each vertical storage unit, identified by SST farm, are presented in Table B2-21.

B2.4.9.3 213-W Building. The 213-W Building was used to compact low-level wastes and is referred to as the Dry Waste Compactor Facility. Compaction activities have ceased and will not be resumed. Activities such as contaminated instrument repair or waste repackaging take advantage of the controlled environment in the 213-W Building, which is unoccupied except during such activities.

The 213-W Building is a preengineered, self-framing metal structure located near the west boundary of the 200 West Area. The 213-W Building has three rooms with a combined floor space of approximately 79 m^2 (850 ft^2). The rooms, arranged in series, include a personnel entry room separated by an airlock from a work room and a package inspection room with a roll-up garage door. The work room is maintained at a slight vacuum and ventilated through two HEPA filters to an external, dedicated 8.8-m (29-ft) monitored exhaust stack. All rooms are protected by a dry pipe fire suppression system and have personnel doors that open to the outside. Floor drains are connected to an inactive, underground retention tank with a pit access. The 213-W Building is adjacent to 272-WA Building, which contains offices, change rooms, support shops, a garage, and a lunchroom.

B2.4.9.4 2727-W Sodium Storage Facility. The 2727-W Sodium Storage Facility houses five horizontally mounted sodium storage tanks in a preengineered, self-framing metal structure located in the south-central part of the 200 West Area approximately 11 m (35 ft) west of a north-south rail spur. The insulated tanks are approximately 4.3 m (14 ft) O.D. and 7.16 m (23.5 ft) long.

The headspace of each sodium storage tank contains pressurized nitrogen gas 14 kPa to 69 kPa (2 to 10 psig) to preclude oxidation of the sodium. A nitrogen gas pressure monitoring system is connected to each tank through an externally mounted, weatherproof control panel. The control panel includes an audible horn, indicating lights, and a strobe light. The 8.5- by 26-m (28- by 84-ft) building encloses one large room with a floor space of approximately 214 m^2 (2,300 ft^2). Features of the building include the following.

- Four gravity-type roof ventilators are located on the ridge line of the roof approximately 6.7 m (22 ft) abovegrade. Personnel doors on each end of the building are louvered for ventilation.
- The metal building is grounded by interconnected, 2.4-m (8-ft) grounding rods in six locations to form a grounding grid. Each internal sodium tank is grounded to the building grounding grid. The external sodium tank pressure control panel and the externally mounted master fire alarm cabinet are independently connected to the building grounding grid.
- No water or steam service is provided and external signs clearly indicate water should not be used to fight fires. No weeds or other combustibles are allowed near the building.

External resistance heaters wrapped around the tanks to melt the sodium are disconnected (i.e., the sodium is solid). An insulating layer of refractory brick held in place by a wire mesh covered with an aluminum sheath surrounds the heaters and tanks.

B2.4.10 Waste Transfer Systems

Liquid wastes are transferred to and from tank farm storage, chemical processing facilities, and related operational units (e.g., tanks within receiver vaults and evaporators) through a network of buried transfer pipelines, operating equipment, and control or transfer structures (diversion boxes, valve pits, DCRTs, and diverter stations). Liquid wastes are also received from operational facilities (e.g., Plutonium Finishing Plant).

The purpose of transfers is to move liquid waste from one location to another over a planned, established route in response to (1) a loss of tank integrity, (2) processing requirements, and (3) changing storage needs. Liquid waste generated in the 200 East and 200 West Areas is transferred through the network of pipelines both to and from the underground storage tanks, vaults, and the 242-A Evaporator. Types of transfers are as follows:

- From tank farms to 242-A Evaporator
- Cross site
- Between process facilities and tank farms
- Farm to farm

- Within a farm
- Catch tank to storage tank
- Condensate collection tank to storage tank.

Transfers are made over both dedicated and nondedicated routes. Dedicated routes do not require valving or jumper changes. Therefore, repetitive transfers are often made through a dedicated route so that jumper placement and valve alignment do not need to be changed. For example, dedicated routes are usually used for transfers into the 241-AW Tank Farm from the PUREX Facility. Nondedicated waste transfer routes require repositioning of jumpers or realignment of valves. In addition to the underground piping network, the routing equipment at tank farms consists of pumps, valves, rigid piping, and rigid and flexible jumpers. Leak detection instrumentation is located in diversion boxes and process pits.

The components of the active Sitewide waste transfer and routing systems related to SST and DST farms are described in this section. The inactive and abandoned (including identified and unidentified) systems will be evaluated at the time of discovery or during decontamination and decommissioning activities.

B2.4.10.1 Transfer Pipelines and Jumpers. Transfer pipelines distribute waste from a generating facility to an individual tank farm or from one tank to another within a tank farm. Waste is transferred from an SST or DST to a receiving tank or facility through existing underground piping or temporary over-the-ground piping. Transfer pipelines are identified and categorized on the basis of the material transferred. The categories are as follows.

- **Process Lines**—Pipelines that return waste from the leak-detection pit or annulus pump pit to a central pump pit. (Process piping is also a general term used for pipelines between processing facilities and a tank farm.)
- **Supernatant Lines**—Pipelines that transfer liquid waste between tanks or processing facilities.
- **Slurry Lines**—Pipelines that transfer liquid-solid slurries between tanks or processing facilities.
- **Sluice Lines**—To support WRSS (Addendum 1).

All active transfer lines in the 200 East and 200 West Areas are identified in Table B2-22. The known inactive transfer lines are identified in Table B2-23.

B2.4.10.1.1 Waste Transfer Lines. The primary pipe used in waste transfer lines is carbon or stainless steel, as detailed in

WHC-SD-TWR-RPT-002. Waste transfer lines used at the Hanford Site are of three general types:

- Encased piping
- Direct buried piping
- Over-the-ground piping.

The term "encased piping" indicates that the primary transfer line is completely enclosed within a secondary confinement barrier. The secondary confinement barrier is usually a larger pipe (newer designs), concrete jacket (older designs), or a pipe trench. The term "direct buried piping" indicates that the piping is not encased and is buried directly in the soil. The term "over-the-ground piping" refers to piping that is not buried.

Most of the underground piping systems are provided with cathodic protection and heat tracing capabilities. The heat tracing system was intended to prevent liquid waste gelling, crystallization, or precipitation in process lines. However, the transfer systems are operated without the heat tracing system. New supernatant lines are constructed without a heat tracing system. All salt well transfer lines, including the jumpers leading to the receiver tank, are heat traced to prevent a temperature drop in the salt well liquor.

When buried, the steel of the piping encased in larger pipe is subject to external galvanic corrosion resulting from bacterial and chemical activity in the soil. Therefore, a cathodic protection system is provided to minimize waste transfer line failures. Most waste transfer lines associated with the DSTs in the 200 East Area are currently protected by an active cathodic protection system.

Encased Piping. To provide secondary confinement, primary encased piping pipes are encased either in concrete or in a larger, extra pipe (Figure B2-37). Encasements collect liquid leaks from a failed process line and deliver the liquid to a detection point.

The concrete encasement used as secondary confinement consists of a reinforced concrete trough and cover block. The width of the trough depends on the number of primary pipes the trough contains. The cover blocks are either precast and placed on top of the trough or the trough is covered with a steel plate and the concrete is poured in place. The concrete joints are sealed with asphalt and tar.

Features associated with the concrete-encased lines include an earth cover and a series of either test or swab risers or leak detectors. At various locations along the encasement, 51-mm (2-in.) test risers have been provided as shown in Figure B2-37. The test risers consist of 51-mm (2-in.) pipes extending from within the encasement to 1 m (3 ft) above ground level. These test risers are monitored routinely for contamination and moisture. Any leaks inside the primary line collect in the concrete void. A location of a leak can be determined with an absorbent leak detection pad inserted into a test riser.

In the pipe-in-pipe design, a second, larger pipe surrounds the primary pipe or waste transfer line. This pipe-in-pipe design provides better leak confinement than concrete, and the encasement can be pressure tested to ensure its integrity. To prevent settling in the primary pipe resulting from elevation changes, each encasement is equipped with an encasement hydrotest riser and a leak detection riser. The pipe-in-pipe encasement drains to a leak detector that alarms if a leak into the encasement occurs. Air purge leak detectors are used in some encased transfer lines. These systems bleed air through the encasement and detect a leak when the pressure in the encasement increases.

A section of pipe-in-pipe encasement is shown in Figure B2-37. Inside an encasement, one method of supporting the primary pipe is to rest the pipe on a flat bar. This bar is welded to the encasement and primary pipe. In a second method of supporting the primary pipe, two bars are welded axially to the primary pipe only. This design allows the primary pipe to expand relative to its encasement. The primary axial supports of the pipe are spaced to eliminate sagging of the primary pipeline.

Associated with each type of encased piping designs are other engineered features to ensure primary line integrity and prevent line blockage. The other engineered features include risers at encased piping end points and cleanout boxes. Risers, which include encasement hydrotest risers, leak detection risers, and test risers, are associated with both types of encased lines. Cleanout boxes are associated with only the pipe-in-pipe encasements. In the following paragraphs, the types of risers are discussed and a cleanout box is described.

- **Encasement Hydrotest Risers**—The capped, 13-mm- (0.5-in.-) dia encasement hydrotest risers, which are located at the high ends of encasements, allow air to escape from an encasement that is being filled with water for pressure testing. After the pressure check, test water is allowed to flow into a process pit drain.

- **Leak Detection Risers**—The leak detection risers are located at the low end of encased lines entering the tank farms and are designed to contain conductivity probe leak detectors. These risers are 38 to 51 mm (1.5 to 2.0 in.) in diameter and are divided into a capped riser and a probe riser.

  The capped riser is used to add water during both pressure testing and testing of the leak detection alarm system. The probe riser contains an electrode connected to a leak detection station and alarm system. Leakage into an encasement pipe flows to the leak detection riser to be contained at the seal loop inside the pit. Opening the seal loop valve allows liquid to flow to the pit floor drain.

  The leak detection risers are not used on short, in-farm lines (between pits) where leakage into encasement drains is detected by leak detectors mounted on pit floors. These risers, however, are used on lines entering the tank farms from outside pits.

- **Test Risers**—The test risers are located on the low end of encased lines not equipped with leak detection risers. The test risers also are located intermittently along the length of especially long lines (e.g., SL-160 and SN-260). The test risers are fabricated from capped, 51-mm- (2-in.-) dia Schedule 40 pipe and are used as filling points for hydrotesting and as entry points for contamination swab testing.

- **Cleanout Boxes**—Slurry transfer lines are subject to plugging from settling solids. The cleanout boxes, shown in Figures B2-38 and B2-39, were installed so that transfer lines could be cleaned if plugs develop. The boxes are positioned approximately every 30.5 m (100 ft) along the slurry transfer lines between evaporator facilities, valve pits, and storage tanks.

Direct-Buried Piping. Direct-buried transfer lines are made of carbon steel, typically 25- to 76-mm- (1- to 3-in.-) dia welded pipe and buried 1 m (3 ft) underground. Direct-buried lines are pressure tested annually. In the past, direct-buried lines were used to transfer process solutions. The use of direct-buried lines in normal transfer service is being discontinued except for occasional use as drain lines or for temporary pumping operations. These lines are heat traced and insulated to keep dissolved substances from precipitating out and plugging the lines.

Over-the-Ground Piping. Some of the tanks that require waste transfer do not have any piping or the tank transfer systems have failed (leaked). A temporary over-the-ground transfer system has been developed to transfer waste for these tanks. The temporary over-the-ground transfer system uses jet or submersible pumps and over-the-ground piping with either earth or earth and concrete block pipe protection systems.

The over-the-ground system consists of a primary pipe inside a secondary confinement pipe and a pipe protection system (concrete barrier). The primary pipe is a 25-mm- (1-in.-) dia, stainless steel-wrapped flexible hose lined with ethylene-propylene-diene monomer (EPDM). The secondary confinement is a 51-mm- (2-in.-) dia, welded, stainless steel pipe. The stainless steel braided tube wrapped around the primary pipe provides abrasion resistance during assembly of the system, and provides reinforcement to minimize the chance of bursting the EDPM hose. The over-the-ground systems are carefully sloped to prevent low spots and to facilitate flushing.

Confinement piping slopes to drain by gravity to each tank pit from approximately the center point of the piping run. Sandbags or other weights are applied to the legs of pipe supports. Berms cover all the exposed pipe between tank pit connections. The temporary piping is connected to a waste transfer pump or to existing tank transfer piping.

B2.4.10.1.2 Jumper Assemblies. Jumpers are rigid or flexible sections of pipeline used to connect separate nozzles located inside diversion boxes and various types of pits. Nozzles are the termination of waste transfer lines going into diversion boxes and pits. Jumper installation or removal requires removal and replacement of the cover block.

Two types of jumpers (Figure B2-40) are used at the Hanford Site.

- **Rigid jumpers**—stainless steel pipe is fitted to specific wall nozzle configurations.
- **Flexible jumpers**—braided, stainless steel, flexible hose permits multiple connections.

The type of head used depends on the nozzle design. The following two types are used at TWRS, one larger than the other.

- The larger connector (Hanford Site head) has a flat-nozzle flange gasket.
- The smaller connector (PUREX head) has a radius-faced beveled flange gasket.

Both types of jumper head connectors are shown in Figure B2-41 together with a crane-supported impact wrench used to tighten the connectors to the nozzles. New construction uses the PUREX head design.

Valves can be installed in rigid jumpers so that waste routes can be changed by opening and closing the valves. The valve handles are located above the top of the valve pit cover blocks, and the valve stems extend downward through penetrations in the cover blocks. A flow diagram painted on the cover blocks and valve handles assists the operator in valving to the correct pipeline and avoiding misrouting of the waste.

Valve pit jumpers and diversion box jumpers are often confused. The difference between the two is that a diversion box jumper generally connects only two nozzles but a valve pit jumper can connect to several wall nozzles (each leading to a different waste transfer line). The valve pit jumper uses built-in two- and three-way valves to divert the flow where needed.

Diverting liquid flow from one tank to another through valve pits usually does not require major changes to the jumper or alignment. Multivalve, multiconnector jumpers are used to reduce radiation exposure and field time (because of the less frequent jumper changes).

B2.4.10.2 Miscellaneous Transfer Equipment. In addition to the equipment identified in the transfer line systems description, other structures or facilities in the transfer line are used to control or direct waste transfers.

B2.4.10.2.1 Valve Pits. Valve pits (Figure B2-42) are located belowground and are reinforced concrete structures that contain valves and jumper assemblies to route the liquid waste through the connected pipelines within a tank farm. Valve pits have 0.3-m- (1-ft-) thick walls and heavy, 0.51-m- (20-in.-) thick grade-level cover blocks. When several tanks are undergoing simultaneous pumping to a single receiver tank, the flow is routed to a valve pit. In the valve pit, the transfer lines of the sending tank are manifolded to the receiver tank line by means of a series of valves and jumper connections. Two- and three-way valves are built into each rigid jumper assembly to divert the flow in the required direction. Each valve pit is equipped with leak detection that is interlocked to shut down pumps. Each

valve pit also has either a flush line connected to a flush pit or a drain line connected to an underground storage tank.

B2.4.10.2.2 Diversion Boxes. Diversion boxes (Figure B2-43) are belowgrade, reinforced concrete structures that provide a flexible method of directing liquid waste from a given point to any other given point. The top of the diversion box is a concrete cover block that usually extends abovegrade. The cover blocks vary in thickness from box to box. Some diversion boxes are lined with steel on the bottom and a portion or all the way up the sides.

Diversion boxes are normally connected to a specific tank farm and are used to establish waste transfer routes between tank farms. The waste transfer route between selected facilities can be established by selecting a combination of lines that are connected by diversion boxes, diverter stations, pump and valve pits, and associated valving and equipment.

Diversion boxes also provide confinement for leaks in waste transfer lines (which drain back to the boxes through the encasement) and leaks at jumper nozzle connections. Waste transfer lines are connected inside the diversion box by installing a jumper between the connecting nozzles. Jumpers may be either rigid or flexible, but rigid jumpers are required when valves are used.

The basic diversion box was designed to operate without valves. However, some transfer operations are better served by using valves (e.g., when wastes are transferred from multiple facilities to a common storage tank). In this type of transfer, rigid jumpers and valves are required.

After a waste transfer is completed, the transfer lines are drained back to tanks in the low points of the line, including the point of origin. The jumper configuration through a diversion box enhances the drain-back capability of a particular transfer route.

All diversion boxes drain to a catch tank or nearby underground storage tank, and all boxes contain a leak detector probe that alarms if a leak occurs that causes waste to accumulate in the diversion box. The 241-ER-151 Diversion Box Pipe Pit supports incoming and discharge transfer lines to and from the Diversion Box 241-ER-151. The Pipe Pit is sealed and below grade and is essentially an extension of pipe encasements connecting into the Pipe Pit. The Pipe Pit drains into Catch Tank 241-ER-311. A typical diversion box is shown in Figure B2-43. The operating connections for a typical diversion box are illustrated in Figure B2-44.

B2.4.10.2.3 Diverter Stations. Diverter stations can accommodate only gravity fluid flow. The 241-AX-152 diverter station is currently the only active diverter station in the 200 Areas.

When jumper changes are necessary, a diverter station allows solution streams to be routed without exposing waste transfer lines. Several incoming waste transfer lines are routed into a 189 L (50-gal) receiver tank. A moveable spout on the bottom of the receiver tank directs the flow of waste to any one of several exit pipe funnels located within the diverter station.

Each routing funnel represents a direct transfer line to a specific receiver tank, as shown in Figure B2-45.

A catch tank located in the bottom cell of the diverter station collects any spillage. The catch tank is equipped with a water jet (similar to a steam jet) so that accumulated waste solutions can be transferred to a waste storage tank.

B2.4.10.2.4 Catch Tanks. Catch tanks (Section B2.4.5.1, "Catch Tanks and Double-Contained Receiver Tanks") are underground storage tanks that collect small amounts of waste drained from diversion boxes, valve pits, diverter stations, and other DST equipment. Although older catch tanks are buried directly in the soil, replacement catch tanks are housed in subsurface concrete vaults that provide secondary confinement for the waste.

B2.4.10.2.5 Double-Contained Receiver Tanks. A DCRT (Section B2.4.5.1), sometimes referred to as a catch station or lift station, is a short-term waste storage facility that is also used as a valve pit for waste transfer operations. The DCRT consists of an underground concrete structure that contains a filter pit, pump pit, and a vault in which a catch tank is installed.

B2.4.10.2.6 Supplemental Covers. A supplemental cover is an engineered secondary barrier to knock down spray leaks from transfer-associated structures smaller than $15m^3$ (530 ft^3), including cleanout boxes, that are physically connected to waste transfer lines with an active transfer pump not under administrative lock. A supplemental cover is designed to meet the following criteria: (1) knock down spray leaks of up to 125 psig; (2) construction material is compatible with tank waste; (3) it allows for maintenance and surveillance activities on the transfer-associated structure; (4) it allows a waste leak of 20 gpm to be released at the bottom of the supplemental cover; (5) it is able to withstand a maximum wind speed of 90 mph; (6) it is able to withstand snow or ash load of 45 psf; and (7) it extends to the ground. The requirements for cover operability are defined in HNF-2296, *Justification for Continued Operation of Transfer Lines Having Structures with Less Volume Than the 241-A-A Valve Pit.*

The supplemental covers for COBs have two basic configurations. One configuration has a one piece solid top. The second configuration incorporates a two piece overlapping top to accommodate the vertical leak detector supports. The basic design consists of 1 1/2 in. x 1 1/2 in. x 1/4 in. stainless steel angle frame on two 6 in. x 3/4 in. stainless steel plate footings with 16 gauge stainless steel side panels and 3/8 in. clear plexiglass (acrylic) top. There is a 1/2 in. space between the lower edge of side panels and the top of the footings. The largest COB enclosure required for current operations is 43 in. x 43 in. x 40 in. Figure B2-69 illustrates a standard supplemental COB enclosure. Refer to HNF-2329, *Calculation For Supplemental Covers On Structures Smaller Than 241-A-A*, for details concerning design of supplemental covers installed on COBs.

The supplemental covers designed for Tanks 241-AX-501 and 241-A-A valve pits are constructed of a 30 mm. thick geomembrane, which is resistant to corrosive ingredients in the tank waste. The cover dimensions allow 1/2 in. clearance on all sides and top. The covers completely enclose pit and cover

block including lifting bails and other miscellaneous objects on cover block but exclude valve handles. The cover extends to within 1 in. of the ground. The seams and edges have 1- to 2-in. overlap for added strength. The covers are anchored to the pit wall with concrete anchors. The pit structure is adequate to support weight of the cover. Refer to HNF-2329 for details concerning design of supplemental covers installed on valve pits.

B2.4.10.3 Pumps. The three types of pumps used at TWRS to move liquids or solids from facility to facility are (1) jet pumps in combination with centrifugal pumps, (2) submersible pumps, and (3) transfer pumps. A fourth type of pump mixes in-tank waste to prevent the buildup of hydrogen gas (Section B2.4.14, "Mixer Pumps").

B2.4.10.3.1 Jet Pumps. The components of a jet pump system (Figure B2-46) located within a pump pit are a centrifugal pumps, flexible or rigid jumpers, a flush line, and a flow totalizer. The centrifugal pump supplies motive fluid to the submerged jet pump system. The jumpers contain piping, valves, and pressure and limit switches. Typically, up to four jet pumps are manifolded to a common waste transfer line.

The combination of a centrifugal pump (Figure B2-47) and jet pump is needed to raise the liquid waste approximately 12 to 15 m (40 to 50 ft) to the pump pit. Raw water fills the jet pump system loop and primes the centrifugal pump for operation. A recirculation loop permits the prime to be maintained on the centrifugal pump while pumping at very low rates.

The centrifugal pump located in the pump pit pressurizes power fluid to the jet assembly. The power fluid passes through a nozzle within the jet assembly and converts fluid pressure head to velocity head, thereby reducing the pressure within the jet assembly chamber. The reduction in pressure allows the interstitial liquid (i.e., liquid within salt cake) to enter the jet assembly chamber and mix with the power fluid. Conversion of velocity head to pressure head above the nozzle lifts power fluid and interstitial liquid to the pump pit.

Jet pump systems are used for salt well pumping. The complete salt well system consists of a jet pump and a 254-mm- (10-in.-) dia salt well casing with a stainless steel salt well screen welded to a Schedule 40 carbon steel pipe. The screen is inserted into the 0.3-m (1-ft) tank riser located in the pump pit. The stainless steel screen portion of the system extends through the tank waste to near the tank bottom. The salt well screen portion of the casing is an approximately 3.0-m (10-ft) length of 254-mm (10-in.-) dia, 300 Series, stainless steel pipe with screen openings (slots) of 1.27 mm (0.050 in.). A flow totalizer, a magnetic element, is attached to the discharge line to measure the quantity of liquid transferred.

B2.4.10.3.2 Submersible Pumps. A submersible pump can be used to raise large volumes of supernatant. The pump motor itself is below the pump intake and is submersed in the liquid being pumped. The pump motor is cooled by the liquid being pumped. A flow director (shroud) installed in the pump helps move the flow past the motor. A sensor shuts off the submersible pump if the submersible pump motor temperature increases.

B2.4.10.3.3 Transfer Pumps. Transfer pumps are installed in a pump pit, with the motor located in the pit and the intake located in the tank waste. Typically, transfer pumps are deep-well, vertical turbine pumps, where the pump intake is a rigid pipe that extends to a fixed depth in the tank waste. Some transfer pumps have a floating intake, which is a flexible jumper connected to rigid pipe that does not extend into the waste. The intake, or flexible jumper, floats on the surface and collects only surface liquids until the jumper is fully extended.

B2.4.10.4 200 East Area Transfer Systems. The active and known inactive transfer systems within the 200 East Area are listed in Tables B2-22 and B2-23, respectively.

B2.4.10.5 200 West Area Transfer Systems. Active transfer lines, line origins, intermediate junctions, and line terminations in the 200 West Area are listed in Table B2-22. The known inactive lines within the 200 West Area are identified in Table B2-23.

B2.4.10.6 Cross-Site Transfer System. The cross-site waste transfer system transports mixed-waste solutions from the 200 West Area to the 200 East Area. The system consists of diversion boxes located in the 200 East and 200 West Areas (241-ER-151 and 241-UX-154, respectively), a vent station, and a reinforced-concrete-encased stainless steel pipeline system approximately 3.7 km (2.3 mi) long.

Four of the six transfer lines placed within the concrete encasement are not usable (i.e., have failed pressure tests). Leak detectors for the cross-site transfer line are located at the diversion boxes. Additionally, 58 encasement test risers are spaced regularly along the concrete encasement between the 241-UX-154 and 241-ER-151 diversion boxes. The test risers provide access to the encasement void space for leak detection purposes. The encasement slopes in both directions from the 241-EW-151 vent station.

The 241-EW-151 vent station is located approximately 457 m (1,500 ft) south of and between the 200 East and 200 West Areas. The elevation of the top of the vent station or cover blocks is 231.8 m (760.5 ft) above sea level. Because the vent station is 15 m (50 ft) higher than the diversion boxes in the 200 East and 200 West Areas, venting the transfer line following a transfer allows liquids to flow from the vent station to catch tanks located in the east and west diversion boxes.

Salt well and miscellaneous 200 West Area plant wastes are collected and stored in Tank 241-SY-102. The waste is transferred from Tank 241-SY-102 through the 244-S DCRT, diversion boxes, and cross-site system structures to the 200 East Area. The waste is then routed through the 244-A DCRT to the 241-A-A valve pit for transfer to the 200 East Area DSTs, where the waste is held for later processing at the 242-A Evaporator. The specific routing of waste through the 200 East Area and the waste destination depends on the type of waste, the availability of tanks for storage, and current procedures controlling waste transfers.

Another cross-site transfer system known as the Replacement Cross-Site Transfer System has been constructed and is described in Addendum 2.

B2.4.11 Common Sitewide Instrumentation and Surveillance Monitoring Systems

The instrumentation and other supporting systems and equipment used in TWRS are common to most facilities on the Hanford Site. The following systems are discussed:

- Computerized surveillance systems
- Liquid- and sludge-level monitoring system
- Leak detection and monitoring systems
- Waste sampling equipment and methods
- Temperature monitoring
- Dome-space gas monitoring
- In-tank surveillance cameras
- Criticality detection systems.

B2.4.11.1 Computerized Surveillance Systems. The two primary computerized surveillance systems, within TWRS include the Tank Monitoring and Control System (TMACS) and the Computer Automated Surveillance System (CASS). The two systems are discussed in following subsections.

B2.4.11.1.1 Computer Automated Surveillance System. The CASS is designed to provide central, computerized surveillance of the Hanford Site underground waste storage tanks and their associated facilities. The central CASS Facility is located in the 2750-E Building in the 200 East Area and is manned on a 24-hour basis by Waste Tank Operations.

The CASS covers most of the tank farm monitoring systems. Field detection and monitoring instrumentation systems are essentially the same for all individual tanks within the tank farms. Detection instruments send data to monitors in the tank farm instrument enclosures, to monitors in the appropriate instrument buildings, or to both. All measured values are converted to electrical signals before transmission to CASS substations. Most monitored data is transmitted automatically to the CASS; however, some data is measured and recorded manually and maintained at each farm without input into the CASS.

Process parameters continuously monitored by the CASS are as follows:

- Substation failures
- Leak detection pit alarms (high radiation, high liquid level)
- Tank pressure alarms (high pressure and vacuum)
- Leak detectors on tank annulus floor

- Exhaust fan failure alarms
- Radiation detection units (annulus exhaust CAMs, HVAC exhaust stack CAMs, instrument building panel alarms)
- Process line, encasement, process pit leak detectors, and cleanout boxes leak detectors.

The CASS scans the following parameters hourly:

- Actual liquid-level measurement
- Deviation from liquid-level baseline criteria
- Failure of liquid-level monitoring equipment.

Signals are monitored and displayed on panel boards within the associated instrument building. Each tank has an associated local panel board, transmitter enclosure, and assigned portion of the pressure switch rack. Some signals are transmitted to the 242-A Evaporator control room for the 200 East Area, and to the 242-S control room for the 200 West Area, as well as to the DST instrument buildings. (For additional information on the 242-A Evaporator, refer to WHC-SD-WM-SAR-023, *242-A Evaporator/Crystallizer Final Safety Analysis Report*.) Instrument panel boards display or record (for both display and record) the monitored conditions of the various parts of the tank farms. Panel board information includes pressure and high-liquid level (currently not in use) in each primary tank, readings from leak detectors and probes monitoring airborne radiation in the annuli, high-liquid level (currently not in use) and high radiation readings in leak detection pits, and alarms relating to operation of the ventilation systems.

Separate CASS program files are kept for data categories and are held in the program's 32-day historical file. Data is transferred daily to the permanent retention file. The CASS reports contain information either received automatically or manually entered through a computer terminal. A few readings (e.g., selected liquid level and weight factor) are not CASS files. These readings are measured manually on each shift and then manually recorded and retained by tank farm and evaporator process control personnel. Reports are generated on standardized report forms. Each tank farm can select and customize the data on the reports.

B2.4.11.1.2 Tank Monitoring and Control System. TMACS was originally designed to monitor waste tank temperatures but has since been expanded for monitoring of other parameters and will eventually replace the CASS. The system continuously monitors temperatures, liquid levels, tank pressures, ventilation flows, and hydrogen gas concentrations. The data inputs to TMACS originate within the tank farms and associated facilities, which communicate by means of dedicated telephone lines with the TMACS main computer system located in the 2750-E Building.

TMACS provides real-time dynamic graphics depicting the status of all parameters associated with the monitoring tank. Features include alarm management, data storage, data trending, reporting, event logging, failure status, and graphical presentation using a hierarchy of displays that allows

progression from the general to the specific. TMACS receives two major data inputs: PANALARM and ACROMAG.

PANALARM is the existing tank farms alarm and annunciator system. The inputs to TMACS include all tank farm alarms, tank pressure, radiation levels, and leak detection signals. TMACS samples the PANALARM system data points at a rate of approximately 100 points per second.

ACROMAG is a data processor that currently collects liquid level data from the ENRAFs (Section B2.4.11.2.1) vapor space gas sample data directly from the standard hydrogen monitoring system, tank vapor space pressure data, tank waste and vapor space temperature data, and the ventilation system exhaust flow rates. TMACS samples most of the SST temperature data every 10 minutes and most of the DST temperature data every 60 seconds. Sample rates for other data (e.g., ENRAF data; standard hydrogen monitoring system data, pressure data, and ventilation flow rates) are based on user needs or requirements.

The user can select a single tank from a graphic display of the tank farms. The tank level is displayed as a horizontal line above the tank bottom (the position of this line changes dynamically as the liquid level in the tank changes). Temperature values are displayed on the basis of the height of the temperature sensor. Tank pressure values (both low and high ranges), as well as the percentage hydrogen (for tanks with a standard hydrogen monitoring system installed), sample flow, and discrete alarm signals are provided on the graphic display. Dynamic trend graphs can be obtained by selecting the parameter of interest from the graphic display. For example, the user can select a temperature sensor and the period of interest (e.g., 1 hour, 8 hours). The current, low, and high numeric values over the selected period are displayed next to the sensor number.

B2.4.11.2 Liquid- and Sludge-Level Monitoring System. The following describes liquid- and sludge-level monitoring in the waste tanks.

B2.4.11.2.1 Liquid-Level Monitoring. Liquid-level monitoring is a primary tool for maintaining strict accountability of radioactive and chemical waste solutions. Surveillance of the liquid level in an isolated tank gives the first indication that liquid may be leaking from the tank or (an unlikely possibility) that liquid is intruding into the tank. Liquid levels in all waste storage tanks are monitored and recorded.

Three devices are used to monitor the liquid level in the primary tanks.

- A level-indicating transmitter assembly provides continual automatic monitoring. The level-indicating transmitter may include Food Instrument Corporation (FIC) gauges and ENRAFS.
- For some tanks, a level indicator assembly or manual tape provides a manual backup for the level-indicating transmitter.
- A high-level detector provides the alarm input for a high liquid level. (The high-level detectors are disconnected in flammable/ hydrogen gas "watch list" tanks.)

Food Instrument Corporation Gauges. Many underground storage tank liquid levels in the 200 East and 200 West Area tank farms are measured by automatic FICs (and read by CASS or TMACS). An automatic FIC gauge (Figure B2-48) consists of the following:

- Plummet suspended on a tape
- Tape reel
- Rotameter
- Sight glass
- Control box
- Air supply
- Flush spray attachments.

FIC gauges are mounted on selected risers. The plummet of an FIC gauge is suspended to rest at the liquid surface in the tank and is raised and lowered to contact the liquid surface. The reading is accomplished either automatically or manually, depending on the FIC. An FIC can operate in one of three distinct modes: automatic, intrusion, and manual.

The automatic liquid-level gauges are connected to the CASS. The FIC gauges can be read automatically or manually in the field or can be requested from the CASS. Automatic liquid-level measurement devices are installed in many of the waste tanks and catch tanks in the tank farms in the 200 East and 200 West Areas. The gauges are mounted on selected risers. The controls automatically raise and lower (bob) the plummet position at the air-liquid interface at 1- to 1.5-minute intervals. When the plummet contacts liquid, an electrical circuit to ground is completed, thus indicating the liquid level. The level-indicating transmitter outputs are transmitted directly to the CASS. Level readouts are also displayed locally at the tank gauge.

When the liquid in a tank has been processed and a sludge or salt cake layer has been left in the tank, the automatic FICs are placed in the intrusion mode. At this point, the main concern is detection of incoming liquids (intrusion). In this method of monitoring surface levels, the plummet in the FIC gauge stays suspended above the salt cake surface. This method is used only to monitor tanks with solid surfaces. An automatic FIC that fails must be read manually and the data input into the CASS.

ENRAFs. An ENRAF (Figure B2-49) consists of a sight glass, control box, and flush spray attachments. ENRAF Series 854 level gauges are certified by Factory Mutual for the National Fire Protection Association (NFPA 70, *The National Electric Code*) hazardous Class I, Division 1, Groups B, C, and D Locations. The measuring principle for these gauges is based on the detection of variations in the weight of a displacer suspended in the process fluid. The displacer is connected to a wire wound on a precision measuring drum. A level change causes a change in the weight of the displacer, which is detected by the gauge force transducer. Electronics within the gauge cause a servo motor to adjust the position of the displacer and compute the tank level

on the basis of the new position of the displacer drum. The gauge displays the level in decimal inches. A digital output signal (analog optional) transmits the level data for remote data processing.

Manual Tapes. Two types of manual tapes are used in TWRS. The flake-box type, described here, is of a more recent design. The older type is generally much taller and has an exposed tape reel. Despite their differences, both operate in essentially the same manner. The reel is permanently attached to the tank riser, and the measuring tape is attached to the reel. The measuring tape is inserted through the hole in the riser flange. Readings are obtained by attaching a portable direct current meter to the terminals provided at the riser. The zero position on the manual tape represents the bottom of the tank or sump.

Flake-box housings are located on primary tank risers (on most DSTs and DCRTs) and on some annulus risers (241-AN, 241-AP, and 241-AW Tank Farms). A flake box consists of a steel housing containing a reel that is wound with a calibrated stainless steel tape. A probe is attached to the end of the measuring tape, which extends down through the tank riser. Flake boxes serve different purposes in different locations. Installed on a primary tank, they provide a means of determining waste liquid level within the tank. On a tank annulus, flake boxes can detect leakage from the primary tank into the annulus.

The elevation of the probe is adjustable by turning a hand crank on the side of the housing to wind or unwind the steel tape. A portable direct current ammeter is connected to the tape and ground (riser flange) to determine when the electrical circuit to ground is completed. The plummet is lowered until the electrical circuit is completed, and the liquid level at the point of contact is read manually from the tape housing. The liquid level in the tank (height in feet from the bottom of the tank or sump) is determined from graduations on the steel tape as measured relative to the tank riser flange, the cross bar or fixed index point on those reels with plexiglass housings, or the edge of the access hole. The zero position on the steel tape represents the bottom of the tank or sump. For most manual tapes, a 13-mm (0.5-in.) line from an instrument air header continually purges the level indicator housing into the primary tank.

On the tanks lacking level instrument systems, liquid-level readings can be obtained either with the manual tape or by means of a calibrated, insulated wire (zip cord). Electrodes are attached to the premeasured, insulated wires. In each instance, readings are obtained by attaching a portable direct current meter to the terminals provided at the riser and lowering the electrodes until deflection of the direct current meter indicates contact with the liquid surface.

High-Level Detectors. The high-level detector assembly consists of an electrode (two electrodes in the 241-AP Tank Farm) suspended from the riser. High-liquid level is detected when liquid contacts the electrodes and completes the electrical circuit across the electrodes. Readings in excess of tank high-level limits will engage the associated area pump interlock (shutdown) system and provide audible and visual alarms.

Weight Factor and Specific Gravity Monitoring. The weight factor and specific gravity monitoring systems (Tank 241-AW-102, DST leak detection pits, and SSTs with operable salt well pumps) consist of three small pipes (known as dip tubes) inserted into a tank through a riser. During operation, compressed air purges are supplied to the dip tubes at a controlled rate, the differential pressure is measured, converted to liquid level or specific gravity, and electrically transmitted to indicators at a remote location (Figure B2-50).

B2.4.11.2.2 Sludge-Level Monitoring. A solid or sludge layer is commonly formed in the bottom of waste storage tanks as the contents concentrate and solids precipitate. The sludge level must be monitored because changes in the sludge level indicate a change in tank solution makeup and, in some instances, could clarify apparent changes in liquid levels.

Two methods are used for measuring sludge levels: (1) a steel doughnut attached to the bottom of a calibrated tape (Figure B2-51) and (2) the ENRAF described in Section B2.4.11.2.1.

- A calibrated tape is attached to the doughnut cable and lowered until the tape becomes slack. The tape reading indicates the sludge level.
- An ENRAF calibrated to a different density (higher density than supernatant) is used to detect the sludge level in a tank.

B2.4.11.2.3 Single-Shell Tank Farm Liquid- and Sludge-Level Monitoring. The surface levels of tanks are monitored by using a manual tape or an automatic level-indicating transmitter. Manual tape readings and manual surface-level readings, taken with the manual-mode level-indicating transmitter gauges, are input to the CASS and readings from level-indicating transmitter gauges connected to CASS transfer automatically. The CASS alarm sounds if the readings are outside set limits. Data from level-indicating transmitter gauges connected to TMACS are transferred to the CASS.

Liquid observation wells have been installed in many tanks to determine interstitial liquid levels within the tanks. Gamma, neutron, or acoustic probes are lowered into the wells to measure the levels. The data from the fully automatic measurements is input into the CASS.

B2.4.11.2.4 Double-Shell Tank Farm Liquid- and Sludge-Level Monitoring. Several methods are used to measure the liquid level in a tank. In all instances, the measurement represents the amount of liquid (in feet and inches) from the bottom of the tank. This figure is multiplied by a conversion factor to calculate the volume (in gallons). In all 23-m-(75-ft-) dia tanks, a 25 mm (1 in.) depth of liquid represents a volume of 10,410 L (2,750 gal).

Sludge-level cables are found at each DST farm. The sludge-level assemblies are bolted on risers.

B2.4.11.3 Leak Detection and Monitoring Systems. In addition to the liquid-level monitors used for leak detection (discussed in Section B2.4.11.2, "Liquid-and-Sludge-Level Monitoring"), dry wells and laterals monitor liquid

intrusion to the soils surrounding and supporting the underground tanks as a second method of leak detection. Dry wells are vertical next to the tank, and laterals are below the tank. A number of wells are randomly situated inside a tank farm or located adjacent to specific tanks about 2 to 3 m (6 to 10 ft) from outer walls of a tank. In Hanford Site soils, liquids spread horizontally, as well as vertically, and a waste tank leak is indicated by increased levels of radiation in these wells. The term "dry" is used because the wells are located above the groundwater table. Leak detection systems are also provided for pits and diversion boxes (Figure B2-52).

Dry wells are mild steel casings, most of which are open at the bottom end to allow any subsurface liquid to enter and rise in the pipe. Their depths range from 23 to 76.2 m (75 to 250 ft). All new dry wells are grouted at the base and around the top to reduce surface water penetration into deeper soil. Presently, approximately 750 monitoring wells are located in the 200 East and 200 West Area SST farms.

Instruments for detecting and confirming leaks in underground storage tanks are inserted through various types and diameters of access channels located beside and underneath the tanks. The instruments are lowered to a predetermined depth to monitor radiation levels.

The probes used to detect radiation within the dry well area are scintillation or Geiger-Mueller probes. A scintillation probe is used in wells with a history of low-level radiation. A Geiger-Mueller probe is used in wells that have higher radiation levels. This type of probe measures the radiation-induced ionization occurring in the gas-filled tube of the instrument. Data retrieved from the radiation readings taken at these dry wells is transmitted to the CASS.

B2.4.11.3.1 Single-Shell Tank Farm Leak Monitoring. Internal tank instrumentation and external dry wells detect leaks in the SSTs. The dry wells are located around the circumference of most tanks and throughout the tank farms. The 241-A Tank Farm and parts of the 241-SX Tank Farm are also provided with lateral (horizontal) dry wells. The lateral dry wells are not currently used to monitor leakage to the soil.

The dry wells are open-bottomed, mild steel casings of either 152- or 203-mm (6- or 8-in.) dia and depths ranging from 23 to 45.7 m (75 to 150 ft). Radiation probes determine the radiation profile in the dry well. The dry-well monitoring systems require electrical power when in use.

B2.4.11.3.2 Double-Shell Tank Farm Leak Monitoring. In a typical DST, three conductivity probes are spaced in the annulus around the tank center at 120° intervals. However, in the 241-SY Tank Farm, only one conductivity probe is mounted in each tank annulus.

For the concrete shell portion of a DST, the leak detection system is known as a "leak detection pit weight factor" system (Figures B2-18, B2-53, and B2-54). This system monitors liquid level in leak detection pit sumps. A small amount of water is kept in the leak detection pit sump so that the operability of the dip tubes may be constantly verified. Detections of higher-than-normal liquid levels are investigated. Two annunciators, one at

the instrument building and the other at the evaporator control room, alarm upon detection of a leak by either leak detector.

Leak detection pit instrumentation consists of a liquid-level detector, a thermocouple, and a radiation detector.

- **Liquid-Level Measurement System**—Each leak detection pit has a specific gravity unit used for liquid-level measurement. The specific gravity monitoring instrumentation converts the pneumatic specific gravity signal to an electrical signal for transmission to a monitoring station.

  Two of the three specific gravity dip tubes in leak detection pits are below a maintained water level. One of these dip tubes is located near the pit floor; a second dip tube is located 254 mm (10 in.) above the floor. The third dip tube is located near the top of the well, above the water level. The differential pressure between the two pipes below the water measures the specific gravity; the differential pressure between the top and the lowest dip tubes measures the weight factor (Figure B2-54).

- **Temperature Measurement System**—Temperature measurement elements (thermocouple assemblies), which are installed at the bottom of each of the leak detection pits, are used in the event of a leak from the annulus tank that drains to the leak detection pit. A dual thermocouple assembly is mounted below the water level in each leak detection well. Temperature measurements may be read in the respective instrument buildings or on the CASS.

- **Radiation Measurement System**—A radiation detector is located in a dry well adjacent to the leak detection pit as part of the leak detection system. Detection of either high radiation level (indicating a potential leak) or radiation detector failure annunciates alarms.

Transmitter enclosures are provided for leak detection pits in the DST farms. A typical enclosure shown in Figure B2-55, contains the following pneumatic transmitters:

- Specific gravity transmitter

- Weight factor transmitter (provides a signal to the leak detection pit weight factor gauge) and alarm switch (provides a signal to the leak detection pit weight factor alarm switch)

- Pressure transmitter (transmits primary tank pressure to high/low pressure alarm, annunciators, and narrow-range [-1 to 0.2 kPa] [-4 in. to +1 in. WG] pressure recorder)

- Pressure transmitter (transmits primary tank pressure signal to the wide-range [-2.5 to 20 kPa] [-10 in. to +80 in. WG] pressure recorder).

Transmitters for pressure, weight factor, and specific gravity convert hydrostatic pressure differences (across dip tubes) into pneumatic signals. The pneumatic signals are transmitted to the pressure switch rack, in the instrument building and activate the respective weight factor alarm switches. These alarm switches convert the pneumatic signals to electrical signals that energize annunciators on instrument building panel boards.

Pit/Box and Transfer System Leak Detection System. Part of this leak detection system encompasses the leak detection equipment associated with the pump pits, sluice pits, valve pits, cleanout boxes, diversion boxes, transfer boxes, and some encased transfer lines. This part of the system includes dual probe electrodes, induction-type relays, fail-safe relays, transmitters, and reset switches. The other part of this system monitors some transfer lines in which 51-mm (2-in.) test risers are installed to provide radiation monitoring and leak detection capability.

Leak detection conductivity probes are located in central pump, tank, annuli, leak detection, valve, flush, and service pits, and in cleanout boxes. Identical control stations (each near the serviced tank) hold single-mounted detection monitors for the central pump, annulus pump, and leak detection pits.

B2.4.11.4 Temperature Monitoring Systems. Temperature monitoring in the waste tanks is required to maintain tank operating conditions. The temperature data provides information about the waste temperature within a tank and identifies an accumulation of solids, or "hot spots." In addition, during transfers temperatures are recorded for the receiving tanks.

B2.4.11.4.1 Single-Shell Tank Farm Temperature Monitoring. Internal tank temperatures are measured with profile thermocouple trees that consist of steel pipes with 4 to 18 thermocouples per tree, usually starting 102 mm (4 in.) from the bottom and placed at 0.6-m (2-ft) intervals up the tree. For tanks lacking a thermocouple tree, a single thermocouple is inserted in the liquid observation well. Temperatures may either be read and recorded manually or transferred automatically to TMACS.

B2.4.11.4.2 Double-Shell Tank Farm Temperature Monitoring. The temperature of each DST and its contents is monitored by using thermocouple elements and digital temperature equipment located in the associated instrument building.

Thermocouple elements are installed during construction of each tank in the following locations (Figure B2-56):

- Insulating concrete (all dual thermocouple elements)
- Primary tank lower walls
- Concrete foundation
- Concrete walls and haunch
- Concrete dome.

The thermocouple system, shown in Figure B2-56, provides access to thermocouple elements located in the liquid in leak detection pits and at 18 different depths in the primary tank contents.

Thermocouples, either individual or installed on thermocouple trees, extend down through the tank risers into the tank contents. Temperature data from these thermocouples can be used to chart a temperature progression from the bottom to the top of the tank over time (a "profile"). In tank farms equipped with stationary temperature display systems, no provisions exist for taking temperature readings at the tank risers. The thermocouple signals are sent directly to the instrument buildings.

A probe with thermocouple elements is suspended in each primary DST. The end of the probe is approximately 152 mm (6 in.) above the bottom of the tank, and the first thermocouple element is 102 mm (4 in.) above the end of the probe and approximately 254 mm (10 in.) above the tank floor. The probe design is shown in Figure B2-57.

Thermocouples are also installed a few inches above the bottom of the tanks at different locations from the center. These thermocouples are specially designed to measure sludge temperatures. The thermocouple arrangement for a representative tank from 241-AP Tank Farm is shown in Figure B2-58.

Dome Thermocouples. These thermocouples monitor temperatures in the tank dome.

Tank Knuckle Thermocouples. Only one or two thermocouples measure the temperatures in the tank knuckles.

Air Lift Circulator Thermocouples. These temperature-monitoring devices are used primarily in AWF tanks. Each air lift circulator is equipped with several temperature elements that can detect hot spots. Each of the 22 air lift circulators have attached thermocouples that extend 76 mm (3 in.) above the liner bottom.

Sludge Thermocouples. Sludge thermocouples detect accumulations of heat-generating solids and are located near the tank bottom.

Sensor Locations. Thermocouples are located throughout the insulating concrete, foundation, and concrete shell.

- **Insulating Concrete**—Thermocouples in the annulus monitor temperatures, the limitation of which is unimportant for ensuring the structural integrity of the tank and concrete shell. Thermocouples are embedded in the concrete layer directly under the primary tank and the foundation to ensure that a uniform temperature is maintained throughout the tank. The thermocouples are close to the underside of the primary tank liner bottom and are equally spaced in a circular arrangement. Additional thermocouples contact the outer surface of the primary tank shell.

  Twenty-four thermocouples are embedded in the insulating concrete pad between the primary and secondary tank (Figure B2-56). The

thermocouple spacing varies slightly to avoid interference with the insulating concrete drain slots. Thermocouple elements attached to the primary tank wall in the annulus monitor the temperature of the tank wall just above the lower knuckle.

- **Foundation**—The foundation thermocouples lie between the bottom of the concrete shell and the earth below. These thermocouples, arranged in pairs, measure temperature gradients in the concrete base.

  Maximum heat transfer between the temperature element and the conduit is achieved by loosely packing aluminum foil into the conduit cap. Foil is epoxied into place before the conduit end is capped.

- **Concrete Shell**—Thermocouple probes measure temperatures near the inner and outer surfaces of the concrete shell, as shown in Figure B2-56. The thermocouple elements are assembled and installed in pairs. One thermocouple element of a pair is located near the inner surface of the shell (on the annulus wall or annulus/primary tank dome), and the other element is located close to the soil on the outer surface of the shell. Twenty-four thermocouple probe units are embedded in the concrete shell wall and another 24 in the haunch and dome.

Portable Potentiometer. The portable potentiometer provides profile temperature data, which is manually read at the tank riser.

The profile temperature thermowells (from which the readings are taken) have been placed inside the tank and bolted onto an existing riser. On top of the riser is a housing box that consists of a plug receptacle and an indicator dial (also called a "Christmas Tree"). To obtain a temperature reading, the portable potentiometer must be plugged into the receptacle.

Heat Trace Sensing System. Three thermocouple probes are attached to the underside of the tank farm process piping. The conduit and probes are held in place with stainless steel straps.

Thermocouple Terminal Boxes. Six terminal boxes equally spaced around the perimeter of the tank are junction boxes for the thermocouple leads. A seventh terminal box, near riser 4, transmits primary tank thermocouple signals. Thermocouple element locations and corresponding instrument building selector switches are shown in Figure B2-59.

Tank Temperature Retrieval. For selected tank farms, the temperature thermocouples have been connected to selector switches located on panel boards in the farm instrument building. The selector switches are labeled to identify the tank and thermocouple numbers. To obtain a temperature reading, the appropriate selector switch is connected to the readout unit with the plug-in cord provided.

Data Acquisition and Signal Conditioning System. For some of the 241-AY and 241-AZ tank farms, the thermocouples are routed to an instrument building, where data from the thermocouples is received by the data acquisition and

signal conditioning system. Equipment in this system scans the thermocouples on command and converts the thermocouple inputs for direct readout in degrees Fahrenheit at the data acquisition and signal conditioning system building.

The 241-AP Tank Farm has a temperature display system used for monitoring tank temperature data. The system has an alarm and historical tracking features.

B2.4.11.5 Waste Sampling Equipment and Methods. Sampling methods depend on the type of waste in each tank. The methods used in support of various TWRS activities include core sampling, grab sampling, auger sampling, and various types of vapor space or gas sampling.

B2.4.11.5.1 Core Sampling. Core sampling remotely obtains samples of solid or semisolid material stored in the tank farm waste storage tanks. Core sampling consists of boring a hole into the solid-sludge mixture in the tank with a hollow, tubular drill string; capturing a portion of the solid-sludge mixture inside the drill string with a sampling assembly; and retrieving the sampling assembly to the surface.

Push mode core sampling is used to obtain solid or supernatant liquid samples of the high-level waste materials in the underground waste tanks. Specially designed core-sampling trucks and sampling devices are used to obtain samples from the tanks. A cylindrical cross-section of the tank contents below the riser used for sampling is obtained by pushing a sampler bit into the waste (Figure B2-60). During a sampling task, the sampler is lowered into the waste by a hydraulically powered drill string. Drill ram hydrostatic pressure is monitored during the sampling operation to measure waste resistance. A series of core samples is taken repeatedly until the bottom of the tank is reached.

A rotary platform is mounted on the sampling truck. The shielded receiver is mounted at one end of the rotary platform; the drill unit is mounted at the other end of the platform. Liquid or nitrogen gas is used as a hydrostatic head fluid. There is a down force limiter, which shuts down push operations when excessive down forces are encountered. A cylindrically shaped, shielded receiver houses the full sampler once it has been withdrawn from the tank. Also mounted on the sampling truck is an electrically operated winch. The winch unit raises and lowers the drill string and additional equipment that connects the riser of the tank being sampled with the drill rig. The system confines the waste sample throughout the entire operation.

B2.4.11.5.2 Auger Sampling. Auger sampling obtains samples of the surface layer of "watch list" tanks that may generate flammable gases or may contain organic solvents or ferrocyanide compounds. Auger sampling may also be used to obtain core samples in tanks containing less than 200 to 300 mm (8 to 12 in.) of waste. Auger samples are obtained by using a stainless steel, hand-turned auger bit contained in a sleeve. The method is similar to wood boring or ice augering. This method cannot be used to sample low viscosity wastes because the sample cannot be properly captured in the sampler.

B2.4.11.5.3 Supernatant and Soft Slurry Grab Samples. A special sampling bottle contained in a cage can obtain liquid or soft slurry samples

of the waste. The bottle is stoppered and lowered to the desired level. The bottle is then opened so that it fills with liquid, is retrieved from the tank, and is restoppered. This "bottle-on-a-string" sampling procedure conforms to ASTM E-300-73, *Weighted Bottle Sample Method.*

B2.4.11.5.4 Vapor or Gas Sampling. Vapor space or gas samples are required to determine the composition of hazardous, explosive, or flammable gas mixtures containing hydrogen (H_2), ammonia (NH_3), and nitrogen oxides (NO_x). Gas samples are obtained by three methods: (1) a sample may be drawn, by fan, through a device that traps or concentrates certain gas constituents; (2) a sample may be collected in a container; or (3) the gas may be analyzed in situ using portable monitors. The various methods are described in WHC-SD-WM-PLN-101, *Fiscal Year 1996 Tank Waste Remediation System Tank Waste Analysis Plan.*

The standard hydrogen monitoring system (SHMS) was developed to operate in a Class 1, Division 1, Group B (hydrogen) atmosphere. Where necessary, system components are designed to meet NFPA 70 requirements for operating in a hydrogen environment. The SHMS can be installed in four different configurations: (1) on the ventilation exhaust duct of DSTs, (2) on a gas probe assembly, (3) on a multifunction instrument tree assembly, or (4) on a modified riser flange for SSTs with passive ventilation.

The SHMS provides online monitoring of gas samples for hydrogen content and enables more detailed laboratory analyses of grab samples. In addition to monitoring, the system provides recording and alarm functions. On some tanks, SHMS provides hydrogen concentration and sample flow rate data to the TMACS. The system is available in five different models and is designed for use on any tank (see Appendix E, "Flammable Gas/Slurry Growth Unreviewed Safety Question: Justification for Continued Operation for the Tank Farms at the Hanford Site" for a listing of tanks equipped with SHMS). Details are provided in WHC-SD-WM-SDD-001, *System Description Standard Hydrogen Monitoring Systems.*

B2.4.11.6 Dome-Space Gas Monitoring. In addition to the standard hydrogen monitoring system which is limited to hydrogen gas, various sampling techniques and equipment are used to monitor the gases (not limited to hydrogen gas) contained in the dome space. Typically, the dome space gas samples or vapor samples are obtained by using a gas-sample probe (unique to the gas sampling and analysis equipment used) installed in the vapor space above the tank contents. A gas-sample probe may also be part of another Tank Monitoring and Control System, as is the multifunction instrument tree. The multifunction instrument tree, which is inserted into the tank waste and connected to TMACS, contains 27 thermocouples and several probe chambers for gas samples.

B2.4.11.7 Pressure Monitoring Systems. For DSTs, the pressures within the primary tank (i.e., vapor space) are continuously monitored. The primary tank pressure (i.e., tank pressure/vacuum systems) is monitored locally at the instrument buildings and remotely at CASS and TMACS. The primary tank pressure/vacuum pressure monitoring system is required to maintain a negative pressure within the vapor space with respect to atmospheric pressure, maintain structural integrity (i.e., prevent buckling resulting from high vacuum), and detect pressurized releases.

Primary tank pressure is monitored by measuring the differential pressure between the tank vapor space and the atmosphere. The primary tanks are equipped with differential pressure monitoring systems to detect excessive vacuum levels (low pressure conditions) and insufficient vacuum (high pressure conditions). Backup pressure monitoring is provided by magnehelic gauges that are located on tank risers or in local instrument buildings. Pressure switches will activate when tank vacuum is lost (e.g., high pressure) as a result of a loss of ventilation or a pressurized release. The switches will also activate when vacuum is excessive (i.e., loss of ventilation system control). The switches will activate local audible alarms and alarms at CASS and TMACS.

B2.4.11.8 In-Tank Surveillance Cameras. In-tank video systems may be either portable (i.e., installed temporarily for a few hours or days) or permanently installed in a tank dome space. Other cameras are designed to be mounted on top of a tank riser for riser inspection. Cameras used in flammable gas tanks are purged and some are also shielded to prevent sparking. Most cameras are equipped with pan, tilt, and zoom features that are operated from a van or control console located on top of or near the tank. All camera systems normally consist of a camera, lights, associated cabling, and a van containing control and recording electronics.

B2.4.11.9 Criticality Detection Systems. There are no criticality detection systems in TWRS (Chapter 6.0). Neutron detection is provided at 244-TX DCRT (Section B2.4.5.1).

B2.4.12 Cathodic Protection Systems

Underground carbon steel and stainless steel pipelines transfer mixed waste in the 200 East and 200 West Areas (Section B2.4.10.1.1). These pipelines form a network connecting process plants, underground tanks, and an evaporator. The steel of the buried pipe-in-pipe (not concrete encased) is subject to external galvanic corrosion resulting from bacterial and chemical activity in the soil. Cathodic protection systems are provided to minimize waste line failures. The cathodic protection systems protect only the underground piping and not the underground tanks.

The NEMA-U, oil cooled, and silicon-dioxide rectifiers of the cathodic protection system are supplied with three-phase alternating current, are insulated with high-density polyethylene, are completely enclosed for protection from the environment, and are located outside tank farm boundaries. Rectifier output voltages are adjustable. Cathodically protected lines are identified in Table B2-22.

B2.4.13 Interlock Systems

Certain tank farm equipment (e.g., process pumps and HVAC fans) is interlocked to detect abnormal conditions and to protect personnel, equipment, and the environment. The tank farm transfer pumps, for example, are interlocked to shut down when a leak is detected in a process pit or in a transfer line encasement.

Pump shutdown interlock sequences are related to various sources, including leak detectors, flush line limit, and pressure switches. In addition, pumps are equipped with their own internal circuitry to shut down the pump upon detection of abnormal operations (e.g., when the pump motors draw unusually high or low amperage). In general, pumps are interlocked with only those devices that can detect an abnormal condition caused by that pump.

Most transfer pumps in the 200 Area DSTs are interlocked to shut down together if any of the following occur:

- Any one of the master shutdown switches in the 242-A Evaporator control room is activated
- A leak is detected in any tank farm valve pit or pump pit.

Anything that activates the master shutdown relay shuts down the 241-AN, 241-AP, 241-AW, 241-AY, and 241-AZ transfer pumps.

If any one of the process pit leak detector relays is activated because of a leak or circuit failure, the interlock relay will activate and send a "fail" signal to three locations. The first signal activates the leak detection alarm for the process pits in the control room. The second signal is sent to the leak detector transmitter in the instrument building. The third signal activates the master shutdown relay if a leak is detected or a detector fails, and trips other interlocks and stops the pumps.

B2.4.13.1 Pump Interlocks. Pump motor shutdown interlocks are linked to various devices, including leak detectors, flush line limit switches, and pressure switches. In addition, pump motor electrical power supplies are interlocked with the internal protective circuitry of the pump motor to avoid pump damage when the pump motors draw unusually high or low current. Pump control, interlock circuitry, and master pump shutdown system devices prevent contamination of the environment, equipment, and facilities if a leak occurs during waste transfer operations. A pump motor power loss of more than 10 to 15 seconds shuts down pumping operations.

Leak detection devices are installed in 200 East and 200 West Area pump, valve, flush, and service pits; cleanout structures; diversion boxes; diverter stations; and pipeline encasements.

All central pump pit pumps in the 241-A, 241-AN, 241-AP, 241-AW, 241-AX, and AWF tank farm complexes are shut down together, under the following conditions:

- Any one of the master shutdown switches in the 242-A control room is tripped
- A leak is detected in any "A Complex" area valve or pump pit.

B2.4.13.2 Pressure and Limit Switches. DST transfer pumps, jumpers, and transfer lines are equipped with safety interlock systems that prevent operation, initiate an alarm, or both when a hazardous condition exists. Pressure switches are used in flush pits where steam or raw water is supplied for tank farm use. Pressure switches are mounted at strategic locations

within the flush pit to sense line pressure fluctuations. In most instances, when the line pressure exceeds a setpoint, the pressure switch causes the associated pump to shut down.

The pressure switches are valved into the raw water/transfer line piping only when the raw water is required for flushing the transfer line. Excessive pressure at the switch may indicate backflow of radioactive waste into the raw water supply. The switch prevents contamination of the raw water system by energizing the associated waste transfer pumps. Operation of waste transfer pumps is not normally required during line flushing operations.

Limit switches are used in valve pits where transfer line routing changes are made. A limit switch is a device that opens or closes a pair of contacts when the transfer line valve stem is rotated. Typically, a small lever extending from the limit switch moves as the valve position is changed. If a limit switch is tripped during a transfer, an interlock will shut down any associated waste transfers.

B2.4.13.3 HVAC Interlocks. HVAC fans are interlocked to shut down if the exhaust stack CAM units detect high radiation in the exhaust stack; or for actively ventilated SSTs, the 204-AR Vault, and DSTs, if the redundant train is automatically started. The interlock circuitry for HVAC equipment shuts down the ventilation systems if CAMs detect high radioactivity in DST or catch tank exhaust lines.

B2.4.14 Mixer Pumps

The bottom layer of waste in the tank is a nonconvective layer that traps hydrogen. The upper layer is a thinner convective layer that freely releases hydrogen. Submersible mixer pumps mix the waste layers in the tank, thereby releasing hydrogen in a controlled manner. The mixer pump located in Tank 241-SY-101 is a submersible pump 17 m (56 ft) long (Figure B2-61) (LA-UR-92-3196, *A Safety Assessment for Proposed Pump Mixing Operations to Mitigate Episodic Gas Releases in Tank 241-SY-101: Hanford Site, Richland, Washington*). The pump intake is submerged to a waste depth of 3.7 m (12 ft) in the thinner, convective waste layer; the pump discharge is in the bottom, nonconvective layer.

Electrical power is supplied to the pump assembly through conduits inside the support column. These conduits are rated for use in an explosive hydrogen environment, and the support column is filled with inert nitrogen. All motor connections, cable, wire, and conduit connections are located below the waste surface in a nonhazardous location within the tank. The pump is equipped with vibration monitors, flowmeters, and pump discharge pressure meters to detect abnormal conditions resulting from a plugged nozzle, frozen jet, or other malfunction.

The data acquisition and control system has been designed to control the Tank 241-SY-101 mixer pump and ancillary systems and equipment. This system consists primarily of a computer-based system that collects, interprets, and displays data and annunciates alarms. This system also monitors the liquid level in 241-SY-101, and data from this system is used as an evaluation input for mixer pump operation.

Because of the size and operating environment of the mixer pump, a special waste packaging system is used during pump removal. This system consists of a flexible receiver, similar to a sleeve, into which the mixer pump is drawn as it is raised from the riser and decontaminated with high-pressure water jets. The sealed flexible receiver confines liquids as the pump is removed from the tank. The flexible receiver containing the mixer pump is loaded into a shipping container for disposal.

B2.4.15 Light-Duty Utility Arm

The light-duty utility arm (LDUA) system provides the capability to reach locations within the waste tank and waste surface that are not directly under the access risers (HNF-SD-WM-HIE-010, *Hazard Identification and Evaluation for Deploying the Light Duty Utility Arm in Flammable Gas Facility Group 3 Tanks*). The LDUA system deploys a family of tools and sensors, called end effectors, into the underground waste tanks by means of a robotic arm on the end of a telescoping mast. The system collects and manages the data retrieved and generated. Access into the tanks is through existing risers. A Mobile Deployment Subsystem transports the mast and arm between tanks and positions them over a 30.5-cm- (1-ft-) tank riser. Ancillary subsystems support the main deployment equipment, performing such functions as maintaining confinement of the tank atmosphere; decontamination of the mast, arm and end effectors; power distribution; and observation of in-tank operations. The system is operated from the remote Operations Control Trailer located outside the tank farm perimeter fence, up to 275 m (900 ft) from the LDUA deployment vehicle.

End effectors are the tools that perform the specific in-tank tasks of the LDUA system. End effectors (and their storage and transportation containers) are available to provide a basic capability to perform visual surveys and inspections of the tanks, to perform in-tank object manipulation, and to collect small waste samples. The Gripper End Effector has the ability to grasp and manipulate objects in the tank or to manipulate other tools, including waste probes which provide information on the consistency of tank waste. The High Resolution Stereo Video System provides the ability to obtain detailed observational data of the waste and tank structures in areas not visible from the other in-tank surveillance cameras (Section B2.4.11.8, "In-Tank Surveillance Camera"). The extended reach end effector provides additional capability by extending the LDUA reach by 2.08 m (6.83 ft) (HNF-2174, *Hazard Evaluation for Deploying the Extended Reach End Effector (EREE) on the Light Duty Utility Arm (LDUA) in Flammable Gas Facility Group 3 Tanks*). It also provides the ability to sample using a pair of pneumatically operated scoops to collect waste samples. The extended reach end effector incorporates a pair of video cameras (one black and white and one color) plus a lighting system mounted for optimum viewing of the sampling.

B2.4.16 Cone Penetrometer

The cone penetrometer (CP) soil sampling technique uses a portable platform to deploy small-diameter push rods (piping segments approximately 1 m [39 in.] long with screwed connections), or rods, to depths of up to 70 m (230 ft) for vadose zone characterization (HNF-SD-WM-HIE-012, *Hazard*

Identification and Evaluation for Deploying the Cone Penetrometer in the Tank Farm for Vadose Zone Characterization). Soil sensor and soil sampling probes are deployed by mounting them on the front end of CP push rods. These sensors and samplers, which have a conical shaped tip, are slowly pushed to target depth(s), by hydraulic cylinders on the CP platform, which can provide as much as 15,900 kg (35,000 lbs) of pushing force. Set up is limited to areas not directly over tanks, transfer lines, or buried utilities. The CP is not intended for in-situ characterization of tank waste. A trailer-mounted support module is located near the platform, providing electrical power and hydraulic support through power cables and hoses.

B2.5 PROCESS DESCRIPTION

The activities and operations performed within the TWRS facilities are described in this section. Typical activities and operations required to support operations are presented in Table B2-24. The activities and operations, in conjunction with the structures, systems, and components described in Section B2.4, are necessary to the TWRS mission. These activities and operations provide the means to safely manage tank farm wastes and, in conjunction with the institutional and safety programs discussed in Chapter 4.0 provide protective layers to prevent or mitigate unwanted releases of radioactive or hazardous materials. Those operations that are directly relied upon to protect the facility worker, the onsite worker, or offsite individuals are identified in Chapter 6.0, and reflected in the Technical Safety Requirements.

B2.5.1 Waste Storage

The objectives of tank waste storage are to isolate the waste from the environment and to avoid human exposure until final disposition of the waste and associated facilities. Tank waste is stored as outlined here.

- Tanks that may receive and store waste from either processing activities or other tanks are considered in-service tanks, and those that cannot or do not receive waste are considered out of service tanks. All 149 underground SSTs received no additional waste after November 1980. The 28 underground DSTs are all considered in-service tanks and those not on the "watch list" may receive liquid waste from processing activities or other tanks.

- In-service tanks such as DCRTs and catch tanks also receive liquid waste from normal tank farm transfer operations and serve as temporary storage locations.

- The 36 inactive miscellaneous underground storage tanks administered by TWRS may temporarily store some uncharacterized hazardous and radioactive waste. The capacities of these tanks are presented in Section B2.4.

- Although the 204-AR Waste Unloading Facility directly transfers newly generated liquid waste to the underground DSTs, amounts less

than 5,680 L (1,500 gal) of dilute waste may be temporarily stored in the catch tank at this facility.

- The 244-AR Vault is out of service, but each of the four storage tanks and the cell sumps contain some quantities of uncharacterized hazardous and radioactive waste. The tanks in this facility are discussed in Section B2.4.

During storage activities, caustic solution (NaOH in water) may have to be added to waste tanks when the hydroxyl ion concentration of the waste is lower than the minimum level required to control corrosion of the primary tank wall. The caustic solution is added to the tank by one of the following methods:

- In the first method, a vendor-owned tank truck carrying caustic solution is connected to a skid-mounted metering pump. A flexible hose is connected between the metering pump and the tank mixer pump, and the caustic solution is transferred to the metering pump. The caustic solution is then pumped into the tank and distributed throughout the waste until the specific amount of solution has been added. This method is used when the hydroxyl ion concentration in the waste is low enough to potentially cause serious corrosion.

- In the second method, 208-L (55-gal) drums containing caustic solution are connected to a skid-mounted metering pump by means of a flexible hose. The caustic solution is then pumped into the tank through an available tank riser. This method can be used for both high- and low-hydroxyl ion concentration in the waste.

B2.5.2 Waste Transfer

Preestablished routes are used to transfer liquid waste safely from one location to another in response to processing requirements, changing tank storage needs, or tank leaks. The waste transfer operations are as follows:

- Internal transfers
  - Tank farm to tank farm
  - DST to DST within a tank farm
  - SST to DST
  - Catch tank to storage tank
  - 204-AR Waste Unloading Facility to DST.
- External transfers
  - Between process facilities and DSTs
  - From process facilities and the 204-AR Waste Unloading Facility.

Before transferring waste, tank farm operations performs several activities. These activities include verifying that sufficient space is available in the receiving tank, verifying the waste chemistry (by sampling and characterization) to ensure that the waste to be transferred is compatible

with the receiving tank waste, performing criticality safety analyses to ensure that stored waste will remain in a subcritical state, and verifying equipment operability. A baseline material balance is developed before the transfer for both the sending and receiving storage tanks. Before cross-site transfers, the transfer line is prefilled with water to verify valve lineups and routing. The material balance is reviewed periodically during the transfer to provide early leak detection and avoid filling tanks above safe levels. After the transfer, all associated equipment is deenergized; transfer lines are flushed with water; and a final material balance is recorded for both tanks.

B2.5.2.1 Salt Well Jet Pump Design and Description. The SWP process utilizes a motor/pump and jet pump, as shown in the Salt Well Jet Pump Isometric View, Figure B2-65. The jet pump is located near the bottom of the salt well screen. The motive power for the pumping process is provided by a centrifugal pump/induction motor (squirrel cage) unit that is located on top of the salt well screen assembly in the pump pit. The motor and centrifugal pump assembly is hermetically sealed and thus is ideal for pumping hazardous materials. There is no exposed pump shaft, which could be a source of leakage if a packing gland were to fail. The pump and motor assembly, as currently procured for salt well pumping, is rated for or otherwise qualifies for service in Ignition Control Set 2 environments.

The recirculation line liquid flow is measured, and a flushing system is included so that the pump motor and recirculation line can be flushed. The recirculation line flow measurement system includes alarms for low flow and a process trip (trip salt well pump) for loss of recirculation flow. An air operated solenoid isolation valve is provided just after the recirculation line connection point on the pump discharge nozzle, to allow forward or back flushing of the pump. The SWP instrumentation includes a pressure switch that monitors the pump discharge pressure. The pump inlet and discharge legs run inside the salt well screen. Adjacent to the pump-discharge leg are three dip tubes. The dip tube system allows the liquid level and specific gravity in the salt well screen to be determined. This instrumentation allows the SWP system to be placed in the automatic mode. In this mode, the pump runs continuously, and the flow through the pump to the transfer system is regulated by the operation of a diaphragm operated valve. In some instances, a fourth dip tube may be added to provide real time waste dilution during pumping. In normal operation, the pump export flow rates will vary between ~5 and 0.05 gpm.

Water-lancing of the tank waste and the waste surface inside the salt well screen may be necessary to minimize installation interferences. The water-lancing procedure would use up to ~1,900 L (~500 gal.) of hot <93 °C (<200 °F) water to penetrate any crust within the salt well screen and create a circular entry area that is large enough for the jet pump unit and dip tubes within the salt well screen. The amount of water used with the lance is metered at the supply source, usually a portable water truck.

The following paragraphs describe the various components that make up the salt well pumping operation:

B2.5.2.1.1 Salt Well Screen. The salt well screen is purely a mechanical device. The screen assembly consists of several components: the top flange,

pipe, screen assembly, bottom cap, and the flush line. The top or open end has a flange welded around a schedule-40 steel pipe. The flange is used to support and stabilize the screen assembly after it has been installed in an available tank riser. The steel pipe portion of the screen extends approximately one-third of the overall length of the screen assembly. The remaining length is made up of a stainless-steel screen assembly. The length of the screen portion of the salt well assembly is normally established for a particular tank so that, when installed, the screen extends above the surface of the waste.

The salt well casing assembly description provided here is typical, and minor variations (e.g. pipe diameter, location and size of openings, etc.) may occur in some applications. The screen portion extending above the waste surface helps ensure that any liquids in the tank can migrate to and into the screen cavity for pumping. The bottom of the salt well screen assembly consists of two flat plates welded to the stainless-steel screen cylinder. These two plates have a solid cylindrical spacer that keeps them apart. The lower plate has several small holes drilled in the plate, uniformly distributed around the plate, and with one hole in the center. A small pipe is connected to the space between the two plates. This pipe extends the length of the salt well screen, inside the screen cavity, and terminates at a threaded coupling just inside the top of the salt well pipe assembly.

During installation, a flushing water hose is connected to this pipe, and water exits the lower plate holes as the salt well screen assembly is lowered into the waste. This flushing water helps to clear the waste away so that the salt well screen will seat properly in the waste. The bottom of the salt well screen is normally close to the bottom of the tank [nominally 5 cm (2 in.)]when fully installed. The screen is equivalent to a number 400 mesh size, which allows liquid waste to pass through the salt well screen (enter the pump cavity) while preventing solid waste from migrating to the jet pump. The jet pump is installed near the bottom of the salt well screen cavity to maximize the amount of interstitial liquid that can be pumped.

B2.5.2.1.2 Jet Pump Unit. The jet pump is located at the bottom of the salt well screen, as shown in the Jet Pump Unit and Foot Valve, Figure B2-66. It is suspended in the screen cavity by supply and return lines. These lines are connected to the salt well pump plate that is installed in the pump pit. Variable pumping rates are achieved in the SWP operations by using a recirculation configuration with bypass valving to allow slower export rates, while maintaining higher circulation rates. The centrifugal pump pressurizes the motive fluid that is pumped to the jet assembly. The motive fluid passes through the nozzle in the jet assembly and converts the fluid pressure head to velocity head, thus reducing the pressure in the jet-assembly chamber. The reduction in pressure allows the interstitial liquid to enter the jet assembly chamber and mix with the motive fluid. Velocity head is then converted to pressure head above the nozzle, lifting the motive fluid and interstitial liquid to the pump-discharge leg.

The jet-pump unit includes an integral foot valve, which is a check valve that is intended to prevent the drainage of the pumped fluid if the salt well pump is shut down for any reason. A combination flush and mechanical lifting line is provided as part of the downcomer lines from the salt well pit. This flush line is made of small diameter stainless-steel instrument tubing. The

tubing is connected by mechanical fittings and is routed to the front of the foot valve at the bottom of the salt well. If foot valve plugging is suspected, hot flush water can be injected at the face of the foot valve to help dissolve any solidified waste material. The tubing is connected to a handle that extends above the pump pit and through the pit cover. Tank farm SWP operations personnel can lift this handle and exert an upward force on the face of the foot valve to help open it if it becomes inoperable.

The instrument tubing is held in place by a series of small steel rings welded to the jet pump downcomer lines. The jet pump unit is connected to the inlet and outlet (downcomer) piping using pipe union fittings. Thus, in the event of failure of the jet pump unit, it is possible to remove the pipe and jet pump unit and install another jet pump unit in the field.

B2.5.2.1.3 SWP System Piping and Valves. The SWP process utilizes a unique pipe and valving arrangement to convey pumped waste from the tanks. The overall piping arrangement is depicted in Figure B2-67, Salt Well Pump Piping and Instrument Diagram. Not shown is the tank in which the jet pump and salt well screen are installed, or the details of the jet pump recirculation line flushing and flow monitoring subsystem (which is shown schematically in Fig. B2-66). Each of the valves in the main system is described below.

Foot Valve: The foot valve is an integral component of the jet-pump assembly, discussed in section B2.5.2.1.2. It is a check valve that prevents liquid from draining from the supply and return lines of the pumping system.

Drain and Pump Valve (JP-1): This is a two-position, three-way valve. It is located above the salt well pump in the pump pit. The valve is actuated manually by a "T"-bar-type valve handle extension by operations personnel standing on the pump pit cover. The valve can be aligned in the recirculate mode, in which case waste fluid is circulated between the centrifugal pump and the jet pump unit, with pumped liquid leaving the system through the diaphragm-operated valve (DOV) or bypass valve (JR-2). In the drain position, flush water passes through the salt well jumper and then into the tank through the salt well casing drain line. In this mode, flushing water goes through the centrifugal pump and the jet pump, and the foot valve prevents flushing water from entering the tank. In the recirculate position, the pump, jet pump, and foot valve may be flushed by pulling up on the foot valve rod and allowing the flush water to run out the foot valve.

Bypass Valve (JR-2): The JR-2 is a manually operated valve used to bypass flow around the main flow control valve (i.e., the DOV). JR-2 also is operated by a "T" bar handle by operations personnel standing on the pump pit cover. JR-2 is usually opened at the beginning of SWP activities. JR-2 also may be opened for flushing and priming operations.

DOV: The DOV is a plug valve with an air operator attached to position (incrementally open or close) the valve to regulate the flow and therefore the pumping rate of the salt well jet pump system. The salt well pump and jet pump essentially act as a closed-loop flow system. When the DOV and JR-2 valve are closed, fluid is simply pumped around the loop. When the DOV or the JR-2 valve are open, the fluid exits the

pumping loop and travels toward its final destination. The DOV is calibrated by adjusting the spring tension in the valve operator to offset the supplied air pressure.

Discharge and Flush Valve (JR-1): The JR-1 is a three-way manually operated valve. It is operated by a "T" bar valve handle by an operator standing on the pump pit cover. JR-1 can be positioned to allow the pumped waste fluid to enter the transfer line or to allow flush water to flush either the transfer line or the salt well pump and jet pump unit. JR-1 has position indication such that the SWP control system can monitor the valve's position.

Flush Water Check Valves: The flush water supply line is provided with two in-series check valves to prevent tank waste from accidentally being pumped into the flush water supply.

Discharge and Flush Jumper Connections: The flush line and the discharge line are connected to the salt well pump assembly. The discharge line of the salt well assembly is connected to a transfer line nozzle in the pump pit by a flexible jumper. The flushing connection is brought out of the top of the pump pit cover, where a quick-disconnect hose connector is used to allow a flush water hose to be connected.

DOV Control Air Line: The DOV control air line is a flexible air hose that is brought out of the pump pit and is connected to an electrical current to pneumatic pressure converter in the SWP control cabinet.

B2.5.2.1.4 Salt Well Assembly Instruments. This section describes the instruments that are mounted on the jet pump assembly in the pump pit and in the SWP control cabinet. All of the instruments in the salt well pump pit are rated for or otherwise qualify for service in Ignition Control Set 2 environments.

Pump Discharge Pressure Switches: The discharge header has two pressure switches installed as a Defense-in-Depth measure. One pressure switch is calibrated to activate when low discharge pressure is observed. This may be caused by the jet pump unit being plugged, the salt well screen being plugged, or another problem causing poor pump prime. Low discharge pressure results in an alarm and a pump trip after a few seconds of low pressure. The second pressure switch is calibrated to operate when high discharge pressure occurs. High discharge pressure could be caused by the transfer path being blocked (e.g., mis-positioned valve or a plugged line). High discharge pressure results in an alarm and pump trip.

Flush Water Supply Pressure Switch: The flush water supply line is provided with a pressure switch. Activation of this switch, caused by a change in pressure in the supply line, will cause an alarm and pump trip. Activation while pumping is in progress would be indicative of possible waste leakage into the flush system.

Process Flow Transmitter and Totalizer: A flow transmitter and associated flow totalizer are provided. The flow transmitter is a non-contact magnetic instrument that measures total system flow from the

jet pump assembly to the site transfer system. This instrument includes the flow totalizer which displays flow rate and total gallons pumped.

Pump Suction and Discharge Pressure Transmitters: Pressure transmitters are installed on the SWP suction and discharge header. These transmitters are connected to the SWP control system. The suction and discharge pressure readings, in conjunction with the pump flow readings, are used to evaluate pump performance and to detect possible line blockage (either suction or discharge). These devices can also be used to provide backup pressure interlocks in the event the pressure switches fail or are found unserviceable.

B2.5.2.1.5 Salt Well Pump Control System. The SWP control system is designed so that several salt well pumps in different tanks can discharge into a common line. Each pump is interlocked with other pumps in its group so as to provide safe and orderly shutdown of the group in the event of any single pump shutdown. The following paragraphs provide additional detail of the SWP control system. In some cases, existing tank farm equipment, including weight factor instrument enclosures, pump and leak detector control stations, water and air services may be used for salt well pumping in lieu of the skid mounted system. The operation of this equipment will be similar to that described herein for the skid mounted system.

B2.5.2.1.5.1 Control Skid and Enclosures (If Used). The control system is skid mounted on a fabricated frame containing four major enclosures. These enclosures, which protect the equipment contained within them, include:

1) Power Rack and Control Assembly: This unit provides the connection point for the incoming power, as well as housing the programmable logic controller, relay, and termination cabinets. All connections to the in-pit instruments are connected to this unit.

2) Water Tank Enclosure: This enclosure holds a water tank, containing sufficient water so that the dip tube system can operate for extended periods of time between refills (using a water truck). The water is freeze protected and pressurized. The enclosure also contains instruments used to monitor tank water level, pressure, and enclosure temperature.

3) Weight Factor Enclosure: This enclosure contains instruments that are used with the dip tubes to determine liquid specific gravity and tank level. The transfer flow meter and pump pressure and suction meters are located in this enclosure.

4) Air Compressor Enclosure: This cabinet contains a small air compressor that provides pressurized, clean, instrument-grade air for use on the control skid. Primary uses are to (1) pressurize the water tank, (2) provide air for the dip tube system, and (3) control air to the electrical current to pneumatic pressure controller for the DOV.

The skid is located next to the pump pit to ensure a "downhill" slope for the portable instrument lines. These lines connect the dip tubes in the salt

well pump pit to the weight factor cabinet. All exposed skid metal and cabinets are painted to protect them from corrosion.

B2.5.2.1.5.2 Power System. AC power will be provided by a temporary connection to the tank farm electrical distribution system. All electrical equipment is grounded to the skid, and a ground conductor is connected to a facility grounding point (field determined).

B2.5.2.1.5.3 Compressed Air System. The compressed air system utilizes an oil-free, direct-drive compressor typically rated at 91 L/min. at 0.62 MPa (3.2 scfm at 90 psig). Air leaves the compressor and is routed through instrument air filters and dryers before reaching the air receiver. A mechanical pressure gauge, visible from the outside of the compressor enclosure, is provided so that operations personnel can monitor system air pressure.

B2.5.2.1.5.4 Dip Tube System - Salt Well Level, Specific Gravity, and Weight Factor. A key instrumentation system for the SWP activity is the dip tube system and related process instrumentation. The dip tube system consists of three pressure measurement pipes that are positioned uniquely in the waste tank so that the tank liquid level and waste fluid specific gravity can be determined. Two of these pipes extend to the bottom of the salt well screen. One of the tubes extends almost to the bottom of the salt well screen, and another is cut accurately so that the vertical distance from the bottom tube opening is 25.4 cm (10 in.). The third tube is installed and terminates inside the salt well cavity to provide a reference leg for the dip tube system. Alternatively, the reference leg may be terminated outside the tank.

Because openings for two tubes in the bottom of the salt well are below the liquid surface, to measure differential and actual pressure, a "bubbler"-type level measurement system is used. This is a standard industrial process in which air is pumped through the submerged tubes and thus air "bubbles" up through the waste liquid. The amount of air is regulated, and the flow rate can be read by a rotameter in the weight factor cabinet. The pressure measured on each tube corresponds to the pressure head created by the waste liquid.

There is a potential for the dip tubes in the waste to be plugged by the waste and create erroneous readings. To prevent this, a small amount of water is "dripped" (allowed to run down) continuously down the dip tubes while SWP activities are in progress. This water helps prevent the formation of or solidification of waste crystals in the dip tubes. The water is supplied from the water tank on the salt well instrumentation skid (if used) or from the tank farm's raw water supply system. The ends of the pipes at the bottom of the salt well also are cut with a notch in them to help prevent waste from plugging the tubes.

B2.5.2.1.5.5 Leak Detection System. The SWP process uses leak detectors in the various transfer pits to help detect possible waste leakage. These leak detectors are actually conductivity probes mounted ~1.5 cm (0.6 in.) above the floor of the valve and pump pits. Because these pits generally slope toward pit drains, the leak detectors are installed near the low point adjacent to these drains. The instruments work on the principle that liquid in the pits will contact these probes and allow an electrical current to flow. There are

leak detectors in the salt well pump pit, valve pits (if any), the COBs (if any), DCRT pit (as applicable) and at the double shell tank receiving pit. The leak detectors are interlocked with the SWP control system such that any leak detector setting off an alarm will result in a visual alarm, and the salt well pump will automatically shut down, causing an audible alarm.

B2.5.2.1.5.6 Flammable Gas Monitoring. Flammable gas monitoring (WHC-SD-WM-FDC-050) is required in the pump pit and the tank vapor space. In addition to the periodic monitoring requirement in TSR AC 5.11.2 (HNF-SD-WM-TSR-006), continuous monitoring shall be performed as an additional measure of conservatism above and beyond what is required by the analyzed consequences as directed by U.S. Department of Energy, Richland Operations Office (RL) (Wagoner, 1998, *Contract Number DE-AC06-96RL13200 - Authorization Basis Amendment Package Transmittal for Saltwell Jet Pumping of Single-Shell Tanks*). Flammable gas data collected can be used in considering future modifications to controls and as input to resolution of the Flammable Gas Safety Issue.

The Pump Pit Monitor is equipped with an automatic interlock and the Tank Vapor Space Monitor with an alarm to shut down pumping if 25% of the lower flammability limit (LFL) is reached as an additional measure of conservatism not required as a result of analyzed consequences as directed by RL (Wagoner, 1998). If any flammable gas monitoring device measures $\geq$25% of the LFL, salt well pumping will be discontinued until all flammable gas monitors indicate < 25% of the LFL.

B2.5.2.1.5.7 Ventilation. A "Standby" Exhauster (WHC-SD-WM-DB-035, *Functional Requirements for Portable Exhauster System to be Used During Saltwell Pumping*, and HNF-S-0490, *Specifications for a Portable Exhauster System for Waste Tank Ventilation*) will be installed as a Defense-in-depth measure for all tanks to be salt well pumped with the exception of Tanks 241-T-104, 241-T-110, and the SX Farm tanks which are actively ventilated. The exhauster function is to reduce the time at risk if 25% of the LFL is reached. The exhauster is an additional measure of conservatism not required as a result of analyzed consequences as directed by RL (Wagoner, 1998). The "Standby" exhausters are turned on immediately if the flammable gas concentration exceeds 25% of the LFL. The exhauster is designed to provide a flow rate equal to or greater than 5,663 L/min. (200 scfm) and meet Ignition Control Set 2 and all environmental and regulatory requirements. A preventive maintenance program shall be in place as directed by RL (Wagoner, 1998) to provide insurance that the exhausters are operable.

B2.5.2.1.6 Single Shell Tank, DCRT (as applicable) and Double Shell Tank Existing Instrumentation. The source tank (SST), DCRT (as applicable) and receiving tank (DST) have existing instrumentation that will be used in conjunction with SWP activities to provide monitoring for level and temperature.

B2.5.3 Waste Characterization

Characterization of the waste in each tank is an integral part of the effort to control the hazards associated with the radioactive waste stored in the tanks. Specifically, waste characterization (1) assists in the understanding and resolution of safety issues, (2) enables the continued safe

storage and management of the wastes until retrieval operations begin, and (3) supports the development and selection of waste removal, treatment, and final disposal options.

Tank waste characterization is performed specifically in the underground SSTs and DSTs, DCRTs, catch tanks, inactive miscellaneous underground storage tanks, the 204-AR Waste Unloading Facility, and the 244-AR Vault because tank waste is stored temporarily in the tanks of these facilities. Although waste characterization is performed at the other tank farm facilities listed in Section B2.4, those activities are performed to meet regulatory requirements and waste acceptance criteria. Tank waste characterization follows the tank waste analysis plan (WHC-SD-WM-PLN-091, *Fiscal Year 1995 Tank Waste Remediation System Tank Waste Analysis Plan*, and WHC-SD-WM-PLN-101, *Fiscal Year 1996 Tank Waste Remediation System Tank Waste Analysis Plan*).

B2.5.4 Waste Concentration

The tank waste concentration process concentrates and evaporates low-heat-producing wastes stored in the underground DSTs to reduce the volume and generate more available space for waste storage. Evaporation of water and its removal from the waste is the principal process used to save tank space at TWRS and is an integral part of the effort to control the hazards associated with radioactive waste stored in the underground tanks.

The 242-A Evaporator (which is not included in the scope of the BIO and is not a TWRS facility) in the 200 East Area, passive evaporation of water from radioactive decay, and the evaporation of water into the induced draft ventilation air stream through actively ventilated tanks all provide means for concentrating the waste.

B2.5.5 Activities at Miscellaneous Tank Farm Facilities

Operations at the less than 90-day waste storage pad; low-level waste storage pad; cribs, ditches, and ponds; and the vertical storage units support other aspects of managing radioactive and hazardous waste and are discussed briefly in the following sections.

B2.5.5.1 209-E Less Than 90-Day Waste Storage Pad. Activities at this facility, which complies with *Resource Conservation and Recovery Act of 1976*, are governed by tank farm operating procedures and include the following:

- Waste acceptance from waste generators
- Waste acceptance at the less than 90-day waste storage pad
- Inspection of the less than 90-day waste storage pads
- Waste repackaging at the less than 90-day waste storage pad
- Investigation of unknown or suspect waste from a tank farm facility.

B2.5.5.2 Low-Level Waste Storage Pad. Activities at this facility are governed by tank farm operating procedures and may include the following:

- Preparing the bulk low-level waste box
- Preparing the low-level waste sample box
- Filling the bulk and sample low-level waste boxes
- Inspecting the low-level waste staging area weekly
- Assisting the vendor in performing assay service
- Assisting the crane crew in weighing wooden boxes
- Preparing low-level waste boxes for shipment.

B2.5.5.3 Cribs, Ditches, and Ponds. Cribs, ditches, and ponds were used in processing operations to decant low-level radioactive and hazardous waste streams to the soil. This practice is no longer acceptable and has ceased. The cribs, ditches, ponds, and trenches described in Section B2.4 are inactive facilities.

B2.5.5.4 Vertical Storage Units. The vertical storage units described in Section B2.4 stored various pieces of contaminated equipment related to the safe storage and transfer of tank wastes. These facilities are inactive and additional evaluation is needed before disturbing one or more of these units.

B2.6 CONFINEMENT SYSTEMS

Confinement systems accomplish the following:

- Minimize the spread of radioactive and hazardous materials within unoccupied process areas
- Prevent or minimize the spread of radioactive and hazardous materials to occupied areas
- Minimize the release of radioactive and hazardous materials in facility effluents during normal operation and anticipated operational occurrences
- Limit the release of radioactive and other hazardous materials resulting from evaluation basis accidents, including severe natural phenomena and manmade events, in compliance with the guidelines contained in DOE 6430.1A[3], Section 1300-1.4.2, "Accidental Releases."

---

[3]Although DOE 5480.7A, 5480.28, and 6430.1A have been rescinded, the contractor is obligated by the existing contract to meet the requirements stated in these orders.

Because TWRS manages large volumes of liquid wastes, confinement systems are not limited to those for the confinement of airborne materials. The same principles apply for those systems relied upon to confine liquids. Therefore, the confinement systems at TWRS include tanks, transfer equipment (e.g., piping, diversion boxes, valve pits), structures, and ventilation systems. The confinement systems within TWRS that are applicable to a particular facility, structure, or process are described in Section B2.4.

B2.7 SAFETY SUPPORT SYSTEMS

Safety support systems for the TWRS facilities consist of radiation protection, effluent monitoring, and fire protection.

B2.7.1 Radiation Protection Systems

In addition to inherent radiation protection features (e.g., buried tanks and piping and thick concrete walls, roofs, and ceilings), the radiation protection system relies on portable and fixed instruments for detecting radioactivity.

B2.7.1.1 Portable Radiation Monitoring Systems. Portable radiation monitoring systems are used as needed at the tank farms. Portable CAMs are generally placed inside operating facilities for personnel safety. The radiation protection program and selection and use of portable instruments are discussed in Chapter 4.0.

B2.7.1.2 Fixed Radiation Monitoring Systems. Fixed radiation monitoring systems in TWRS facilities include radiation detectors and CAMs.

- **Radiation Detectors**—Radiation detection probes are located in the dry wells adjacent to leak detection pits. The systems serve dual purposes: (1) indicating radiation levels and (2) serving as a backup for liquid detection systems.

- **Continuous Air Monitors**—CAMs sample and monitor air for the presence of radionuclides in areas of potential airborne radioactivity. CAMs are installed in areas such as primary and secondary exhaust stack air outlets, annulus exhaust stack air outlets, and process buildings. However, no fixed CAMs are present within the 200 West Area TWRS instrument and process buildings.

All tank farm fixed radiation detection instruments are designed with fail-safe mechanisms so that any system failure activates an alarm.

B2.7.2 Effluent Monitoring Systems

One exhaust stack effluent monitoring program is associated with radionuclide sampling and monitoring, and a second is associated with ammonia sampling and monitoring. Programs associated with sampling and monitoring

hydrogen gas and other flammable compounds are related to the tank vapor space. The following subsections contain general descriptions of the systems supporting the radionuclide and ammonia gas sampling and monitoring programs.

B2.7.2.1 Stack Radionuclide Sampling and Monitoring Systems. The following sections discuss the stack sampling and monitoring systems.

B2.7.2.1.1 Elements. The stack radionuclide sampling and monitoring system consists of CAMs and fixed record samplers. A stack radionuclide sampling system consists of the following components:

- Sampling probe that inspirates the air sample from the stack
- Sample transport line that transports the sample to a sample collector point (i.e., fixed record sampler) or other detectors (i.e., CAMs)
- Collection or detection devices that collect the sample
- Rotameter that measures flow through the system
- Totalizer or gas meter that totals the sample volume
- Pressure or vacuum gauge that measures the vacuum in the system
- Flow switch that indicates when the sample flow rate falls below specified limits
- Flow regulator that adjusts the flow to maintain specified flow rates through the sampling system
- Vacuum pump that draws the sample stream through the sampling system
- Timer that indicates the time the collection devices have been operating.

Most of the TWRS exhaust stack sampling systems sample isokinetically. The stack sampling probes are sized to sample specified sample flow rates and to measure average stack flow rates. Isokinetic sampling results when the velocity of a particle in the sampled stream does not change (no acceleration occurs) as the particle enters the sample probe nozzle inlet. Isokinetic sampling is discussed in detail in WHC-SD-WM-ES-291, *Tank Farm Sampling System Configuration and Efficiency Study*. Setpoints and system requirements are discussed in WHC-EP-0479, *Facility Effluent Monitoring Plan for the Tank Farm Facility*. The radionuclide monitoring systems used in TWRS are identified in Table B2-25 by facility and stack number.

B2.7.2.1.2 Equipment. The stack sampling and monitoring system (Figure B2-62) comprises record samplers and CAMs.

- **Record Samplers (fixed)**—Data from record samplers is used for regulatory purposes. Record samplers quantify the dose the public receives from operation of that particular emission point.

- **Continuous Air Monitors**—CAMs are used for safety purposes. CAMs are set to alarm if emissions are detected above predetermined levels (WHC-EP-0479-1). CAMs can also be used to provide backup regulatory information.

A record sampler has only a collection filter. A CAM has a detector above or near the collection filter.

Some facility sampling systems have a sampling probe for the record sampler and a sampling probe for the CAM. Sampling systems at other facilities have a single sampling probe, from which the sample is split and routed separately to the record sampler and the CAM.

To ensure that a representative sample is obtained, flowmeters and regulators, flow totalizers, and vacuum pumps control and measure the flow rate through the sampling system, as shown in Figure B2-62. Air coming from the stacks is run through the fixed record sampler filter paper, then the flowmeter and flow totalizer, and finally the vacuum pump, which sucks the air through the system. Flow regulators automatically maintain a specified flow within the system. A flow switch is also provided to (1) prevent damage to the sample collection filter paper, (2) prevent nonrepresentative sampling due to nonisokinetic sampling conditions, and (3) indicate vacuum pump problems (e.g., no flow or a failed condition).

B2.7.2.2 Ammonia Sampling and Monitoring Systems. Ammonia gas monitors are installed in waste tank exhaust trains where ammonia may be present. The two monitoring methods currently used at TWRS are the photoacoustic infrared detection method and the ammonia detector tube method.

B2.7.2.2.1 Photoacoustic Infrared Detection Method. The ammonia monitor at the 241-AW and 241-SY Tank Farms uses the photoacoustic infrared detection method. Samples of the 241-SY exhaust stream are obtained from the exhaust stack downstream of the HEPA filters. The sample probe, constructed of corrosion-resistant or process-compatible materials, is inserted in the ventilation duct through a flange and turned 90° into the flow at the center of the duct. The sample is drawn through a 4-mm- (0.2-in.-) OD Teflon[4] tube inside the 6.4-mm- (0.25-in.-) ID stainless steel tube. The sample line is heat traced between the sample point and the enclosure housing the instrument to avoid sample condensation and freezing. System requirements for the photoacoustic infrared detection method are as follows (WHC-SD-WM-WP-254, *Engineering Work Plan for SY Farm Ammonia Stack Monitor 531-1972*).

- The system shall be capable of measuring ammonia from 10 ppm to 15,000 ppm in a gaseous mixture of ammonia, hydrogen, nitrous oxide, and moist air. Interference from the noted gases will be less than 2% of the total reading.

- Ammonia is to be measured in gas streams with temperatures ranging from 4.4 to 54.4 °C (40 to 130 °F).

---

[4]Teflon is a trademark of E.I. duPont de Nemours and Company, Wilmington, Delaware.

- The ammonia monitor shall have an accuracy of ±10%of reading at 500 ppm.

- The ammonia monitor shall be qualified to sample process gases that are classified by NFPA 70 as Class I, Division 1, Group B.

B2.7.2.2.2 Ammonia Detector Tube Method. The second ammonia monitoring method used at TWRS facilities where ammonia may be present depends upon ammonia detector tubes or similar devices, including a dräeger tube. The ammonia detector tube system consists of a tube containing gas absorption materials and a sample probe inserted into the exhaust stream. This system relies on laboratory analysis of the absorption materials following a chemical reaction with the ammonia in the sample stream. This is not a real-time monitoring method and is not as accurate as the method used at the 241-SY Tank Farm.

B2.7.3 Fire Protection Systems

Fire protection systems at tank farms consist of fire detection, alarm, and suppression elements. Details of the fire protection systems are located in WHC-SD-WM-FHA-020, *TWRS Fire Hazards Analysis*, and details of the fire protection programs are located in Chapter 4.0. Important elements of the fire protection systems are discussed in the following subsections.

B2.7.3.1 Water Supply. All water for the 200 East and 200 West Areas is supplied by two separate systems, the raw water system and the sanitary water system. The systems provide water for sanitary, process, and fire protection uses and are all piped and valved independently. See Section B2.8.1, "Water Supply Systems" for a more detailed description of the tank farm water supply systems.

B2.7.3.2 Fire Suppression and Extinguishing Systems. Fire suppression and extinguishing systems in the tank farm facilities are limited to wet and dry pipe sprinkler systems and a Halon[5] total flooding system. The fire suppression systems associated with each facility are identified in Table B2-26. The adequacy of these systems is discussed in WHC-SD-WM-FHA-020.

B2.7.3.3 Tank Farm Fire Detection Systems. Smoke, heat, and manual fire detection are provided in tank farm facilities where required (Table B2-26). The detectors transmit alarms to the Hanford Fire Department via radio frequency alarm reporters, which transmit a radio signal to the Hanford Site 200 Area East/West Fire Station. Signal types are (a) a trouble alarm (i.e., problem with a system component), (b) a supervisory alarm (i.e., a monitored gate valve being closed), or (c) a fire alarm. The Hanford Fire Department takes appropriate action in response to an alarm. Installation and coverage of fire alarms are in accordance with NFPA 72, 1996, *National Fire Alarm Code*. Adequacy of the location and installation of detectors and alarms is assessed in WHC-SD-WM-FHA-020.

[5]Halon is a trademark of Allied Chemical Corporation, New York, New York.

B2.7.3.4 Fire Hydrants. Fire hydrants connected to the raw water system or sanitary water system grids are located throughout the 200 East and 200 West Areas. Coverage and adequacy of the hydrants are evaluated in WHC-SD-WM-FHA-020.

B2.7.3.5 Fire Extinguishers. Portable fire extinguishers are provided throughout the tank farm facilities. Mobile equipment is also equipped with portable fire extinguishers. Installation of extinguishers, their inspection and maintenance, and employee training in their use are in compliance with NFPA 10, *Portable Fire Extinguishers*.

B2.8 UTILITY DISTRIBUTION SYSTEMS

Utility distribution systems for the TWRS underground waste storage tanks and their associated facilities are as follows:

- Water supply
- Steam supply
- Compressed air
- Electrical power distribution.

B2.8.1 Water Supply Systems

All water for the 200 East Area is supplied from the Hanford Site export water system. Export water is defined as water pumped from the Hanford Site reservoir to reservoirs located in the 200 East and 200 West Areas. Water is distributed throughout the area by two separate systems, the raw water system and the sanitary water system. Raw water is untreated and is used principally for cooling, flushing, and dilution systems. Sanitary water is treated (e.g., filtered, purified) and is used for drinking and sanitary facilities.

Raw export water is pumped from the Columbia River through 1.1-m (42-in.) lines via 182-B (100 B Area) and 182-D (100 D Area) Pump Houses. The water is then pumped to the 2901-X Valve House, where two 0.8-m (30-in.) lines feed the water to the 2901-Y Valve House. The water is again split at the 2901-Y Valve House. One 610-mm (24-in.) line goes to a 11.4-million-L (3.0-million-gal) storage reservoir (282-W), and two 0.6-m (24-in.) lines go to a 12.1-million-L (3.2-million-gal) storage reservoir (282-E). These two reservoirs supply raw water to facilities in the 200 East and 200 West Areas and the 283-E and 283-W water treatment facilities. The two supply lines each have two different cross connections. The 283-E and 283-W water treatment facilities process the raw water into sanitary water for use in the 200 East and 200 West Areas.

Raw water is pumped from the 282-E reservoir by four manually started electric pumps and one standby steam pump that starts automatically. The steam pump is preset to start automatically when the water pressure drops to 621 kPa (90 lb/in^2). Each pump has a rating of 378 L/s (6,000 gal/min) at a total dynamic head of 82.3 to 107 m (270 to 350 ft). This raw water is used

primarily for process needs and fire protection. The fire protection systems are discussed in Section B2.7.3, "Fire Protection Systems."

A portion of the raw water from the 282-E reservoir is diverted to the 283-E water treatment facility for filtering and sanitizing. Water is similarly diverted from the 282-W reservoir to the 283-W water treatment facility. This sanitary water is supplied to the 200 East Area by electric pumps of 202 L/s (3,200 gal/min) total capacity equipped with two steam turbine standby pumps of 76 L/s (1,200 gal/min) total capacity. The sanitary water system provides water for sanitary, process, and fire protection uses.

Due to the (1) lack of redundant water supplies, (2) use of unapproved pumps and controllers, and (3) lack of verification that the water system can sustain earthquake damage, the water supplies do not meet the minimum requirements of the National Fire Protection Association, Factory Mutual, DOE 5480.7A, and DOE 6430.1A[6]. Project B-604, an upgrade of the fire protection water supply, will bring the systems into full compliance with DOE 5480.7A; DOE 6430.1A[6]; and RLID 5480.7, *Fire Protection*.

Both the Columbia River and the emergency cooling water system provide cooling water for the condensers in the AWF (well 299-E2S-6, located approximately 268 m [880 ft] north of the 241-A-CT-400 cooling tower). This system consists of a cold water sump and warm water sump, each with two pumps, and an induced draft cooling tower, all located outside the restricted area, east of the 241-A-401 Condenser Building. The deep well pump and emergency cooling water equipment are supplied with standby power from the backup diesel generator.

All water supply piping that has the potential for contacting other water or radioactively contaminated liquids is protected with backflow preventers. In addition, to monitor raw water usage in TWRS facilities, flow totalizers have been installed in some systems (Table B2-27). The water supplies to the TWRS facilities are summarized by area and facility category (e.g., SST, DST, catch tank) in Table B2-27, and the uses of the water are identified. Additional detailed information is contained in WHC-SD-WM-FHA-020.

B2.8.2 Steam Supply Systems

All systems that require steam are out of service. Most steam lines have been blanked.

B2.8.3 Compressed Air Systems

Pressurized-air supply systems are provided and maintained for the air spargers, jets, process flowmeters (instrument air), ventilation controllers, and air samplers. Emergency (backup) air supply systems are readily available as either portable or stationary compressor units.

---

[6]Although DOE 5480.7A, 5480.28, and 6430.1A have been rescinded, the contractor is obligated by the existing contract to meet the requirements stated in these orders.

The compressors supply the instrument air systems essential for supplying purge air to the tank liquid-level FIC gauges and operating the pneumatic diaphragm differential pressure instruments and diaphragm-operated valves. The instrument air also purges the instruments and instrument lines of condensate.

Interruption of power to the compressors cuts off the air supply needed for the instruments to operate correctly. Backup electrical generators restore power to the compressor motors to restore the air supply system to normal operation. However, in facilities lacking emergency or backup generators or if the backup generator will not start, backup air compressors are available.

In Table B2-28, the compressed air supply provided to the TWRS facilities is summarized by area and facility category (e.g., SST, DST, catch tank), and the use of the compressed air is identified. Additional detailed information can be found in WHC-SD-WM-HIE-007.

B2.8.4 Electrical Power Distribution System

The Bonneville Power Administration (BPA) provides the main source of power to the 200 East and 200 West Areas by means of a major substation known as Midway. The BPA Midway substation, which is located near Priest Rapids Dam, has three 230-kV buses. Each BPA Midway bus section is supplied by a line from the Priest Rapids generating station. BPA Midway buses No. 1 and No. 3 are also supplied by lines that are connected to the Grand Coulee 230-kV substation and to 230-kV substations in the lower Columbia River power system. The Grand Coulee and lower Columbia River substations are interconnected to the BPA 500-kV transmission system. The BPA 500-kV and 230-kV transmission systems are interconnected to all the Columbia and Snake River hydroelectric generating stations and northwest steam generating plants and are also interconnected to California and British Columbia power network systems.

In addition to supplying power to the Hanford Site and other U.S. Department of Energy substations, the Hanford Site 230-kV loop normally supplies power to Ashe and White Bluffs substations. However, if both Midway power sources are lost, sufficient power for normal operations will flow into the Hanford Site 230-kV loop from the Ashe line.

Power from the Ashe line into the Hanford Site 230-kV loop is supplied by a 115-kV line connected to the White Bluffs substation. One 115-kV line at the White Bluffs substation is connected to the BPA Franklin substation. The other 115-kV line is connected to the BPA Benton switch.

Power is fed by two lines to the A-8 substation located near the intersection of the Yakima Barricade and 100 N highways (Route 11A and Route 4 North, respectively). The 251-W Building adjacent to the A-8 substation contains the switchgear and control equipment. The A-8 substation reduces the power and distributes it through four lines each to the 200 East and 200 West Areas. The power is then distributed to each individual tank farm via the 200 East and 200 West Areas power distribution system (Figures B2-63 and B2-64).

B2.9 AUXILIARY SYSTEMS AND SUPPORT FACILITIES

Auxiliary systems and support facilities include administrative areas, control facilities, change houses, communication systems, lighting, and sewage treatment.

B2.9.1 Administrative Areas

The administrative areas within TWRS include the 200 East and 200 West Area tank farm operations buildings and document control centers. The 200 West Area operations offices are housed in mobile facilities that are located within the 200 West Area as needed and in the 272-WA Tank Farm Support Facility. The 200 East Area operations offices are housed in the 272-AW Tank Farm Support Facility. Other TWRS staff are located in the 209-E, 2750-E, 2751-E, 2752-E, 2753-E, and 2704-HV buildings in the 200 East Area, the 1100 Jadwin Building, and the Federal Building in Richland.

B2.9.2 Control Facilities and Change Houses

Control facilities and change houses for the SST and DST farms are listed in Table B2-29. The typical control facility houses all alarms and monitors for ventilation, temperature, and leak detection. Electrical power distribution is also routed from the control facility. The steel frame building, typically 6.1 m (20 ft) by 9.8 m (32 ft), is constructed of fire-resistant materials. The walls are metal-insulated sandwich panels and fiberglass batting with plastic backing insulates the steel-frame roof. Other control facilities or control rooms are located within existing processing facilities. A typical change house has a wooden frame and provides an area for workers to change their personal protection equipment when entering and leaving the tank farm area.

These other control facilities or control rooms monitor alarms and support waste transfers between facilities. For example, within the 242-A Evaporator control room, monitors, alarm annunciators and control systems monitor 200 East Area tank farm system parameters (e.g., ventilation and tank level) or valve positioning, pump operation, and tank level data during waste transfers (WHC-SD-WM-SAR-023). Another example is the 242-S Evaporator control room in which monitors, alarm annunciators, and control systems monitor 200 West Area tank farm system parameters (e.g., ventilation and tank level) or valve positioning, pump operation, and tank-level data during waste transfers. The 242-S Evaporator control room is also used to monitor and control Site transfers from the 200 West Area to the 200 East Area (WHC-SD-WM-SSP-002, *242-S Facility Shutdown/Standby Plan*).

B2.9.3 Communication Systems

Telephones or handheld two-way radios are used for routine and emergency communications in the TWRS facilities. The telephones located in the control areas can be used to contact shift personnel. Telephones located in each change trailer are used to contact Radiological Control Technicians or other

support personnel responsible for responding to abnormal events. All personnel within a facility are alerted to facility emergencies by in-plant signals (e.g., fire gongs and CAM alarms) and to Site emergencies via the crash telephone system.

B2.9.4 Lighting

Lighting, either fixed or portable, is provided at all TWRS facilities to support 24-hour surveillance and monitoring activities. In addition to the existing systems, high-mast lighting is provided in some tank farm facilities (e.g., 241-SY and 241-C) to support 24-hour operations.

B2.9.5 Sewage Treatment

Sewage streams originating in restrooms and change room toilets are routed via underground piping to septic tanks and tile fields for treatment. To prevent cross contamination, these sewage streams are isolated from other facility liquid effluent streams.

Table B2-2. Projects Not Included in the Tank Waste Remediation System Basis for Interim Operation that have the Potential to Impact Existing Facility Design or Operations Descriptions.

Project number	Project description	Current status	
		Project	Safety documentation
Authorized Projects			
B-604	Water System Reservoir Area Upgrades: Project upgrades raw and sanitary water reservoir in the 200 East. Raw and sanitary water tielines will connect the 200 East and 200 West Areas.	Construct	NI
W-211	Initial Tank Retrieval Systems: Provides mobilization and retrieval systems for 10 DSTs.	Design	Safety documentation prepared
W-369	Watch List Tank Standard Monitoring System, Phase II: Provides a standardized hydrogen monitoring system for the watch list tanks.	Construct	NI
W-451	Tank Farm Gas Characteristics.	Construct	NI
W-454	AW Jumper Manifold Upgrade: Provides valved manifolds with jumpers in the 241-AW tank farm valve pits AW-A and AW-B.	Design	NI
W-314	Tank Farm Restoration and Safe Operations: Provides capital upgrades to selected tank farm instrumentation/control, ventilation, waste transfer, and electrical systems. Phase I supports waste transfer systems for TWRS privatization with the exception of the TWRS privatization feed tanks. Phase II supports tank farm-wide ventilation, electrical, and in-tank instrumentation upgrades.	Design	Phase I: Safety documentation in preparation Phase II: NI

FSAR = Final Safety Analysis Report
DST = double-shell tank
TWRS = Tank Waste Remediation System
NI = None identified

Table B2-3. Current Status of Single-Shell and Double-Shell Underground Waste Storage Tanks
(For current status of SSTs and DSTs,
see most current version of HNF-EP-0182,
Tank Farm Surveillance and Waste Status Summary Report For Month Ending...
The report is published each calendar month.)

Table B2-4. Typical Compounds Generated by Production Processes at the Hanford Site.

Process	Typical compounds
Bismuth phosphate	$NaOH$, $NaNO_3$, $NaAlO_2$, Na_2SiO_3, $NaNO_2$, Na_2CO_3, Na_2SO_4, Na_3PO_4, $Fe_2(SO_4)_3$, $(NH_4)_2SiF_6$, $(NH_4)_2SO_4$, $Cr(NO_3)_3$, NH_4NO_3
Reduction oxidation (REDOX)	$NaAlO_2$, $NaOH$, $NaNO_3$, $NaNO_2$, Na_2SiO_3, $Na_2Cr_2O_7$, Na_2SO_4, $Cr(OH)_3$, $Fe(OH)_3$
Plutonium uranium extraction (PUREX)	KOH, $NaOH$, $NaNO_3$, $NaPO_4$, $NaSiO_3$, KF, NaF, Na_2SO_4, $Fe(OH)_3$, $Cr(OH)_3$, $Ni(OH)_2$, $NaNO_2$, ZrO_2-$2H_2O$, Sn, $NaAlO_2$, Na_2CO_3, MnO_2
Uranium recovery	SO_4^{-2}, PO_4^{-3}, NO_3^-, Cl^-, Na^+, $Fe(OH)_3$
B Plant Waste Fractionization Process	$H^3[P(W^3O^{10})^4]$-$14H_2O$ phosphotungstic acid, 2-hydroxyethylthylenediamine-triacetic acid (HEDTA), ethylenediaminetetraacetic acid (EDTA), hydroxyacetic acid, citric acid, Na_2SO_4

Table B2-5. Major Facilities that Interface with Tank Waste Remediation System. (2 sheets)

Facility of origin[a,b]	Mode	Junction	Destination[b]	Waste stream
200 East Area				
WESF/B Plant	Transfer line	Diversion box 241-ER-152[c]	241-AW Tank Farm, 241-AP Tank Farm	Facility decontamination solutions
242-A Evaporator[d]	Transfer line (steam transfer)	Valve pit 241-AW-A, 241-AW-B	241-AW (dedicated transfer, dump, and diversion lines)	Evaporator product (double-shell slurry feed)
PUREX Facility (no longer active)	Transfer line	Diversion box 241-A-151[c]	241-AW Tank Farm	Facility decontamination solutions
Transition facilities	Tanker trailer, transfer line, or railcar	N/A	Unspecified tank farm	Flush solutions and other radioactive waste water
Tank farms	Truck	N/A	Solid waste facilities	Solid waste, low- and high-level radioactive waste
TWRS facilities	Truck	N/A	Solid waste facilities	Solid waste
200 West Area				
219-S Building	Transfer line	N/A	244-S DCRT	Laboratory waste 222-S
T Plant	Railcar	204-AR Waste Unloading Facility[e]	241-A Tank Farm	Facility decontamination solutions
Z Plant (PFP)	Transfer line (steam transfer)	Double-contained receiver Tank 244-TX[e]	Tank SY-102	Facility decontamination solutions
U Plant	Transfer line	Diversion box 154-UX[c]	Tank SY-102	Facility decontamination solutions
222-S Laboratory/ REDOX Facility	Transfer line	204-AR Waste Unloading Facility[e]	241-A Tank Farm	Dilute tank farm, TWRS, or other facility liquid sample analysis wastes
Transition facilities	Tanker trailer, transfer line, or railcar	N/A	Unspecified tank farm	Flush solutions and other radioactive waste water
Tank farms	Truck	N/A	Solid waste facilities	Solid waste, low- and high-level radioactive waste
Tank farms	Cross-site transfer line	Valve pits 241-SY-A, 241-SY-B, 241-UX-154[c]	Valve pit 241-ER-151	Low- and high-level waste solution
TWRS facilities	Truck	N/A	Solid waste facilities	Solid waste

Table B2-5. Major Facilities that Interface with Tank Waste Remediation System. (2 sheets)

300 Area				
340 Building	Railcar	204-AR Waste Unloading Facility[a]	241-A Tank Farm	Radioactive waste water

[a]Other facilities, not identified in this table, are in transition and may transfer liquid wastes to tank farm facilities or hazardous wastes to 209-E Complex.
[b]See Figures 2-1 and 2-2 for facility locations.
[c]TWRS is responsible for valving, piping, and jumpers within diversion box on valve pit and transfer lines exiting diversion box or valve pit.
[d]The following 242-A Evaporator transfer lines (1) interface with Tank 241-AW-102 drain and pump pits and TWRS valve pits 241-AW-A and 241-AW-B and (2) are outside of the scope of this BIO:
SN-269, -270: double-shell slurry feed lines to 242-A
DR-335: 242-A drop out line
DR-334, -343, -338: 242-A drain lines
SL-167, 168, -113, -114: slurry out lines to valve pits.
[e]TWRS is responsible for in-facility operations and transfer lines from facility.
N/A = not applicable.
PFP = Plutonium Finishing Plant.
PUREX = Plutonium Uranium Extraction.
REDOX = Reduction Oxidation.
TWRS = Tank Waste Remediation System.
WESF = Waste Encapsulation and Storage Facility.

[a]To convert ft^3/min to m^3/s, multiply by 0.472; to convert Fahrenheit to Celsius, subtract 32 degrees and multiply by 5/9.

[b]Only one fan operates at a time; flow is for each fan.

DCRT = double-contained receiver tanks.
HEPA = high-efficiency particulate air (filter).
PF = prefilter non testable.

Table B2-12. Catch Tank Capacity and Use.

Catch tank	Maximum capacity		Use
	L	gal	
200 East Area			
241-A-302A	31,940	8,438	Drainage from DB-241-A-151
241-A-350	2,940	776	Receives drainage from 241-A Tank Farm. Provides for routing 207-A Retention Basin waste (if out of specification) to Tank 241-AW-102
241-A-417	167,315	44,200	Drainage from 241-AY/241-AZ ventilation condensate system and possibly steam condensate from 241-AX-501 valve pit and 241-AZ-154
241-AX-152	41,640	11,000	Drainage from 241-AX-152 diverter station, DB-241-AX-155, AY-501 and 702-A seal pot
241-AZ-151	45,046	11,900	Drainage from DB-241-AZ-152, AZ loop seals, leak detection pits, 801-AZ Instrumentation Building, 241-AZ-702 Ventilation System, and precipitation and runoff
241-AZ-154	3,290	869	Drainage from TK-241-AZ-101 and TK-241-AZ-102 steam coils and precipitation and runoff
241-ER-311	66,934	17,682	Drainage from DB-241-ER-151 and DB-241-ER-152
200 West Area			
241-S-304	23,850	6,300	Drainage from DB-241-S-151 and precipitation and runoff
241-TX-302C	66,930	17,681	Drainage from DB-241-TX-154 and precipitation and runoff
241-U-301B	133,530	35,275	Drainage from DB-241-U-151, DB-241-U-152, DB-241-U-153, and DB-241-U-252
241-UX-302A	66,934	17,682	Drainage from DB-241-UX-154, 291-U stack, and precipitation and runoff
600 Area			
241-EW-151	2,940	776	Receives drainage from cross-site transfers vent station.

DB = diversion box.
TK = waste storage tank.

Table B2-13. Summary of Catch Tank Dimensions.

Catch tank	Material	Inside dimensions

N/A = not applicable.
RC = reinforced concrete.

Table B2-15. Double-Contained Receiver Tanks.

Double-contained receiver tank	Use
200 East Area	
244-A	Cross-site, B Plant, and some evaporator feed transfers. Drain for transfer lines.
244-BX	Receives 241-B and 241-BY Tank Farm salt well liquids.
244-CR TK-003	Receives salt well waste from the 241-C Tank Farm.
200 West Area	
244-S	Receives 241-S and 241-SX Tank Farms salt well waste and miscellaneous plant wastes. Drain for cross-site transfer line. Contains jumpers for Tank 241-SY-102.
244-TX	Receives 241-T Tank Farm salt well waste and miscellaneous Plutonium Finishing Plant wastes. Serves as the Plutonium Finishing Plant transfer line drain.
244-U	Will receive 241-U Tank Farm salt well wastes. Drain for transfer line to 241-SY Tank Farm.

Note: Tank identification taken from WHC-SD-WM-PD-046, 1995, Tank Waste Remediation System Inactive Miscellaneous Underground Storage Tanks Program Plan, Rev. 0, Westinghouse Hanford Company, Richland, Washington. Information in this table except tank characteristics and current status is taken from WHC-EP-0681, 1993, Interim Criteria for Organic Watch List Tanks at the Hanford Site, Rev. 0, Westinghouse Hanford Company, Richland, Washington. Tank characteristics are from WHC-SD-EN-ES-040, 1994, Engineering Study of 50 Miscellaneous Inactive Underground Radioactive Waste Tanks Located at the Hanford Site, Rev. 0, Westinghouse Hanford Company, Richland, Washington. Current status is from WHC-SD-EN-ES-040 and HNF-EP-0182, March 31, 1997, Waste Tank Summary Report for Month Ending March 31, 1997, Rev. 108, Fluor Daniel Hanford, Inc., Richland, Washington.

*Reinforced concrete is steel lined.

AL = assumed leaker.
C = catch tank.
CS = carbon steel.
DC = decontamination tank.
DV = diverter station.
F = flush tank.
G = partially grouted.
I = isolated.
IS = interim stabilized.
N = neutralization tank.
R = receiver tank.
RC = reinforced concrete.
S = settling tank.
SS = stainless steel.
SU = steel unspecified.
V = vault tank.

Table B2-18. Summary of 204-AR Waste Unloading Facility Ventilation Systems Equipment.

Facility	Area vented	Stack description			Exhaust fan description		Ventilation systems	
		Number	Height		Number	Design capacity (ft^3/min)*	Equipment	Filtration
			m	ft				
204-AR Waste Unloading Facility	Primary	296-A-26	8.2	27	EF-1	2,000	Moisture separator	PF - 1 HEPAs - 2 in series per bank, 2 banks one on each side of the moisture separator

Source: WHC-SD-WM-ES-291, 1994, Tank Farm Sampling System Configuration and Efficiency Study, Rev. 1, Westinghouse Hanford Company, Richland, Washington.

*To convert ft^3/min to L/s, multiply by 0.472.

HEPA = high-efficiency particulate air (filter).

PF = prefilter.

Table B2-19. Summary of 244-AR Vault Ventilation Systems Equipment (as Designed).

Facility	Area vented	Stack description			Exhaust fan description		Ventilation systems
		Number	Height		Number	Design capacity (ft^3/min)[a]	Filtration
			m	ft			
244-AR Vault	Vessel vent	296-A-12	45.7	150	K4-11-1	950	PF - 1 LEF - 1 per bank HEPAs - 2 in series per bank, 2 banks in parallel
244-AR Vault	Canyon/ cell	296-A-13	18.6	61	K-3-91[b] K-3-92	15,000	HEPAs - 2 in series

Source: WHC-SD-WM-ES-291, 1994, Tank Farm Sampling System Configuration and Efficiency Study, Rev. 1, Westinghouse Hanford Company, Richland, Washington.

[a] To convert ft^3/min to L/s, multiply by 0.472.

[b] Only one fan operates at a time; flow is for each fan.

HEPA = high-efficiency particulate air (filter).

LEF = low-efficiency filter.

PF = prefilter.

Source: WHC-SD-WM-HIE-007, 1996, Tank Waste Remediation System FSAR Hazard Identification/Facility Configuration Verification Report, Rev. 0, Westinghouse Hanford Company, Richland, Washington.

[a] In the notes column:
L = leak detection, unspecified
L1 = low point leak detection
L2 = no leak detection
L3 = leak detection probe
L4 = leak detection by smears
V = ventilation system, unspecified
V1 = ventilation provided by tanks
V2 = no ventilation provided

[b] To convert lb/in^2 to Pa multiply by 6,894.8.

[c] In the heat trace and cathodic protection columns:
N = no
Y = yes

[d] Could not verify

[e] Temporary blank

ASTM = American Society for Testing and Materials
CS = carbon steel
DCRT = double-contained receiver tank
Ga = gauge
N/A = not available
PUREX = Plutonium Uranium Extraction (Facility)
SSTL = stainless steel
VP = valve pit

Table B2-24. Typical Primary and Supporting Activities at Tank Waste Remediation System Facilities Required to Support Operations. (2 sheets)

Activity	Waste storage/ concentration	Waste transfer	Waste characterization
Primary activities to support operations			
Air lance	X		
Air lift circulators	X		X
Ammonia gas sampling	X		
Auger sampling	X		X
Cathodic protection		X	
Chemical additions	X	X	
Core sampling - push and rotary modes [a]	X		X
Gas vapor sampling - in-tank	X		X
HEPA filter change out	X		
Infrared scanning	X		
Interim stabilization or salt well pumping	X		
Intrusion prevention	X		
Lighting augmentation	X	X	X
Line integrity assessments		X	
Liquid-level monitoring	X	X	X
Liquid observation wells	X		
Liquid (grab) sampling	X	X	X
Photography (in-tank or pit)	X	X	
Raw and treated water additions	X	X	
Salt well screen	X	X	
Sample handling	X	X	X
Sludge-level monitoring	X		X
Sludge sampling	X		X
Slurry distributor	X		
Specific gravity probe monitoring	X	X	X
Thermocouple or multiple instrument tree	X		
Utility additions or upgrades	X	X	
Valve positioning and jumper installation		X	
Waste minimization activities	X		

Table B2-24. Typical Primary and Supporting Activities at Tank Waste Remediation System Facilities Required to Support Operations. (2 sheets)

Activity	Waste storage/ concentration	Waste transfer	Waste characterization
Waste transfer leak detection (swabbing or surveillance camera)		X	
Supporting activities			
Cover block installation and removal	X	X	X
Crane operations	X	X	X
Decontamination activities	X	X	X
Dry well scanning	X		
Electrical grounding and bonding	X	X	X
Flammable gas monitoring (sniffing)[b]	X	X	X
Greenhouse or confinement construction, decontamination, and removal	X	X	X
Groundwater monitoring	X		
In-tank equipment installation, operation, and removal	X	X	X
Radiological monitoring and surveys	X	X	X
Riser access	X	X	X
Vehicle operations	X	X	X

[a] With the exception of flammable gas hazards, rotary mode core sampling is outside the scope of this Basis for Interim Operation; see WHC-SD-WM-SAD-035, 1996, A Safety Assessment for Rotary Mode Core Sampling in Flammable Gas Single-Shell Tanks, Hanford Site, Richland, Washington, Rev. 0a, Westinghouse Hanford Company, Richland, Washington.

[b] Using portable monitors

HEPA = high-efficiency particulate air (filter)

Table B2-25. Tank Farm Radionuclide Monitoring Systems by Facility and Stack Number. (2 sheets)

Facility	Area monitored	Stack description number	Monitor description	
			Type	Material
Single-shell tanks				
241-C-105/106	Portable	296-P-16	CAM	Beta-gamma

[a]Flexible hoses can be used for flush water where no water identified.
[b]Use as identified in WHC-SD-WM-HIE-007, 1996, Tank Waste Remediation System FSAR Hazard/Identification Facility Configuration Verification Report, Rev. 0, Westinghouse Hanford Company, Richland, Washington.
[c]Water supply systems have flow totalizers
NI = none identified, no valve number provided, no use provided
RW = raw water
SW = sanitary water
V = valve
*Before BIO implementation, U Farm water was isolated outside of farm by air gap. Water will be required in future to support salt well activities.

Table B2-28. Compressed Air Supply to Tank Waste Remediation System Facilities. (2 sheets)

Facility or tank farm	Compressed air supply		Primary use
	Primary	Other	
200 East Area			
Single-shell tank farms			
241-A	241-A-701	Portable	Purge air, weight factor
241-AX	241-A-701	Portable	Purge air, weight factor
241-B	241-B-701	Portable	Purge air
241-BX*	Conex	241-BY-302 241-BY-302A	Purge air
241-BY*	Conex	241-BY-302 241-BY-302A	Purge air
241-C	241-C-701	Portable	Purge air
Double-shell tank farms			
241-AN	241-AN-273	Portable	Leak detection, tank pressure
241-AP	241-AP-273	Portable	Leak detection, tank pressure
241-AW	241-AW-273	242-A	Leak detection, tank pressure (air lift circulators, specific gravity, Tank 241-AW-102 only)
241-AY	241-A-701	Portable	Purge air, air lift circulators, specific gravity, weight factor
241-AZ	241-A-701	Portable	Air lift circulators, specific gravity, weight factor
Double-contained receiver tanks			
244-A*	Fixed	Portable	Purge air, specific gravity, weight factor
244-BX*	Conex	Portable	Purge air, weight factor
244-CR	241-C-701	Portable	Purge air, specific gravity, weight factor
200 West Area			
Single-shell tank farms			
241-S	Salt well pump skid	Portable	Specific gravity, weight factor
241-SX	Salt well pump skid	Salt well pump skid	Specific gravity, weight factor
241-T	Salt well pump skid	Salt well pump skid	Specific gravity, weight factor
241-TX	NI	Portable	As required
241-TY	NI	Portable	As required
241-U	241-U-701	Salt well pump skid/Portable	Specific gravity, weight factor
Double-shell tank farms			
241-SY	242-S	Portable	Leak detection, tank pressure, specific gravity, weight factor
Double-contained receiver tanks			
244-S	244-S-271	Portable	Specific gravity, weight factor
244-TX	242-T-701 (Conex)	Portable	Specific gravity, weight factor
244-U	241-U-701	Portable	Specific gravity, weight factor

Table B2-28. Compressed Air Supply to Tank Waste Remediation System Facilities. (2 sheets)

Facility or tank farm	Compressed air supply		Primary use
	Primary	Other	
Other area tank farms, catch tanks, or double-contained receiver tanks, and other support facilities			
204-AR*	Fixed	Portable	Weight factor, specific gravity
244-AR*	Fixed	Portable	Weight factor
209-E	209-A	Portable	As required
213-W	Portable	NI	As required
2727-WA	Portable	NI	As required
241-AZ-702A	241-AZ-701	Portable	Ventilation system controls

NOTE: Primary usage taken from WHC-SD-WM-HIE-007, 1996, Tank Waste Remediation System FSAR Hazard Identification/Facility Configuration Verification Report, Rev. 0, Westinghouse Hanford Company, Richland, Washington.

*Fixed or conex system installed; no building or structure identified.

NI = None identified.

Table B2-29. Control Facilities and Change Trailers for Tank Waste Remediation System Facilities. (2 sheets)

Facility	Instrument building or control room number[a]	Change trailer building number[a,b]
200 East Area		
Single-shell tanks		
241-A Tank Farm	241-A-271	MO-439, T-121
241-AX Tank Farm	241-A-271	MO-439
241-B Tank Farm	244-BX	MO-825
241-BX Tank Farm	244-BX	MO-824
241-BY Tank Farm	241-BY-254, 241-BY-301	MO-121
241-C Tank Farm	241-CR-271, MO-211, 241-C-91	MO-822, MO-826, T-120
Double-shell tanks		
241-AN Tank Farm	241-AN-271, 241-AN-274	MO-820
241-AP Tank Farm	241-AP-271, 242-A	MO-815
241-AW Tank Farm	241-AW-271, 242-A	MO-818
241-AY Tank Farm	241-A-271, 241-AY-801	MO-439, T-121
241-AZ Tank Farm and 241-AZ-156	241-A-271, 241-AZ-801-A	MO-439, T-121
241-AY and -AZ Tank Farm	241-AZ-271	Not applicable
Other facilities		
Catch tanks	None	None
DCRTs[b] 244-A 244-BX	 244-A 244-BX	 MO-816 None
B Pond	216-B-3A1	None
200 West Area		
Single-shell tanks		
241-S Tank Farm	241-S-271	MO-295
241-SX Tank Farm	241-SX-271	MO-298
241-T Tank Farm	None	MO-821
241-TX Tank Farm	None	MO-817
241-TY Tank Farm	None	None
241-U Tank Farm	241-U-271	MO-297

Table B2-29. Control Facilities and Change Trailers for Tank Waste Remediation System Facilities. (2 sheets)

Facility	Instrument building or control room number[a]	Change trailer building number[a,b]
Double-shell tanks		
241-SY Tank Farm	241-SY-271, 242-S, DACS-1	MO-296
Other facilities		
Catch tanks	None	None
DCRTs[c]		
244-U	No building number available	None
		None
244-S	No building number available	None
244-TX	No building number available	
600 Area		
241-EW-151	None	None

[a] None. No building was identified during walkdown.
[b] No building number available. Building or facility exists, but no building number is assigned to the facility.
[c] Most facilities not identified
DACS = Data Acquisition and Control System
DCRT = double-contained receiver tank
MO = mobile office
T = trailer
