C1-32 Natural Phenomena Design and Evaluation Criteria for New and Existing Hazard Category 2 Facilities TC-25

LIST OF TERMS

CRBG	Columbia River Basalt Group
DOE	U.S. Department of Energy
HMS	Hanford Meteorological Station
PUREX	Plutonium Uranium Extraction (Facility)
Supply System	Washington Public Power Supply System
TWRS	Tank Waste Remediation System
WNP	Washington Nuclear Plant
YFB	Yakima Fold Belt

This page intentionally left blank.

C1.0 SITE CHARACTERISTICS

C1.1 INTRODUCTION

The objective of this chapter is to describe characteristics of the Hanford Site that are applicable to the hazard and accident analyses of specified Tank Waste Remediation System (TWRS) facilities. Applicable TWRS facilities are the single-shell tank farms, the double-shell tank farms, and associated support systems and transfer equipment. See Appendix B, "Facility and Process Description," for details of the facilities addressed in this report.

Much of the Site characteristics information used in this chapter is based on PNL-3509, *Standardized Input for Hanford Environmental Impact Statements, Part II: Site Description*, and PNL-6415, *Hanford Site National Environmental Policy Act (NEPA) Characterization* and DOE/EIS-0189, *Final Environmental Impact Statement for the Tank Waste Remediation System, Hanford Site, Richland, Washington*. Site characteristics are factored into the analyses described in Chapter 5.0, "Safety Analysis."

The figures provided in this chapter have been included to aid the reader in visualizing information that is presented in the text. These sketches should not be considered design drawings, and they must not be used to make engineering modifications to any systems, structures, or components depicted. Facility modifications are approved in accordance with detailed design information found in established procedures, configuration-controlled drawings, and vendor information.

C1.2 REQUIREMENTS

The following are current standards, regulations, and U.S. Department of Energy (DOE) orders that establish the requirements for Hanford Site characterization in support of safety analysis and design. Additional requirements may be imposed on new facilities and facility modifications to meet DOE safety requirements:

- DOE 5480.28, *Natural Phenomena Hazards Mitigation*, Change 0 (1993)[1]
- DOE 6430.1A, *General Design Criteria*, Change 0 (1989)[1]
- DOE-STD-1020-94, *Natural Phenomena Hazards Design and Evaluation Criteria for Department of Energy Facilities*, Change 1 (1994)
- DOE-STD-1021-93, *Natural Phenomena Hazards Performance Categorization Guidelines for Structures, Systems, and Components*, Change 1 (1993)

---

[1]Although DOE 5480.28 and DOE 6430.1A have been rescinded, the contractor is obligated by the existing contract to meet the requirements in these orders.

- DOE-STD-1022-94, *Natural Phenomena Hazards Characterization Criteria*, Change 1 (1994)
- DOE-STD-1023-95, *Natural Phenomena Hazards Assessment Criteria*, Change 1 (1995)
- DOE-STD-1024-92, *Guidelines for Use of Probabilistic Seismic Hazard Curves at Department of Energy Sites*, Change 1 (1992)
- UCRL-15910, *Design and Evaluation Guidelines for DOE Facilities Subjected to Natural Phenomena Hazards.*

C1.3 SITE DESCRIPTION

The following sections address the geography and demography of the area encompassed by, and surrounding, the Hanford Site.

C1.3.1 Geography

C1.3.1.1 Hanford Site Vicinity. The Hanford Site is a 1,450-km^2 (560-mi^2) area located in the state of Washington, as depicted in Figure C1-1. The Columbia River enters the Hanford Site boundary at the northwest corner and crosses over to form the eastern boundary as it flows southward. The section of the river that forms the eastern boundary is a free flowing stretch commonly referred to as the Hanford Reach. The Yakima River flows from west to east, south of the Hanford Site, and empties into the Columbia River at the conjoined cities of Kennewick, Pasco, and Richland as shown in Figure C1-1.

The Hanford Site is bordered on the north by the Saddle Mountains and on the west by the Rattlesnake Hills. Dominant natural features of the Hanford Site include the Columbia River, anticlinal ridges of basalt in and around the Site boundary, and sand dunes near the Columbia River. The surrounding basaltic ridges rise to 1,100 m (3,600 ft). See Figures C1-1 and C1-2 for maps showing some of the prominent natural features in and around the Hanford Site vicinity.

The location of the Hanford Site with respect to local counties and regional highways is shown in Figure C1-3. The Site extends into Benton, Franklin, Grant, and Adams counties. State Highway 240 passes through the Site and within 1.6 km (1.0 mi) of the 200 West Area facilities and within 4.24 km (2.65 mi) of the nearest TWRS facility.

C1.3.1.2 Hanford Site. The majority of the land within the Hanford Site boundary is a limited-access area under DOE control for use in environmental restoration and remediation efforts. The DOE nuclear and nonnuclear industrial activities within an 8-km (5-mi) radius of the TWRS facilities are described in detail in Section C1.7. DOE nuclear facilities are located in what are called operational areas. Site operational areas are identified by area numbers and letters. These areas are shown in Figure C1-4. Several other areas at the Hanford Site are managed under a multipurpose concept and

serve to isolate the areas of DOE nuclear activities (Figure C1-4). All industrial activities on Hanford Site leased land must be compatible with DOE activities and must be approved by DOE.

With the exception of subsurface contamination due to releases (inadvertent or planned) and the relatively isolated location of the Hanford Site (away from major population centers) there are no other unique or special features associated with the Site. Subsurface contamination (as it relates to accident analyses) is briefly discussed in Section C1.4.2. DOE/EIS-0189, DOE/RL-92-19, *200 East Groundwater Aggregate Area Management Study Report*, and DOE/RL-92-16, *200 West Groundwater Aggregate Area Management Study Report*, identify and describe existing subsurface and surface contamination areas and radiological and toxicological constituents.

Public access to the Hanford Site is controlled for DOE at the Wye and Yakima Barricades on State Highway 240 (Figure C1-5). Hanford Patrol, the Site security organization, is responsible for control at the barricades. A recently constructed additional access point to the 200 East and 200 West Areas from State Highway 240, with limited hours of operation, is located near the southeast corner of the 200 West Area. Public access through the Hanford Site on State Highways 24, 240, and 243 is not DOE-controlled under normal circumstances. Traffic on the Columbia River, in the airspace over the Hanford Site, and on onsite access routes to areas used by non-DOE organizations (e.g., U.S. Ecology, Incorporated; Washington Public Power Supply System [Supply System]) is also not subject to DOE controls under normal circumstances. Under emergency plan conditions, all access to the Site (with the exception of the Columbia River) will be DOE-controlled and all Site routes to traffic not associated with official and approved activities may be closed.

C1.3.1.2.1 Hanford Site Areas. In 1943, the U.S. Army Corps of Engineers selected the Hanford Site for the construction of nuclear reactors and chemical processing facilities in support of the war effort. The current mission is the management, storage, and disposal of radioactive and hazardous wastes. Approximately 6% of the total available Hanford Site land area is occupied with DOE operational areas (Figure C1-4). The remaining 94% of the Site land area is unoccupied and managed by DOE. Site operating areas are identified by area numbers and are briefly outlined below.

100 Areas. There are six 100 Areas (100-B and -C, 100-D and -DR, 100-F, 100-H, 100-KW and -KE, 100-N) bordering directly on the Columbia River in the northernmost portion of the Site. The nine graphite-moderated plutonium production reactors (awaiting decontamination and decommissioning) are located in these areas. The 100 Areas cover about 11 km^2 (4 mi^2).

200 Areas. The 200 East and 200 West Areas are located near the center of the Hanford Site. The 200 East and 200 West Areas are located on a relatively flat terrace known as the 200 Areas Plateau (Figure C1-6). A number of waste management, storage, and disposal activities are currently being performed in these areas. Activities in the 200 East and 200 West Areas are within the DOE-controlled zone, which is surrounded by a security fence that serves to limit general access. The TWRS facilities addressed in this report are located in the 200 East and 200 West Areas (Figures C1-7 and C1-8).

There are no permanent residences in this area. The 200 East and 200 West Areas cover approximately 15.5 km^2 (6 mi^2).

300 Area. The 300 Area, located north of Richland, is the site of nuclear research and development. This area covers 1.5 km^2 (0.6 mi^2).

400 Area. The 400 Area is located northwest of Richland and is the site of the Fast Flux Test Facility. The 400 Area covers 1.5 km^2 (0.6 mi^2).

600 Area. The 600 Area includes all of the Hanford Site that is not part of the 100, 200 East, 200 West, 300, or 400 Areas. A cross-site transfer line, operated by TWRS, traverses the 600 Area and is used to transfer liquid wastes between underground storage tanks located in the 200 East and 200 West Areas. See Figure C1-4 for a map showing the location of these areas.

- **Fitzner-Eberhardt Arid Lands Ecology Reserve**—The Fitzner-Eberhardt Arid Lands Ecology Reserve occupies the southwest segment of the Hanford Site. This area is a limited-access area managed by Pacific Northwest National Laboratory and has been set aside for ecological studies. This area covers 310 km^2 (120 mi^2). The Big Bend Alberta Company owns mineral rights to several parcels of land in the reserve and holds the right to perform exploratory drilling.

- **State of Washington**—A segment covering 4 km^2 (1.5 mi^2) is leased by Washington State. A part of this segment between the 200 East and 200 West Areas is used for commercial low-level radioactive waste disposal. U.S. Ecology, Incorporated is a private company responsible for managing disposal of the solid, low-level radioactive waste from commercial—not Hanford Site—sources in this area. Another segment of this area measuring 2.6 km^2 (1 mi^2) has been transferred to Washington State as a potential site for disposal of nonradioactive hazardous wastes.

- **Washington Public Power Supply System**—An area measuring 4.4 km^2 (1.6 mi^2) is used by the Supply System for commercial nuclear power plants. This area is located approximately 17 km (10.5 mi) southeast of the 200 East Area and approximately 5 km (3 mi) west of the Columbia River. Washington Nuclear Plant (WNP) Number 2, a boiling-water reactor, is currently in operation at this location.

- **Saddle Mountains National Wildlife Refuge**—About 130 km^2 (50 mi^2) of land north of the Columbia River is managed under a revocable use permit by the U.S. Fish and Wildlife Service. This area is designated as the U.S. Fish and Wildlife Service Saddle Mountains National Wildlife Refuge. The U.S. Fish and Wildlife Service also manages seven islands in the Hanford Reach section of the Columbia River as part of the McNary National Wildlife Refuge.

- **Wahluke Wildlife Recreational Area**—An area measuring 225 km^2 (87 mi^2) is under a revocable use permit to the Washington State Department of Wildlife for recreational game management. This area is also located north of the Columbia River and is designated as the Wahluke Wildlife Recreational Area. Public outdoor recreational use is permitted in this area.

- **Bonneville Power Administration**—Support facilities for the controlled access areas and an electrical transmission substation at Midway, Washington, near the northwest corner of the Hanford Site, are maintained by the Bonneville Power Administration. Site transmission lines are also maintained by the Bonneville Power Administration. See Figure C1-4 for a map showing transmission line locations.

The facilities in each area are accessible via existing Hanford Site streets and railroad lines and most have utilities (i.e., steam, raw water, electricity, communications) and radioactive waste pipelines. The roads and rail lines in the 200 East and 200 West Areas and Route 3 in the 600 Area are shown in Figures C1-7 and C1-8.

C1.3.1.2.2 Hanford Site Boundaries. The Hanford Site boundary that has been established for calculating impacts of potential Site facility accidents is shown in Figure C1-4. TWRS activities in the 200 East, 200 West, and 600 Areas are within this zone. The zone is surrounded by a security fence that limits general access. DOE has the authority to regulate all activities in this zone including exclusion or removal of personnel and property. There are no permanent residences in this zone or elsewhere on the Hanford Site. The minimum distance to the Site boundary, 11 km (7 mi), was determined by measuring from a rectangular "box" around the 200 East and 200 West Areas to the nearest point on the Hanford Site boundary.

C1.3.2 Demography

The population density on the Hanford Site is very low as a result of the federal ownership of the land, and the population distribution in the area surrounding the Hanford Site is not uniform. Most of the area adjacent to the Site to the east, north, and west is used for farm or range land and is populated with scattered farming communities.

Benton and Franklin Counties, which are adjacent to the Hanford Site, make up the Kennewick-Pasco-Richland metropolitan statistical area. Other major cities within Benton County include Benton City, Prosser, and West Richland. The second largest city in Franklin County is Connell. Other counties in the vicinity of the Hanford Site include Yakima, Walla Walla, Adams, and Grant Counties in Washington State, and Umatilla and Morrow Counties in Oregon (Figure C1-9). Table C1-1 lists the Kennewick-Pasco-Richland metropolitan statistical area population for 1980 through 1995.

Regional population (residential and transient) distribution data is used by the DOE Richland Operations Office for emergency response planning. Accident consequences are calculated to a maximum offsite individual located nearest to the 200 East or 200 West Areas (Section C1.3.1). The consequence data can be used in emergency response planning to determine offsite evacuation routes and mitigative features (i.e., shielding or shelters) required to protect the public. The emergency response plan for the Hanford Site is described in DOE/RL-94-02, *Hanford Emergency Response Plan*.

Note that the population figures presented in Table C1-1 do not identify transient populations (i.e., recreational users and migrant workers).

Evacuation time studies performed in support of Supply System emergency planning indicate that to the east of the Supply System operating reactor, migrant worker populations are roughly two times the recreational user populations (Mogle 1987, *WNP-1, 2 Ten Mile EPZ Evacuation Time Assessment Study*). To the northwest of the reactor (i.e., in the direction of the 200 East and 200 West Areas) the transient population is comprised predominantly of recreational user populations (e.g., boaters).

Individuals on the Columbia River, as well as those individuals on State Highways 24, 240, and 243, are considered transient. Access to the highways or the Columbia River is not controlled, except during emergency conditions (DOE/RL-94-02).

Individuals, such as tribal organizations, universities, or other federal, state, or local government agencies, who have received approval from DOE-RL to access areas within the Hanford Site (e.g., Fitzner-Eberhardt Arid Lands Ecology Reserve) are also considered transient. The DOE-RL, in accordance with DOE RLID 1210.1, *Hanford Visitor Policies and Procedures*, may permit uncontrolled access to the Hanford Site; however, all individuals, permitted either controlled or uncontrolled access to the Hanford Site, are required to receive emergency preparedness training (DOE/RL-94-02).

Approximately 15,000 persons were employed on the Hanford Site in late 1995. Figures C1-10 and C1-11 are maps that identify estimated onsite employee distributions by zones as of March 1996. Some Hanford Site work assignments include shift and weekend coverage, therefore, the total number of persons on the Site at any one time varies with the time of day, the staffing requirements for active projects, and daily fluctuations in employee work attendance patterns.

There are currently no hospitals, nursing homes, or penal institutions within 20 km (12 mi) of TWRS facilities. The three closest schools—Edwin Markham Elementary School, Cypress Gardens School, and Country Christian School—are at least 21 km (13 mi) southeast of the 200 East Area. The schools have a total population of less than 500.

C1.3.3 Regional Land and Water Use

This section characterizes regional land and water use outside the Hanford Site boundaries based on information contained in DOE/EIS-0113, *Final Environmental Impact Statement: Disposal of Hanford Defense High-Level, Transuranic, and Tank Wastes, Hanford Site, Richland, Washington*, and in PNL-6415.

Land use in the six-county region surrounding the Hanford Site (i.e., Adams, Franklin, Walla Walla, Benton, Yakima, and Grant) is predominantly agricultural. The main industries in the conjoined cities of Kennewick, Pasco, and Richland are either agriculture and energy production or are related to these industries. More than 75% of the land area in the six-county region is used for agricultural purposes, compared to less than 40% agricultural land use statewide. The percentage of agricultural land that is irrigated in this region varies from a low of 33% in Yakima County to a high

of 73% in Grant County. Areas of Yakima County near the Hanford Site are irrigated extensively.

The land used for agricultural purposes lies primarily north and east of the Columbia River and south of the Yakima River. The principal agricultural crops associated with irrigated and dryland farming include hay, wheat, potatoes, corn, apples, soft fruit, and vegetables. Land in the area just outside the Hanford Site to the south and west is available for farming, but the present area is used mainly for grazing cattle and sheep. In the early 1800s the dominant regional plant was big sagebrush, but today cheatgrass is the dominant plant due to livestock grazing, crop raising, and wildfires.

Major regional water uses, in decreasing order, are agricultural, industrial, and municipal.

A U.S. Army training facility, the Yakima Firing Center, is located northwest of the western Hanford Site boundary (Figure C1-12). The nearest boundary of the firing center is more than 24 km (15 mi) west of the 200 West Area. The facility is primarily used as a training area for large-scale maneuvers, particularly those involving tracked vehicles and the use of large long-range weapons (DOE-RW-0070, *Environmental Assessment, Reference Repository Location, Richland, Washington*).

C1.4 ENVIRONMENTAL DESCRIPTION

The following sections briefly define the meteorology, hydrology, and geology of the Hanford Site. This information has been used in calculating impacts of postulated TWRS facility accidents to receptors (i.e., onsite, offsite, environmental) and in evaluating facility needs for adequate response to natural phenomena threats. Chapter 5.0 for results of these calculations and evaluations.

C1.4.1 Meteorology

This section summarizes Site-specific meteorology data. This information is used in hazards and accident analyses (e.g., wind, tornado, precipitation) in accordance with DOE-STD-1023-95 and to verify the applicability of existing natural phenomena hazard codes and standards. The Site average wind speeds are used to develop postulated accident consequences and to perform consequence determinations in Chapter 5.0. Criteria from DOE-STD-1020-94 are identified in the applicable subsections of this chapter.

An extensive meteorological monitoring program is conducted at the Hanford Site. Various meteorological data is measured, observed, and stored as part of this program. Program data is used in the preparation of safety documentation and in the preparation of emergency response planning. A wide range of meteorological variables is measured or observed at the HMS, including temperature, relative humidity, precipitation, atmospheric pressure, solar radiation, cloud cover, visibility, and subsurface temperature. Wind data is measured at various levels on a 125-m (410-ft) tower located 492 m (1,614 ft) east of the HMS. Wind and temperature measurements are recorded at various levels at three 60-m (200-ft) towers in the 300, 400, and 100-N Areas

and at 23 active 9.1-m (30-ft) towers distributed on the Hanford Site and in the nearby vicinity (Figure C1-13). Data from all towers is telemetered to the HMS. The towers and the HMS make up the Hanford Site meteorological monitoring network. The Site monitoring network is described in detail in PNL-6684, *The Data Collection Component of the Hanford Meteorological Monitoring Program.*

Meteorological data collected at the HMS since 1945 is available. Data from the HMS is representative of the general meteorological conditions for the Site, and specifically for the 200 Areas Plateau. Local variation in the topography of the Hanford Site may cause some aspect of the climate at portions of the Site to differ significantly from those at the HMS. For example, winds near the Columbia River are different from those at the HMS, and, similarly, precipitation along the slopes of the Rattlesnake Hills differs from that at the HMS. Information contained in this section and the associated subsections is taken primarily from PNNL-11107, *Climatological Data Summary 1995, with Historical Data*, and PNL-4622, *Climatological Summary for the Hanford Area.*

C1.4.1.1 Regional Climate. The climate of the Hanford Site region can be classified as midlatitude semiarid, midlatitude desert, or semiarid shrub-steppe depending on the climatological classification scheme used (Critchfield 1974, *General Climatology*). Summers are warm and dry with abundant sunshine. Large diurnal temperature variation results from intense solar heating during the day and radiational cooling at night. Daytime high temperatures in June, July, and August periodically exceed 38 °C (100 °F). Winters are cool with occasional precipitation. Cold air associated with modified arctic air masses can reach the area and cause temperatures to drop below -18 °C (0 °F). Overcast skies and fog periodically occur during the winter season (PNL-4622).

Topographic features have a significant impact on the Hanford Site climate. All air masses that reach the region undergo some modification as a result of passage over the complex Pacific Northwest terrain. The climate of the region is strongly influenced by the Pacific Ocean and the Cascade Range. The relatively low annual average rainfall of 168 mm (6.6 in.) is caused largely by the rain shadow created by the Cascade Range. This mountain range limits much of the maritime influence of the Pacific Ocean that would exist if the mountains were not present. Maritime influences are experienced in the region during the passage of frontal systems that pass through gaps (e.g., Columbia River Gorge) in the Cascade Range.

The Rocky Mountains to the east and north of the Site also impact the regional climate by protecting the region from the severe winter storms and the extremely low temperatures associated with modified arctic air masses that move southward through Canada. Yakima Ridge, Rattlesnake Hills, Horse Heaven Hills, Saddle Mountains, and the Columbia River are other topographic features that impact the local climate (Figure C1-14).

The position of the jet stream directs storm systems into Washington State during the cooler months. These storm systems cause the majority of the precipitation at the Site. The cold, or occluded, fronts associated with these storm systems originate in maritime polar, continental polar, or arctic air masses. Warm fronts occur as warmer maritime air flows over colder

continental air. An average of 10 identifiable warm fronts and 52 cold fronts pass through the region each year, the majority of which occur during the colder months (PNL-4622). The passage of fronts leads to increased frequency and intensity of precipitation. Persistent high-pressure ridges in the upper troposphere also periodically occur in the cool season. The high-pressure ridges can trap cold air near the surface and cause extended periods of wintertime air stagnation.

The position of the jet stream directs most storm systems north of Washington State during the warm months, which results in fewer and weaker frontal passages than in the cool months. High pressure with stable, subsiding air is the dominant meteorological condition during the warmer period. Warm weather precipitation tends to be associated with convective activity and the advection of moist, maritime air into the region (PNL-4622).

C1.4.1.1.1 Temperature. Average and extreme temperatures recorded at the HMS are listed in Table C1-2. The annual average temperature is 12 °C (53 °F). July is typically the warmest month with an average maximum temperature of 33 °C (91 °F), an average minimum temperature of 16 °C (61 °F), and a monthly average temperature of 25 °C (76 °F). January tends to be the coolest month with an average maximum temperature of 4 °C (38 °F), an average minimum temperature of -4 °C (24 °F), and a monthly average temperature of 0 °C (32 °F). Observed temperature extremes for the Hanford Site since 1944 range from 45 °C (113 °F) to -31 °C (-23 °F). The highest temperature ever recorded on the Hanford Site was 46 °C (115 °F) on July 27, 1939. The lowest temperature ever recorded on the Hanford Site was -33 °C (-27 °F) on December 12, 1919. The high and low temperatures were recorded before the HMS was operational and are not included in Table C1-2.

Table C1-3 shows the average number of days that maximum and minimum temperatures at the HMS were above or below specified limits. Maximum temperatures greater than or equal to 38 °C (100 °F) occur an average of 12 days per year with a range of one to 28 days. Maximum temperatures greater than or equal to 32 °C (90 °F) occur an average of 51 days per year with a range of 29 to 79 days. Maximum temperatures less than or equal to 0 °C (32 °F) occur an average of 25 days per year with a range of 2 to 58 days. Minimum temperatures less than or equal to 0 °C (32 °F) occur an average of 106 days per year with a range of 70 to 143 days. Minimum temperatures less than or equal to -18 °C (0 °F) occur an average of three days per year with a range of 0 to 18 days. An average of 183 days per year are free of freezing temperatures with the recorded range being 142 to 216 days.

Severe and abrupt temperature changes occur in the Hanford Site vicinity. During winter, rapid temperature increases, accompanied by surface winds varying from calm to greater than 32 km/h (20 mph), frequently occur. This phenomenon, known as a Chinook wind, may produce dramatic temperature variations. For example, on February 10, 1971, a 9 °C (16.2 °F) rise in 12 minutes was observed at the HMS (PNL-4622).

C1.4.1.1.2 Precipitation. The annual average precipitation at the Hanford Site is 168 mm (6.6 in.) in the wettest year (1995) being 312 mm (12.3 in.) and the driest year (1976) being 76 mm (3 in.). Monthly averaged and annual extreme precipitation amounts recorded at the Hanford Site are listed in Table C1-4. On average, 54% of normal annual precipitation falls

during November through February. December is the wettest month with 25 mm (1 in.) and July is the driest month with 5.1 mm (0.2 in.). The wettest month on record is June 1950 with 74 mm (2.9 in.). September 1991, August 1988, and August 1955 are the driest months on record with no precipitation. A trace (i.e., less than 0.1 mm [0.005 in.]) or more of precipitation falls an average of 125 days per year. The average number of days per month in which a trace or more of precipitation falls ranges from 16 days in January to five days in July. Precipitation totalling 2.5 mm (0.1 in.) or more in a day occurs 24 days a year. During a 49-year period of record (1945 through 1995), precipitation totaling 25 mm (1 in.) or more in a day has occurred 63 times. The greatest recorded one-day precipitation was 41 mm (1.6 in.) on October 1, 1957 (PNNL-11107).

A recent cooperative study by the National Oceanic and Atmospheric Administration, the Bureau of Reclamation, and the U.S. Army Corps of Engineers updates the probable maximum precipitation estimates for the Pacific Northwest. Hansen et al. 1994, *Probable Maximum Precipitation - Pacific Northwest States*, documents the findings of this study which supersede earlier work done by the three organizations. The probable maximum precipitation values, shown in Table C1-5, are estimates of the maximum precipitation physically possible for both general storms (i.e., large air mass interactions) and local storms (i.e., unstable air, thunderstorms). Hansen et al. (1994) shows that at the Hanford Site the probable maximum precipitation for a six-hour local storm produces more than that produced in the probable maximum for a 24-hour general storm. The probable maximum precipitation for a six-hour local storm is related to the area of the storm, the smaller area yielding the most intense storm and highest precipitation. Data is presented for the 2.6-km^2 (1.0-mi^2) and the 26-km^2 (10-mi^2) storm. No annual probability of exceedance is given in Hansen et al. (1994) for the probable maximum precipitation for either storm. The probable maximum precipitation is conservatively assumed to have a less than 1×10^{-6} annual probability of exceedance based on ASCE-7, *Minimum Design Loads for Buildings and Other Structures*.

The probable six-hour maximum precipitation for more frequent storms is based on the analysis of extreme values from 22 years of Hanford Site meteorological data (Table C1-5). The precipitation estimates for 100- and 1,000-year return periods are based on HMS data. Although the estimated values cannot be compared directly with the 2.6-km^2 (1-mi^2) local storm or the 26-km^2 (10-mi^2) general storm, the values do provide a data-based estimate for extreme precipitation on the 200 Areas Plateau. The six-hour precipitation hazard curve has been estimated using the 100- and 1,000-year average return period values (1×10^{-2} and 1×10^{-3} annual probability exceedance, respectively) from BNWL-1605, *Climatography of the Hanford Area*, and using the six-hour probable maximum precipitation at an assumed frequency of 1×10^{-6} (Figure C1-15).

Total annual snowfall (i.e., all frozen precipitation) varies from a low of 7.6 mm (0.3 in.) to 1,422 mm (56 in.). The average snowfall is 381 mm (15 in.) a year. Table C1-6 presents the monthly average and seasonal maximum snowfalls. The maximum snow depth recorded at HMS (396 mm [15.6 in.]) occurred in December 1985, but the maximum recorded snow depth for the Hanford Site (610 mm [24 in.]) occurred in February 1916. The record number of days with snow depth greater than or equal to 152 mm (6 in.) was 43 days in the

winter of 1992-1993. The probability that the depth of snow on the ground will exceed 152 mm (6 in.) is 30% during the winter season. The scatter plot in Figure C1-16 shows Hanford Site snow depth probabilities based on the maximum depths of snow on the ground at the Site that were recorded from the winter of 1946-1947 to the winter of 1980-1981.

Model building codes and standards specify the design criteria for snow loads (DOE-STD-1020-94). The building standards for snow loads are found in ASCE-7. The design ground snow load for the Hanford Site is 73.2 kg/m^2 (15 lb/ft^2).

Glaze ice is a coating of ice formed when rain or drizzle freezes on contact with any surface having a temperature that is below freezing. The annual average number of days with glaze ice is six. Glaze ice generally occurs between November and March. The highest number of days with glaze ice in any winter season is 18. The lowest number of days with glaze ice in any winter season is one. The highest number of days with glaze ice in any given month was nine in January 1970. Rime ice (i.e., supercooled droplets that freeze on contact with solid objects) is another type of icing phenomena that is generally associated with supercooled fog in the nearby hills or along the banks of the Columbia River.

C1.4.1.1.3 Thunderstorms. A thunderstorm day is a calendar day in which thunder is heard at the HMS observing station one or more times. Table C1-7 shows the average number of thunderstorm days recorded at the HMS per month and per year. The average number of thunderstorm days per year is 10, with the total of days varying from a low of three to a high of 23. The largest number of thunderstorm days in a single month was eight. Thunderstorm season is essentially from April through September, but thunderstorms can occur during any month of the year although none have been observed in November or January.

Thunderstorms are classified as severe by the National Weather Service when wind gusts exceed 93 km/h (58 mph) or when hail diameter equals or exceeds 25 mm (1 in.). Of all thunderstorm events observed at the HMS, 1.9% have been severe (PNL-6415). Of the 1.9%, all of the severe storm events met the wind gust classification criteria, but hail was seldom observed. The maximum recorded number of days with hail in a year is two.

Large differences in electrical potential between cloud and earth can occur during thunderstorms and can lead to lightning strikes. There is an average of 0.06 lightning strikes per year per square kilometer at the Hanford Site (WHC-SD-WM-ES-387, *Probability, Consequences, and Mitigation for Lightning Strikes of Hanford High Level Waste Tanks*). The probability of lightning directly striking one of 161 tanks (i.e., the 16 smaller single-shell tanks excluded) was calculated as 3×10^{-5} every year. Considering all 177 tanks, the probability of a lightning strike in some tank farm area is about 1×10^{-2} strike a year. Lightning strikes in the tank farms have not been documented.

C1.4.1.1.4 Extreme Winds and Tornados. The maximum peak gusts recorded at the HMS are shown in Table C1-8. The highest peak gust, measured at 15 m (50 ft) above ground level, was 129 km/h (80 mph) in January 1972. Peak wind gusts at the other 23 meteorological towers located throughout the Site have

been observed to be as high as 147 km/h (91 mph). On the basis of peak gusts observed from 1945 through 1980, an extreme peak gust at 15 m (50 ft), 100-year return period, is estimated in PNL-4622 to be 137 km/h (86 mph), and an extreme peak gust at 15 m (50 ft), 10-year return period, is estimated to be 114 km/h (70 mph).

Two probabilistic wind hazard assessments have been completed for the Hanford Site. The first assessment, UCRL-53526, *Natural Phenomena Hazards Modeling Project: Extreme Wind/Tornado Hazard Models for Department of Energy Sites*, is based on more than 30 years of pre-1979 Hanford Site wind data. The results of the assessment addressed in UCRL-53526 are shown in Figure C1-17 and are the basis for the recommended Hanford Site wind speeds for calculating hazard assessments listed in DOE-STD-1020-94.

NUREG/CR-4492, *Methodology for Estimating Extreme Winds for Probabilistic Risk Assessments*, is the other probabilistic wind hazard assessment that describes a procedure for estimating extreme wind probabilities. The application of this methodology to Hanford Site data, including post-1979 data, resulted in the hazard curves shown in Figure C1-17.

The wind hazard annual probability of exceedance for Performance Category 1 and 2 is 2×10^{-2} (DOE-STD-1020-94). In Figure C1-17, this is about 89 km/h (55 mph) on the UCRL-53526 curve and about 93 km/h (58 mph) on the NUREG/CR-4492 curve. A minimum-design wind speed of 113 km/h (70 mph) is required in ASCE-7 and recommended in DOE-STD-1020-94. The Hanford Site design-basis wind speed for Performance Categories 1 and 2 is 113 km/h (70 mph). All wind speeds are fastest mile speeds at 9 m (30 ft) off the ground.

The straight wind hazard exceedance probability for Performance Category 3 is 1×10^{-3}. In Figure C1-17, this is approximately 108 km/h (67 mph) on the UCRL-53526 curve and 116 km/h (72 mph) on the NUREG/CR-4492 curve. The minimum straight wind speed for a Performance Category 3 design basis in DOE-STD-1020-94 is 129 km/h (80 mph), which is higher than either of the wind hazard studies and is, therefore, the design basis for the Site.

The minimum Performance Category 4 wind speed is 145 km/h (90 mph). This exceeds values for both of the straight wind curves and is, therefore, the design wind speed for Performance Category 4.

The point at which the straight-wind and tornado hazard curves intersect determines whether tornadoes should be included in the design and evaluation criteria for the TWRS facilities (UCRL-53526). If the exceedance probability at the intersection is less than 2×10^{-5}, straight winds control the design criteria. In Figure C1-17, the intersection is at 3×10^{-6} on the UCRL-53526 curve and 8×10^{-6} on the NUREG/CR-4492 curve. Therefore, following DOE guidance the Hanford Site does not have a DOE design-basis tornado (UCRL-53526).

C1.4.1.1.5 Dust and Blowing Dust. Dust and blowing dust conditions occur with some frequency at the Hanford Site. Dust and blowing dust conditions are recorded at HMS when horizontal visibility is reduced to 9.6 km (6 mi) or less. Dust conditions occur when dust is carried into the area from distant sources. Dust conditions may or may not occur during strong winds and

have been observed with wind speeds ranging from 6 km/h (4 mph) to 48 km/h (30 mph). Blowing dust conditions occur when dust is being picked up locally and occurs with strong winds. Wind speeds during blowing dust conditions range from 31 km/h (19 mph) to 129 km/h (80 mph). Dust and blowing dust conditions occur at HMS but blowing dust is most common. Table C1-9 shows the average number of days of dust or blowing dust conditions recorded at the HMS. The average number of days per year with dust or blowing dust conditions is five. The greatest number of such days in any year has been 20, while the fewest has been zero. The greatest number of days with dust or blowing dust in any month was nine in May 1980. Dust and blowing dust conditions occur most frequently between March and May, and again in September, and occur least frequently during November and December. There is no specific design basis criteria associated with dust and blowing dust. Past evaluation of dust and blowing dust has been similar to volcanic ash for design and evaluation purposes.

C1.4.1.1.6 Fog and Cloud Cover. Fog conditions are recorded at the HMS any time horizontal visibility is reduced to 9.6 km (6 mi) or less due to suspension of water droplets in the surface layer of the atmosphere. Table C1-10 shows the average monthly and annual number of days with fog and dense fog at the Hanford Site. Dense fog conditions are recorded when horizontal visibility is reduced to 0.40 km (0.25 mi) or less. Most of the fog recorded at HMS is radiation fog, a common type of fog that forms on nights with light wind, clear sky, and moist air in the lower levels of the atmosphere. Nearly 90% of fog and dense fog conditions occur during the late autumn and winter months. The longest recorded duration of fog was 114 hours in December 1985 and the longest duration of dense fog was 47 hours in December 1957 (PNNL-11107).

Cloud cover is a term used to express the condition when a portion of the celestial dome is (1) covered but not necessarily hidden by clouds or obscuring phenomena aloft; (2) hidden by an obscuring phenomenon on the ground (e.g., fog, smoke); or (3) a combination of (1) and (2). Cloud cover at the HMS is measured hourly by scanning the sky and estimating the number of tenths that are covered. Cloud cover designation on a given day is based on the cloud cover average from sunrise to sunset. Cloud cover designations are as follows:

- Clear (zero to three tenths)
- Partly cloudy (four to seven tenths)
- Cloudy (eight to 10 tenths).

Table C1-11 shows the average monthly sunrise to sunset sky cover values from 1946 through 1994, and Table C1-12 shows the average number of clear, partly cloudy, and cloudy days from 1954 to 1995. During the period of record (1954 through 1995), an average of 199 sunny days (sum of clear and partly cloudy days) was recorded per year at the HMS.

C1.4.1.1.7 Relative Humidity. The annual mean relative humidity recorded at HMS is 55% with the highest average monthly relative humidity (80%) occurring in December and the lowest average monthly relative humidity (33%) occurring in July. Daily relative humidity can change 20% to 30%

between early morning and late afternoon. Changes in relative humidity are less pronounced during the winter months (PNL-4622). Higher relative humidity can be expected at locations near the Columbia River and at some locations on the Site periphery where there is increased airborne water vapor from the Columbia River and from irrigated land.

C1.4.1.1.8 Dispersion Climatology. Atmospheric dispersion, the transport and diffusion of gases and particles within the atmosphere, is a function of wind speed, duration and direction of wind, the intensity of atmospheric turbulence (i.e., wind motion at very small time scales that acts to disperse gas and particles rather than transport them downwind), and mixing layer. Atmospheric turbulence often cannot be measured directly and is estimated by the atmospheric stability. Atmospheric stability is the thermal stratification or vertical temperature structure of the atmosphere. The more unstable the atmosphere, the more atmospheric turbulence.

Conditions are favorable for dispersion when (1) the atmosphere is considered to be unstable or neutral, (2) the winds are moderate to strong, and (3) the mixing layer is deep. These three conditions are most common in the summer when neutral and unstable stratification exists about 56% of the time (PNL-4622). Less favorable dispersion conditions may occur when the wind speed is light and the mixing layer is shallow. Less favorable conditions are most common during the winter when moderately to extremely stable stratification exists about 66% of the time (PNL-4622). Less favorable conditions also occur periodically for surface and low-level releases in all seasons from around sunset to around an hour after sunrise as a result of ground-based temperature inversions and shallow mixing layers. There are occasional extended periods of poor dispersion conditions associated with stagnant air in stationary high-pressure systems, primarily during the winter months (PNL-4622). Table C1-13 provides a summary of the mixing-layer thicknesses by season and time of day.

Estimates of the probability of extended periods of poor dispersion conditions are documented in BNWL-1605. The probability of an inversion, once established, persisting more than 12 hours varies from a low of about 10% in May and June to a high of about 64% in September and October. These probabilities decrease rapidly for durations of more than 12 hours. Table C1-14 contains percentages of the probabilities (percent) associated with extended periods of surface-based inversions.

To estimate atmospheric diffusion factors, the dispersion models used in the TWRS facility accident analyses required a joint frequency distribution of wind speed, wind direction, and atmospheric stability. Tables C1-15 and C1-16 present the joint frequency distribution of hourly averaged wind data collected at the 200 East and 200 West Areas from January 1983 to December 1991. Before March 1983, atmospheric stability was determined at the HMS on the basis of sky cover or wind speed (Pasquill 1961, "The Estimation of the Dispersion of Windborne Material"). Since March 1983, atmospheric stabilities have been determined by using the U.S. Nuclear Regulatory Commission temperature gradient method (NUREG 1.23, *Onsite Meteorological Programs*).

The frequency of each stability class that occurred at the 200 East and 200 West Areas during the years 1983 to 1991 is listed in Table C1-17.

Stability Class D, relatively neutral diffusion conditions, occurred 28% of the time. Conditions favorable for turbulent dispersion, represented by the unstable classes A, B, and C, occurred about 23% of the time. Classes E, F, and G, indicative of conditions unfavorable for turbulent dispersion, occurred about 49% of the time.

Graphical representations of the wind direction and wind speed distribution at the 200 East and 200 West Areas are shown in Figures C1-18 and C1-19. For the 200 East Area, winds from the west-northwest occur most frequently (about 20% of the time). Winds out of the northwest and west also occur with a relatively high frequency (12% and 11%, respectively). For the 200 West Area, winds out of the west-northwest (15% of the time), northwest (15% of the time), and west (12% of the time) occur most frequently. For the hours of unstable conditions (stability classes A, B, and C), winds from the northwest occur most frequently in the 200 East and 200 West Areas, and for the hours of stable conditions (classes E, F, and G), winds from the west-northwest occur most frequently.

C1.4.2 Hydrology

This section presents the hydrostratigraphy (water and soil characteristics) of the Hanford Site, focusing on the characteristics of the unsaturated zone or vadose zone and the saturated zone or groundwater. Summary discussions of actual or estimated liquid plume travel times through the zones are included. These discussions are based on observed data for known release locations and release mechanisms. Section C1.4.3 for a detailed discussion of Hanford Site geology.

This hydrostratigraphy data has been used in the TWRS facilities hazards and accident analyses to evaluate releases to the soil column. The data has been used to model and calculate the consequences of associated surface pools (i.e., infiltration), near-surface plumes (i.e., adsorption), or deep underground plumes (i.e., travel times through the unsaturated and saturated zones).

The Columbia River and its tributary, the Yakima River, are the primary Hanford Site surface water features (Figure C1-20). West Lake, about 0.04 km^2 (0.02 mi^2) and less than 1 m (3 ft) deep, is the only natural lake on the Hanford Site. Artificial surface water bodies include ponds and ditches created and used for wastewater disposal.

The vadose zone (i.e., zone of unsaturated sediments between the water table and the ground surface) at the Hanford Site is comprised mainly of unconsolidated gravels and sands. The thickness of the vadose zone ranges from 0 m (0 ft) at the Columbia River bank and West Lake to more than 100 m (328 ft) at the 200 East and 200 West Areas.

Saturated sediments make up a series of aquifers (i.e., permeable bodies of rock) and aquitards (i.e., beds of low permeability adjacent to an aquifer). Sand- and gravel-dominated stratigraphic units form aquifers, and fine-grained deposits form aquitards. The shallowest suprabasalt aquifer is unconfined beneath most of the Hanford Site. Confined aquifers are present in sedimentary interbeds and interflow zones between dense basalt flows. The

main water-bearing portions of the interflow zones are networks of interconnecting vesicles and fractures of the flow tops and flow bottoms.

C1.4.2.1 Surface Water. An overview of flood potential from natural and artificial surface water bodies in and around the 200 East and 200 West Areas is presented in the following subsections.

C1.4.2.1.1 Columbia River. The Columbia River originates in the mountains of eastern British Columbia, Canada, and drains an area of approximately 70,800 km^2 (27,300 mi^2) en route to the Pacific Ocean (Figure C1-21). The average annual flow of the Columbia River is 1.1×10^{11} m^3 (3.9×10^{12} ft^3) where it enters the Hanford Site and 1.6×10^{11} m^3 (5.6×10^{12} ft^3) where it exits the Site. The river elevation is approximately 120 m (396 ft) near the 100-B and -C Area and approximately 104 m (343 ft) at the 300 Area (Figure C1-4 for area locations).

PNL-7500, *1988 Hanford Riverbank Springs Characterization Report*, contains a comparison of Columbia River water quality upstream and downstream of the Hanford Site. Most radioactive constituents were not detected or were detected in similar concentrations at both sampling locations. Only tritium and technetium-99 concentrations were higher downstream than upstream. Tritium was measured at 580 $\pm$180 pCi/L at the downstream location, compared with 180 $\pm$170 pCi/L upstream. The minimum (0.6 $\pm$1.2 pCi/L) and maximum (1.8 $\pm$1.2 pCi/L) levels of technetium overlapped; therefore, no environmental impact from technetium is apparent.

Flow on the Columbia River is regulated by three upstream dams in Canada and by seven upstream dams in the United States (Figure C1-21). The Hanford Reach, approximately 81 km (50 mi) in length, extends from Priest Rapids Dam to just north of the 300 Area. Flow through the Hanford Reach fluctuates significantly and is controlled at Priest Rapids Dam. The three dams with the largest reservoirs upstream from the Hanford Site are the Mica and Hugh Keenleyside dams in Canada and the Grand Coulee dam in the United States. The controlled flow of the Columbia River caused by these dams results in a lower flood hazard for high-probability floods (e.g., 100-year floods); however, dam-failure scenarios are significant contributors that result in high flood flows.

The U.S. Army Corps of Engineers evaluated a number of scenarios on the effects of failures of Grand Coulee Dam, assuming flow conditions on the order of 11,000 m^3/s (400,000 ft^3/s). The discharge resulting from a 50% breach at the outfall of Grand Coulee Dam was determined to be 600,000 m^3/s (21 million ft^3/s). No determinations were made for breaches greater than 50% of Grand Coulee, for failures of dams upstream, or for associated failures downstream of Grand Coulee. The 50% scenario was believed to represent the largest realistically conceivable flow resulting from either a natural or human-induced breach (DOE-RW-0070).

A flood scenario of a 50% breach of Grand Coulee dam results in a flood level of about 143 m (470 ft) above mean sea level at Columbia River mile 365; this low point is the closest flood route to the 200 Areas Plateau (Figure C1-22). River mile 365 is about 46 m (150 ft) below the ground surface of the lowest elevation tank farm. The 50% breach of the Grand Coulee Dam would not impact the 200 East and 200 West Areas or the land within the

600 Area (i.e., between the 200 East and 200 West Areas) occupied by TWRS. Therefore, this scenario bounds all other Columbia River flood scenarios. UCRL-21069, *Probabilistic Flood Hazard Assessment for the N Reactor, Hanford, Washington* provides a detailed hazard assessment of other flood scenarios.

C1.4.2.1.2 Yakima River. The Yakima River is approximately 20 km (12 mi) south of and greater than 60 m (200 ft) in elevation below the 200 East and 200 West Areas. The Yakima River is not a flood hazard for the TWRS facilities.

C1.4.2.1.3 Cold Creek. Cold Creek and its tributary, Dry Creek, are ephemeral, discontinuous streams in the Yakima River drainage basin (Figure C1-23). The Cold Creek watershed, located in the southwestern portion of the Hanford Site, extends about 16 km (10 mi) up the Cold Creek and Dry Creek valleys. A flood risk analysis of Cold Creek, documented in RHO-BWI-C-120, *Flood Risk Analysis of Cold Creek Near the Hanford Site*, was conducted in 1980 to determine the probable maximum precipitation flood for the Cold Creek system. A map of the extent of the probable maximum flood determined in the risk analysis is presented in Figure C1-23. A recurrence interval is not estimated for this flood, but any occurrence would be a flash flood of short duration. The postulated probable maximum precipitation flood reaches an elevation of about 195 m (640 ft) above mean sea level on the southwestern portion of 200 West Area. Because the surface elevation of the lowest elevation tank farms (i.e., 241-S, 241-SY, 241-SX, 241-U) is 201 to 204 m (660 to 670 ft) above mean sea level, surface flooding is not anticipated; however, the bottoms of the tanks are below the flood level. Because of the expected short duration of a flash flood, a significant rise in the water table in these areas is not anticipated, therefore, some contaminants from previous waste leak discharges may be mobilized but the tanks would not be impacted.

C1.4.2.1.4 Artificial Waterbodies. In the past, there were numerous artificial surface water bodies (e.g., cribs, ditches, ponds) in the 200 East and 200 West Areas. Effluent disposal wastewater infiltrated the ground and, in many instances, affected groundwater flow and chemistry. Today, only B Pond and the Treated Effluent Disposal Facility located east of 200 East Area and the state-approved land disposal site located in the 200 West Area receive significant volumes of effluent.

C1.4.2.2 Vadose Zone. The vadose zone in the 200 West Area is comprised of interlayered gravel, sand, and silt. The thickness of the vadose zone ranges from less than 50 m (164 ft) near the southwest corner to more than 100 m (328 ft) in the northwest corner of the 200 West Area (DOE/RL-93-88, *Hydrogeologic Setting of the 200 Areas*). The fine-grained units beneath the 200 West Area produced perched water units (i.e., saturated portions of the vadose zone) near liquid waste disposal facilities when those facilities were active. The Plio-Pleistocene/Early Palouse soils interval appears to be the primary perching unit throughout the 200 West Area. The lower fine-grained sequence of the Hanford formation also may have produced perched water near active facilities in south 200 West Area. Perched water was observed during well drilling near the 216-U-14 ditch, the 216-Z-20 crib, and the

216-Z-21 seepage basin. See Figure C1-24 for a graphical representation of characteristic Hanford Site stratigraphy, lithology, and hydrogeologic conditions.

The vadose zone in the 200 East Area is comprised of interlayered gravel, sand, silt, and "mud" (i.e., silt and clay). In some 200 East Area locations, the basalt has been uplifted and comprises part of the vadose zone. Thickness of the vadose zone in the 200 East Area ranges from 37 m (122 ft) near B Pond to 104 m (341 ft) near the southern border of the area (DOE/RL-93-88). Fine-grained units in the Hanford formation and the Ringold Formation Lower Mud unit significantly influence the lateral distribution and flux of water in the 200 East Area.

Flow rate of water through the vadose zone is a function of the moisture content, matrix potential, and unsaturated hydraulic conductivity for each hydrostratigraphic unit. Water generally flows and spreads laterally at a much greater rate in fine-grained units than in coarse-grained units. Fine-grained units in the vadose zone significantly influence the lateral distribution of water and the flux of water to the uppermost aquifer. Coarse-grained units may impede the flux of water through the vadose zone because of the formation of a capillary pressure barrier between the coarse-grained units and overlying fine-grained units.

The fine-grained sedimentary units in the 200 East Area may produce perched water conditions near active waste disposal facilities. Perched water has been observed to the east of the 241-BY Tank Farm and above the Lower Mud unit near B Pond and the Treated Effluent Disposal Facility (DOE-RL-93-88).

Two sources of data were used to estimate the magnitude of recharge from natural precipitation on the 200 Areas Plateau: (1) moisture accumulation in an 18-m- (59-ft-) deep 200 East Area lysimeter for 13 years, and (2) distribution of cesium-137 in a solid-waste burial ground (200 West Area) in which contaminated soil had been buried for 10 years (Routson and Johnson 1990, "Recharge for the Hanford Site 200 Areas Plateau"). There had been no detectible moisture accumulation in the bottom of the lysimeter since 1972. The recharge rate was approximately zero over the 13-year period. Soil contaminated with cesium was placed in a burial ground in 1970. After 10 years, the distribution of cesium was determined from core-drilled samples. No cesium above the background level for the burial ground was detected beneath the bottom of the trench, indicating there was no measurable downward movement. Cesium was detected above the trench, most likely from evapotranspiration.

Under natural, minimally disturbed conditions, there appears to be little potential for downward movement of contaminants in the upper vadose zone beneath the 200 Areas Plateau (Routson and Johnson 1990). However, highly disturbed sites with little vegetation (e.g., the tank farms) may allow more movement of water through the vadose zone. The addition of water from effluent disposal or leaks could also increase recharge.

PNL-10285, *Estimated Recharge Rates at the Hanford Site*, and PNL-10508, *Estimation of Natural Ground Water Recharge for the Performance of a Low-Level Waste Disposal Facility at the Hanford Site*, summarize recent recharge studies. The results of the two reports are consistent with those of the

earlier Routson and Johnson (1990) studies and indicate recharge rates that vary from near zero in vegetated fine-grained soils to greater than 100.0 mm/yr (3.9 in./yr) in course-grained unvegetated soils similar to the gravel cover used in tank farm sites.

Recharge estimates using chloride and chlorine-36 as tracers indicate very low rates of recharge in undisturbed areas of the Hanford Site (Murphy et al. 1994, "Evaluation of Net Residual Fluxes Determined by Chloride Mass Balance in the Pasco Basin, Southeastern Washington"; USGS 1995a, *Using Chloride and Chlorine-36 as Soil-Water Tracers to Estimate Deep Percolation at Selected Locations on the U.S. Department of Energy Hanford Site, Washington*). Recharge rates estimated from tracer studies are similar to, but are generally lower than, results presented in PNL-10285 and PNL-10508.

A groundwater impact assessment of the 216-U-14 ditch in the 200 West Area includes a study of infiltration rates and travel times through the vadose zone (WHC-EP-0698, *Groundwater Impact Assessment Report for the 216-U-14 Ditch*). Conclusions of the study include the following.

- There is a zone of perched water near the ditch that is up to 17-m- (56-ft-) thick beneath the east portion and 1- to 2-m- (3- to 7-ft-) thick beneath the west portion of the ditch. The water appears to perch on the lower fine-grained unit of the Hanford formation at a depth of approximately 20 to 40 m (66 to 131 ft).

- Changes to the perched water level virtually coincide with changes in the effluent discharge rate, indicating there was a rapid travel time when discharge rates were high.

- The perched zone dissipates when effluent discharge rates decrease to less than 586 L/min (155 gal/min).

- When discharge was 1,363 L/min (360 gal/min), the water table rose 0.5 m (1.6 ft).

- Infiltration rates for the ditch ranges from 15 to 622 m/yr (49 to 2,040 ft/yr) during its period of use.

Infiltration rates estimated for several disposal facilities in the 200 West Area range from 37 to 2,825 m/yr (121 to 9,266 ft/yr) (Swanson 1994, *Infiltration Rate and Hydraulic Conductivity Results*; Law 1993, *Infiltration Rates at the Preferred Soil Column Disposal Site*). See Table C1-18 for a list of these rates. The wide range is assumed to be caused by variables such as the presence of caliche layers and the clogging of pores with fine sediments over time.

A one-dimensional unit-gradient model, originally developed in 1990, has been revised to include soil profiles characterized by using wells near the ditch. An infiltration rate of 74 m/yr (243 ft/yr) is modelled, and the rate is one-half the design infiltration capacity for most cribs, ponds, and ditches in the 200 East and 200 West Areas. Estimated time for moisture to reach the unconfined aquifer ranges from 117 to 165 years. Most of the travel time is accounted for by one fine-grained sedimentary unit in the Hanford

formation. Sediment testing shows a highly variable hydraulic conductivity for that unit. When a higher conductivity is input to the model, the travel time is approximately six years.

A groundwater model designed for the 216-U-17 crib suggests that lateral spreading of moisture, caused by layering of sediments, is the most significant factor in distribution of moisture and contaminants (Reidel et al. 1993, *Groundwater Impact Assessment for the 216-U-17 Crib, 200 West Area*). By the time the simulated wetting front in the U-17 crib model reached the water table, the volume of moistened soil was broader and more diffuse than previously predicted for other crib sites.

Site-specific variables must be considered when estimating time for water to travel through the vadose zone. Variables include the amount of moisture infiltrating, the grain size and stratigraphy of the sediments, the amount of moisture already in each sedimentary layer, and hydraulic conductivity. WHC-SD-EN-TI-014, *Hydrogeologic Model for 200 West Groundwater Aggregate Area*, contains calculation travel times in four example cases with steady recharge rates of 5 and 50 mm/yr (0.2 and 2.0 in./yr). Calculated travel times range from 150 years to more than 2,000 years. The methods applied in WHC-SD-EN-TI-014 are not valid for transient conditions (e.g., spill, pipe leak).

The fate of a potential leak from a tank or a diversion box depends on the stratigraphy at the leak location. The presence of fine-grained layers in the shallow vadose zone causes the leaked effluent to remain near the leak site vertically and to diffuse horizontally. The effluent migrates downward more rapidly without spreading laterally if sediments near a leak source are coarse grained. Tables C1-19 and C1-20 provide a description of the hydrogeologic properties of the partially saturated and saturated vadose zones in the 200 East and 200 West Areas (PNL-10550, *Environmental Settings for Selected U.S. Department of Energy Installations - Support Information for the Programmatic Environmental Impact Statement and the Baseline Environmental Management Report*).

A conceptual model of hypothetical sources of waste leaks and of potential pathways for leaked waste to reach groundwater is illustrated in Figure C1-25. The model was developed on the basis of observed vadose zone and groundwater measurements near tanks that are known to have leaked. Contaminants may spread laterally when they encounter an increase in sediment compaction or a decrease in grain size. Most of the radioactive contamination from a leak remains in the unsaturated zone. Potential pathways to groundwater include old monitoring wells without seals between casing and sediments, clastic dikes, and discontinuities in the caliche layer (Section C1.4.3). The most mobile constituents (e.g., tritium and technetium) have the highest potential for reaching groundwater.

Travel time through the vadose zone to the Columbia River is difficult to calculate accurately, even with the most sophisticated available models because of the nonlinear variation of hydraulic conductivity with moisture content. Many simplifying assumptions have been made at the Hanford Site in applying vadose zone models. For these reasons, there is a large amount of uncertainty in travel time calculations for the vadose zone. Recent information on contaminants beneath tanks shows that some previously

calculated and modeled travel times through the vadose zone for both nonretarded and retarded species may be incorrect.

Assuming that the technetium-99, that appeared in the aquifer beneath the 241-SX Tank Farm during the late 1980s was from tank leaks that occurred in the 1950s and 1960s, the best conservative estimate of travel time through the vadose zone for nonretarded contaminants is 25 to 30 years. Contaminants may have been transported through improperly sealed wells or driven to the aquifer by water from the 216-S-25 crib. About 3.0×10^7 L (8.0×10^6 gal) of water were pumped to the 216-S-25 crib in 1985. Low-permeability layers in the vadose zone may have caused the infiltrating water to travel horizontally through the vadose zone to the area beneath the 241-SX Tank Farm and mobilize contaminants in the vadose zone. The source of the technetium-99 and the migration of other contaminants through the vadose zone at the 241-SX Tank Farm is being investigated.

Travel time through the aquifer is much easier to determine than travel through the vadose zone. Groundwater flow through the saturated zone is easier to model and, at the Hanford Site, the historical movement of plumes in the groundwater provides direct information on travel times and a set of data that can be used to calibrate flow and transport models. Groundwater velocity (average pore velocity) through the aquifer from the 200 East Area is 3.3 m/day (11 ft/day) based on the movement of the tritium plume from the Plutonium Uranium Extraction (PUREX) Facility cribs to well 699-24-33. This results in a travel time of approximately 16 years from the 200 East Area to the Columbia River (PNL-10550). Travel time from the 200 West Area is greater because of the lower permeability of sediments in the vicinity of the 200 West Area. The average pore velocity near 200 West Area is calculated at 0.2 m/day (0.7 ft/day) based on movement of the nitrate plume in this area. The travel time from 200 West Area tank farms to the more permeable sediments near 200 East Area is calculated at 55 years (PNL-10550), and the total travel time to the Columbia River is calculated at 71 years (i.e., 16 years through groundwater and 55 years through the vadose zone). These estimates are comparable to those of USGS 1987a, *Subsurface Transport of Radionuclides in Shallow Deposits of the Hanford Nuclear Reservation - Review of Selected Previous Work and Suggestions for Further Study*, and PNL-6328, *Estimation of Ground-Water Travel Time at the Hanford Site: Description, Past Work, and Future Needs*, which estimate 10 to 20 years and 21 to 23 years, respectively, from the 200 East Area to the Columbia River. ARH-ST-149, *Hanford Pathline Calculational Program - Theory, Error Analysis and Applications*, estimates a minimum of 27 years from 200 East Area and 84 years from 200 West Area on the basis of modeling. Assuming vadose travel times of 25 to 30 years, the estimated travel times from the 200 East and 200 West Areas to the Columbia River are roughly 45 and 100 years, respectively.

C1.4.2.3 Aquifers. Two major aquifer systems, the suprabasalt aquifer system and the basalt and interbed aquifer system, lie beneath the 200 East and 200 West Areas (Figure C1-24). The stratigraphy of the 200 East and 200 West Areas is discussed in greater detail in Section C1.4.3.

C1.4.2.3.1 Suprabasalt Aquifer System. The suprabasalt aquifer system at the 200 East and 200 West Areas occurs primarily in the Ringold Formation and Hanford formation stratigraphic segments. The sediment in these segments contains interlayered coarse- and fine-grained units, forming a series of

aquifers and aquitards. The depth to the water table below the ground surface ranges from less than 40 m (131 ft) near B Pond in the 200 East Area to approximately 104 m (341 ft) west of 200 East Area.

The suprabasalt aquifer system occurs primarily below the surface in the 200 West Area. The uppermost part of the aquifer is unconfined in a sand and gravel unit and is more than 75-m (246-ft) thick (WHC-SD-ER-TI-003, *Geology and Hydrology of Hanford Site: A Standardized Text for Use in Westinghouse Hanford Company Documents and Reports*). The lower part of the aquifer sediments is generally confined by fine-grained sediments of the Lower Mud unit stratigraphic segment. The thickness of this confined zone ranges from less than 6 m (20 ft) beneath the northern portion of the 200 West Area to greater than 15 m (49 ft) in the southern portion of that area (PNL-6820, *Hydrogeology of the 200 Areas Low Level Burial Grounds*). The entire suprabasalt aquifer system is unconfined in the northern portion of the 200 West Area.

The suprabasalt aquifer system at the 200 East Area occurs in the Ringold Formation and parts of the Hanford formation. The suprabasalt aquifer system ranges in thickness from zero where basalt is present above the water table to 60 m (197 ft) in the south and west portions of the 200 East Area.

Horizontal hydraulic conductivity of units within the suprabasalt aquifer system varies considerably (Table C1-21). WHC-SD-EN-TI-019, *Hydrogeologic Model for the 200 East Groundwater Aggregate Area*, compiles and maps hydraulic conductivity data for the upper portion of the uppermost aquifer in the 200 East and 200 West Areas. The highest conductivity occurs in a channel stretching northwest to southeast across the 200 East Area.

Groundwater flow beneath the 200 East Area is complex because of the convergence of flow from the natural groundwater flow system from the west and the artificial recharge from B Pond from the east. The high transmissivity beneath most of the 200 East Area causes hydraulic gradients to be very small. Groundwater in the suprabasalt aquifer generally flows from west to east beneath the 200 West Area. Figure C1-26 shows groundwater contours and steady streamlines from the 200 East and 200 West Areas waste sites to the Columbia River. Contaminant plume maps of the 200 East and 200 West Areas indicate long-term trends in groundwater flow directions and indicate a north to northwest direction of flow in the extreme north central portion of the 200 East Area and a south to southeast direction of flow in the southeast portion of the 200 East Area (BNWL-2000, "An Investigation of Regional Flow Patterns Over an Area of Complex Terrain").

Groundwater in the suprabasalt aquifer system at the 200 East and 200 West Areas is contaminated with various hazardous and radioactive constituents. The most significant contaminants include nitrate, carbon tetrachloride, tritium, and technetium (BNWL-2000). PNL-6328 compiles various estimates of groundwater travel times from the 200 East and 200 West Areas to the Columbia River.

C1.4.2.3.2 Basalt and Interbed Aquifer System. The basalt flows and associated sedimentary interbeds form a series of aquifers and aquitards. The dense basalt flows generally form aquitards and interflow zones (fractured basalt zones), and the sedimentary interbeds form aquifers. The uppermost

extensive confined aquifer beneath the 200 East and 200 West Areas is comprised of a single interbed and adjacent interflow zones. The interbed, called the Rattlesnake Ridge interbed, is 15- to 25-m (49- to 82-ft) thick beneath the 200 East and 200 West Areas and generally thickens toward the west (RHO-ST-42, *Hydrology of the Separations Area*; RHO-RE-ST-12P, *An Assessment of Aquifer Intercommunication with B Pond-Gable Mountain Pond Area of the Hanford Site*). Recharge to the Rattlesnake Ridge interbed aquifer occurs in the higher elevations to the west, north, and northeast of the 200 East and 200 West Areas. Groundwater generally flows toward the west to west-northwest beneath the 200 East Area and toward the northeast beneath the 200 West Area (WHC-SD-ER-TI-003).

The Rattlesnake Ridge interbed aquifer is generally separated from the uppermost aquifer system by a segment of the basalt flow known as the Elephant Mountain Member that is up to 35-m (115-ft) thick. The segment of the Elephant Mountain Member north of the 200 East Area has been locally removed by erosion. Erosion of this member has allowed for hydraulic communication between the interbed aquifer and the suprabasalt aquifer system. Contamination found in the Rattlesnake Ridge interbed aquifer results from intercommunication through erosional windows between the interbed and the overlying unconfined aquifer (RHO-RE-ST-12P). Transmissivity rates of the Rattlesnake Ridge interbed and the Elephant Mountain interflow zone are included in Table C1-21.

C1.4.3 Geology

This section provides a summary of the geologic processes that have occurred and continue to occur in and around the Hanford Site. Included are discussions summarizing historical and recent geologic events that have defined the Site stratigraphy as it relates to the geohydrological and seismic characteristics. These events include volcanism, flooding, and tectonic deformation (seismic). The Site stratigraphy, developed from borehole data, provides the bases for the conclusions and observations of the liquid plume travel times through the saturated and unsaturated zones discussed in Section C1.4.2. The structural and seismic data is used to identify and develop a seismic hazard evaluation in accordance with the guidance provided in DOE-STD-1023-95. The volcanic activity discussion provides data used in the volcanic hazard evaluation to be used in accident analyses (i.e., roof loading and loss of high-efficiency particulate air filters).

The Hanford Site lies in the Pasco Basin, one of the largest sub-basins of the Columbia Plateau. The Columbia Plateau is a broad plain situated between the Cascade Range to the west and the Rocky Mountains to the east (Figure C1-27). There are no nearby mountains to the north or south. The Columbia Plateau is often called the Columbia Basin. In the central and western sections of the Columbia Basin, the Miocene Epoch Columbia River Basalt Group (CRBG) is underlain predominantly by continental sedimentary rocks from the Tertiary Period and overlain by fluvial and glaciofluvial deposits from the Tertiary and Quaternary Periods.

C1.4.3.1 Physiography. The physiography of the Hanford Site is dominated by the low-relief plains of the Central Plains physiographic region and the anticlinal ridges of the Yakima Folds physiographic region (Figure C1-28).

The physiography of the Columbia Basin is the result of late Cenozoic faulting and folding of the CRBG and overlying sediments of the Ringold Formation. The surface topography of the Site has been modified in the past several million years by geomorphic processes related to (1) Pleistocene Epoch cataclysmic floods, (2) Holocene Epoch eolian activity, (3) continuous landslides, and (4) Columbia River erosion.

C1.4.3.2 Stratigraphy. The stratigraphy of the Pacific Northwest is comprised of a collection of accreted terrane rocks added onto the North American craton between the Precambrian and early Cenozoic Eras that are now mostly covered by Cenozoic Era volcanic rocks. Sedimentary rocks derived from eroding uplands areas are intercalated with the volcanic rocks in structural basins and along the evolving continental margin.

The generalized stratigraphy of the CRBG is shown in Figure C1-29. The principal bedrock of the Hanford Site is basalt and intercalated and overlying sedimentary rocks. Rocks older than the CRBG are exposed primarily along the margin of the Columbia Basin and vary widely in age, lithology, and structure. The complex stratigraphy and structure that underlie the CRBG at the Columbia Basin are the probable sources for seismic hazards under the basalt. Because of the thick basalt cover, the stratigraphy and types of structure under the Hanford Site are poorly constrained. The sedimentary rocks that overlie the CRBG are principally the fluvial deposits of the Ringold Formation and the Pleistocene Epoch cataclysmic flood deposits of the Hanford formation.

C1.4.3.2.1 Columbia River Basalt Group. The CRBG is a series of tholeiitic flood basalt flows that were erupted between 17 and 6 million years ago (Figure C1-29). The CRBG covers approximately 164,000 km^2 (63,304 mi^2) and consists of 280,000 km^3 (67,164 mi^3) of basalt (Tolan et al. 1989, "Revisions to the Estimates of the Areal Extent and Volume of the Columbia River Basalt Group"). The CRBG flows were erupted from north-northwest-trending fissures or linear vent systems in north-central and northeastern Oregon, eastern Washington, and western Idaho (USGS 1979a, *Reconnaissance Geologic Map of the Columbia River Basalt Group in Eastern Washington and Northern Idaho*).

C1.4.3.2.2 Stratigraphy of Intercalated and Overlying Sediments. The Hanford Site is situated on a sequence of sedimentary units that overly the CRBG. These sediments are confined largely to the synclinal valleys and basins of the western Columbia Basin. Although the sedimentary record is incomplete, it is a direct reflection of the structural development of the area (Fecht et al. 1987, "Paleodrainage of the Columbia River System on the Columbia Plateau of Washington State — A Summary"). The upper Miocene Epoch to middle Pliocene Epoch record of the Columbia River system in the Columbia Basin is represented by the upper Ellensburg Formation, Ringold Formation, and Snipes Mountain conglomerate. Except for local deposits (e.g., the Plio-Pleistocene unit and the Early Palouse soils unit) there is a hiatus (i.e., due to erosion or lack of sedimentation) in the stratigraphic record between the end of the Ringold (3.4 million years ago) and the Pleistocene Epoch cataclysmic flood deposits (1.6 million years ago) (DOE-RW-0164, *Site Characterization Plan Reference Repository Location, Hanford Site, Washington*).

Pleistocene Epoch to Recent Epoch sediments overlying the CRBG at the Hanford Site include cataclysmic flood gravels and slackwater sediments of the Hanford formation; terrace gravels of the Columbia River and adjacent rivers (i.e., Snake and Yakima); and eolian deposits.

Late Neogene Sediments. Two main late Neogene Period sedimentary units, the Ellensburg Formation and the Ringold Formation, occur in the Hanford Site region (Figure C1-29). The Ellensburg Formation includes epiclastic and volcaniclastic sedimentary rocks that are intercalated with and overlie the CRBG (Waters 1961, "Stratigraphic and Lithologic Variations in the Columbia River Basalt"; USGS 1979b, *Revisions in Stratigraphic Nomenclature of the Columbia River Basalt Group*). At the Hanford Site, the Ellensburg Formation is mixed with sediments deposited by the ancestral Clearwater and Columbia Rivers. The stratigraphy of the Ellensburg Formation at the Hanford Site is discussed in RHO-BWI-ST-14, *Subsurface Geology of the Cold Creek Syncline*, and Fecht et al. (1987).

Fluvial sediments of the Ringold Formation were those that continued to be deposited in most synclinal valleys of the central Columbia Basin long after the eruptions of the CRBG. Although exposures of the Ringold Formation are limited to the White Bluffs on the east side of the Hanford Site and isolated exposures on the west side, extensive data on the Ringold Formation is available from boreholes at the Hanford Site.

The Ringold Formation consists of semi-indurated clay, silt, pedogenically altered sediment, fine- to coarse-grained sand, and granule-to-cobble gravel layers. Strata of the Ringold Formation are typically below the water table. The textural variations of the strata influence groundwater flow.

The upper part of the Ringold Formation consists of a sequence of fluvial sands, overbank deposits, and lacustrine sediments. The fluvial sand facies is the principal facies of the upper Ringold Formation under the tank farms. The fluvial sand facies consists of quartzo-feldspathic, cross-bedded, and cross-laminated sands that are intercalated with lenticular silty sands, clays, and thin gravels. These sands usually contain less than 15% basalt lithic fragments and fining upwards sequences are common. Strata were deposited in wide, shallow channels.

C1.4.3.2.3 Quaternary Period Stratigraphy. Sediment layers of the Quaternary Period, as thick as 100 m (328 ft) in the Pasco Basin, overlie the Ringold Formation and are the main layers beneath the tank farms. In the Hanford formation, the most extensive Quaternary Period layer is the Pleistocene-aged cataclysmic flood deposits (Figure C1-30). The Hanford formation and underlying Ringold Formation are separated locally by several laterally discontinuous and informally defined units.

Fluvial deposits from major rivers (i.e., Yakima, Snake, Columbia) are represented in the Pasco Basin, dating since at least the late Tertiary Period (Baker et al. 1991, "Quaternary Geology of the Columbia Plateau"). Two main alluvial units, the Plio-Pleistocene Epoch unit and the Pre-Missoula gravels unit, are recognized at the Hanford Site. In the central Pasco Basin, mainstream alluvium lies stratigraphically between the Ringold Formation and the Hanford formation. The Pre-Missoula gravels unit, a thick sheet of

well-rounded and well-sorted gravel, disconformably overlies the Ringold Formation in much of the central Pasco Basin. This unit is interpreted to be of the early Pleistocene Epoch on the basis of magnetic polarity and stratigraphic position. The mainstream alluvium of probable early Pleistocene Epoch is exposed along Cold Creek and the Yakima Bluffs.

Overlying the tilted and truncated Ringold Formation in an unconformable relationship, the western Cold Creek syncline (near the 200 West Area) is the laterally discontinuous Plio-Pleistocene unit (DOE-RW-0164). The Plio-Pleistocene unit appears to be correlative to other sidestream alluvial and pedogenic deposits found near the base of the ridges bounding the Pasco Basin on the north, west, and south. These sidestream alluvial and pedogenic deposits are inferred to be of the late Pliocene to early Pleistocene Epoch on the basis of stratigraphic position and magnetic polarity of interfingering loess units.

Eolian Deposits. Loess deposits at the Hanford Site contain a detailed Quaternary record. Five units of the Quaternary record are represented in the Pasco Basin (WHC-MR-0391, *Field Trip Guide to the Hanford Site*). These units are informally referred to as L1 through L5 and are differentiated on the basis of position relative to other stratigraphic units, color, soil development, and paleomagnetic polarity.

The main eolian unit in the subsurface at the Hanford Site is the Early Palouse soils. The Early Palouse soils unit consists of up to 20 m (66 ft) of massive, brown-yellow, compact loess-like silt and minor fine-grained sand (RHO-ST-23, *Geology of the Separations Areas, Hanford Site, South-Central Washington*; RHO-BWI-ST-14; DOE-RW-0164). Granule-sized grains, consisting primarily of basalt, are common in this unit. These deposits overlie the Plio-Pleistocene Epoch unit in the western Cold Creek syncline around the 200 West Area. See Figure C1-30 for a graphic representation of this stratigraphy. The main eolian unit is differentiated from overlying graded rhythmites by greater calcium carbonate content, massive structure in core, and high natural gamma response in geophysical logs (DOE-RW-0164). The upper contact of the eolian unit is poorly defined and the unit may grade up-section into silty strata commonly found in the lower part of the Hanford formation. The unit is inferred to be of the early Pleistocene Epoch on the basis of a predominantly reversed polarity.

The Plio-Pleistocene Epoch deposits and Early Palouse soils form a fine-grained unit in the vadose zone that results in increased lateral spreading of downward moving moisture.

Hanford Formation. Hanford formation is the informal name given to all cataclysmic flood deposits from the Pleistocene Epoch. The Hanford formation is the main stratigraphic unit at the surface of the tank farms. The formation consists of pebble to boulder gravel, fine- to coarse-grained sand, and silt. These deposits are divided into the (1) gravel-dominated, (2) sand-dominated, and (3) silty facies. These facies are referred to as coarse-grained deposits, plane-laminated sand facies, and rhythmite facies, respectively (RHO-BW-SA-563A, *Quaternary Geology of the Pasco Basin, Washington*). The rhythmite facies are also referred to as the "touchet beds." The Hanford formation is thickest in the vicinity of the 200 East and 200 West Areas (up to 65-m- [213-ft-] thick). Hanford formation deposits are absent on

ridges above approximately 385 m (1,263 ft) above sea level, the highest level of cataclysmic flooding in the Pasco Basin (RHO-BW-SA-563A).

Volcanic Ash Deposits. Volcanism in the Cascade Range was active throughout the Pleistocene Epoch and has continued through the Holocene Epoch (10,000 years before present to present). The eruption history of the current Holocene Epoch best characterizes the most likely types of activity in the next 100 years. Many of the Cascade Range volcanoes have been active in the last 10,000 years, including Mount Mazama (Crater Lake) and Mount Hood in Oregon and Mount St. Helens, Mount Adams, and Mount Rainier in Washington. These eruptions are recorded in the Quaternary sediments in the form of ash deposits that are interlayered with the sediments. Maps in Figures C1-31 and C1-32 depict the annual probability of volcanic ash accumulation on the Hanford Site.

C1.4.3.3 History of Cataclysmic Flooding in the Pasco Basin. Cataclysmic floods inundated the Pasco Basin several times during the Pleistocene Epoch when ice dams failed in northern Washington. Net erosion caused by these floods was minimal and is assumed to have been associated with only the earliest floods. Later floods partially incised older flood deposits before backfilling. Deciphering the history of cataclysmic flooding in the Pasco Basin is complicated due to the probable occurrence of numerous smaller individual floods. Evidence for cataclysmic flooding in the Pasco Basin, besides the sediments, includes high-water marks and faint strandlines along the basin margins. Floods from multiple sources and the paths of Missoula floodwaters migrated and changed course with the advance and retreat of the Cordilleran ice sheet. The best preserved cataclysmic flood record is that of the last Missoula flood, which apparently came down the Columbia River.

C1.4.3.4 Geologic Structures of the Columbia Basin. The geologic structure of the Pacific Northwest is controlled by a basement rock assemblage of accreted terranes fused onto the structurally complex North American craton from the early Mesozoic to early Cenozoic Eras. The accreted terranes form the backbone of the Cascade Range, Okanogan Highlands, and the Blue Mountains. The terranes are now extensively covered by Cenozoic Era rocks that were folded and faulted in a north-south-oriented compressive regime. North-south compression is continuing in the Pacific Northwest east of the Cascades. This pattern of Cenozoic Era deformation is expected to continue into the future.

The Columbia Basin is a structurally and topographically low area surrounded by mountains ranging in age from the late Mesozoic Era to Recent Epoch. The Columbia Basin has two major structural subdivisions or subprovinces: the Yakima Fold Belt (YFB) and the Palouse Slope (Figure C1-28). The YFB is a series of anticlinal ridges and synclinal valleys in the western and central Columbia Basin. The Hanford Site is in the east part of the YFB. The Palouse Slope forms the eastern part of the Columbia Basin and is mainly a westward-tilting paleoslope. The west boundary of the Palouse Slope is at the east boundary of the Hanford Site.

C1.4.3.4.1 Major Structural Features of the Columbia Basin. Three major structural features cross-cut the Columbia Basin and influence the geology of the Hanford Site. These are the Olympic-Wallowa lineament, the Hog Ranch-Naneum Ridge anticline, and the YFB. The Olympic-Wallowa lineament passes along the southern boundary of the Hanford Site and the Hog

Ranch-Naneum Ridge anticline forms the western structural boundary of the Pasco Basin. A map of these major structural features of the YFB is shown in Figure C1-33.

Olympic-Wallowa Lineament. The Olympic-Wallowa lineament (Figure C1-33) is a major topographic feature in Washington and Oregon that crosscuts the Columbia Basin and forms the southern boundary of the Hanford Site. The alignment of the topographic features of this lineament parallels prebasalt structural trends along the northwest margin of the Columbia Basin, but it has not been linked to any individual structure (Campbell 1989, *Structural and Stratigraphic Interpretation of Rocks Under the Yakima Fold Belt, Columbia Basin, Based on Recent Surface Mapping and Well Detail*; Reidel and Campbell 1989, "Structure of the Yakima Fold Belt, Central Washington").

The portion of the Olympic-Wallowa lineament that crosses the Columbia Basin is called the Cle Elum-Wallula lineament (Keinle et al. 1978, "Geologic Reconnaissance in the Cle Elum-Wallula Lineament and Related Structures"). It is a 10-km- (6-mi-) wide, moderately diffuse zone of anticlines that have a N 50° W orientation. As defined in Keinle et al. (1978), the Cle Elum-Wallula lineament consists of three structural parts: (1) a broad zone of deflected or anomalous fold and fault trends extending south from the City of Cle Elum to Rattlesnake Mountain; (2) a narrow belt of topographically aligned domes and doubly plunging anticlines extending from Rattlesnake Mountain to Wallula Gap; and (3) the Wallula fault zone extending from Wallula Gap to the Blue Mountains.

The structural significance of the Olympic-Wallowa lineament has been called into question by two recent geophysical studies. Neither a seismic profiling survey nor a gravity survey revealed any obvious geophysical signatures of this lineament below the CRBG (Jarchow 1991, *Investigations of Magmatic Underplating Beneath the Northwestern Basin and Range Province, Nevada, Seismic Data Acquisition and Tectonic Problems of the Columbia Plateau, Washington and the Nature of the Mohorovicic Discontinuity Worldwide*).

Hog Ranch-Naneum Ridge Anticline. The western structural boundary of the Pasco Basin is the Hog Ranch-Naneum Ridge anticline (Figure C1-33). This anticline is a broad south-trending anticline in the CRBG that crosses the YFB in a north-south direction. This south plunging structure passes through five YFB folds and the Olympic-Wallowa lineament. The Hog Ranch-Naneum Ridge anticline was active in the late to middle Miocene Epoch as demonstrated by thinning of basalt flows across it (Reidel et al. 1989, "The Geologic Evolution of the Central Columbia Plateau"). The east-trending YFB folds show no apparent offset by the cross-structure (Campbell 1989; Keinle et al. 1978; Reidel et al. 1989) nor is the Hog Ranch-Naneum Ridge anticline offset where the Olympic-Wallowa lineament and Cle Elum-Wallula lineament cross it. Growth of the Hog Ranch-Naneum Ridge anticline continued from the Miocene Epoch to Recent Epoch and is now marked by the highest structural points along the ridges that cross it.

Yakima Fold Belt. The YFB subprovince covers about 14,000 km^2 (5,404 mi^2) of the western Columbia Basin (Figure C1-33). The YFB formed as basalt flows and intercalated sediments were folded and faulted under north-south directed compression. The Pasco Basin is near the eastern border

of the YFB. The YFB gives the Hanford Site its principal physiographic features and has been the primary structure influencing Hanford Site geohydrologic conditions.

C1.4.3.4.2 Structure of the Hanford Site. The Cold Creek syncline, shown in Figure C1-33, lies between the Umtanum Ridge-Gable Mountain uplift and the Yakima Ridge uplift and is an asymmetric and relatively flat-bottomed structure. The 200 East and 200 West Areas lie on the northern flank of the Cold Creek syncline where the bedrock dips approximately 5° to the south. The 300 Area lies at the east end of the Cold Creek syncline where it merges with the Pasco Basin syncline.

The Wahluke syncline is the principal structural unit that underlies the 100 Areas (Figure C1-34). The Wahluke syncline is an asymmetric and relatively flat-bottomed structure similar to the Cold Creek syncline. The northern limb dips approximately 5° to the south. The steepest limb of the Wahluke syncline is adjacent to the Umtanum Ridge-Gable Mountain structure.

The Umtanum Ridge-Gable Mountain structural trend is a segmented anticlinal ridge extending for a length of 110 km (68 mi) in an east-west direction and passes north of the 200 East, 200 West, and 300 Areas and south of the 100 Areas. The Umtanum Ridge plunges from west to east and joins the Gable Mountain-Gable Butte segment just east of the west boundary of the Hanford Site. The easternmost segment of the Umtanum Ridge, the Southeast anticline, trends southeast off the east boundary of the Gable Mountain-Gable Butte segment.

The 200 East, 200 West, and 300 Areas are situated on the south flank of the Umtanum Ridge-Gable Mountain anticline where the Miocene-aged basalt bedrock dips to the southwest into the Cold Creek syncline. The 100 Areas lie north of the Umtanum Ridge-Gable Mountain anticline in the Wahluke syncline. The deepest parts of the Cold Creek syncline, the Wye Barricade depression and the Cold Creek depression, are approximately 12 km (8 mi) southeast of the 200 East and 200 West Areas. The Cold Creek syncline and Cold Creek depression are under the 200 West Area.

Geology of the 200 East Area. The general geology and geologic stratigraphy of the 200 East Area is depicted in Figures C1-35, C1-36, and C1-37. Suprabasalt sediments under this area consist of the Ringold Formation and Hanford formation. The Ringold Formation conforms to the basalt bedrock surface and tilts southeast toward the axis of the Cold Creek syncline. The Ringold Formation is dominated by gravel units E and A (i.e., the main unconfined aquifers) that are separated by the Lower Mud unit. The Ringold Formation thins from 50 m (164 ft) at the south end to nearly pinching out at the north end of the formation. The units have been truncated and are unconformably overlain by the Hanford formation. The Hanford formation is between 75- and 100-m (246- and 328-ft) thick at the 200 East Area.

Geology of the 200 West Area. The geology and geologic stratigraphy of the 200 West Area are depicted in Figures C1-35, C1-37, and C1-38. The Elephant Mountain Member of the CRBG forms the bedrock under the 200 West Area. 241-T, 241-TY, and 241-TX Tank Farms, located in the northern part of the 200 West Area, overlie sediments that rest on the CRBG.

The suprabasalt sediments at the 200 West Area consist of the Ringold Formation unit, Plio-Pleistocene/Early Palouse soils unit, and Hanford formation unit. The sediments conform to the basalt bedrock surface and tilt south toward the axis of the Cold Creek syncline. The Ringold Formation thins slightly from north to south and is dominated by gravel units E and A, which are separated by the Lower Mud unit. The Ringold Formation varies from 110- to 130-m (361- to 427-ft) thick, and gravel units A and E are the main unconfined aquifers. The upper Ringold unit is present only in the north part of the 200 West Area and consists mainly of sands. The Plio-Pleistocene/Early Palouse soils units overlie the Ringold Formation and are present throughout the 200 West Area. The Hanford formation overlies the Plio-Pleistocene and Early Palouse soils units and thickens from north to south. The Hanford formation varies from about 10 to 40 m (33 to 131 ft) in thickness.

C1.4.3.5 Tectonic Development of the Hanford Site. The geologic history of the Hanford Site from the Precambrian Period to the present significantly impacts hazards analyses (WHC-SD-W236A-TI-002, *Probabilistic Seismic Hazard Analysis, DOE Hanford Site, Washington*). This section summarizes the principal geologic events in the development of the Site geology.

The present structure of the Columbia Basin is the product of north-south compression that began in the early Tertiary Period before the eruption of the CRBG and continues today. The Columbia Basin is composed of two fundamental subprovinces, the Palouse Slope and the YFB.

The pattern of deformation in the Columbia Basin has been dominated by north-south compression and subsidence. The YFB is the principal product of the compression and subsidence. This deformation has controlled the location of the Columbia River system since the late Miocene Epoch and has also controlled the depositional pattern of the post-basalt sediments.

The rates of deformation, both regional subsidence and rate of local uplift, in the Columbia Basin have declined since the early Tertiary Period. The present rate of subsidence in the basin is estimated at 3.0×10^{-3} mm/yr (1.0×10^{-4} in./yr) and the rate of ridge growth is estimated at 0.05 mm/yr (0.002 in./yr).

Microseismicity (i.e., high in-situ stress conditions) and the geometry of Quaternary-Holocene Epoch faulting indicate that the Columbia Basin is still experiencing north-south compression. Although known late Cenozoic faults are found exclusively on the anticlinal ridges, earthquake focal mechanisms and strain measurements suggest that most stress release is occurring in the synclinal areas. The high in-situ stress in the Cold Creek syncline explains the microseismicity in the region but the absence of microseismicity associated with the anticlinal ridges may result from weakened fault zones, lubricated with groundwater, that have a component of a seismic or below-detection limit seismic slip, or the fault zones may be locked up.

C1.4.3.6 Contemporary Stress and Strain from Seismicity. Seismic monitoring at the Hanford Site began in the summer of 1969 when the U.S. Geological Survey installed a small array of seismograph stations around the Site. A closely spaced seismic network was installed at the Site in 1982 to characterize Site microseismicity for a possible high-level waste repository. The complete network operated until 1988 when the number of stations in the

network was reduced. Earthquakes of magnitude 2.5 and larger do occur throughout most of eastern Washington State, however, earthquakes of magnitudes 1.0 (coda amplitude magnitude) and larger have been recorded at the Hanford Site.

Earthquakes at the Hanford Site can be related to three crustal layers and five general sources (Tables C1-22 and C1-23). All layers and sources are monitored at the Hanford Site except the Cascadia Subduction Zone source, which is monitored at the University of Washington.

C1.4.3.6.1 Vertical Patterns. There are three horizontal layers of stratigraphy related to seismicity at the Hanford Site and vicinity: the CRBG, the prebasalt sediments, and the crystalline basement (Table C1-22). About 75% percent of Site earthquake events originate in the CRBG layer. The prebasalt sedimentary layer has been the origin of 8% of the events and the crystalline basement has been the origin of 17% of these events.

Shallow Earthquakes in the Basalt. The majority of the seismicity at the Hanford Site and the surrounding area originates from the basalt layer that extends from the surface to approximately 5 km (3 mi) belowground.

Earthquakes in Sedimentary Rock Below the Basalt. The seismicity in the pre-CRBG sedimentary rock under the Hanford Site appears to be confined to the top 3 km (2 mi). The seismicity of this sedimentary layer is relatively low when compared with the basalt layer but may be related to localized detachment zones that have resulted from the growth of anticlinal structures.

Earthquakes in the Crystalline Basement. Deep earthquakes below 10 km (6 mi) appear to be concentrated in the west and southwest portion of the Hanford Site. The deepest earthquakes located below the Site are shallower than 30 km (19 mi) (WHC-SD-W236A-TI-002).

C1.4.3.6.2 Spacial Patterns. There are five different tectonic environments (i.e., earthquake sources) where earthquakes can occur at the Hanford Site (Table C1-23). The five environments are as follows:

- Reverse and thrust faults in the CRBG associated with major anticlinal ridges (e.g., Rattlesnake Mountain, Yakima Ridge, and Umtanum Ridge)
- Secondary faults occurring on the major anticlinal ridges
- Small geographic areas of unknown geologic structure that produce clusters of events, called swarms, usually in the CRBG in synclinal valleys
- Basement source structures
- The Cascadia Subduction Zone.

Very little is known about geologic structures in the crystalline basement beneath the Hanford Site; therefore, earthquakes cannot be directly tied to a

mapped fault or other basement structure. The Cascadia Subduction Zone has recently been postulated to be capable of producing a Richter magnitude 5.6 earthquake (WHC-SD-W236A-TI-002).

Floating Earthquakes. Because of a special tectonic environment covering the entire Columbia Basin, the basin is considered a "floating" earthquake region. A floating earthquake is one that, for seismic design purposes, can occur anywhere in a tectonic province, is not associated with any known geologic structure, and can therefore "float" anywhere in the province.

Earthquake Swarm Areas. The major source of earthquakes at the Hanford Site is swarm activity. Swarm activity originates in synclinal areas in the YFB. Earthquake swarm events provide evidence for the stress regime in the Pasco Basin. Swarm events do not pose a significant hazard to the Site because these are of relatively small magnitude. There are four general areas of significant swarm activity that can impact the Hanford Site: the Wooded Island Swarm Area, Coyote Rapids Swarm Area, Cold Creek, and the West Saddle Mountains Swarm Area (Figure C1-39).

The Wooded Island Swarm Area, located near the 300 Area, occurs at the eastern edge of the YFB where it abuts against the Palouse Slope. This boundary marks the suture zone between the old accreted terranes to the west and the stable Precambrian-Paleozoic craton to the east (Reidel et al. 1994, "Late Cenozoic Structure and Stratigraphy of South-Central Washington"). This zone is also marked by an abrupt increase in thickness of basalt and sub-basalt sediment over the accreted terranes and abrupt thinning of basalt and sediment over the craton.

The Coyote Rapids swarm area is located at the horn of the Columbia River between the 100-K and 100-N Areas. The swarm area occurs over no known geologic structure, but does lie at the intersection of two paleoslopes that make a northeast-southwest trough extending from the City of Spokane, through the Hanford Site, to the Columbia River Gorge. This intersection zone may be a basement weakness zone but there is currently no known reason for swarms to occur in its present position.

The Saddle Mountains swarm area is located along the north side of the Saddle Mountains. The swarm area is located north of the Saddle Mountains fault zone in an area that has no mapped geologic structures. There is evidence of recent faulting (past 13,000 years) on the Saddle Mountains fault but there is no evidence of faults at the Saddle Mountains swarm area. The cause of the earthquake swarm is not known at this time.

Magnitude of Earthquakes. Since July 1982, approximately 650 earthquakes between magnitudes 0.0 and 3.8 have been recorded on and around the Hanford Site. The pattern of earthquake activity in the Hanford Site area between 1990 and 1995 is shown in Figure C1-40. The greatest seismic activity is in the low-Richter magnitude range, with only five events exceeding a magnitude of 3.0. The largest regional earthquake recorded was Richter magnitude 5.7 on July 16, 1936, 100 km (62 mi) southeast of the Hanford Site. The 1936 earthquake was estimated to have a peak acceleration of 0.03 *g*.

The largest earthquake recorded on the Hanford Site was magnitude 3.8 near the Coyote Rapids on the Columbia River, which are near the N Reactor and

15 km (9 mi) from the nearest TWRS facilities. The largest, recent, felt earthquake was Richter magnitude 3.3 on June 12, 1995, in the Wooded Island swarm area. Very shallow earthquakes of 3.8 Richter magnitude in soils similar to the Hanford Site would be expected to produce a ground motion of 0.01 to 0.05 *g* at a distance of 5 km (3 mi). There is very high uncertainty with ground motions of small earthquakes because of the limited data. Instruments that record ground motion are set to activate recording at higher ground motions than are produced by this event.

Contemporary Stress in the Cold Creek Syncline. Contemporary stress in the Cold Creek syncline is expressed principally as horizontal shortening and subsidence. Geodetic surveys were performed across the Pasco Basin to determine rates of shortening (Prescott and Savage 1984, *Crustal Deformation Near Hanford, Washington*). The data suggests north-south shortening but the rate of shortening is not statistically significant at the 95% confidence level.

Contemporary stress measurements were performed at the Hanford Site as part of the Basalt Waste Isolation Project. Hydraulic fracturing tests were conducted in boreholes drilled in the Cold Creek syncline at about 1 km (0.6 mi) depth (DOE-RW-0164). The results also indicated high in situ stress. The maximum horizontal stress was shown to range from 52.6 to 67.4 Mpa (7,630 to 9,780 lbf/in.^{2}) and the minimum horizontal stress ranges from 30.3 to 35.7 Mpa (4,400 to 5,180 lbf/in.^{2}) with a mean horizontal-to-vertical ratio of 1.77 $\pm$0.20. The mean orientation of induced fractures, and the direction of the maximum horizontal stress, are consistent with north-south compression.

Subsidence has been occurring in the Pasco Basin since at least the Eocene Epoch. Estimates of subsidence since the middle Miocene Epoch (17 million years ago) indicate the rates of subsidence have declined to the present. From 17 to about 15.6 million years ago, the rate of subsidence was about 7.6 to 10 mm/yr (0.3 to 0.4 in./yr). This subsidence rate decreased to about 0.3 mm/yr (0.01 in./yr) 15.6 to 14.5 million years ago. The present rate of ridge growth is estimated at 0.51 mm/yr (0.02 in./yr) and the rate of subsidence in the basin is estimated at 0.003 mm/yr (0.0001 in./yr).

The patterns of subsidence in the Cold Creek syncline are shown in Figure C1-41. There are two broad areas of subsidence in the Cold Creek syncline: the Wye Barricade depression and the Cold Creek depression. Both areas have had a long, slow history of subsidence (RHO-BWI-ST-19, *Preliminary Interpretation of Tectonic Stability of the Reference Repository Location - Cold Creek Syncline, Hanford Site*), but neither is located near the 200 East or 200 West Areas.

C1.4.3.7 Geologic Hazards. The geologic hazards that affect the performance of TWRS facility activities have been assessed on the basis of the geologic data addressed in previous sections. These hazards are discussed below and, where appropriate, are quantified for use in the structural evaluations and safety analyses for the TWRS facilities addressed in this report.

C1.4.3.7.1 Seismic Hazard Assessment. A seismic hazard analysis was recently completed for the DOE-controlled areas on the Hanford Site (WHC-SD-W236A-TI-002). Power et al. 1981, "Seismic Exposure for the WNP-2 and WNP-1/4 Site," documents a previous Site seismic hazard analysis performed for

the Supply System. Application of the analysis findings to the DOE-controlled areas on the Hanford Site is documented in WHC-MR-0023, *Evaluation of Seismic Hazard for Nonreactor Facilities, Hanford Reservation, Hanford, Washington.*

WHC-SD-W236A-TI-002 incorporates seismo-tectonic data and interpretations that postdate the Power et al. (1981) assessment. Potential seismic crustal sources determined to be major contributors to the seismic hazard in and around the Hanford Site are as follows:

- Fault sources related to the YFB
- Shallow basalt sources that account for the observed seismicity in the CRBG and not associated with the anticlines
- Crystalline basement source region.

The mean seismic hazard curves for the 200 East and 200 West Areas are shown in Figure C1-42. Proximity to the YFB fault sources is the chief reason for seismic hazard differences across the Hanford Site. The difference between 200 East and 200 West Area hazard curves is chiefly related to the distance from the Yakima Ridge buried extension. Figure C1-43 illustrates contributions of individual YFB folds to the mean seismic hazard at the 200 East and 200 West Areas.

The seismic hazard exceedance probabilities for each Performance Category are derived in DOE-STD-1020-94 and presented in Table C1-24. The peak horizontal surface ground accelerations for the 200 East and 200 West Areas are also shown in Table C1-24.

Horizontal equal-hazard response spectra were developed for the 200 East and 200 West Areas. The 200 West Area Performance Category 3 response spectra at 5% damping are shown in Figure C1-44. The response spectra are anchored to the peak surface ground acceleration. Additional response spectra damping values are presented in WHC-SD-W236A-TI-002 and Tables C1-25, C1-26, and C1-27.

The Site response characteristics of the soils underlying the 200 East and 200 West Areas are similar to those represented in the California empirical strong motion database (WHC-SD-W236A-TI-002). This similarity was determined by comparing the relative response of characteristic Hanford Site soil profiles and dynamic soil properties with those of California deep soil strong-motion recording stations. Time histories representative of the events contributing to the Hanford Site hazard were used for ground motion input (WHC-SD-W236A-TI-002).

The TWRS waste tanks were analyzed and designed to the seismic response spectra criteria in place at the time of their analysis or design. Figure C1-44 also illustrates two previously used response spectra for comparative purposes. The horizontal design response spectrum used from October 1, 1973, to September 5, 1989, was developed for the Fast Flux Test Facility reactor. The response spectrum criterion from September 6, 1989, to present was developed in compliance with UCRL-15910. DOE-STD-1020-94 provides

guidance for evaluating existing facilities from which the response spectrum for existing 200 East and 200 West Area facilities was developed (Figure C1-44).

C1.4.3.7.2 Volcanic Hazard Assessment. Two types of volcanic hazards have affected the Hanford Site in the past 20 million years. The hazards were (1) continental flood basalt volcanism that produced the CRBG, and (2) volcanism associated with the Cascade Range. Several volcanoes in the Cascade Range are currently considered to be active, but activity associated with flood basalt volcanism has ceased.

The flood basalt volcanism that produced the CRBG occurred between 17 and 6 million years ago. Most of the lava was extruded during the first 2 to 2.5 million years of the 11-million-year volcanic episode. Volcanic activity has not recurred during the last six million years, suggesting that the tectonic processes that created the episode have ceased. The recurrence of CRBG volcanism is not considered to be a credible volcanic hazard (DOE-RW-0164).

Volcanism in the Cascade Range was active throughout the Pleistocene Epoch and has remained active through the Holocene Epoch. The eruption history of the current Holocene Epoch best characterizes the most likely types of activity in the next 100 years. Many of the volcanoes have been active in the last 10,000 years, including Mount Mazama (Crater Lake) and Mount Hood in Oregon and Mount Saint Helens, Mount Adams, and Mount Rainier in Washington (Figures C1-31 and C1-32). The Hanford Site is approximately 150 km (93 mi) from Mount Adams, 175 km (109 mi) from Mount Rainier, and 200 km (124 mi) from Mount Saint Helens, the three closest active volcanoes. At these distances, the tephra (ash) is the only hazard. Mount Saint Helens has been considerably more active throughout the Holocene Epoch than Mount Rainier or Mount Adams, which is the least active of the three.

Probabilistic volcanic hazard studies of the Cascade Range have been completed by the U.S. Geological Survey (USGS 1987b, *Volcanic Hazards with Regards to Siting Nuclear-Power Plants in the Pacific Northwest*; USGS 1995b, *Volcanic Hazards in the Mount Adams Region, Washington*). Figure C1-31 illustrates the annual probability of exceeding 10 mm (0.4 in.) of volcanic ash accumulation in Washington and Oregon following the eruption of a major Cascade Range volcano and Figure C1-32 illustrates the annual probability of exceeding 100 mm (4 in.) of volcanic ash accumulation. Figure C1-45 presents this information as a volcanic ash hazard curve for the Hanford Site.

C1.4.3.7.3 Subsurface Stability. The tank farms and associated facilities are all on the 200 Areas Plateau, a large flood bar formed by cataclysmic flooding during the Pleistocene Epoch. The foundation material is predominantly the sand-dominated facies of the Hanford formation with varying amounts of gravel. The backfill used at the tank farm sites consists of native soil that has been compacted. Though the 200 Areas Plateau soils have the same genesis, variations in the depositional energy results in textural variation across the plateau. The static and dynamic properties of the plateau soils are quite similar, but the specific characteristics at each tank farm must be evaluated for certain analyses.

Soils investigations completed at a site near the west boundary of the 200 East Area and at a site in the 200 West Area for proposed new tanks provided information on static, dynamic, and general soil characteristics (ICF KH 1995a, *Geotechnical Investigation KEH W-236A, Multi-Function Waste Tank Facility, 200 East Area, Hanford Site, Richland, Washington*; ICF KH 1995b, *Geotechnical Investigation KEH W-236A, Multi-Function Waste Tank Facility, 200 West Area, Hanford Site, Richland, Washington*). Tables C1-28 and C1-29 summarize the static soil properties near the 200 East and 200 West Areas. The dynamic soil properties for the two areas are shown in Tables C1-30 and C1-31. These property lists illustrate the general characteristics of the 200 Areas Plateau soils.

Soil properties are presented in these tables for several strata. Stratum 1 is the loose wind-blown surface material that is characterized as loose to dense silt with sand and is not considered a structural foundation material. Stratum 2, the next underlying layer, is medium dense to very dense, fine to coarse gravel. The next lower layer is Stratum 3, a dense to very dense, fine to medium sand. Materials lying below the Hanford formation sands and gravels have been previously discussed in Section C1.4.3 and shown in Figure C1-37. Tables C1-28, C1-29, C1-30, and C1-31 refer to materials below elevation 42.7 m (140 ft) as bedrock. Backfill is excavated material from Strata 2 and 3, which has been mixed-conditioned, and then placed as engineered fill.

Field and laboratory studies that have been completed at many of the tank farm sites are summarized in WHC-SD-GN-ER-30009, *Bibliography and Summary of Geotechnical Studies at the Hanford Site*. These studies reveal that there are no areas of potential surface or subsurface subsidence, uplift, or collapse at the Site, with the minor exceptions of the Cold Creek and Wye Barricade depressions discussed previously. With the exception of the loose superficial wind-deposited silt and sand in some locations, the in-place soils are competent and form good foundations.

Liquefaction is the sudden decrease of shearing resistance of a cohesionless soil, caused by the collapse of the structure by shock or strain, and is associated with a sudden but temporary increase of the pore fluid pressure. Saturated or near-saturated soil (sediments) are required for liquefaction to occur. Therefore, liquefaction of soils beneath the tank farms is not a credible hazard because the water table is greater than 65 m (213 ft) below ground surface.

C1.5 NATURAL PHENOMENA THREATS

The meteorology, hydrology, geology, seismology, and geotechnical site information presented in previous sections of this chapter are summaries of the data required by DOE-STD-1022-94. This data provides the fundamental input for development of the natural phenomena hazard following guidance in DOE-STD-1023-95. Hazard curves were developed and are presented for straight wind and tornado, local precipitation, seismic ground motion, and volcanic ash.

DOE-STD-1020-94 presents a graded approach to hazard mitigation, including graded performance goals based on the Safety-Class designation and

hazard of the facility, design guidance for the natural phenomena hazard, and a probability of exceedance for each hazard.

The following natural phenomena have been addressed in the preceding sections. These phenomena represent initiating events that should be addressed in Chapter 5.0. Design or evaluation criteria are provided in Table C1-32 for each of the natural phenomena threats that have been identified as requiring evaluation in the hazards and accident analysis.

- **Temperature**—No design or evaluation guidance is provided for evaluation of extreme temperatures. Although extreme temperatures are not considered initiating events, extreme temperature must be considered during the evaluation of systems important to safety.

- **Precipitation**—No design or evaluation guidance, with the exception of that for snowfall, is provided for the evaluation of maximum precipitation. However, in addition to snow loading, as a potential initiator, the impacts associated with flash flooding of the Cold Creek should be evaluated.

- **Thunderstorms**—No design or evaluation guidance is provided for the evaluation of thunderstorms; however, the phenomena associated with thunderstorms (i.e., hail and lightning) are appropriate for consideration. There has been limited observances of hail on the Hanford Site (maximum observance is two days in one year); however, because of the potential for lightning strikes and the potential for lightning to be an initiating event, this should be evaluated.

- **Extreme Winds and Tornadoes**—Design or evaluation guidance is provided for the evaluation of extreme winds and tornadoes. High winds are considered an initiating event and dispersion mechanism. Tornadoes are not considered credible following the methodology prescribed in UCRL-53526.

- **Dust and Blowing Dust**—No design or evaluation guidance is provided for the evaluation of dust or blowing dust. These phenomena will have similar impacts associated with blowing or falling volcanic ash and should be addressed similarly.

- **Fog and Cloud Cover**—No design or evaluation guidance is provided for the evaluation of fog and cloud cover. This is not considered an initiating event; however, fog and cloud cover may impact dose consequence evaluations.

- **Relative Humidity**—No design or evaluation guidance is provided for the evaluation of relative humidity. Although these are not considered initiating events, humidity must be considered during evaluation of systems important to safety.

- **Dispersion Climatology**—This data is used to determine consequences to receptors. The data is used to determine plume travel times and distances, and contaminant concentration levels. This data is provided as joint frequency data, which is input into dose consequence models used in Chapter 5.0.

- **Hydrology**—No design or evaluation guidance is provided for the evaluation of hydrogeolgic properties, including infiltration rates, liquid travel times through the vadose zone and the groundwater, and flooding. The discussion associated with liquid travel times is presented to provide an understanding of the potential impacts of releases to the soil column for consideration in the hazards and accident analysis. Dam flooding is not considered credible because of the elevation of the 200 East, 200 West, and 600 Areas with respect to the Columbia River. As identified in the maximum precipitation discussion, the impacts associated with flash flooding of the Cold Creek should be evaluated.

- **Seismic Hazards**—Seismic events are considered credible accident initiators at the Hanford Site and should be evaluated. Design or evaluation guidance, specific to the Hanford Site, are provided for the evaluation of seismic events. All events (i.e., low- and high-magnitude earthquakes) should be considered in the hazards and accident analyses.

- **Volcanic Hazards**—Design or evaluation guidance is provided for the evaluation of ashfall loading as a potential initiating event. Although no criteria are provided for blowing or falling ash, ash should be evaluated as an initiating event (e.g., loss of ventilation systems).

- **Subsurface Stability**—No design or evaluation guidance is provided for the subsurface stability. The discussion associated with subsurface stability is presented to provide an understanding of the potential for impacts to facilities or structures from long-term (40+ years) settling of compacted soils.

C1.6 EXTERNAL MAN-MADE THREATS

This section identifies and investigates specific man-made threats associated with the TWRS facilities and considered to be potential accident initiators, exclusive of sabotage and terrorism. Transportation activities discussed separately include potential accidents from roadway vehicles, railcars, and aircraft.

The highways traversing the Hanford Site and the restricted-access Site roadways are transportation routes for trucks delivering gas, diesel fuel, and chemicals. Because of the distance from these highways to the TWRS facilities, the impact of a highway accident involving toxic and hazardous chemicals will be less severe than a worst-case chemical or toxic material accident occurring in the 200 East and 200 West Areas. The restricted access onsite roadways are routinely used for transporting personnel to and from TWRS facilities and for delivery and removal of parts, process chemicals, and solid or liquid waste. Many of these roadways are adjacent to (i.e., within 15 m [50 ft] of a facility or tank farm gate) and provide access to the facilities. Therefore, vehicular impacts on the onsite roadways should be evaluated.

The main line of the Hanford Site railroad passes within about 250 m (820 ft) of the 241-T, 241-TX, and 241-TY Tank Farms (Figure C1-8). A toxic

or hazardous chemical spill from a nearby railcar could impact the facilities; however, the potential for a railcar physically impacting a TWRS facility is credible only at the 204-AR Waste Unloading Facility (Chapter 5.0).

No commercial refineries or major oil, ammunition, or explosive storage facilities are located within 32 km (20 mi) of the TWRS facilities. The nearest natural gas transmission pipeline is approximately 48 km (30 mi) from the facilities. The distance of the refineries, storage facilities, and the pipeline from the 200 East and 200 West Areas makes the hazard from explosions or fires at the commercial refineries and storage facilities almost nonexistent.

There are no private, commercial, or DOE-owned airports within 32 km (20 mi) of the 200 East and 200 West Areas. The three nearest airports are the Richland Airport, the Tri-Cities Airport in Pasco, and Vista Field in Kennewick. The small, general-utility Richland Airport is the nearest. Commercial air carriers use the Tri-Cities Airport, located approximately 48 km (30 mi) southeast of the 200 East and 200 West Areas. The probability of commercial aircraft at the Tri-Cities Airport or of small private and commercial aircraft at Richland Airport and Vista Field adversely impacting the TWRS facilities is remote given the low air traffic volume and the airport distance from the 200 East and 200 West Areas.

C1.7 NEARBY FACILITIES

Accidents in certain nearby facilities have the potential to impact TWRS facilities and operations. Conversely, certain nearby facilities can be affected by accidents in the TWRS facilities.

C1.7.1 Potential Effects from Nearby Facilities

Potential hazards to TWRS facilities from onsite or offsite hazardous operations or facilities are examined under three general classifications:

1. Nonreactor nuclear and nonnuclear industrial facilities within 8 km (5 mi) of the TWRS facility sites, including all activities conducted in and near the 200 East and 200 West Areas
2. Nuclear reactors within an 8-km (5-mi) radius of the tank farms
3. Military activities.

C1.7.1.1 Hazards to TWRS Facilities from Nonreactor Nuclear Facilities. Safety documentation for facilities not part of this Basis for Interim Operation were reviewed for hazard potential. The facilities selected for identification are those believed to pose the most risk to safe operations of TWRS facilities. The facilities were those (1) currently operating, (2) recently operating, or (3) with potential to impact TWRS facilities in the 200 East and 200 West Areas. Safety analysis reports and accident analyses prepared for the nonreactor nuclear facilities were reviewed to determine possible hazards (e.g., radiological doses to personnel resulting from direct radiation, release of airborne radioactivity, exposure to toxic chemicals).

Hazard potential from the burial grounds, Liquid Effluent Retention Facility, Effluent Treatment Facility in the 200 East Area, T Plant, U Plant, Reduction Oxidation Plant, and 222-S Laboratory was considered. These facilities have radiological or toxicological inventories that are insufficient to support an accident. Facilities specifically discussed include the following:

- PUREX Facility (200 East)
- Grout Treatment Facility (200 East)
- B Plant (200 East)
- Waste Encapsulation and Storage Facility (200 East)
- 242-A Evaporator (200 East)
- Plutonium Finishing Plant (200 West)
- Low-Level Waste Disposal Site (200 West)
- K Basins (100 KE and 100 KW Areas).

Each of the postulated facility accidents has the potential to impact TWRS operations; however, should a release occur, the impacts and response actions (facility or Hanford Site) are identified in the facility (where the release originated), TWRS, and Hanford Site emergency response plans (DOE/RL-94-02).

Plutonium Uranium Extraction Facility. The PUREX Facility is located in the 200 East Area, southwest of the 241-AW Tank Farm. This facility is the most recently constructed of the irradiated fuel separation facilities and was used for processing N Reactor fuel. The principal product was a solution of plutonium nitrate that was transferred to the Plutonium Finishing Plant for further processing. Another product was uranyl nitrate solution, which was processed at the Uranium Oxide Plant. The PUREX Facility is shutdown and undergoing preparations for eventual decontamination and decommissioning. The postulated PUREX Facility accidents having the most severe radiological consequences to a maximally exposed individual are associated with a cooling coil leaking into the 216-A-25 pond and a fission product release from the PUREX Facility pipe and operating gallery.

Grout Treatment Facility. The Grout Treatment Facility is located approximately 400 m (1,312 ft) due east of the 241-AP Tank Farm (Figure C1-7). At this facility tank wastes are combined with grout-forming solids to create a grout slurry. The waste feed stream constituent of this slurry consists of low-level fractions of radioactive wastes. The slurry is ultimately pumped into near-surface concrete-lined vaults for permanent disposal. Only one vault has been filled with grout (completed in 1987), even though additional vaults have been designed and constructed. The Grout Treatment Facility is currently not operational, but there is a possibility that the facility will operate again in the future.

B Plant Facility. The B Plant is located in the 200 East Area southwest of the 241-BX Tank Farm in the 200 East Area. B Plant was operated as a fuel separation facility until 1952. In 1968, the plant was converted to a waste fractionation plant to remove cesium-137 and strontium-90 from radioactive waste streams to reduce the heat load in the double-shell tanks. The B Plant now provides essential support to the Waste Encapsulation and Storage Facility and is undergoing preparations for a transition to shutdown status. The most credible accident at B Plant results from the simultaneous occurrence of (1) a solvent fire in which hot gases from the fire heat filters drive off material on the filters, and (2) a blowback of process solution into the pipe gallery caused by tank pressurization (WHC-SD-WM-TI-385, *B Plant Preliminary Accident Analysis*).

Waste Encapsulation and Storage Facility. The Waste Encapsulation and Storage Facility is distinct from B Plant even though it shares a common wall at the west end of B Plant. Historically, activities at the Waste Encapsulation and Storage Facility involved converting cesium and strontium into cesium chloride and strontium fluoride salts. These materials were then encapsulated in double-walled metal containers and stored in a water-filled cooling basin. Strontium fluoride and cesium chloride capsules are still being stored at the facility in the cooling basin, but no new capsules are being produced. The worst-case credible accidents postulated for B Plant involve a truck fire with a leaking gas tank that catches fire in the plant truck port and causes an extended loss of water in the pool cells.

242-A Evaporator. The 242-A Evaporator is located directly south of the 241-A Tank Farm and directly north of the 241-AW Tank Farm. At the 242-A Evaporator, evaporative concentration is used to reduce the volume of liquid wastes (low-heat-generating tank wastes). Once reduced, the concentrated slurry is transferred and stored in an underground waste storage tank. The process condensate is routed to the Liquid Effluent Retention Facility for storage and eventual treatment at the Effluent Treatment Facility. Following startup of the Effluent Treatment Facility, the process condensate will be routed directly to that facility.

There were five 242-A Evaporator design basis accidents analyzed that involved radiological releases (WHC-SD-WM-SAR-023, *242-A Evaporator/ Crystallizer Safety Analysis Report*). The worst-case scenario involved a release from a spray leak in the pump room and a failure of the exhaust system high-efficiency particulate air filters.

Plutonium Finishing Plant. The Plutonium Finishing Plant is located near the western boundary of the Hanford Site in the 200 West Area, southwest of the 241-TX Tank Farm. At this plant, plutonium nitrate solution is converted to plutonium metal, and plutonium handling and storage operations are performed. Contaminated liquid waste streams from the Plutonium Finishing Plant are routed to the tank farms. The plant is currently in a standby mode and is not anticipated to operate again in the future. The worst-case accident scenario at this point is associated with a postulated fire having an airborne release of plutonium-239 (WHC-SD-SQA-TI-013, *Safety and Risk Assessment Technical Information to Support Plutonium Finishing Plant Restart*).

Low-Level Waste Disposal Site. The commercial low-level waste disposal site, operated by U.S. Ecology, Incorporated, is the only non-DOE industrial facility within 8 km (5 mi) of the nearest TWRS facilities. The disposal site is on land leased from Washington State (Section C1.3.1). The low-level waste is buried in lined containers. Monitoring of groundwater, vegetation, and other activities is performed as required by the facility U.S. Nuclear Regulatory Commission operating license and environmental impact statement.

K Basins. The K Basins include the fuel storage pools located in the 100 K East and 100 K West Area fuel storage facilities. The facilities were constructed as storage for spent nuclear fuel following irradiation in 100 K East and 100 K West reactors prior to processing. A review of WHC-SD-SNF-TI-013, *K Basin Environmental Impact Statement Technical Input*, indicates that the worst-case event at either basin is a cask dropped into a spent fuel pool. This event would result in a release of spent fuel and canister sludge.

C1.7.1.2 Hazards to the Tank Farms from Nonnuclear Industrial Facilities. A number of nonnuclear industrial facilities operating in the 200 East and 200 West Areas pose the potential for accidental fires, explosions, or releases of toxic fumes. These facilities include the Essential Materials Warehouse (Building 275-EA), oil and paint storage buildings, fabrication shops, gas cylinder storage buildings, the spare parts and electrical warehouse, B Plant storage buildings, maintenance facilities, gasoline service stations, and the powerhouse complexes (284-E and 284-W).

Building 275-EA is an essential materials warehouse that is considered representative of most warehouses and fabrication shops on Site. The building is located approximately 150 m (500 ft) north of the PUREX Facility and approximately 100 km (328 ft) southwest of the 204-AR Waste Unloading Facility. Building 275-EA is classified as an unprotected wood frame structure and is susceptible to collapse as a result of an external event (e.g., earthquake, wind, snow, or ash loading) or an internal event (e.g., forklift collision with a bearing wall, or fire). More than 100 different types of potentially hazardous solids and liquids are currently stored in Building 275-EA. The solids and liquids include acids, bases, solvents, fluorides, pesticides, and herbicides. Radioactive materials are not stored in this building. The worst-case chemical release postulated in the safety analysis occurs following a building collapse whereupon 2,450 kg (5,445 lb) of 1,1,1-trichloromethane evaporates under adverse atmospheric conditions.

The three boilers in the 242-A Package Boiler System provide steam for evaporator operation and building heat loads. The system description and potential hazardous conditions to TWRS was discussed and evaluated in HNF-1727, *Hazard Evaluation of the 242-A Package Boiler System Impact on Tank Farms*. Based on the evaluation, the 242-A Package Boiler System does not increase the frequencies or consequences or present any new or modified accidents not already addressed by the BIO.

Other nonnuclear industrial facilities with the potential to impact TWRS operations are those facilities that provide raw water and electricity. Raw water is supplied to the 200 East Area from the 282-E Building and in the 200 West Area from the 282-W Building. Electricity is supplied to the

200 East and 200 West Areas from the 284-E and 284-W powerhouses. Only programmatic impacts (i.e., loss of facility capability) have been identified. No other nonnuclear industrial facilities or operations have been identified that may impact TWRS operations.

C1.7.1.3 Hazards to TWRS Facilities from Nuclear Reactors. The N Reactor, Fast Flux Test Facility, and Critical Mass Laboratories facility are three reactors that have recently been in operation but no longer pose threats to TWRS facilities. The N Reactor and Fast Flux Test Facility are undergoing decontamination and decommissioning, and the Critical Mass Laboratories facility (in 209-E Building, north of the PUREX Facility) is presently being used as TWRS office facility.

The N Reactor was a 4,000 MW, dual-purpose, pressure tube, light-water cooled, graphite-moderated reactor. The reactor, which is located in the 100-N Area, began operating in 1964 and was used to produce plutonium for the defense program and steam for electrical power generation. The reactor was shut down in 1987 for safety improvements and then subsequently defueled and placed in cold standby in 1988. N Reactor is currently undergoing decontamination and decommissioning.

The Fast Flux Test Facility is a 400 MW, sodium-cooled, mixed-oxide fueled, breeder reactor that is currently in "hot shutdown" and has been defueled. The reactor is located in the 400 Area and is approximately 7.2 km (4.5 mi) west of the nearest Hanford Site boundary.

The only nuclear reactor on the Hanford Site that may be operating during the lifetime of the TWRS facilities is WNP-2 (Figure C1-4). WNP-2 is an operational commercial nuclear power plant using a boiling-water reactor steam supply system. Worst-case accidents at the WNP-2 reactor do not carry any potential for adversely impacting TWRS operations or personnel.

C1.7.1.4 Hazards to TWRS Facilities from Military Facilities. The Yakima Firing Center, a subinstallation under the command of Fort Lewis (Tacoma, Washington), is the site of the only significant military activity in the vicinity of the Hanford Site (DOA 1979, *Final Environmental Impact Statement - Ft. Lewis Military Installation*). The multiple launch rocket system is the only weapon currently in use at the center that is known to present a hazard to Hanford Site facilities. With a range of approximately 26 km (16 mi), a rocket launched from the system has the potential to impact the 200 West Area (Figure C1-46); however, the rocket system is only fired with dummy warheads from the perimeter of the Yakima Firing Center, away from the Hanford Site, and into a centrally located impact zone. The approximate range of the multiple launch rocket system is shown in Figure C1-46.

A more probable hazard from the Yakima Firing Center to Hanford Site facilities is a scenario in which a fire starts in the Yakima Firing Center boundary and spreads to the Hanford Site. Exploding artillery shells, sparks from tracked vehicles or other machines, and careless smoking by troops may start brush fires that, under adverse meteorological conditions, could spread rapidly beyond the firing center boundaries. Hazards associated with range fires are discussed in Chapter 5.0.

C1.7.2 Potential Effects to Nearby Facilities

TWRS facility accidents with the potential to affect the maximum onsite individual (which may include persons at some of the facilities cited in Section C1.7.1) are specifically limited to those accidents discussed in Chapter 5.0.

C1.8 VALIDITY OF EXISTING ENVIRONMENTAL ANALYSES

No significant discrepancies have been identified between the Site characteristic assumptions herein and those existing in DOE/EIS-0113 or DOE/EIS-0189.

Table C1-17. Percent Frequency of Occurrence of Atmospheric Stability Classes A Through G in the 200 East and 200 West Areas (1983 to 1991).

Class	Occurrence per year (%)
A (extremely unstable)	13.9
B (moderately unstable)	4.5
C (slightly unstable)	4.3
D (neutral)	27.9
E (slightly stable)	26.0
F (moderately stable)	15.7
G (extremely stable)	6.9

Note: Due to rounding, values may not total to 100%.

Table C1-18. Infiltration Rates in the 200 West Area.

Location	Infiltration rate		Comments	Reference
	m/yr	gal/d/ft^2		
216-Z-20 Crib	699 to 1,041	47 to 70	1-2 day test	Law, A. G., 1993, *Infiltration Rates at the Preferred Soil Column Disposal Site* (internal letter 81233-93-002 to K. J. Koegler, February 24), Westinghouse Hanford Company, Richland, Washington
	254	17.1	1981-1985 actual infiltration rate (may not be maximum)	
216-U-16 Crib	238 and 535	16 and 36	1-2 day test	
Powerhouse Pond	253 to 446	17 to 30	1-2 day test	
216-U-12 Crib	165	11.1	8 month actual infiltration rate	
216-S-26 Crib	62	4.2	1984 to 1988 actual infiltration rate; low rate may be caused by sediment clogging pores	
SALDS: east borehole	37	2.5	Falling head test of known calcrete layer	Swanson, L. C., 1994, *Infiltration Rate and Hydraulic Conductivity Results* (internal letter 86B20-94-001 to R. S. Pavlina, June 27), Westinghouse Hanford Company, Richland, Washington
SALDS: west borehole	744 to 2,825	50 to 90	Falling head test of known calcrete layer	
216-U-14 Ditch	15 to 622	1 to 42	Actual infiltration rate during use	WHC-EP-0698, 1994, *Groundwater Impact Assessment Report for the 216-U-14 Ditch*, Rev. 0, Westinghouse Hanford Company, Richland, Washington

SALDS = state-approved land disposal site.

Table C1-19. Hydrogeologic Environmental Setting Data for the 200 East Area Vadose Zone.

Parameter	Units	PZ1	PZ2	PZ3	SZ
Darcian velocity	m/yr	0.03	0.03	0.03	--
Thickness	m	10.00	50.00	19.00	9.10
Bulk density	g/cm^3	1.76	1.60	1.76	1.64
Total porosity	percent	36.00	42.00	36.00	18.00
Field capacity	percent	19.00	8.50	19.00	--
Conductivity	m/day	1.32	4.32	1.32	--
Longitudinal dispersion	m	0.10	0.50	0.19	50.00
Transverse dispersion	m	--	--	--	10.00
Vertical dispersion	m	--	--	--	0.06
Effective porosity	percent	--	--	--	10.00

OMC = nominal percentage of organic matter present in the soil or sediment.
PZ = partially-saturated zone.
SOILC = the soil type exponent used to estimate water retention in an unsaturated soil.
SZ = saturated zone.

Table C1-21. Hydraulic Conductivity of Suprabasalt Aquifer System Units Under the 200 East and 200 West Areas.

Interval	Hydraulic conductivity		Transmissivity		Data source
	m/day	ft/day	m^2/day	ft^2/day	
Both 200 East and 200 West Areas					
Elephant Mountain Member interflow zone	--	--	0.70 to 569.00	2.30 to 1,866.80	RHO-ST-42, 1981, *Hydrology of the Separations Area*, Rev. 0, Rockwell Hanford Operations, Richland, Washington
Rattlesnake Ridge interbed	--	--	0.74 to 108.00	2.43 to 354.33	RHO-RE-ST-12P, 1984, *An Assessment of Aquifer Intercommunication with B Pond-Gable Mountain Pond Area of the Hanford Site*, Rev. 0, Rockwell Hanford Operations, Richland, Washington
200 East Area					
Top of unconfined aquifer (Hanford and Ringold)	8.00 to 7,600.00	26.25 to 24,934.38	--	--	WHC-SD-EN-TI-019, 1992, *Hydrogeologic Model for the 200 East Groundwater Aggregate Area*, Rev. 0, Westinghouse Hanford Company, Richland, Washington
200 West Area					
Ringold unconfined aquifer	0.20 to 61.00	0.66 to 200.13	--	--	PNL-6820, 1989, *Hydrogeology of the 200 Areas Low Level Burial Grounds*, Rev. 0, Pacific Northwest Laboratory, Richland, Washington
	0.09 to 475.00	0.30 to 1,558.40	--	--	WHC-SD-EN-TI-019, 1992, *Hydrogeologic Model for the 200 East Groundwater Aggregate Area*, Rev. 0, Westinghouse Hanford Company, Richland, Washington
Ringold Lower Mud	1.60×10^{-5}	5.24×10^{-5}	--	--	PNL-6820, 1989, *Hydrogeology of the 200 Areas Low Level Burial Grounds*, Rev. 0, Pacific Northwest Laboratory, Richland, Washington

Table C1-22. Three Crustal Layers Related to Earthquakes at the Hanford Site.

Layer	Depth	
	km	mi
Columbia River Basalt Group	0-5	0-3
Prebasalt sediments	8.5	5
Crystalline basement	>8.5	>5

Table C1-23. Five General Sources of Earthquakes at the Hanford Site.

Area	Layer
Major reverse faults on ridges	Mainly basalt, also prebasalt sediments
Secondary faults on ridges	Basalt
Swarm area	Basalt
Basement	Crystalline basement
Cascadia Subduction Zone	Lithosphere-plate tectonic boundary

Table C1-24. Seismic Hazard Exceedance Probabilities and Peak Horizontal Surface Ground Accelerations for Each Performance Category.

Performance Category	Exceedance probability	Return period (yr)	Horizontal ground surface acceleration	
			200 West Area (*g*)	200 East Area (*g*)
1	2.0 E-03	500	0.13	0.13
2	1.0 E-03	1,000	0.19	0.18
3	5.0 E-04	2,000	0.26	0.24
4	1.0 E-04	10,000	0.48	0.44

Table C1-25. Safety-Class Hanford Site Response Spectra—10/01/73 to 09/06/89 (Fast Flux Test Facility Design Basis).

Frequency (hertz)	Damping

Note: To convert feet to meters, multiply by 0.30; to convert pounds to grams, multiply by 453.6; to convert inches to millimeters, multiply by 25.4.

[a] Computed from large strain geophysical crosshole test.

[b] Small strain parameters at 10^{-6} shear strain.

[c] Large strain parameters at 10^{-1}% shear strain.

[d] Groundwater elevation approximately 121.9 m (400 ft).

[e] Estimated soil properties include native soils and rock below a depth of 42.7 m (140 ft) (maximum depth of site borings) and backfill.

[f] Shear and compressional wave relocation estimated from measurements in Shannon and Wilson, 1993, Geologic Studies of the Columbia River Basalt Structures and Age of Deformation, The Dalles-Umatilla Region, Boardman Nuclear Project, Shannon and Wilson, Inc., Seattle, Washington. Shear wave velocities in the basalt ranged from 3,000 to 10,000 ft/s, while compressional wave velocities ranged from 5,700 to 79,000 ft/s.

E = young's modulus of elasticity.

El. = elevation.

G = shear modulus.

V_a = shear wave velocity.

V_p = compressional wave velocity.

Table C1-31. Summary of Dynamic Soil Properties Southwest of 200 West Area.

Material (El. in ft)	Moist density (lb/in^3)	Friction angle (degree)	Poissons[a] ratio	Low-strain[b] parameters				High-strain[c] parameters	
				V_s (ft/s)	V_p (ft/s)	G ($\frac{kips\ 1{,}000\ lb}{in^2}$)	E ($\frac{kips\ 1{,}000\ lb}{in^2}$)	G^a ($\frac{kips\ 1{,}000\ lb}{in^2}$)	E^a ($\frac{kips\ 1{,}000\ lb}{in^2}$)

APPENDIX D
HAZARD ANALYSIS RESULTS REPORT

D1.0 INTRODUCTION

This Appendix describes the methodology used for the Tank Waste Remediation System (TWRS) Basis for Interim Operation (BIO) hazard analysis and documents the results. Any exception to the methodology taken in the development of the addenda are identified in each specific addendum. The hazard analysis was performed in accordance with DOE-STD-3009-94, *Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports.*

The data generated by the hazard analyses were captured in a hazard analysis database and the results are presented in this Appendix and Chapter 5.0, "Safety Analysis," except for separate projects identified in the addenda.

D2.0 HAZARD ANALYSIS METHODOLOGY

This section presents the methodology used to perform the TWRS hazard analysis. A flow diagram of the hazard analysis process is illustrated in Figure D2-1, "Flow Diagram of the Hazards Analysis Process." Hazards that can contribute to the uncontrolled release of radioactive or hazardous materials are systematically and comprehensively identified through the hazard identification process (Section D2.1, "Hazard Identification"). Representative analysis cases are identified and applied to appropriate TWRS facilities by hazard topography (Section D2.2, "Hazard Topography"). The hazard evaluation process (Section D2.3, "Hazard Evaluation") identifies hazardous conditions for the representative cases and identifies causes, existing preventive and mitigative features, and qualitative estimates of the frequency and consequence. Representative analysis was necessary to reduce the cost and schedule associated with development of the TWRS hazards analysis. Analyzing representative cases is valid for two reasons:

1. The hazard evaluations are qualitative assessments which apply to any specific situation with similar characteristics.

2. The 177 tanks in TWRS share similar characteristics.

Results of the hazard evaluations are used to select candidate accidents for quantitative analysis (Section D2.4, "Candidate Accident Selection"). Results of the hazard and accident analyses are then used to identify the safety structures, systems, and components (SSCs); Technical Safety Requirements (TSRs); and other controls required to protect the public, worker, and environment (Section D2.5, "Controls Identification"). The hazard and accident analyses results also support determination of the final facility hazard classification (Section D2.6, "Hazard Classification"). The results of hazard analysis activities are recorded in a hazard analysis database, except for separate projects identified in the addenda.

D2.1 HAZARD IDENTIFICATION

The hazard analysis includes identification of the hazards associated with TWRS design, processes, and operations. Hazards are defined as material, referred to as material at risk, with a potential adverse effect on people or the environment and the energy sources that could contribute to the uncontrolled release of that material. The hazard identification methods and techniques include the following:

- Review of past TWRS safety documents
- Review of TWRS reportable event history (e.g., unusual occurrence reports)
- Review of historical records of similar operations (e.g., Savannah River Site)
- Participation by current and former TWRS Operations and Engineering personnel in the hazard analysis effort
- Use of standardized checklists of potential hazardous materials and energy sources
- Information regarding TWRS material at risk
- TWRS facilities and operations descriptions
- Existing TWRS hazard analyses.

An initial set of hazards is identified on a tank farm level and other facility level using the form and related checklist in Tables D2.1-1, "Hazards Identification Form," and D2.1-2, "Hazard Identification Checklist and Energy Designators." A field verification by means of a TWRS document review and facility walkdown supports identifying material at risk (type, form, quantity, and location) and relating the hazard identification to each tank.

This information about the material present in each TWRS facility is used to confirm or adjust the assumptions made about the material at risk used in the hazard evaluations. The accident analysis also is based on conservative assumptions about what material might be present, not the existing inventory. These assumptions about material at risk are as follows.

Chemical Inventory. The maximum hazardous chemical inventory for TWRS is developed using two sources. The first source is a listing of chemicals from the Hanford Site hazardous material inventory database (system), which is used to meet the requirements of *Superfund Amendments and Reauthorization Act (SARA) of 1986*. This database contains a list of purchased and stored chemicals within the facility. The second source of information is WHC-SD-WM-SARR-011, *Toxic Chemical Considerations for Tank Farm Releases*. This document contains the bounding limits for chemical unit liter concentrations for the tanks within the facility.

Radiological Inventory. The TWRS worst-dose radiological inventory is based on information given in WHC-SD-WM-SARR-016, *Tank Waste Compositions and Atmospheric Dispersion Coefficients for Use in Accelerated Safety Analysis Consequence Assessments* and WHC-SD-WM-SARR-037, *Development of Radiological Concentrations and Unit Liter Doses for Tank Waste Remediation System Final Safety Analysis Report Radiological Consequence Calculations.* These documents contain bounding unit liter doses for the tanks within the facility.

D2.2 HAZARD TOPOGRAPHY

The TWRS hazard topography is used to ensure comprehensive coverage of material at risk, phenomena, configurations, operations, and facilities. TWRS documents, including WHC-EP-0182, *Waste Tank Summary Report for Month Ending March 31, 1996*; WHC-SD-WM-SARR-009, *Construction, Maintenance, and Operational Activities Analysis Summaries*; and WHC-SD-WM-HIE-007, *Tank Waste Remediation System Final Safety Analysis Report Hazard Identification/Facility Configuration Verification Report* are used to help define the hazard topography.

The hazard topography is specifically used to accomplish the following.

- Identify the types of TWRS facility situations that are directly analyzed by a hazard evaluation (e.g., identify the specific representative analyses).
- Map the representative hazard evaluation results to each TWRS facility in the scope of the TWRS BIO.
- Store the results of the hazard identification effort for each TWRS facility in the scope of the TWRS BIO.

The hazard topography data are stored in the hazard topography database and include the following information:

- **Facility Identifier**—The facility identifier used by the TWRS Project.
- **Facility Type**—The TWRS facility type code (Table D2.2-1, "Tank Waste Remediation System Facility Type Codes") used to relate hazard evaluation results to each facility. For example, a double-shell tank (DST) on the flammable gas watch list would be coded with a facility type code of DS.H. All hazardous conditions involving DSTs and hydrogen gas fires or explosions also would be assigned the DS.H code. This allows all hazardous conditions involving hydrogen fires/explosions to be related to the appropriate DSTs.
- **Capacity**—The design capacity of the vessel(s) at a facility.
- **Material Inventory**—The inventory of radioactive or hazardous materials in a facility. It includes the type, form, quantity, and location of the material (the location identification is generally the same as the facility identification).

- **Energy Sources**—The identification of potential energy sources associated with a facility (Tables D2.1-1 and D2.1-2).

- **Unique Phenomena**—The unique phenomena associated with each facility. Unique phenomena include high heat, flammable gas, organics, and radiolysis.

- **Unique Configuration**—The unique major configuration items for each facility. Unique configurations include interfaces with other facilities, the existence of active or passive ventilation, DSTs, and single-shell tanks (SSTs).

- **Representative Analyses**—The hazard evaluations which contain results applicable to a facility.

D2.3 HAZARD EVALUATION

The hazard evaluation is a structured and systematic examination of the TWRS facilities and operations using standard industry (American Institute of Chemical Engineers [AIChE]) hazard evaluation techniques. It is performed by a team of cognizant TWRS Operations and Engineering personnel, safety analysts familiar with TWRS, and technical experts in specialty areas.

Hazard evaluations representative of all TWRS facilities are performed. The representative hazard evaluations are chosen using selection criteria designed to ensure comprehensive coverage of TWRS facilities and their design and operation variations. Those variations for which specific hazard evaluations were performed include the following:

- Major or unique material at risk inventory

- Major phenomenology (e.g., high heat, flammable gas, organics, radiolysis)

- Major configuration variations (e.g., interface with evaporator, active ventilation, passive ventilation, DSTs, SSTs)

- Routine TWRS operations (e.g., waste transfers, in-tank activities, waste sampling)

- Unique facilities (e.g., 204-AR Waste Unloading Facility, 2727-W Sodium Storage).

The representative hazard evaluations and the technique used for the respective analyses performed are listed in Table D2.3-1, "Representative Hazard Analysis." Hazardous conditions were developed from the information obtained from hazard evaluations performed by hazard and operability studies (HazOps), preliminary hazards analyses (PHAs), or What-If analysis. These hazard evaluation techniques use a tabular format to capture pertinent information. The sequential numbering system used in the HazOp, PHA, or What-If tables is the basis for the hazardous condition alpha-numeric identifiers.

In the case of PHAs and What-If analyses, the identifier is straightforward. An abbreviated designation for a PHA or What-If is combined with the sequential numbering of the table to create the identifier. For example, CRN-13-b would be the thirteenth item in the PHA for crane activities. The -b indicates that further development of the item resulted in more than one hazardous condition. In the case of HazOps, the identifier is based on an abbreviated designation for the HazOp combined with the node number and process parameter. In some cases, a sequential numbering system was substituted for the process parameter. For example, 102AW-01-FLOW01 would indicate that this hazardous condition originated in the first node of the HazOp on Tank 241-AW-102 for the process parameter FLOW. The 01 specifies that this is the first deviation guide word in the table for this process parameter. In the case of 114SX-05.b.2, the hazardous condition came from the HazOp on the 114-SX tank farm, fifth node, second process parameter, second guide word. In all cases, the alpha-numeric identifier for each hazardous condition permits tracing the condition to the specific item in the applicable HazOp, PHA, or What-If table.

The hazard evaluation technique which is applied depends on the nature of the TWRS facility or operation being analyzed. The following hazard evaluation techniques are used:

- **HazOp:** systems, equipment, and processes
- **PHA:** facility operations and situations that are primarily operations driven
- **"What If" analysis:** external events, natural phenomena, and potential common-cause failures.

HazOp. The HazOp was developed to identify and evaluate safety hazards in systems, equipment, and processes and to identify operability problems which, although not hazardous, could compromise the productivity goals for which the plant was designed to achieve. Although originally developed to anticipate hazards and operability problems for technology with which organizations have little experience, the HazOp is very effective with existing operations. However, completion of a HazOp is time consuming, and depending on the complexity of the failure being investigated, can require considerable resources (e.g., personnel, information, software, etc.). Use of the HazOp requires a detailed source of information concerning the design and operation of a process.

In a HazOp, an interdisciplinary team uses a creative, systematic approach to identify hazard and operability problems that could lead to undesirable consequences. Because these problems usually are caused by deviations from the process design, an experienced team leader systematically guides the team through the plant design. A fixed set of words (termed "guide words") is applied at specific points or "study nodes" in the plant design and combined with specific process parameters to identify potential deviations from the intended operation. Process parameters that may be examined include flow, temperature, pressure, viscosity, composition, phase, level, addition, reaction, maintenance, testing, instrumentation, and sampling. Guide words (and their meanings) include the following:

- "No/none"—Negation of design intent
- "More"—Quantitative increase
- "Less"—Quantitative decrease
- "As well as"—Qualitative increase
- "Part of"—Qualitative decrease
- "Reverse"—Logical opposite of intent
- "Other than"—Complete substitution.

Guidelines for Hazard Evaluation Procedures (AIChE 1992) gives a more detailed description of this technique.

PHA. The PHA technique is derived from Mil-Std 882B, *Military Standard System Safety Program Requirements* (DOD 1987). This technique is used to analyze facility operations and situations that are primarily operations driven. In a general way, a PHA focuses on the hazardous materials and major process areas of a plant. While the PHA technique normally is used in the preliminary phase of plant development for cases where experience provides little or no insight into potential safety problems, it also may be helpful when analyzing large, existing facilities or prioritizing hazards when circumstances prevent use of a more extensive technique. A PHA can be performed by one or two people who have a process safety background.

A list of hazards and generic hazardous situations are considered using the following process characteristics:

- Raw materials
- Intermediate and final products (and their reactivity)
- Plant equipment
- Facility layout
- Operating environment
- Operational activities (testing, maintenance, etc.)
- Interfaces among system components.

A PHA yields a qualitative description of the hazards related to a process design. A PHA also provides a qualitative ranking of hazardous situations that can be used to prioritize recommendations for reducing or eliminating hazards in subsequent life-cycle phases of the process.

Use of the PHA technique requires that analysts have access to available plant design criteria, equipment specifications, material specifications, and other sources of information. A detailed description of this technique is provided (AIChE 1992).

What-If Analysis. The What-If analysis is used to analyze external events, natural phenomena, and potential common-cause failures. The What-If analysis is a brainstorming approach in which a group of experienced personnel familiar with the subject process ask questions or voice concerns about possible undesired events. It is not as inherently structured as some other techniques (e.g., HazOp analysis). Instead, it requires the analyst to adapt the basic concept to the specific application.

Because the What-If analysis is so flexible, it can be performed at any stage of the process, using whatever process information and knowledge are available. For each area of the process, two or three people should be assigned to perform the analysis; however, a larger team may be preferred. It is better to use a large group for a complex process, dividing the process into smaller pieces, than to use a small group for the entire process.

The What-If analysis encourages the hazard analysis team to think of questions that begin with "what if." However, any process safety concern can be voiced even if the concern is not phrased as a question. Usually, a scribe records all questions on a chart pad, marking board, or computer. The questions are then divided into specific areas of investigation (usually related to consequences of interest), such as electrical safety, fire protection, or personnel safety. Each area is subsequently addressed by a team of knowledgeable members. The questions are formulated on the basis of experience and are applied to existing drawings and process descriptions. For an operating plant, the investigation may include interviews with plant staff not represented on the hazard analysis team.

A more detailed description of this technique is provided (AIChE 1992).

For each technique used, the hazard evaluation is summarized in the hazard analysis database and includes the following information:

- Hazardous condition
- Cause
- Consequence
- Frequency category
- Safety consequence category
- General remarks.

Potential hazardous conditions (excluding those identified as common industrial hazards) are developed using the hazards identified and the application of the hazard evaluation methods described above. The description of each hazardous condition includes release of material from a location caused by an event.

The hazard analysis database contains descriptions of causes for hazardous conditions. Identification of causes was based on the hazard identification results, reviews of the systems, historical event data, and other sources of information (existing safety documentation) including discussions with experienced facility personnel. Typical potential causes of

the postulated hazardous conditions included equipment failures, operational errors, abnormal operating conditions, poor operating practices, and environmental conditions. The potential causes of a postulated hazardous condition are identified to support a qualitative frequency evaluation.

Each hazardous condition was assessed to determine a qualitative frequency of occurrence and consequence in accordance with Tables D2.3-2, "Likelihood Categories" and D2.3-3, "Consequence Categories," respectively. The assessment of likelihood and consequence for each hazardous condition is a collective, qualitative judgment made by the hazard analysis team. The assessment is made for the initial hazard analysis, with the impact of existing controls taken into consideration. Subsequent likelihood and consequence assessments are made without considering controls and with considering controls (safety SSCs and TSRs).

These assessments are input to the hazard analysis database.

The likelihood assessments are made in occurrences per tank farm year. The general criteria for likelihood assessments are as follows:

F3: The hazardous condition based on the cause(s) postulated has occurred or is likely to occur

F2: The hazardous condition based on the cause(s) postulated is foreseeable, but unlikely

F1: The hazardous condition based on the cause(s) postulated is perhaps possible, but extremely unlikely

F0: The hazardous condition based on the cause(s) postulated is considered too improbable to warrant further consideration.

Frequency assessments for hazardous conditions that are close to the upper limit of a category are conservatively assigned to the higher-likelihood category.

The consequence category assessments address potential impacts on health and safety, and the environment. The general criteria for consequence assessments are as follows:

S3: On the basis of material at risk and cause(s) postulated, there is sufficient material and release energy to impact a receptor at the Hanford Site boundary

S2: On the basis of material at risk and cause(s) postulated, there is sufficient material and energy to impact a receptor 100 m from the source of the material at risk

S1: On the basis of material at risk and cause(s) postulated, the release is confined to the facility in which it occurred

S0: On the basis of material at risk and cause(s) postulated, there is insufficient material released to affect facility workers

E3: All S3 hazardous conditions or major leaks from large storage tanks

E2: All S2 hazardous conditions or liquid releases or leaks outside facility boundaries

E1: Postulated releases not included in E3 or E2

E0: No release postulated.

The more severe consequence categories include the less severe consequences. For example, a hazardous condition assessed as having onsite consequences (S2) is also considered to have facility worker consequences (S1).

The original hazard analyses identified preventive features (existing controls) that have the potential to prevent, and therefore reduce, the estimated frequency of a postulated hazardous condition. Design and administrative controls (e.g., procedures, polices, and programs) are included as preventive features. Preventive controls were identified primarily by reviewing selected facility procedures and process description documentation, and by consulting experienced facility personnel.

The hazard analyses also identified mitigative features (existing controls) that have the potential to mitigate the consequences of a postulated hazardous condition. Design and administrative controls (e.g., procedures, polices, and programs) are included as mitigative features. Mitigative controls are identified primarily by reviewing selected facility procedures and process description documentation, and by consulting experienced facility personnel.

The hazard evaluations are documented in individual reports which identify the participants and hazard evaluation scope, material at risk, major assumptions, references, and the information in the HazOp, PHA, and "What If" forms (WHC-SD-WM-TI-759, *Hazard Evaluations for the Tank Waste Remediation System Final Safety Analysis Report*).

D2.4 CANDIDATE ACCIDENT SELECTION

The hazardous conditions identified by the hazard evaluation are used to select candidate accidents for more detailed, quantitative analysis. The general selection criteria used are consistent with DOE-STD-3009-94: "The range of accident scenarios analyzed in a SAR should be such that a complete set of bounding conditions to define the envelope of accident conditions to which the operation could be subjected are evaluated and documented." Information generated by the accident selection process is included in the hazard analysis database.

The concept of selecting candidate accidents from all hazardous conditions identified is based on the feasibility of characterizing risk and developing controls from a representative set of accidents. An accident is considered to be representative of a set of accidents if it has similar accident release characteristics or involves similar accident phenomena. Accidents which represent the most severe consequences and the highest risk (combination of frequency and consequence) are selected.

Representative accidents will be selected using the following criteria: accidents that bound those of lesser but similar potential consequences; accidents that represent the highest risk; and other accidents, while not necessarily bounding, that represent accidents presenting some unique but important phenomenological challenge to system safety. The selection process comprises six steps:

1. Initial screening
2. Assignment of accident release attributes
3. Creation of hazardous material release bins
4. Sorting of the hazardous conditions by cause
5. Selection of representative bounding accidents for each release attribute category
6. Selection of unique accidents.

In accordance with DOE-STD-3009-94 and consistent with the graded approach, the risks of a facility/activity may be characterized and appropriate controls developed using the detailed analysis of a representative set of accidents.

Initial Screening. All hazardous conditions not assessed as S3 (offsite consequences) or S2 (onsite consequences) are dropped from the selection process. These hazardous conditions will be addressed using the qualitative hazard analysis results only.

Assignment of Accident Release Attributes. Each hazardous condition (e.g., accident) is described with certain accident release attributes (Table D2.4-1, "Accident Release Attributes") related to uncontrolled release of the material at risk. This is done to ensure that at least one candidate accident representing the possible spectrum of release conditions is selected.

The hazardous material release attributes used are as follows:

- Initial energy available to release the hazardous material
- Initial release location
- Initial form of the release.

Initial conditions are used for these assignments because it is possible (and sometimes likely) that other conditions may evolve during the course of the accident progression. For example, a release may begin as a pool of liquid on the ground but become airborne as wind blows over the pool. The progression of the accident is more thoroughly examined in the detailed accident analysis.

The attributes related to energy level have three designations: high, moderate, and low (Table D2.4-1). A high energy level (A) is assigned to energetic events such as explosions, fires, and criticality. A moderate energy level (B) is assigned to events such as liquid spray from pressurized

lines and from dropping hardware into a material that disturbs or causes it to splash or become airborne. A ventilation system that is breached when the fans are running could be assigned to a moderate energy classification. A low energy level (C) includes events such as leaks from nonpressurized liquid containers and leaks from passive ventilation systems.

The attributes related to the initial release location have three designations: atmospheric, ground surface, and subsurface (Table D2.4-1). In some cases, the accident may result in release to more than one destination. An accident resulting in significant portions of materials being released to more than one destination is assigned one location attribute associated with the most severe consequence. If it is clear that the overall accident significance is related to one location, and only minor effects are possible from the others, then only one location attribute is also assigned.

Three attributes are related to the initial form of the release: vapor/gas/aerosol, liquid/slurry, and solid/sludge (Table D2.4-1). Again, in some cases, the accident may result in release of more than one form of material and thus be assigned the attribute associated with the most severe consequence. If it is clear that the overall accident significance is related to one form, and only minor effects are possible from the others, then one form attribute is also assigned.

Creation of Hazardous Material Release Bins. Once the release attributes are assigned to each hazardous condition (accident), they are collected to form accident release categories or bins. Collecting accidents into bins involves grouping all accidents with common release attributes. For example, a certain accident may be assigned a high energy level for material that is released to the atmosphere as a vapor; its attributes would therefore be high/atmosphere/vapor. If bins are labeled using combinations of designators for the attributes shown in Table D2.4-1, the designation for the example would be A-1-a. All accidents with designator A-1-a are grouped together.

Sorting of the Hazardous Conditions by Cause. The hazardous conditions within each accident release category are organized by cause. This includes grouping by common accident phenomena (e.g., fire, criticality). The codes used to bin the accidents (hazardous conditions) by cause are listed in Table D2.4-2, "Hazardous Condition Cause Codes." For example, hazardous conditions involving a dome collapse and the dropping of a load are coded C10. Those accidents resulting in dome collapse caused by structural degradation are coded B12. All of these hazardous conditions are grouped in the same release attribute bin. Examination of the various causes supports selection of a representative set of accidents from each release attribute bin.

Selection of Representative Bounding Accidents for Each Release Attribute Category. Within each release attribute bin the most severe accident in terms of consequence, and the highest risk accident considering likelihood and consequences, are selected. In some cases, they are the same accident.

Selection of Unique Accidents. Accidents are selected to represent additional, unique causes within each release attribute bin. This is done to support development of controls for accidents with similar consequences but with different causes.

The final list of candidate accidents represents all S3 (offsite) and S2 (onsite) hazardous conditions identified by the hazard analysis. These hazardous conditions are grouped by candidate accident to facilitate incorporation of the information and conclusions from the accident analysis into the hazard analysis results when considering controls and hazard classification.

Adjustments are made to the list of accidents analyzed on the basis of results from accident analysis activities. To accommodate this anticipated situation, a table is developed to identify the candidate accidents and the accidents analyzed. The reasons for any differences are explained and the hazardous conditions are regrouped on the basis of the final set of analyzed accidents.

D2.5 CONTROLS IDENTIFICATION

The hazard analysis results and the accident analysis results are used to identify Safety-Class and Safety-Significant SSCs, TSRs, and other controls required to protect the public, workers, and environment. The process of control identification is illustrated in Figure D2.5-1, "Process to Identify Controls." Controls for protection of the public and onsite workers (100 m) are based on the results of the hazard analysis and the accident analysis. Controls for protection of facility workers and the environment are based primarily on the qualitative hazard analysis results.

The principal basis used for identifying safety SSCs and TSRs is risk guidelines. The objective is to identify the necessary and sufficient safety SSCs and TSRs that result in satisfying the risk guidelines. The risk guidelines for the public and onsite workers are given in Table D2.5-1, "Risk Guidelines." For facility workers, Safety-Significant SSCs and TSRs may be required for hazardous conditions with significant facility worker consequences (S1) and an uncontrolled frequency of anticipated (F3). Figure D2.5-2, "Risk Matrix" is a risk matrix that illustrates the application of the risk guidelines for all hazardous conditions.

The relationship between the quantitative risk guidelines and the qualitative risk matrix is determined by the frequency/consequence results of the accident analysis. For example, if the most severe consequence result for a hazardous condition (accident) exceeds the dose limit for the onsite worker, that hazardous condition is considered to have a consequence of S2 with the corresponding frequency. This combination of frequency/consequence determines the risk index of a hazardous condition based on Figure D2.5-2. If a hazardous condition has a frequency of F2 and a consequence of S2, it has a risk index of 12. For those hazardous conditions not directly analyzed as accidents, the risk index is determined by the qualitative frequency/ consequence results of the hazard evaluations as refined by the information from the accident analysis.

Decisions regarding classifying SSCs as Safety-Class or Safety-Significant, and identifying TSR controls, require the involvement of the cognizant hazard and accident analysts within TWRS Operations and Engineering. Control decisions are based on the best available information for the potential hazardous condition or postulated accident and the uncontrolled risk; the hazard topography; the hazardous conditions represented by the

postulated accident; and the existing and possible alternative controls, their estimated risk reduction effectiveness, and their estimated engineering and operations impacts (e.g., capital and operating costs, increased facility worker radiation/hazardous material exposure, environmental compliance, TWRS retrieval and disposal mission).

As shown in Figure D2.5-1, the safety SSCs, TSRs, and other controls are identified in a four-step process. First, for each postulated accident selected for quantitative analysis, a necessary and sufficient set of controls is identified. Second, using the hazard topography, a determination is made concerning whether the selected controls acceptably prevent or mitigate the postulated accident at all TWRS facilities where the accident could occur. If necessary, controls are identified for other TWRS facilities and operations. Third, a review of each hazardous condition represented by the analyzed accident is performed to determine if the selected controls acceptably prevent or mitigate the represented hazardous condition. Again, if necessary, additional or different controls are identified for the represented hazardous condition. Fourth, and finally, the total set of controls chosen to protect the public and onsite worker are reviewed to determine whether any significant facility worker hazards remain uncontrolled. If necessary, additional controls are identified for worker protection.

The decisions concerning safety SSCs, TSRs, and other controls providing Defense-in-Depth are documented. These controls have been incorporated into the hazard and accident analyses of the BIO (Chapter 5.0).

D2.6 HAZARD CLASSIFICATION

A final hazard classification of TWRS facilities is based on the results of the hazard and accident analyses. Hazard classification is based on the definitions of hazard categories in DOE 5480.23, *Nuclear Safety Analysis Reports* and the methodology for hazard classification in DOE-STD-1027-92, *Hazard Categorization and Accident Analysis Techniques for Compliance with DOE Order 5480.23, Nuclear Safety Analysis Reports*. As allowed by DOE-STD-1027-92, TWRS facilities that are independent (i.e., hazardous materials in one facility cannot interact with hazardous materials in another facility) are segmented and their individual hazard classifications are determined.

D2.7 HAZARD ANALYSIS DATABASE

The hazard analysis database is used to collect the results of the hazard analysis activities and to generate reports and evaluations to support the hazard and accident analyses. The results from the initial hazard analysis activities are input to the hazard analysis database. This database supports the activities of hazard identification, hazard topography, hazard evaluation, and safety SSC and TSR identification. As these activities proceed, along with the accident analysis, additional information becomes available that results in refinements of the initial qualitative judgments made in the hazard analysis. These refinements are incorporated in the hazard analysis results by updating the hazard analysis database. The final hazard analysis results are reflected in the updated database.

The hazard analysis database contains the TWRS hazard topography and the hazard identification and evaluation results. These data are related through use of the facility type code (Table D2.2-1). The contents of the hazard identification and hazard topography data tables are described in Sections D2.1 and D2.2, respectively. The hazard evaluation results are contained in the database, as follows.

1. **Identifier**—An identifier for each entry in the database that includes an indication of the facility or operation analyzed.

2. **Material at Risk**—A place keeper that indicates the location of the material inventory considered for release in each entry (Table D2.7-1, "General Material at Risk Categories"). Specific inventory information for each facility or location is contained in the hazard topography. Place keepers are used by the hazard evaluations to allow the analysis to be developed on a representative basis. For example, the hazardous conditions postulated in the hazard evaluation that result in the uncontrolled release of material from tank ventilation systems use the material at risk for these events as "contamination in ventilation system." The accident analysis uses a reasonably conservative quantified description of this material at risk for determining potential consequences.

3. **Hazardous Condition**—A brief description of the uncontrolled release of material including the location of the release and the condition of release.

4. **Cause**—A brief description of the cause of the uncontrolled release; generally, an identification of the initiating event for the release.

5. **Frequency**—The qualitative assessment of the frequency of the hazardous condition (Table D2.3-2). Two frequency estimates are included: frequency without controls, and frequency with selected SSCs and TSRs. These entries are subject to update using accident analysis results.

6. **Consequence**—Qualitative assessment of the consequence of the hazardous condition (Table D2.3-3). This entry is subject to update using accident analysis results.

7. **Risk**—The combination of frequency and consequence (Figure D2.5-2). Two risk estimates are included: risk without controls, and risk with selected SSCs and TSRs. These entries are subject to update using accident analysis results.

8. **Selected Controls**—Identifies selected SSCs and TSRs and whether they are preventive and mitigative features.

9. **Release Attribute**—This code is from the accident selection process (Table D2.4-1) and used to support candidate accident selection.

10. **Cause Group**—This is the hazardous condition cause group code (Table D2.4-2) used to support candidate accident selection and selection of controls.

11. **Facility Type**—TWRS facility-type code (Table D2.2-1) used to relate the hazard evaluation results to each TWRS facility using the hazard topography.

D3.0 HAZARD ANALYSIS RESULTS

The results of the hazard analysis include information on TWRS hazard topography, hazard identification, accident selection, hazard evaluation, and control identification. These results are presented in tabular form in Tables D3.4-1 through D3.4-5. Results of analyses performed in addition to those presented by the analyses results contained in those tables are included in the addenda to this BIO. The results of the hazard analysis for WRSS are contained in Addendum 1, "Tank 241-C-106 Sluicing Safety Analysis." The results of the hazard analysis for the replacement cross-site transfer system are contained in Addendum 2, "Replacement Cross-Site Transfer System Safety Analysis." The results of the hazard analysis for the 702-AZ ventilation system are contained in Addendum 3, "702-AZ Ventilation System (241-AZ-702) Safety Analysis." The results of the hazards analysis for the 241-AZ-101 mixer pump test are contained in Addendum 4, "Safety Analysis for Tank 241-AZ-101 Mixer Pump Test."

D3.1 HAZARD TOPOGRAPHY RESULTS

The TWRS hazard topography captures the list of TWRS facilities within the scope of the TWRS BIO, results of the hazard identification activities, and relates the individual hazard evaluations to TWRS facilities. The three principle sources of information for the hazard topography are as follows:

- WHC-SD-WM-HIE-007
- The TWRS hazard evaluation results
- The TWRS accident analysis results.

The hazard topography is displayed in Tables D3.1-1, D3.1-2, D3.1-3, and the D3.1-4 series (D3.1-4-A, D3.1-4-AN, D3.1-4-AP, D3.1-4-AW, D3.1-4-AX, D3.1-4-AY, D3.1-4-AZ, D3.1-4-B, D3.1-4-BX, D3.1-4-BY, D3.1-4-C, D3.1-4-S, D3.1-4-SX, D3.1-4-SY, D3.1-4-T, D3.1-4-TX, D3.1-4-TY, D3.1-4-U).

D3.2 SUMMARY OF OCCURRENCES

The hazard identification activity included a review of occurrence reports for TWRS (200 Area tank farms and affiliated facilities). These reports were examined to assure that a comprehensive set of hazards and potential accident causes were addressed by the hazard analysis activity. Comprehensiveness was assured by comparing the nature of the occurrences to the potential causes or accidents identified by the hazard analysis, and

verifying that those occurrences not covered are not material to the hazard analysis results. Review of the occurrences also was used to assist in determining frequencies for some of the hazardous conditions in the TWRS HazOps and PHAs.

Two databases of occurrences associated with the 200 Area tank farms and affiliated facilities have been generated in support of the TWRS BIO. Development of these databases included a review of all unusual occurrence reports produced by Atlantic Richfield Hanford Company from January 1972 through June 1977, Rockwell Hanford Company from June 1977 through June 1987, and Westinghouse Hanford Company from June 1987 through December 1989. Copies of tank farm-associated unusual event reports, critiques, and event fact sheets for the years 1986 through 1990 were reviewed and included in the databases, where appropriate. The Occurrence Reporting and Processing System (ORPS) database was obtained electronically for the years 1990 to May 1998. This database includes all unusual occurrence reports, off-normal events, and critiques generated by the Westinghouse Hanford Company. The ORPS database was searched for occurrences in the tank farms and associated facilities. Actions that resulted in minor skin contaminations or reports of a minor spread of contamination (specks or contamination spread to personal clothing) from a tank farm or associated facility were not included in the databases, which are documented in Tables D3.2-1, "Tank Farm Events, Off-Normal (ON) and Critiques" and D3.2-2, "Summary of Occurrences."

Table D3.2-3, "Hazard Analysis Cause Groups and Associated Occurrences" is a summary of the occurrences which were reviewed and compared to the list of cause groups from the hazard analysis results. The list consists of the representative accidents and causes of the accidents. Table D3.2-4, "Occurrences Not Included in the Hazard Analysis" is the list of occurrences not included in the hazard analyses and the number of times they occurred. All occurrence causes which potentially contribute to uncontrolled releases were addressed in the hazard analysis.

D3.3 ACCIDENT SELECTION RESULTS

The TWRS hazard evaluations identified hazardous conditions resulting in uncontrolled releases of radioactive or hazardous material and their frequency of occurrence and consequences. From the list of hazardous conditions resulting in significant offsite or onsite consequences, a set of accidents was selected to represent these hazardous conditions. Table D3.3-1, "Analyzed Accidents" lists the accident selected for analysis. Table D3.3-2, "Analyzed Accidents and the Represented Hazardous Conditions" lists the selected accidents along with the hazardous conditions they represent.

D3.4 HAZARD EVALUATION RESULTS

The hazard evaluations identified hazardous conditions with the potential for significant health, environmental, occupational, and radiation exposure consequences. Tables D3.4-1, D3.4-2, D3.4-3, D3.4-4, and D3.4-5 list the hazardous conditions by consequence category (Note: hazardous conditions are listed in decreasing order of frequency for each consequence category).

Included in the tables are potential environmental consequences. All consequence and frequency assessments in these tables are based on an assumed TWRS configuration with no controls.

D3.5 CONTROL IDENTIFICATION RESULTS

Controls (e.g., safety SSCs and TSRs) were identified using hazard and accident analysis results. The safety SSCs and TSRs were allocated to all hazardous conditions identified by the hazard evaluations. Tables 5.4-1, 5.4-2, and 5.4-3 in Chapter 5.0 of the main text contain the results of the control identification.

Table D2.1-1. Hazards Identification[a] Form.

Energy Classification[b]	Tank A		Facility B		Facility C	
	PT	PE	PF	PE	PF	PE
Corrosive						
Explosive/Pyrophoric						
Nuclear Criticality						
Flammable Materials						
Thermal Radiation						
Chemical Reactions						
Friction						
Electrical						
Kinetic-Rotational						
Kinetic-Linear						
Mass, Gravity, Height						
Pressure-Volume						
Thermal (except radiant)						

EXAMPLE

[a]The hazards identification represents the hazards that could potentially cause an uncontrolled release of radioactive or hazardous materials only. Hazards only resulting in personnel injury are not included.

[b]See Table 3-1b for the specific energy classifications represented by the numeric designators.
PT = Potentially Present in the tanks.
PF = Potentially Present in the facility.
PE = Potentially Present elsewhere in/adjacent to facility.

Table D2.1-2. Hazard Identification Checklist and Energy Designators.

A Corrosive
1 Acids
2 Caustic
3 Natural chemicals
4 Decon solution
5 High temperature waste
6 Other

B Explosive/Pyrophoric
1 Caps
2 Primer cord
3 Dynamite
4 Scrub chemicals
5 Dusts
6 Hydrogen
7 Gases, other
8 Nitrates
9 Peroxides-superoxides
10 Pu and U metal
11 Other

C Nuclear Criticality
1 Vaults
2 Temporary storage areas
3 Shipping and receiving areas
4 Filters
5 Casks
6 Burial ground
7 Storage racks
8 Canals and basins
9 Decon solution
10 Trucks, forklifts, dollies
11 Hand carry
12 Cranes/lifts
13 Hot cells, assembly, inspection
14 Laboratories
15 Tanks
16 Other

D Flammable Materials
1 Packing materials
2 Rags
3 Gasoline
4 Lube oil
5 Coolant oil
6 Paint solvent
7 Diesel fuel
8 Buildings and contents
9 Trailers and contents
10 Grease
11 Hydrogen
12 Nitric acid
13 Organics
14 Gases-other
15 Liquids-other
16 Sodium
17 Other

E Thermal Radiation
1 Furnaces and boilers
2 Steam liners
3 Lab equipment
4 Solar
5 Other

F Chemical Reactions
1 Uncontrolled chemical reactions
2 Other

G Friction
1 Belts
2 Bearings
3 Fans
4 Gears
5 Motors
6 Power tools
7 Other
8 All

H Electrical
1 Battery banks
2 Diesel units
3 Transformers
4 Wiring
5 Switchgear
6 Underground wiring
7 Cable runs
8 Service outlets/fittings
9 Pumps
10 Motors
11 Heaters
12 Power tools
13 Small equipment
14 Electrical equipment
15 Hot plates
16 High voltage
17 Locomotive, electrical
18 Transmission lines
19 Other

I Kinetic-Rotational
1 Centrifuges
2 Motors
3 Pumps
4 Fans
5 Laundry equipment
6 Shop equipment
7 Other

J Kinetic-Linear
1 Cars, trucks, buses
2 Forklifts, dollies, carts
3 Railroad
4 Obstructions
5 Crane loads
6 Pressure vessel blowdown
7 Other

K Mass, Gravity, Height
1 Human effort
2 Stairs
3 Lifts and cranes
4 Bucket and ladder
5 Trucks
6 Slings
7 Hoists
8 Elevators
9 Jacks
10 Scaffold and ladders
11 Pits
12 Elevated doors
13 Vessels
14 Vaults
15 Excavations
16 Raw water lines
17 Other

L Pressure-Volume
1 Boilers
2 Surge tanks
3 Autoclave
4 Test Loops
5 Gas bottles
6 Pressure vessels
7 Stressed members
8 Gas receivers
9 Negative pressure collapse
10 Steam headers and lines
11 Positive pressure release
12 Other

M Thermal (except radiant)
1 Convective
2 Exposed components
3 Heaters
5 Fire boxes
6 Electric wiring, equip
7 Furnaces
8 Steam lines
9 Welding torch
10 Other

Table D2.2-1. Tank Waste Remediation System Facility Type Codes.

Effluent Retention	
ER	Cribs, ditches, ponds
Facilities	
F204	204-AR Unloading Facility
F213	213-W Compactor Building
F244	244-AR Vault
Multiple	
M	Multiple facilities (e.g. as in the case of common cause event)
Other	
A	Abandoned or inactive TWRS equipment
G	General
O	Other (interfacing facilities/equipment)
OM	Miscellaneous Inactive Storage Facility
Pipes	
PA	Above ground pipe
PC	Contained pipe (e.g. cross-site line)
PD	Double encased pipe
PS	Single encased pipe (direct buried)
Storage Facilities	
S90	90-Day Storage Pad, Intermediate Holding Area, Satellite Accumulation Area
SS	2727 W Sodium Storage
SV	Vertical Storage

Tanks * (See Example Section Below)	
T	Tanks, non-specific (Add any appropriate tank type designators. If applicable to all tanks, do not add any tank type designator.)
CD	DCRT (244-TX, 244-U)
CN	Non-DCRT catch tank, drainage type (vent and lift station, aging waste vent)
DS	Double Shelled Tanks non-specific (Add any appropriate characteristic designators.)
	A Air lift circulators (aging waste tanks)
	C Caustic addition tank (e.g. 107-AN)
	E Evaporator feed tank
	H Flammable gas tanks (hydrogen)
	O Organic tanks
	P Active transfer/mixer pumps (e.g. 102-SY)
	V Active ventilation
SS	Single Shelled Tanks non-specific (Add any appropriate characteristic designators.)
	D Dry crust tank (114-SX)
	H Flammable gas tanks (hydrogen)
	L High heat load (>40,000 btu)
	O Organic tanks
	V Active ventilation tanks
SD	Double Shelled Tanks or Single Shelled Tanks (Add any appropriate Characteristic designators. - See DS and SS)
Pits Boxes and Caissons	
WB	Clean out box, sluice transfer box
WD	Diversion box, diverter station, pump pit, valve pit
WF	Flush pit, service pit, caisson, leak detection pit

*EXAMPLE OF FACILITY TYPE CODE FOR TANKs:
The letter T indicates that the facility is a tank of some kind. Each additional designator separated by periods will supply additional information as indicated in the column under the Tank section of the table.

- T.DS.A.H - Flammable gas (hydrogen), double shelled tank with air lift circulators.
- T.SD.L.V - High Heat load tank, either single shelled or double shelled with active ventilation.
- T.SS.D - Dry crust, single shelled tank.
- T.CD.V - DCRT with active ventilation.

Table D2.3-1. Representative Hazard Analysis.

Facility/topic	Hazard evaluation identifier	Technique	Characteristics
Facility interfaces - 222-S Laboratory, 242-A Evaporator, 242-S Evaporator, 242-T Evaporator, B Plant, T Plant, U Plant, PUREX, PFP	I-222S, I-242A, I-242S, I-242T, I-BPLANT, I-TPLANT, I-UPLANT, I-PUREX, I-PFP	HazOp	Impacts on TWRS facilities of active physical interfaces
204-AR Transfer Facility	204AR	HazOp	Lab waste, transfer of waste by vehicle
244-AR Vault	244AR	HazOp	Storage for liquid waste
Overground transfers	OGT	HazOp	SST waste transfer overground
Tank 241-C-106	106C	HazOp	SST, high heat, active ventilation
Tank 241-AN-107	107AN	HazOp	DST, caustic addition
Tank 241-AW-102	102AW	HazOp	DST, evaporator interface, active ventilation
Tank 241-S-102	102S	HazOp	SST, flammable gas, organics, passive ventilation
Tank 241-SX-114	114SX	HazOp	SST, dry crust, high heat, active ventilation
Cross-site transfer (Tank 241-SY-102) (selected portions of Project W-058)	XS, W058	HazOp	DST, waste transfer by pipeline
209-E Storage Area	90D	PHA	Storage for RCRA[a] and low-level waste
213 Compactor	213W	PHA	Equipment decontamination activities
244-AR Vault	244AR-PH	PHA	Storage for liquid waste
2727-W Building	2727W	PHA	Liquid sodium storage
Cleanout boxes	COB	PHA	Interface with waste transfer system
Cribs, ditches, and ponds	CDP	PHA	Disposal of liquid waste
Inactive miscellaneous underground storage tank (plus other inactive facilities)	Identifier ends in - I, e.g., CRN-05-I	PHA	Various types and forms of radioactive and hazardous material
Siphoning	TSF	PHA	Various types and forms of radioactive and hazardous material
Tank operations (Tank 241-AZ-102)	BND, CVR, CRN, DCN, FR, GRN, ITK, RAD, RSR, SFF, VEH	PHA	DST, aging waste
Tank operations (Tank 241-BX-109)	BND, CVR, CRN, DCN, FR, GRN, ITK, RAD, RSR, SFF, VEH	PHA	SST, passive ventilation
Tank operations (Tank 241-SY-101)	BND, CVR, CRN, DCN, FR, GRN, ITK, RAD, RSR, SFF, VEH	PHA	DST, flammable gas, active ventilation, mixer pump
Vertical storage units	VSU	PHA	Storage for solid low-level waste
Common cause failure	CCF	"What If"	Events with potential impact on multiple TWRS facilities
External events	EE	"What If"	Events with potential impact on multiple TWRS facilities
Natural phenomena	NP	"What If"	Events with potential impact on multiple TWRS facilities

[a] Resource Conservation and Recovery Act of 1976, 42 USC 6901, et seq.

Table D2.3-2. Likelihood Categories.

F3 ($>10^{-2}$)	Anticipated events: Frequency greater than once in 100 operating years
F2 (10^{-4} to 10^{-2})	Unlikely: Frequency between once in 10,000 years and once in 100 operating years
F1 (10^{-6} to 10^{-4})	Extremely unlikely: Frequency between once in 1 million years and once in 10,000 operating years
F0 ($<10^{-6}$)	Beyond extremely unlikely: Frequency of less than once in a million operating years.

Table D2.3-3. Consequence Categories.

Category	Definition
S3	Significant radiological or chemical exposure to the public
S2	Significant radiological or chemical exposure to onsite worker
S1	Significant radiation or chemical exposure to facility worker
S0	No significant effect outside facility systems. No consequences for facility workers, onsite workers, or public.
E3	Offsite discharge OR discharge to groundwater
E2	Significant discharge onsite
E1	Localized discharge of hazardous material
E0	No significant environmental consequence

Table D2.4-1. Accident Release Attributes.

Accident release attributes (BIN)		
Initial energy level	Initial release location	Initial release form
A. High	1. Atmosphere	a. Vapor/gas/aerosol
B. Moderate	2. Ground surface	b. Liquid/slurry
C. Low	3. Subsurface	c. Solid/sludge
OCC - Occupational Safety		
RP - Radiation Protection		

Table D2.4-2. Hazardous Condition Cause Codes.

Cause description	Criticality	Fire/ Explosion	Tank Dome Collapse	Release	Human Error Release	Non-release/ Occupational
Addition of aggravating materials/Exothermic reaction	A01	B01	C01	D01	E01	F01
Internal aggravating causes	A02			D02	E02	
Over concentration	A03				E03	F03
Intrusive activity	A04	B04		D04	E04	F04
Non-specific/Multiple external events or phenomena/Other	A05		C05	D05	E05	F05
Error in transfer/Backflow/ Overflow/Filling DST annulus	A06	B06	C06	D06	E06	F06
Ventilation failure		B07	C07	D07	E07	F07
Internal buildup of flammable gas/Internal ignition source		B08				F08
External fire/External ignition source		B09		D09		F09
Excess weight/Dropping/Heavy snow			C10	D10	E10	F10
Vacuum			C11	D11		
Structural degradation/Leak		B12	C12	D12		F12
Over rated equipment			C13		E13	
Confinement failure				D14	E14	F14
Excess agitation					E15	
Corrosion				D16		
Water hammer				D17		
Seismic event/Volcanic activity				D18		
Flooding, pipe failure			C19	D19		
High winds/Tornados/Hail				D20		
Lightning		B21		D21		
Excavation				D22		F22
Aircraft crash		B23		D23		
Low temperature/Freezing				D24		
Vehicle accidents		B25		D25	E25	F25
Structural Damage		B26	C26	D26	E26	F26

Table D2.5-1. Risk Guidelines.

Event frequency category	Event frequency (yr^{-1})	Onsite	Offsite
Radiological risk guidelines			
		Effective dose equivalent (rem)	
Anticipated	$>10^{-2}$ to 10^{0}	.5	.1
Unlikely	$>10^{-4}$ to $\leq 10^{-2}$	5	.5
Extremely unlikely	$>10^{-6}$ to $\leq 10^{-4}$	10	4
Toxic chemical risk guidelines			
		Primary concentration guidelines	
Anticipated	$>10^{-2}$ to 10^{0}	$\leq$ ERPG-1	$\leq$ PEL-TWA
Unlikely	$>10^{-4}$ to $\leq 10^{-2}$	$\leq$ ERPG-2	$\leq$ ERPG-1
Extremely unlikely	$>10^{-6}$ to $\leq 10^{-4}$	$\leq$ ERPG-3	$\leq$ ERPG-2

*Source: Bacon, R. F., 1996, Tank Waste Remediation System Accident Analysis Risk Evaluation Guidelines (Letter 9651709 to J. E. Kinzer, U.S. Department of Energy, Richland Operations Office, April 22), Westinghouse Hanford Company, Richland, Washington.

ERPG = emergency response planning guideline.
PEL = permissible exposure limit.
TWA = time-weighted average.

Table D2.7-1. General Material At Risk Categories.

Material at risk for contents	1. Tank contents
	2. Tank headspace
	3. Rail or truck tanker contents
	4. Ventilation filter contents
	5. Contents of pipeline and/or source tank during transfer
	6. Contents of sump or encasement
Material at risk for contamination	7. Contamination in ventilation system
	8. Contamination in pit of box
	9. Contamination on vehicle
	10. Contamination on equipment or tools

This page intentionally left blank.

Table D3.1-1. Material at Risk Table.[1] (94 sheets)

Field Name	MAR-Subject	MAR-Description	MAR-Classification	Capacity	Material Type	Physical Form	Volume or Activity	Transient	Quantity	Comments
2727-WA-M	Tank Contents	None	NA	NA	NA	NA	NA	NA	NA	No tanks associated with 2727-WA.
2727-WA-M	Tank Headspace	None	NA	NA	NA	NA	NA	NA	NA	No tanks associated with 2727-WA.
2727-WA	Rail or Truck Tanker Contents	Tanker truck heel	NA	5000 gal estimated	NA	Liquid/ Residual	Heel of liquid	Yes	NA	An abandoned truck tanker is parked within the fenced area near 2727-WA. Inside has been rinsed out, radioactive heel expected to remain.
2727-WA	Contamination on Vehicle	Tanker truck (noted above)	NA	NA	NA	Residual	One spot about 1 mR/hr	Yes	NA	Contaminated tanker truck stored near 2727-WA.
2727-WA-M	Contamination on Equipment or Tools	None	NA	NA	NA	NA	NA	NA	NA	2727-WA is a clean storage area with the exception of the truck tanker noted above and a buffer area with possibly contaminated wood pallets.
2727-WA-M	Ventilation Filter Contents	None	NA	NA	NA	NA	NA	NA	NA	No ventilation associated with 2727-WA.
2727-WA-M	Contamination In Ventilation System	De-entrainer	NA	NA	NA	NA	NA	NA	NA	No de-entrainer.
2727-WA-M	Contamination In Ventilation System	Seal loop	NA	NA	NA	NA	NA	NA	NA	No seal loops.
2727-WA-M	Contents of Pipeline and/or Source Tank During Transfer	NA	NA	NA	NA	NA	NA	NA	NA	See transfer line Table 7.
2727-WA-M	Contents of Sump or Encasement	None	NA	NA	NA	NA	NA	NA	NA	No sumps or encasements.
2727-WA-M	Contamination in Pit or Box	None	NA	NA	NA	NA	NA	NA	NA	No pits or boxes.
2727-WA-M	SARA 313 Materials	None	NA	NA	NA	NA	NA	NA	NA	NA
2727-WA-O	Other	Unlabeled drum	Unknown	55 gal drum	NA	Unknown	Unknown, up to 55 gallons	Yes	NA	Recently dropped off. Found in the Northwest corner of the fenced area, outside the building.

Table D3.1-1. Material at Risk Table.[1] (94 sheets)

Field Name	MAR-Subject	MAR-Description	MAR-Classification	Capacity	Material Type	Physical Form	Volume or Activity	Transient	Quantity	Comments
2727-WA-O	Other	Gas bottles	Acetylene, oxygen, Ar	480 cubic feet per bottle	NA	Vapor	Four bottles @ 480 cubic feet, max.	Yes	4 bottles, 2 Ar, 1 oxygen, 1 acetylene	Used as a mobile welding unit. Stored behind 2727-WA.
2727-WA-O	Other	Calcium chloride	Calcium chloride	55 gallons	NA	Solid	<55 gallons	Yes	One container	Stored in connex near 2727-WA.
2727-WA-O	Other	Scale clean	Scale clean	55 gallons	NA	Liquid	55 gallons	Yes	One container	Stored in connex near 2727-WA.
2727-WA-O	Other	Dry inhibited acid descier	Dry inhibited acid descier	55 gallons	NA	Solid	<55 gallons	Yes	One container	Stored in connex near 2727-WA.
2727-WA-O	Other	Neutrasorb	Neutrasorb	55 gallons	NA	Liquid	30 gallons	Yes	One container	Stored in connex near 2727-WA.
2727-WA-O	Other	Kenite D.E., celite	Diatomaceous earth	55 gallons	NA	Solid	55 gallons	Yes	One drum	Stored in connex near 2727-WA.
2727-WA-O	Other	Sodium carbonate	Sodium carbonate	110 gallons	NA	Liquid	55 gallons	Yes	One drum	Stored in connex near 2727-WA.
2727-WA-O	Other	Neutracit 2	Caustic neutralizer	165 gallons	NA	Solid	165 gallons	Yes	Three drums	Stored in connex near 2727-WA.
2727-WA-O	Other	Absorbent	Solid absorbent	500 lbs estimated	NA	Solid	About 20 bags, each about 10 lbs	Yes	About 20 bags, each about 10 lbs.	Stored in connex near 2727-WA.
2727-W	Tank Contents	Tank 1	Sodium	About 15,000 gal (12' dia x 21'-3" with dished head)	NA	Solid	300 gal heel	No	NA	Total of 178 tons of sodium remaining in all three tanks.
2727-W	Tank Contents	Tank 2	Sodium	About 15,000 gal (12' dia x 21'-3" with dished head)	NA	Solid	300 gal heel	No	NA	There is 50,503 kg of sodium in this tank. This material was transferred to FFTF. Total of 178 tons of sodium remaining in all three tanks.
2727-W	Tank Contents	Tank 3	Sodium	About 15,000 gal (12' dia x 21'-3" with dished head)	NA	Solid	7500 gal (half full)	No	NA	There is 43,127 kg in this tank. Some of the sodium was removed at FFTF. Total of 178 tons of sodium remaining in all three tanks.

Table D3.1-1. Material at Risk Table.[1] (94 sheets)

Field Name	MAR-Subject	MAR-Description	MAR-Classification	Capacity	Material Type	Physical Form	Volume or Activity	Transient	Quantity	Comments
2727-W	Tank Contents	Tank 4	Sodium	About 15,000 gal (12' dia x 21'-3" with dished head)	NA	Solid	15000 gal (full) 50,855 kg	No	NA	Total of 178 tons of sodium remaining in all three tanks.
2727-W	Tank Contents	Tank 5	Sodium	About 15,000 gal (12' dia x 21'-3" with dished head)	NA	Solid	15000 gal (full) 48,828 kg	No	NA	Total of 178 tons of sodium remaining in all three tanks.
2727-W	Tank Headspace	Tank 1	Nitrogen	NA	NA	Vapor	14700 gal (capacity - contents)	No	NA	Tank headspace filled with nitrogen cover gas.
2727-W	Tank Headspace	Tank 2	Nitrogen	NA	NA	Vapor	14700 gal (capacity - contents)	No	NA	Tank headspace filled with nitrogen cover gas.
2727-W	Tank Headspace	Tank 3	Nitrogen	NA	NA	Vapor	7500 gal (capacity - contents)	No	NA	Tank headspace filled with nitrogen cover gas.
2727-W	Tank Headspace	Tank 4	Nitrogen	NA	NA	Vapor	Minimal	No	NA	Tank headspace filled with nitrogen cover gas.
2727-W	Tank Headspace	Tank 5	Nitrogen	NA	NA	Vapor	Minimal	No	NA	Tank headspace filled with nitrogen cover gas.
2727-W-M	Rail or Truck Tanker Contents	None	NA	NA	NA	NA	NA	NA	NA	No rail or truck tankers associated with sodium storage building.

AR-204	Tank Headspace	Tank 5 - chemical make-up	NA	NA	NA	NA	NA	NA	NA	No data available.
AR-204	Tank Headspace	Underground storage tank	NA	NA	NA	NA	NA	NA	NA	No data available.
AR-204	Rail or Truck Tanker Contents	Railroad tank car	Between 7-14 pH, chloride <0.01 M, no separable organic phase, <0.01 g/gal fissile material	20,000 gal	NA	Liquid	Up to 20,000 gal*	No	NA	Transporting waste from 340 facility. *Railcar just being hooked up during walkdown, exact volume unknown.
AR-204	Rail or Truck Tanker Contents	Tank trailer	Between 7-14 pH, chloride <0.035 M, no separable organic phase, <0.01 g/gal fissile material	5,000 gal	NA	Liquid	Up to 5,000 gal*	No	NA	Waste from 222-S laboratory. Other facilities hope to send waste to 204-AR in the future. *No tank trailer present during walkdown.
AR-204-M	Contamination on Vehicle	See vehicles above	NA	NA	NA	NA	NA	NA	NA	NA
AR-204-M	Contamination on Equipment or Tools	Contaminated equipment (e.g., pumps) in unloading area	Residual contamination	NA	NA	Residue	NA	Yes	NA	NA
AR-204-M	Contamination on Equipment or Tools	Shed with contaminated material	Soiled laundry	NA	NA	Solid	NA	Yes	NA	Located outside building on east side. Shed locked up, not entered during walkdown.
AR-204-M	Ventilation Filter Contents	Primary HEPAs HSG-1 and HSG-2*	NA	1 R/hr at six inches	NA	Particu-late	NA	Yes, filters disposed of in accord with EP-0063, Rev 4 (9/93)	NA	*For main unloading area ventilation system.
AR-204-M	Ventilation Filter Contents	HEPA HSG-3*	NA	1 R/hr at six inches	NA	Particu-late	NA	Yes, filters disposed of in accord with EP-0063, Rev 4 (9/93)	NA	*For catch tank ventilation.

Table D3.1-1. Material at Risk Table.[1] (94 sheets)

Field Name	MAR-Subject	MAR-Description	MAR-Classification	Capacity	Material Type	Physical Form	Volume or Activity	Transient	Quantity	Comments
AR-204-M	Contamination In Ventilation System	Moisture separators	Process condensate	NA	NA	Liquid	NA	No	2 moisture separators	Moisture separators on main unloading area vent system and on catch tank vent system.
AR-204-M	Contamination In Ventilation System	Seal loop	NA	NA	NA	NA	NA	NA	NA	No seal loops identified associated with ventilation system.
AR-204-M	Contents of Pipeline and/or Source Tank During Transfer	NA	NA	NA	NA	NA	NA	NA	NA	See transfer line Table 7.
AR-204-M	Contents of Sump or Encasement	Catch tank pit sump	None*	5 gal (1' x 1' x 8")	NA	NA	None*	NA	NA	*No known spills from catch tank.
AR-204-M	Contamination in Pit or Box	Catch tank pit	None*	3300 gal (6' x 7' x 10'-6")	NA	NA	None*	NA	NA	*No known spills from catch tank.
AR-204-M	SARA 313 Materials	Plastic bottles/jugs of disodium phosphate	Disodium phosphate	20 lbs = max reported in 1995	NA	Solid	20 lbs on 12/19/95	Yes	NA	Not observed on walkdown. Cog unaware of this - no longer used.
AR-204-M	SARA 313 Materials	Bag of sodium hydroxide	Sodium hydroxide, 100%	1100 lbs = max reported in 1995	NA	Solid	650 lbs on 12/19/95	Yes	NA	Not observed on walkdown. Make-up material for sodium hydroxide solution.
AR-204-M	SARA 313 Materials	Sodium hydroxide solution	18.6% sodium hydroxide solution	145 gal = max reported in 1995	NA	Liquid	45 gal on 12/19/95	Yes	NA	Material is located in tank 3 noted above.
AR-204-M	SARA 313 Materials	Sodium nitrite solution	11% sodium nitrite solution	265 gal = max reported in 1995	NA	Liquid	187 gal on 12/19/95	Yes	NA	Material is located in tank 2 noted above.
AR-204-M	SARA 313 Materials	Diesel fuel	Diesel fuel	500 gal	NA	Liquid	500 gal on 1/1/95	No	NA	Material is located in below ground tank, noted above.
AR-204-O	Other	204-AR spill kit	Spill clean-up materials	Small shed*	NA	Solid	NA	Yes	NA	*Small shed behind (North of) 204-AR. Locked, not entered during walkdown.
213 Compactor Bldg	Tank Contents	213-W-TK-1	Believed to be rainwater	1875 gal	NA	Liquid	1875	No	NA	This IMUST is on the non-TWRS owned IMUST list.
213 Compactor Bldg	Tank Headspace	213-W-TK-1	NA	NA	NA	NA	0 gal (tank believed to be full of rainwater)	NA	NA	No available headspace believed present.

Table D3.1-1. Material at Risk Table.[1] (94 sheets)

Field Name	MAR-Subject	MAR-Description	MAR-Classification	Capacity	Material Type	Physical Form	Volume or Activity	Transient	Quantity	Comments
213 Compactor Bldg*	Rail or Truck Tanker Contents	None	NA	NA	NA	NA	NA	NA	NA	No rail or truck tankers associated with 213-W.
213 Compactor Bldg*	Contamination on Vehicle	None	NA	NA	NA	NA	NA	NA	NA	No contaminated vehicles stored in 213-W.
213 Compactor Bldg	Contamination on Equipment or Tools	Possibly contaminated instruments*	NA	Small shelf in work room, all <100 mR/hr	NA	Residue	<100 mH/hr	Yes*	NA	*Possibly contaminated instruments are brought into the work area for repairs. All contamination is low level.
213 Compactor Bldg	Ventilation Filter Contents	HEPA filters for 213-W bldg. ventilation	NA	1 R/hr at six inches	NA	Residue	NA	Yes	4 HEPA filters	Two parallel sets of two HEPAs in series.
213 Compactor Bldg	Ventilation Filter Contents	Breather filter for IMUST (213-W-TK-1)	NA	1 R/hr at six inches	NA	Residue	NA	Yes	NA	Breather filter on IMUST adjacent to 213-W.
213 Compactor Bldg*	Contamination In Ventilation System	De-entrainer	NA	NA	NA	NA	NA	NA	NA	No de-entrainer.
213 Compactor Bldg*	Contamination In Ventilation System	Seal loop	NA	NA	NA	NA	NA	NA	NA	No seal loops.
213 Compactor Bldg	Contents of Pipeline and/or Source Tank During Transfer	NA	NA	NA	NA	NA	NA	NA	NA	See transfer line Table 7.
213 Compactor Bldg*	Contents of Sump or Encasement	None	NA	NA	NA	NA	NA	NA	NA	No sumps or encasements.
213 Compactor Bldg	Contamination in Pit or Box	IMUST pit	Looked empty	About 240 gal (4' x 4' x 2'?)	NA	NA	Looked empty, no warnings of contamination	No	NA	Concrete pit with steel lid. Opened lid on walkdown; could see risers to tank, no evidence of contaminated material in pit.
213 Compactor Bldg*	SARA 313 Materials	None	NA	NA	NA	NA	NA	NA	NA	NA
213 Compactor Bldg	Other	Asphalt emulsion cleaner	Cleaning compound	55 gal drum	NA	NA	Unknown, up to 55 gallons	Yes	NA	Believed to be temporarily stored in building, not used in building.

Table D3.1-1. Material at Risk Table.[1] (94 sheets)

Field Name	MAR-Subject	MAR-Description	MAR-Classification	Capacity	Material Type	Physical Form	Volume or Activity	Transient	Quantity	Comments
213 Compactor Bldg	Other	Chemical cleaners, degreasers*	Solvent cleaners	Small quantities, <1 gal	NA	Liquid	None during walkdown*	Yes	NA	*Chemical cleaners/degreasers may be brought into facility temporarily. None observed during walkdown.
AR-244	Tank Contents	244-AR-001	Unknown*	46,400 gal (20' dia x 19'-9")	NA	Liquid	2300 gal	No	NA	*No data obtained.
AR-244	Tank Contents	244-AR-002	Strontium sludge from tank 104-AX and flush water*	46,400 gal (20' dia x 19'-9")	Liquid Sludge	Liquid Solid	23,000 gal total, believed to be 600 gal of sludge, remainder = liquid* Activity of 200 Ci/gal for the sludge calculated, (196 Ci/gal Sr90 and 3.22 Ci/gal Cs137)	No	NA	*600 gallons of sludge from AX-103 stored in tank 4, word-of-mouth from retired operator recalls transfer of sludge and other liquids in tank 4 to tank 2. Remainder of liquid believed to be water transferred from cell 3 sump, flush water from tank 4, and sump transfers conducted when new filter vault was installed.
AR-244	Tank Contents	244-AR-003	Unknown*	4700 gal (9'-6" dia x 9')	NA	Liquid	2000 gal	No	NA	*No data on tank contents obtained.
AR-244	Tank Contents	244-AR-004	Unknown*	4700 gal (9'-6" dia x 9')	NA	Liquid	<300 gal	No	NA	*600 gallons of sludge from AX-103 stored in tank 4, word-of-mouth from retired operator recalls transfer of sludge and other liquids in tank 4 to tank 2.
AR-244	Tank Contents	Underground fuel tank	Diesel fuel	550 gal	NA	Liquid	525 gal	No	NA	Reading read off level gauge during walkdown.
AR-244	Tank Headspace	244-AR-001	No hydrogen or organics	NA	NA	Vapor	About 44,100 gal (capacity - contents) activity unknown	No	NA	NA
AR-244	Tank Headspace	244-AR-002	0.222 mole % hydrogen	NA	NA	Vapor	About 23,400 gal (capacity - contents) activity unknown	No	NA	NA
AR-244	Tank Headspace	244-AR-003	No hydrogen or organics	NA	NA	Vapor	About 2700 gal (capacity - contents) activity unknown	No	NA	NA

Table D3.1-1. Material at Risk Table.[1] (94 sheets)

Field Name	MAR-Subject	MAR-Description	MAR-Classification	Capacity	Material Type	Physical Form	Volume or Activity	Transient	Quantity	Comments
AR-244	Tank Headspace	244-AR-004	No hydrogen or organics	NA	NA	Vapor	About 4400 gal (capacity - contents) activity unknown	No	NA	NA
AR-244-M	Rail or Truck Tanker Contents	None	NA	NA	NA	NA	NA	NA	NA	No rail or truck tankers associated with 244-AR vault.
AR-244-M	Contamination on Vehicle	None	NA	NA	NA	NA	NA	NA	NA	No contaminated vehicles associated with 244-AR vault.
AR-244-M	Contamination on Equipment or Tools	Contaminated equipment stored in wind reduction facility	NA	62'-8" x 40' x 18' are dimensions of wind reduction facility	NA	Solid	Unknown*	Yes*	NA	*This building contained numerous bags of waste material. Old cameras and other equipment, possibly contaminated have been stored within this building and are currently being sorted out. Four 55 gal drums of material with labels indicating lead were stored at the far west end of the building, actual contents unknown.
AR-244-M	Contamination on Equipment or Tools	Failed equipment in storage tubes	NA	Each 4200 gal (4'-6" dia x 35')	NA	Solids	Unknown*	Yes	NA	*Failed equipment was put in tubes below cover blocks within the canyon. The vault has been in stand-by mode for years. Actual contents of the storage tubes is currently unknown.
AR-244-M	Ventilation Filter Contents	Canyon ventilation filters	NA	NA	NA	Residue	Unknown*	Yes	NA	*The ventilation associated with 244-AR has not been operated since 1993. Some filters have been removed for use in other locations. Most are located in underground vaults (current quantities and activity levels are unknown).

Table D3.1-1. Material at Risk Table.[1] (94 sheets)

Field Name	MAR-Subject	MAR-Description	MAR-Classification	Capacity	Material Type	Physical Form	Volume or Activity	Transient	Quantity	Comments
AR-244-M	Ventilation Filter Contents	Vessel ventilation filters	NA	NA	NA	Residue	Unknown*	Yes	NA	*The ventilation associated with 244-AR has not been operated since 1993. Most filters are located in underground vaults (current quantities and activity levels are unknown).
AR-244	Contamination In Ventilation System	De-entrainer	NA	NA	NA	NA	NA	NA	NA	No de-entrainer associated with ventilation, but liquids are collected in a seal pot.
AR-244	Contamination In Ventilation System	Seal pot	Process condensate	100 gal (2' dia x 4'-1")	NA	Liquid	Unknown*	No	NA	*The ventilation associated with 244-AR has not been operated since 1993. (current quantity and activity level of liquid in seal pot is unknown).
AR-244-M	Contents of Pipeline and/or Source Tank During Transfer	NA	NA	NA	NA	NA	NA	NA	NA	See transfer line Table 7.
AR-244	Contents of Sump or Encasement	Vault cell sumps	NA	25 gal (18" x 18" x 18") estimated	NA	Liquid	2400 gal in cell 3* about 15 gal in cell 1 (wt factor reading of 23) and about 2 gal in cell 2 (Wt. factor reading of 3)	No	One sump in each of the three cells	*Sump has overflowed; liquid in the bottom of the cell.
AR-244	Contamination in Pit or Box	Valve pit	Residual contamination*	1300 gal (4'-6" dia x 11')	NA	Residue	NA	No	NA	*Lines 717 and 716 (drain lines) pass through this valve pit on the way to tanks in the 244 AR vault.

WHC-EP-0063, 1993, Hanford Site Solid Waste Acceptance Criteria, Rev. 4, Westinghouse Hanford Company, Richland, Washington.

CC = complexant concentrate waste.
COB = cleanout box.
DC = dilute complexed waste.
DOT = U.S. Department of Transportation.
FFTF = Fast Flux Test Facility.
HEPA = high-efficiency particulate air (filter).
IMUST = inactive miscellaneous underground storage tank.
MAR = material at risk.
NA = not applicable.
NCAW = neutralized current acid waste.
NCPLX = non-complexed waste.
NHW = neutralized high-level waste.
RCRA = Resource Conservation and Recovery Act of 1976.
RMW = radioactive mixed waste.
SARA = Superfund Amendments and Reauthorization Act of 1986.
SWP = special work procedure (refers to protective clothing worn in radiation zone).
TWRS = Tank Waste Remediation System.

Table D3.2-1. Tank Farm Events, Off-Normal (ON) and Critiques. (11 sheets)

Date	Event #	Event Type	Event Description
1-8-86	86-01	ON	Diesel generator at 244-AR Vault failed, ran out of fuel
1-8-86	86-02	ON	Tank 101-AW pressurized after transfer, reason unknown
1-9-86	86-03	ON	Tank 101-AW slurry distributor plugged during transfer.
1-16-86	86-06	ON	Valve AX-B-15 leaked, allowing AY-102 to AW-102 transfer to enter AN-101.
1-23-86	86-07	ON	Failure to shutdown AY-102 annulus ventilation when required during transfer, @ minimum level.
2-2-86	86-10	ON	AY and AZ tanks pressurized due to primary and backup exhauster failure.
2-6-86	86-11	ON	204-AR 702 leak detector switch mislabeled, improperly bypassed. Transfer stopped due to bypass signal.
2-7-86	86-12	ON	Inst. technician proceeded with work w/o approval, caused exhauster to shutdown. 241-A control room.
2-11-86	86-13	ON	Primary exhauster shutdown, backup failed. Portable backup started, over-pressurized AY and AZ tanks.
3-28-86	86-14	ON	701-SX air compressor oil line ruptured, spraying oil causing smoke. Smoke detector tripped.
7-22-87	86-15	ON	152-AX catch tank level limit exceeded. Deentrainer flush valve left open.
2-25-86	86-16	ON	Primary exhauster shutdown, backup failed. Portable exhauster started, then backup started. 101-AZ tank pressurized.
2-25-86	86-17	ON	Primary exhauster shutdown, backup failed. Six AW tanks pressurized.
3-3-86	86-18	ON	SY-101 tank burp. Pressurized SY-101 & 103.
11-18-86	86-19	ON	241-AW annulus exhauster fan failed, loose blade caused hole in housing.
1-17-87	86-20	ON	Tank 106-AW pressurized during slurry transfer.
3-26-86	86-21	ON	Tank 105-AW pressurized during PUREX E-5 transfers. (4 times)
4-9-86	86-22	ON	Primary exhauster shutdown, backup failed. AY and AZ tanks pressurized.
4-8-86	86-24	ON	244-AR backup air compressor failed on loss of oil. Primary compressor had failed.
1-17-87	86-25	ON	241-AW primary & annulus exhauster failure. AW tanks pressurized.
1-21-87	86-27	ON	241-AW portable exhauster failed during primary exhauster maintenance. AW tanks pressurized.
6-30-86	86-29	ON	102-AW pressurized due to sump jet air DOV leak-through.
7-21-86	86-31	ON	Power shut off to 241-AN tank farm. Operations notified 30 days prior, but not at the time.
7-21-86	86-32	ON	271-AN air conditioner repair tripped building power off.
7-23-86	86-33	ON	241-AW portable exhauster fail, would not restart. AW tanks pressurized.
8-7-86	86-35	ON	Backup exhauster failed to start on test. AZ tanks pressurized.
1-17-87	86-36	ON	102-AW tank pressurized during transfer, pressure instruments valved out.
9-17-86	86-38	ON	241-AW Raw water service pit strainer leaked 850 gallons due to improper size of hold down lid.
10-3-86	86-41	ON	AY & AZ farm steam diverter valve stuck during test, flow to 216-A-08 crib.
10-7-86	86-45	ON	AN farm air compressor failed causing loss of air to farm instruments.
11-7-86	86-49	ON	AZ farm airlift circulators shutdown too long. (out for test)
12-1-86	86-52	ON	Tank 101-AZ below minimum level requirement.
1-17-87	86-53	ON	Raw water filter drain left open, filled seal loop, allowed pressurization of AY tanks.

Table D3.2-1. Tank Farm Events, Off-Normal (ON) and Critiques. (11 sheets)

Date	Event #	Event Type	Event Description
11-29-86	86-54	ON	Electrical outage at 200-East farm, AN, AP, and AW tanks pressure alarms activated.
12-1-86	86-55	ON	Power supply tripped to AP farm, tripped vent systems. Tanks pressurized.
12-1-86	86-56	ON	I-129 emissions from AW exhauster exceeding yearly guidelines.
12-9-86	86-58	ON	216-Z-20 crib level at 36", exceeding vapor barrier @ 30". Insufficient infiltration rate.
7-3-87	WHC-C-87-008	Critique	Four personnel had irritated nose and throats due to breathing in 241-C farm.
8-25-87	WHC-C-87-057-TF-03	Critique	Failure to take vacuum readings in SX farm. No vacuum gauge to read.
1-14-88	WHC-C-88-035-TF01	Critique	Water in crib 216-U-17 riser before crib startup.
2-1-88	WHC-C-88-048-TF-02	Critique	Elevated Ruthenium-106 effluent from 241-AP farm exhaust.
5-21-88	WHC-C-88-105-TF-05	Critique	Contamination spread from 241-S farm while washing sludge to pit drain.
7-14-88	WHC-C-88-118-TF-06	Critique	Liquid observation well failure, resulting contamination spread.
8-2-88	WHC-C-88-128-TF-07	Critique	241-SY exhauster failure, tanks pressurized. Pressure alarms failed.
9-12-88	WHC-C-88-132-TF-08	Critique	Crib 216-S-26 not handling 222-S flows. Level rising.
9-19-88	WHC-C-88-161-TF-09	Critique	101-SY exceeded level increase criteria.
12-10-88	WHC-C-88-185-TF-10	Critique	Misrouted condensate from A-417 to 101-AZ tank, instead of 102-AY receiver tank.
3-22-89	WHC-C-89-54-TF-02	Critique	Weight factor and radiation levels exceed criteria in 101-AX leak detection pit.
4-30-89	WHC-C-89-55-TF-03	Critique	Weight factor and radiation levels exceed criteria in 102-AZ leak detection pit.
9-28-89	WHC-C-89-106-TF-08	Critique	Employee felt ill after walking by AP farm. Assumed ammonia inhalation.
10-27-89	WHC-C-89-117-TF-09	Critique	241-AZ vent header found to contain cracks through the wall.
9-14-90	WHC-TANKFARM-1990-54	ON	1500 gallon leak through open raw water valve to 244-BX DCRT.
10-1-90	WHC-TANKFARM-1990-102	ON	241-AN annunciator panel power loss, loss of alarm capabilities for AN farm.
10-11-90	WHC-TANKFARM-1990-134	ON	Level decrease in tank C-103. Assumed evaporation.
10-19-90	WHC-TANKFARM-1990-162	ON	One acre of land along Powerhouse ditch found contaminated.
10-24-90	WHC-TANKFARM-1990-173	ON	101-SY vents through crust and level drops.
10-24-90	WHC-TANKFARM-1990-181	ON	Employee smoking, eating and drinking in radiation zone, 271-SY-241 instrument building.
11-04-90	WHC-TANKFARM-1990-205	ON	244-BX flush-pit valve leak adds 700 gallons to 244-BX DCRT.
11-11-90	WHC-TANKFARM-1990-219	ON	242-A Monitoring and Control System failed. No monitoring of some East Area alarms.
11-13-90	WHC-TANKFARM-1990-223	ON	Portable exhauster monitoring failure on tank C-106. Stack effluent not monitored.
12-4-90	WHC-TANKFARM-1990-291	ON	Liquid level increase in 241-BY-10. Assumed crystal growth.
12-10-90	WHC-TANKFARM-1990-315	ON	Radiation readings under tanks A-101, 102, & 105 not taken.
12-19-90	WHC-TANKFARM-1990-346	ON	AW farm backup exhaust fan failed to start as required. High pressure in tank farm.
12-20-90	WHC-TANKFARM-1990-352	ON	Frozen water pipe in 244-TX instrument building ruptured and leaked into 244-TX DCRT. (700 gallons)
12-22-90	WHC-TANKFARM-1990-373	ON	Frozen water line in 244-BX instrument building ruptured and leaked into 244-BX DCRT. (550 gallons)

Table D3.2-1. Tank Farm Events, Off-Normal (ON) and Critiques. (11 sheets)

Date	Event #	Event Type	Event Description
12-23-90	WHC-TANKFARM-1990-376	ON	Raw water valve in 244-TX service pit ruptured due to freezing, leaked 1750 gallons into 244-TX DCRT.
1-1-91	WHC-TANKFARM-1991-001	ON	244-AR steam leak tripped fire alarm.
1-11-91	WHC-TANKFARM-1991-32	ON	241-AW primary exhaust fan restarted during testing, while personnel near by. "Near-miss" injury.
1-15-91	WHC-TANKFARM-1991-43	ON	702-A exhauster shutdown, standby fan out-of-service. Portable fan started, air-lift circulators stopped. (AY and AZ tanks)
1-23-91	WHC-TANKFARM-1991-72	ON	Portable air compressor failure causes loss of inst. air at 244-AR vault.
1-23-91	WHC-TANKFARM-1991-74	ON	Above ground sensing line failed causing 101-AY high pressure alarm.
1-26-91	WHC-TANKFARM-1991-82	ON	Broken water line in BY-302 compressor building causes fire alarm.
1-28-91	WHC-TANKFARM-1991-85	ON	Annunciator panel failure @ 271-AP caused loss of AP tank farm alarms.
2-16-91	WHC-TANKFARM-1991-141	ON	101-SY pressure increased and level decreased due to venting.
2-28-91	WHC-TANKFARM-1991-175	ON	Sanitary water system underground leaks in 241-BY farm.
3-13-91	WHC-TANKFARM-1991-203	ON	101-SY hydrogen monitor vacuum pump failure.
3-14-91	WHC-TANKFARM-1991-206	ON	SX-106 liquid level increase beyond limit.
3-21-91	WHC-TANKFARM-1991-226	ON	241-AP primary exhauster failed causing pressurization in 105-AP tank.
4-8-91	WHC-TANKFARM-1991-1003	ON	241-A warm water sump level control out-of-service, not calibrated for four years.
4-9-91	WHC-TANKFARM-1991-1004	ON	241-A evacuation due to valving out instrument air line during maintenance.
4-9-91	WHC-TANKFARM-1991-1005	ON	TY-104 and 105 failed breather filters not replaced within time limit due to windy conditions.
4-23-91	WHC-TANKFARM-1991-1010	ON	244-AR stack CAM and record sampler vacuum pumps out-of-service.
4-30-91	WHC-TANKFARM-1991-1011	ON	Compressor failure causes loss of exhausters at 242-S and high pressure alarm at 102-SY tank.
5-16-91	WHC-TANKFARM-1991-1013	ON	High pressure alarm due to venting in 101-SY.
6-4-91	WHC-TANKFARM-1991-1018	ON	S-302-A catch tank level increase due to hose leak into diversion box. (90 gallons)
6-18-91	WHC-TANKFARM-1991-1019	ON	Control room unmanned during pumping of 102 and 109-BY tanks.
6-19-91	WHC-TANKFARM-1991-1020	ON	216-S-26 crib level 6" above limit.
6-21-91	WHC-TANKFARM-1991-1022	ON	241-BY drywells high radiation readings during 102 and 109-BY transfers.
6-22-91	WHC-TANKFARM-1991-1023	ON	Portable compressor seized, high pressure alarms tripped at 241-AW farm.
6-29-91	WHC-TANKFARM-1991-1026	ON	Power lost to 200-East Area during electrical storm.
7-16-91	WHC-TANKFARM-1991-1028	ON	Employee contaminated while taking liquid level readings at 152-AX.
8-6-91	WHC-TANKFARM-1991-1031	ON	Momentary power loss to 200-East and West Areas.
8-23-91	WHC-TANKFARM-1991-1035	ON	Many waste tank FIC instruments are out-of-service, they are not a priority item for maintenance.
8-26-91	WHC-TANKFARM-1991-1036	ON	Failure to obtain tank AN-103 level reading as required.
8-30-91	WHC-TANKFARM-1991-1037	ON	Water valve left open at 244-TX spilling 600 gallons on the ground.
9-6-91	WHC-TANKFARM-1991-1038	ON	Three employees reported vapor inhalation in 103-C farm.
9-16-91	WHC-TANKFARM-1991-1043	ON	Construction worker reported inhaling an unknown vapor in 241-C farm.
9-19-91	WHC-TANKFARM-1991-1045	ON	Failure to take liquid level reading at TK-003-CR vault.
10-4-91	WHC-TANKFARM-1991-1051	ON	Exceeded two-year limit on tank BX-104 dome deflection survey.
10-22-91	WHC-TANKFARM-1991-1054	ON	Tank 244-CR-003 Ph readings too low hydroxide concentration.

Table D3.2-1. Tank Farm Events, Off-Normal (ON) and Critiques. (11 sheets)

Date	Event #	Event Type	Event Description
11-12-91	WHC-TANKFARM-1991-1061	ON	Review determined that 88 tanks were not being monitored for temperature as required for non-watchlist tanks.
11-22-91	WHC-TANKFARM-1991-1065	ON	Tank 101-SY calculated heat loading exceeded OSD limits.
11-26-91	WHC-TANKFARM-1991-1067	ON	Front-end loader backed into and broke a thermocouple riser at T-108 tank.
11-28-91	WHC-TANKFARM-1991-1068	ON	AY-102 level increased during transfer from 244-CR-003 to AY-101.
12-4-91	WHC-TANKFARM-1991-1069	ON	101-SY level decrease and pressurization during tank venting.
12-4-91	WHC-TANKFARM-1991-1070	ON	76 counts per second spike found when lateral radiation scan completed on tank 103-A.
12-5-91	WHC-TANKFARM-1991-1071	ON	55 gallon drum exceeded requirements for 90-day storage.
12-6-91	WHC-TANKFARM-1991-1072	ON	Liquid level limit exceed for tank AN-103.
12-7-91	WHC-TANKFARM-1991-1074	ON	Water leak into AY service water pit during airlift circulator flush.
12-10-91	WHC-TANKFARM-1991-1075	ON	Employee exceeded weekly radiation exposure limit working in 151-S diversion box.
12-17-91	WHC-TANKFARM-1991-1077	ON	241-AN exhauster shutdown, attempts to start fans failed. Seven tanks had static flow for two hours.
12-20-91	WHC-TANKFARM-1991-1078	ON	Sample bottle exceeded 90-day storage requirement.
12-26-91	WHC-TANKFARM-1991-1082	ON	Data on 1-7-AN annulus leak detection record copied from previous shift. No new report recorded.
12-31-91	WHC-TANKFARM-1991-1085	ON	Air compressor failure leads to 241-SX exhauster shutdown.
1-1-92	WHC-TANKFARM-1992-01	ON	Truck at 241-TX farm picked up tumbleweeds on carriage, tumbleweeds ignited.
1-6-92	WHC-TANKFARM-1992-03	ON	Both leak detector systems for SY-101 lost. Probe failed while CAM was out-of-service.
1-24-92	WHC-TANKFARM-1992-09	ON	During a transfer line hydro test in 241-S farm, water leaked and drained into valve pit.
1-24-92	WHC-TANKFARM-1992-10	ON	C-105 and 106 exhauster failed.
2-25-92	WHC-TANKFARM-1992-15	ON	SX farm exhauster shutdown due to portable compressor shutdown when it ran out of fuel.
2-25-92	WHC-TANKFARM-1992-16	ON	Engineer tracing annunciator wires tripped airlift circulator alarm and farm high pressure alarm.
2-28-92	WHC-TANKFARM-1992-20	ON	While fueling a portable compressor at 241-BY, fuel was spilled on the ground.
2-28-92	WHC-TANKFARM-1992-23	ON	244-TX receiver tank over-filled due to bad instrumentation.
3-6-92	WHC-TANKFARM-1992-25	ON	Tank C-100 inadvertently transferred to 102-AW.
3-10-92	WHC-TANKFARM-1992-26	ON	DANGER tag at SY farm cleared without proper authorization.
3-24-92	WHC-TANKFARM-1992-29	ON	Operator backed a van into a riser and punctured the gas tank. Spilled fuel onto the ground.
4-2-92	WHC-TANKFARM-1992-31	ON	Hazardous substance in railcar not pumped at 204-AR within time limits.
4-20-92	WHC-TANKFARM-1992-32	ON	101-SY gas venting, level decreased about 9 inches.
4-29-92	WHC-TANKFARM-1992-36	ON	Transformer failure interrupts 241-S farm leak detection and level monitoring instruments.
5-14-92	WHC-TANKFARM-1992-40	ON	Transfer line SL-116 in 241-S farm, failed hydro test, leak sprayed out heat trace conduit.
5-14-92	WHC-TANKFARM-1992-41	ON	Small animals tracked contamination along the fence line of 241-AY farm.
6-10-92	WHC-TANKFARM-1992-45	ON	Attempting to hydro test transfer line SL-115, 200 gallons more than the calculated line holdup was added. Assume line failed.
6-12-92	WHC-TANKFARM-1992-46	ON	Attempted to hydro test transfer line SN-215, line did not hold pressure for 30 seconds. Assume line failed.
6-18-92	WHC-TANKFARM-1992-49	ON	Failure to comply with lock and tag requirements doing work in 241-TX farm.

Table D3.2-1. Tank Farm Events, Off-Normal (ON) and Critiques. (11 sheets)

Date	Event #	Event Type	Event Description
7-15-92	WHC-TANKFARM-1992-54	ON	Transfer made through diversion box which drains to catch tank A-302-A which level above 50%. Exceeded level limit.
7-20-92	WHC-TANKFARM-1992-56	ON	105/106-C exhauster CAM failed efficiency test due to moisture inside CAM.
7-28-92	WHC-TANKFARM-1992-57	ON	Improper installation of cryogenic vacuum pump on tank 103-C. Samples invalid because of pump location.
8-21-92	WHC-TANKFARM-1992-58	ON	Personnel entered SX farm without proper respiratory protection.
8-20-92	WHC-TANKFARM-1992-60	ON	High level of contamination in Liquid Observation Well in 104-SX tank.
9-3-92	WHC-TANKFARM-1992-63	ON	Increased pressure and decreased level during venting of 101-SY tank.
9-10-92	WHC-TANKFARM-1992-64	ON	101-SY venting seemed to have broken off one of four air lances in tank.
8-14-92	WHC-TANKFARM-1992-65	ON	Increased radiation readings in 241-C drywell.
9-19-92	WHC-TANKFARM-1992-67	ON	Lock and tag cleared from tank farm without proper authorization.
9-25-92	WHC-TANKFARM-1992-70	ON	Personnel contamination from working in 241-SY farm.
9-30-92	WHC-TANKFARM-1992-72	ON	During 106-AN to 102-AP transfer, 102-AW level increased. 3575 gallon discrepancy in tank level.
10-6-92	WHC-TANKFARM-1992-76	ON	Thermocouple tree stuck, then bent and broken while removing it from 101-SY.
10-7-92	WHC-TANKFARM-1992-77	ON	Unauthorized pressure increase needed to remove thermocouple tree from 101-SY tank.
10-19-92	WHC-TANKFARM-1992-78	ON	SX-103 level decrease exceeded limits.
10-19-92	WHC-TANKFARM-1992-79	ON	Seven deteriorated waste bags found in 241-S farm. Some broken and spilled on ground.
10-21-92	WHC-TANKFARM-1992-83	ON	AW-101 pressurization and level decrease. Tank placed on flammable gas watchlist.
11-6-92	WHC-TANKFARM-1992-85	ON	Aging waste temperature readings not taken because the data sheet was missing.
10-9-92	WHC-TANKFARM-1992-86	ON	SX-105 level decrease exceeded limits. Assume evaporation is cause.
10-22-92	WHC-TANKFARM-1992-87	ON	Procedure compliance deficiencies during 107-C vapor sampling.
12-3-92	WHC-TANKFARM-1992-88	ON	Personnel contamination during excavation in 241-SY tank farm.
12-8-92	WHC-TANKFARM-1992-90	ON	Periodic higher than normal radiation readings on AN-107 annulus CAM.
1-7-93	WHC-TANKFARM-1993-02	ON	Personnel contamination during piping grinding operation in 241-SY excavation.
1-13-93	WHC-TANKFARM-1993-06	ON	Packaged air lances in 241-SY farm exceeded 120-day storage limit.
1-15-93	WHC-TANKFARM-1993-08	ON	Transfer from 204-AR to 101-AY failed due to frozen jumpers in path.
1-21-93	WHC-TANKFARM-1993-10	ON	Air lance package leakage while in 241-SY farm.
1-26-93	WHC-TANKFARM-1993-14	ON	Transfer from 204-AR railcar to 101-SY made. Some of flow ended up in 102-AY.
2-2-93	WHC-TANKFARM-1993-16	ON	Pressurization and level decrease resulting from 101-SY venting.
2-1-93	WHC-TANKFARM-1993-17	ON	Fire in waste drum in 241-T due to welding activity catching paper towels on fire.
2-2-93	WHC-TANKFARM-1993-18	ON	204-AR ventilation fan failure, failed to re-start manually.
1-28-93	WHC-TANKFARM-1993-19	ON	Ammonia-like odor in 241-T farm.
2-4-93	WHC-TANKFARM-1993-20	ON	242-A circuits deenergized for modifications, control valve opened allowing raw water flow to 106-AW tank.
2-5-93	WHC-TANKFARM-1993-21	ON	Service water valve left open after flushing in 241-AX, caused unaccounted for raw water usage.

Table D3.2-1. Tank Farm Events, Off-Normal (ON) and Critiques. (11 sheets)

Date	Event #	Event Type	Event Description
2-12-93	WHC-TANKFARM-1993-24	ON	202-B tank level increase limit exceeded.
2-22-93	WHC-TANKFARM-1993-25	ON	Tank T-101 pumping schedule not met.
2-24-93	WHC-TANKFARM-1993-26	ON	Attempt to install shield plug in 101-SY riser found riser was not symmetrical. Mixer pump will have to be modified to fit in riser.
3-8-93	WHC-TANKFARM-1993-29	ON	Ammonia-like odors from 241-SY farm.
3-10-93	WHC-TANKFARM-1993-30	ON	Failure to return 104-BY ventilation system to service after testing. O.O.S. from Feb. 24 to Mar. 4.
3-17-93	WHC-TANKFARM-1993-31	ON	Aging waste ventilation system recirc. pump out-of-service, but not tagged out.
1-18-93	WHC-TANKFARM-1993-36	ON	103-BX level increase exceeded level criteria.
4-7-93	WHC-TANKFARM-1993-38	ON	Ammonia-like odors from 241-BX farm.
4-21-93	WHC-TANKFARM-1993-40	ON	102-T core sample casks uncontrolled.
5-10-93	WHC-TANKFARM-1993-47	ON	Raw water leak to ground at 107-C during and after raw water line pressure test.
5-24-93	WHC-TANKFARM-1993-49	ON	241-AP in-service exhauster heater breaker found open.
5-25-93	WHC-TANKFARM-1993-50	ON	Raw water valve left open after maintenance, puddle formed over 102-BY tank. Check valve failed, 3442 gallons spilled.
6-17-93	WHC-TANKFARM-1993-55	ON	Operator smelled foul odor in at 101-A, resulted in headache and dry throat.
6-26-93	WHC-TANKFARM-1993-58	ON	101-SY pressurized and level decrease during venting.
7-14-93	WHC-TANKFARM-1993-62	ON	Portable exhauster supporting 241-SY farm shutdown. Primary exhauster out-of-service. Tripped high pressure alarm.
7-29-93	WHC-TANKFARM-1993-65	ON	Work done on ferrocyanide and organic watchlist tank (TX-118) without electrically bonded tools.
7-31-93	WHC-TANKFARM-1993-68	ON	Unexplained raw water usage after flush of 241-AZ airlift circulators. 665 gallons unaccounted for.
8-8-93	WHC-TANKFARM-1993-70	ON	Attempt to start primary exhauster and shutdown backup exhauster results in high pressure alarm, 241-AN farm.
8-10-93	WHC-TANKFARM-1993-71	ON	Attempting to check for un unplugged drain, a rock was tied to a rope and lowered into open nozzle in tank. Contaminated personnel.
8-12-93	WHC-TANKFARM-1993-73	ON	Administrative hold on tank farm work was imposed due to lapses in management and employee accountability.
8-14-93	WHC-TANKFARM-1993-74	ON	Requirement exceeded for taking pressure readings in 241-SX farm.
8-16-93	WHC-TANKFARM-1993-75	ON	Personnel cut off tip of finger while changing nitrogen bottles in 241-SY farm.
8-17-93	WHC-TANKFARM-1993-76	ON	Personnel backed van into riser in 241-S farm. Ruptured fuel tank under van.
8-22-93	WHC-TANKFARM-1993-77	ON	Personnel failed to abort 101-SY mixer pump test when indicator failed.
8-26-93	WHC-TANKFARM-1993-78	ON	On numerous occasions the temperature data for watchlist tanks was not taken.
8-27-93	WHC-TANKFARM-1993-79	ON	101-SY tank atmosphere was pressurized momentarily after mixer pump operation.
9-2-93	WHC-TANKFARM-1993-81	ON	Personnel experienced headache and sore throat from unusual odors from 241-TX farm.
9-6-93	WHC-TANKFARM-1993-83	ON	Aging waste tank farm pressure recorder out of paper, violating an Operational Safety Requirement.
9-7-93	WHC-TANKFARM-1993-84	ON	Unexplained raw water usage in 241-AX farm.
9-26-93	WHC-TANKFARM-1993-88	ON	Continuous air monitor at 241-AY and AZ farm (Aging waste) failed.
10-25-93, 11-2-93	WHC-TANKFARM-1993-93	ON	Rollover of 101-SY tank waste caused shutdown of mixer pump due to high pressure trip. (2 occasions)
11-16-93	WHC-TANKFARM-1993-98	ON	241-SX sludge cooler exhauster operating with a vacuum beyond limits.

Table D3.2-1. Tank Farm Events, Off-Normal (ON) and Critiques. (11 sheets)

Date	Event #	Event Type	Event Description
11-23-93	WHC-TANKFARM-1993-100	ON	Low dP alarm for 241-SY exhauster second stage HEPA filter found disabled.
4-13-93	WHC-TANKFARM-1993-102	ON	241-SY ventilation filters not tested within 72 hours of maintenance, as required.
11-30-93	WHC-TANKFARM-1993-103	ON	Waste tank level requirement changed, 101-AW level exceeds new limit of 416".
12-2-93	WHC-TANKFARM-1993-106	ON	18-inch clay pipe discovered within the 110 foot buffer zone in 241-T farm. Pipe installed in 1943.
12-3-93	WHC-TANKFARM-1993-110	ON	Potential USQ concerning T-111 core samples containing uncharacterized reactive components.
12-10-93	WHC-TANKFARM-1993-111	ON	East/West vent station catch tank level limit exceeded.
12-6-93	WHC-TANKFARM-1993-112	ON	Lock and tag violation on electrical plug in DACS trailer in 241-SY farm.
12-15-93	WHC-TANKFARM-1993-114	ON	241-C farm breathing air carbon monoxide alarm trip due to sampling truck running next to compressor intake.
12-16-93	WHC-TANKFARM-1993-115	ON	U-107 tank added to flammable gas watchlist.
1-8-94	WHC-TANKFARM-1994-01	ON	Transfer not aborted as required when leak detector tripped.
1-26-94	WHC-TANKFARM-1994-04	ON	AN-105 annulus continuous air monitor removed from service without invoking surveillance as required.
1-27-94	WHC-TANKFARM-1994-05	ON	Failure to install required alarms in DCRTs.
2-1-94	WHC-TANKFARM-1994-06	ON	Steam trap failure in 241-SX farm causes steam plume.
2-10-94	WHC-TANKFARM-1994-07	ON	Primary ventilation lost at 241-AN farm for one hour. Pressures reached atmospheric, but did not go higher.
2-11-94	WHC-TANKFARM-1994-08	ON	Lack of filter paper in alpha radiation detector and faulty microswitch caused exhauster to trip in 241-SY farm. Portable exhauster started.
3-10-94	WHC-TANKFARM-1994-14	ON	Missed filter differential pressure readings in 241-AW and AP tank farms.
4-27-94	WHC-TANKFARM-1994-23	ON	Spurious shutdown signal at evaporator caused 2000 gallons of waste to dump back into 102-AW.
5-16-94	WHC-TANKFARM-1994-027	ON	East/West vent station catch tank level exceeded limit.
5-4-94	WHC-TANKFARM-1994-29	ON	Sample supporting line broke allowing sampling device to fall into 107-AN riser.
6-3-94	WHC-TANKFARM-1994-33	ON	Electrically "hot" taped wires touched terminal strip housing causing a breaker trip that tripped 241-AP primary exhauster. High pressure alarm tripped.
6-9-94	WHC-TANKFARM-1994-34	ON	Lock and danger tag on 101-SY mixer pump breaker left unlocked.
7-5-94	WHC-TANKFARM-1994-38	ON	Steam heat not returned to service after 241-SY exhauster maintenance.
8-5-94	WHC-TANKFARM-1994-40	ON	Electrical utilities severed power cable, lost ventilation in AN, AP, AW, and C farms, and 244-BX and 244-CR.
8-8-94	WHC-TANKFARM-1994-42	ON	Truck driver drove under steam line near 103-SY tank, striking steam line and knocking off insulating material.
8-19-94	WHC-TANKFARM-1994-45	ON	Feeder breaker to 241-AN farm opened, tripping both primary and annulus ventilation fans. Pressurized waste tanks.
8-19-94	WHC-TANKFARM-1994-46	ON	The Ph values for 102-AY and 104-AP samples were below 12. Hydroxide concentrations too low.
8-19-94	WHC-TANKFARM-1994-47	ON	106-S liquid level float missing, wire had corroded after being installed only two months.
8-25-94	WHC-TANKFARM-1994-48	ON	244-CR vault fan #2 out for repair, fan #1 removed from service due to vibration problems. Loss of both fans violates OSD requirements.
9-13-94	WHC-TANKFARM-1994-49	ON	241-SY continuous air monitor tripped and fan shutdown when testing. Procedure did not include trip bypass step. Tanks pressurized due to fan shutdown.
10-1-94	WHC-TANKFARM-1994-55	ON	241-AW primary ventilation shutdown, could not be restarted. Loss of confinement in farm.

Table D3.2-1. Tank Farm Events, Off-Normal (ON) and Critiques. (11 sheets)

Date	Event #	Event Type	Event Description
10-4-94	WHC-TANKFARM-1994-57	ON	101-AW tank had gas release event. Tank pressure increased, hydrogen concentration increased, and level decreased. Tank is on hydrogen watchlist.
10-26-94	WHC-TANKFARM-1994-59	ON	Transfer line SL-503 failed during transfer from 204-AR to 102-AY. Tripped leak detector in sluice pit on tank 102-AY.
11-2-94	WHC-TANKFARM-1994-60	ON	Excavators in 241-SY farm discovered, and subsequently punched a hole in the top of, an underground tank they did not know was there.
11-2-94	WHC-TANKFARM-1994-62	ON	During saltwell pumping of 109-BY a high radiation dose rate existed. Saltwell pump discharge also developed a leak.
11-16-94	WHC-TANKFARM-1994-64	ON	101-BX manual tape level readings not taken due to airborne activity in area.
12-8-94	WHC-TANKFARM-1994-67	ON	Main control power breaker tripped at 241-AN. Primary and annulus exhausters shutdown.
12-27-94	WHC-TANKFARM-1994-73	ON	104-SX LOW readings showed 102% of LFL and ammonia >700 PPM. Stopped work in area.
12-28-94	WHC-TANKFARM-1994-74	ON	106-AW exhaust isolation valve closed to watch position indicator. Pressurization alarm tripped.
12-29-94	WHC-TANKFARM-1994-75	ON	This occurrence covers many discoveries of suspect parts. Including 56 bolts in 241-U farm.
1-18-95	WHC-TANKFARM-1995-07	ON	241-SY portable exhauster shutdown while HPT was testing continuous air monitor. Primary system out-of service.
1-20-95	WHC-TANKFARM-1995-08	ON	Potential environmental regulatory deficiency exists due to unknown status of Miscellaneous Underground Storage Tanks.
1-26-95	WHC-TANKFARM-1995-11	ON	Rotary Mode Core Sampler was operated in an unapproved manner ("bumped" while in push mode) while sampling BY-106.
2-1-95	WHC-TANKFARM-1995-13	ON	Personnel failed to wear correct dosimetry (finger rings) while in 106-C sluice pit.
2-15-95	WHC-TANKFARM-1995-14	ON	Rotary Mode Core Sampler operated without proper detector in service.
2-17-95	WHC-TANKFARM-1995-15	ON	Electrical utilities personnel tripped off electrical power to East/West Areas while installing a microwave transfer trip.
2-22-95	WHC-TANKFARM-1995-16	ON	Installation of new level instrument in 104-AP resulted in current level indication below limit.
2-23-95	WHC-TANKFARM-1995-17	ON	Incorrect valve locked out in 241-TX, to replace air dryer and regulating valve.
1-30-95	WHC-TANKFARM-1995-18	ON	Tank B-103 breather filter isolated from tank by drywell. Tank in contact through other tanks in cascade.
2-13-95	WHC-TANKFARM-1995-20	ON	Propylene glycol leaked from the Rotary Mode Core Sampler truck causing an electrical short and resulted in a fire.
3-7-95	WHC-TANKFARM-1995-22	ON	Caution tag hung in 241-AN farm without authorization signature.
3-7-95	WHC-TANKFARM-1995-23	ON	Transfer from 204-AR to 102-AY leaked into A-350 catch tank, leak in 241-A-A pit nozzle.
3-13-95	WHC-TANKFARM-1995-26	ON	241-T farm breather filter valve discovered in the closed position.
3-16-95	WHC-TANKFARM-1995-27	ON	In preparation for taking a vapor sample from S-111, a valve that was "danger" tagged out for another job was opened.
3-24-95	WHC-TANKFARM-1995-31	ON	General operating condition; potential environmental regulatory deficiency: failure to remove liquids from catch tanks in a timely manner.
3-30-95	WHC-TANKFARM-1995-34	ON	WHC lock and tag removed from S-111 valves, but ICF KH locks and tags still hung. Violation of procedure.
3-29-95	WHC-TANKFARM-1995-35	ON	Auger rod incorrect length for C-101 auger sampling.
4-4-95	WHC-TANKFARM-1995-36	ON	Aging waste facility stack CAM functional test not completed within time limit.
4-11-95	WHC-TANKFARM-1995-39	ON	Rotary mode core sampling truck energized by 120 volts due to incorrect wiring. (no injuries occurred)
4-12-95	WHC-TANKFARM-1995-40	ON	Work done on TY-104 without using bonded tools as required.

Table D3.2-1. Tank Farm Events, Off-Normal (ON) and Critiques. (11 sheets)

Date	Event #	Event Type	Event Description
4-13-95	WHC-TANKFARM-1995-41	ON	Leak found by 244-A camera crew during B Plant transfer.
4-26-95	WHC-TANKFARM-1995-42	ON	Failure to meet weekly readings requirement for S-108 liquid observation well.
5-3-95	WHC-TANKFARM-1995-44	ON	241-AW pressurization alarm occurred during camera installation in 106-AW central pump pit.
5-2-95	WHC-TANKFARM-1995-45	ON	Subcontractor employee unescorted in 241-TX farm. Violated radiological controls.
5-6-95	WHC-TANKFARM-1995-47	ON	Rotary mode core sampling truck shielded receiver bent due to transversing the drilling rig while the receiver was in the stored position.
5-24-95	WHC-TANKFARM-1995-49	ON	Sampling done in U-103 tank without using the required bonded tools.
5-30-95	WHC-TANKFARM-1995-50	ON	Energized electrical wire struck during hand excavation near 102-AZ tank.
6-16-95	WHC-TANKFARM-1995-52	ON	Discovery of drug contraband in 241-SX instrument shack.
6-16-95	WHC-TANKFARM-1995-53	ON	Failure of mechanical interlock switches allowed rotation of rotary mode core sampler platform beyond design limits.
6-29-95	WHC-TANKFARM-1995-54	ON	242-T isolated, monitoring discontinued. Monitoring requirements were not changed, so discontinuing the monitoring violated the requirements.
5-15-95	WHC-TANKFARM-1995-56	ON	241-AW lockout installed without proper signature authorization.
7-25-95	WHC-TANKFARM-1995-64	ON	241-SY stack CAM high radiation alarm would not alarm on high radiation.
8-3-95	WHC-TANKFARM-1995-65	ON	Personnel exceeded weekly exposure limit working at BY-105.
8-4-95	WHC-TANKFARM-1995-66	ON	Rotary mode core sampler unable to retrieve complete sample from BY-108 due to failure to install the waste collection sampler in drill string.
8-7-95	WHC-TANKFARM-1995-67	ON	Diesel generator at BX/BY farm fuel leaked into soil.
8-29-95	WHC-TANKFARM-1995-70	ON	Vapor sample taken from B-110 instead of B-112. Person-in-charge was directing operation from outside farm and directed sampling truck to wrong tank.
8-31-95	WHC-TANKFARM-1995-72	ON	244-BX exhauster shutdown. Saltwell pumping from 103, 106, and 109-BX continued into DCRT without exhauster operation as required.
8-31-95	WHC-TANKFARM-1995-73	ON	Potential organic-nitrate chemical reaction discovered for 13 waste tanks. USQ evaluation in progress.
9-13-95	WHC-TANKFARM-1995-75	ON	Lockout at 102-AY airlift circulator valve had unsecured chain.
9-25-95	WHC-TANKFARM-1995-77	ON	241-SY exhauster shutdown, pressurization alarm.
9-27-95	WHC-TANKFARM-1995-78	ON	Core sampling in S-107 found vapor sample drill string reading 130% of Lower Explosive Limit (LEL). Tank headspace sample read 6% LEL.
10-4-95	WHC-TANKFARM-1995-81	ON	Transfer line SN-274 leaked during transfer between AX-B valve pit and 101-AN. Leak at flexible jumper connection. 2 gallons leaked.
10-3-95	WHC-TANKFARM-1995-82	ON	Result of personnel opening breaker at 241-S farm caused shutdown of backup exhauster at 241-SY.
10-5-95	WHC-TANKFARM-1995-86	ON	Implemented new criticality specifications for transfer systems without changing the Interim Safety Basis.
9-26-95	WHC-TANKFARM-1995-90	ON	Found 8000 gallons of liquid in 240-S-151 diversion box. Assume liquid from snow melt and rain, diversion box out of service since March, 1987.
10-19-95	WHC-TANKFARM-1995-91	ON	Incorrect transfer line filled for pressure test. SN-245 filled rather than SN-246.
10-23-95	WHC-TANKFARM-1995-93	ON	Gravel spreading truck entered and left Radiological Buffer Area in 241-TY farm without proper controls in place.
10-26-95	WHC-TANKFARM-1995-94	ON	Vapor sample of rotary mode core sampler drill string from BY-110 read 300% Lower Explosive Limit. Tank headspace sample read <1% LEL.

Table D3.2-1. Tank Farm Events, Off-Normal (ON) and Critiques. (11 sheets)

Date	Event #	Event Type	Event Description
10-31-95	WHC-TANKFARM-1995-96	ON	Mobile crane repositioned in 241-AN farm, crushed edge of electrical pull box.
11-2-95	WHC-TANKFARM-1995-97	ON	High pressure alarm at AW-106 tank. High vacuum alarm setpoint outside LCO limit.
11-6-95	WHC-TANKFARM-1995-99	ON	Potential National Fire Prevention Association (NFPA) code deficiency on push and rotary mode core sampling trucks.
11-9-95	WHC-TANKFARM-1995-100	ON	Waste drum at BX/BY Satellite Accumulation Area exceeded stay time limit.
11-13-95	WHC-TANKFARM-1995-101	ON	241-AZ annulus exhauster shutdown and started smoking.
11-15-95	WHC-TANKFARM-1995-105	ON	Grab sample from 102-AY contains less than the requirement for hydroxide.
11-21-94	WHC-TANKFARM-1995-109	ON	Pressure test of supernate transfer line SN-246 (yard line) failed, indicating loss of integrity.
12-5-95	WHC-TANKFARM-1995-111	ON	Unused 1.5" test riser in 241-TY farm found to contain 450% of LFL.
12-6-95	WHC-TANKFARM-1995-112	ON	AN farm exhauster pre-filter changeout occurred without required air sample taken prior to start of work.
12-11-95	WHC-TANKFARM-1995-114	ON	107-AN tank pressure instrument air line froze due to tripped breaker on heat trace line.
12-13-95	WHC-TANKFARM-1995-115	ON	High winds blew off the AN Farm Primary Ventilation System sheet metal cover, shearing the annulus filter differential pressure instruments when the cover came to rest against the annulus stack.
12-22-95	WHC-TANKFARM-1995-120	ON	Discrepancy found between the Operating Specifications Documents (OSD-T-151-00031) requirement for liquid level readings in Tank 102-S and the operator rounds sheets that had been completed.
1-4-96	WHC-TANKFARM-1996-002	ON	Psychometrics performed on 241-AN-tank farm without proper signatures on work package.
1-8-96	WHC-TANKFARM-1996-003	ON	Personnel skin contamination due to pumping leak detection pits in 241-AW farm without wearing any Personal Protective Equipment.
1-15-96	WHC-TANKFARM-1996-007	ON	Sampling results indicated the waste in DCRT 244-TX did not meet the requirements for hydroxide concentration.
1-17-96	WHC-TANKFARM-1996-009	ON	When lifting the quill rod portion of the rotary mode core sampler out of tank 109-U (a flammable gas watchlist tank) a mechanical spark was generated.
1-17-96	WHC-TANKFARM-1996-010	ON	During work in the 241-S tank farm to remove the above ground ventilation system ducting, the required surveys of the vacuum outlet HEPA filters had not been performed.
1-22-96	WHC-TANKFARM-1996-011	ON	Inadequate work release at 242-A Evaporator results in near-miss electrical incident.
1-30-96	WHC-TANKFARM-1996-012	ON	Pressure transmitter for tank 106-AW failed which disabled the alarm capabilities.
2-1-96	WHC-TANKFARM-1996-013	ON	Failed pressure switch caused shutdown of 241-SY primary exhauster.
2-7-96	WHC-TANKFARM-1996-014	ON	Decontamination spray wand was being tested when a leaking connection sprayed contamination on the operator. To be used on tank 107-AN camera.
2-9-96	WHC-TANKFARM-1996-015	ON	209-E car and mixer room exhauster unscheduled shutdown due to a fire system valve opening.
2-13-96	WHC-TANKFARM-1996-016	ON	Discovered cesium-137 under 241-SX tank farm at the 110 foot depth. This is much deeper than previously assumed or modeled.
2-15-96	WHC-TANKFARM-1996-017	ON	While removing a thermocouple tree from 101-AZ the tree got stuck with 37 feet of it out, and 18 feet still in the tank. Operator used his hands to shake the tree and received a high radiation dose.
2-21-96	WHC-TANKFARM-1996-019	ON	Railcar was scheduled to have 1000 to 1500 gallons pumped into it at T-Plant. It was found to have 15,000 to 18,000 gallons in it instead of the 1000 to 1500 gallons.

Table D3.2-1. Tank Farm Events, Off-Normal (ON) and Critiques. (11 sheets)

Date	Event #	Event Type	Event Description
3-8-96	WHC-TANKFARM-1996-022	ON	The AY-02A pit center cover block was removed for pit upgrade. Cores had been drilled in it, and cracks were appearing, making the structural integrity questionable. To be replaced.
3-7-96	WHC-TANKFARM-1996-023	ON	Plugged instrument air line to 101-AY pressure instruments, caused failure of remote monitoring.
3-18-96	WHC-TANKFARM-1996-026	ON	Unauthorized low flying helicopters performing aerial radiological surveys over 241-A, AW, AX, AY, AZ, and C farms.
3-20-96	WHC-TANKFARM-1996-027	ON	Discovered no pressure on 204-AR Fire Suppression System when conducting fire system tests.
3-21-96	WHC-TANKFARM-1996-028	ON	101-SY mixer pump operated with no ammonia monitoring to the DACS system. One monitor was out of service, the other failed during the pump run.
4-9-96	WHC-TANKFARM-1996-032	ON	241-SY primary exhauster shutdown automatically for no apparent reason. Tanks did not pressurize.

This page intentionally left blank.

Table D3.2-2. Summary of Occurrences. (33 sheets)

OCCURRENCE NUMBER	DISCOVERY DATE	DESCRIPTION OF EVENT	EVENT CAUSE
72-26	04/20/1972	WASTE TRANSFER LINE THAT FLOWS TO 241-A-152 LEAKED INTO ENCASEMENT, THEN THRU COVER BLOCK JOINTS TO GROUND.	WASTE LINE FAILED, ENCASEMENT DRAINS PLUGGED.
72-49	07/06/1972	IRONWORKER-RIGGER PREPARING TO RELEASE A JAM, CABLE LET GO AND BROKE HIS FINGER.	ERROR IN JUDGMENT WHEN WORKING AROUND PINCH POINTS.
72-54	08/11/1972	BROKE 6-INCH SANITARY WATER LINE WITH BACKHOE.	PERSONNEL ERROR, FAILURE TO NOTE WATER LINE USING DETAILED DRAWING.
72-67	10/29/1972	MISROUTED 3,700 GALLONS OF PAS TO TANK 101-AY INSTEAD OF 003-CR.	PERSONNEL ERROR/INCORRECT SETTING FOR TRANSFER ROUTE MADE AT 151-AX DIVERTER STATION.
72-72	11/20/1972	LEAK FROM TRANSFER LINE DURING FLUSHING CAUSED SPRAY UP THROUGH VALVE OPERATOR HOLES IN VALVE PIT COVER.	GASKET FAILURE IN VALVE PIT.
73-1	01/08/1973	LIVE 13.8 KV LINE DOWN NEAR 244 UR, LINE WAS FLASHING AND BURNING.	WIRE BROKE FROM APPARENT FATIGUE ON WIRE FROM COLD WEATHER AND VIBRATION.
73-45	07/05/1973	BACKHOE RAN OVER AND BROKE A FLANGE ON A BELOW GRADE RISER ON A TRANSFER LINE AT 241-T TANK FARM. WATERY LIQUID WAS SEEN SEEPING FROM THE GROUND.	PIPE FLANGES ON TRANSFER LINES AT T-FARM WERE NOT ADEQUATELY MARKED.
73-73	11/01/1973	FAILURE OF A HEATER IN 241-TX-118 VENTILATION EXHAUST CAUSED LOADING OF PRIMARY FILTER.	MECHANICAL FAILURE OF OFF-GAS HEATER.
73-78	11/14/1973	DURING TRANSFER FROM 107-S TO 102-S THE TRANSFER LINE PLUGGED AND WASTE BACKED UP AND FLOWED OUT THE TANK RISER ONTO THE GROUND.	APPARENT PLUGGING OF TRANSFER LINE BY CRYSTALLIZED MATERIAL.
73-80	11/15/1973	POSSIBLE TANK DOME OVERLOADING AFTER WASTE SPILL IN S-FARM. SOIL WAS PLACED OVER THE SPILL AND POSSIBLY OVERLOADED 102-S AND 103-S DOMES.	PROCEDURE/ WEIGHT OF COVER SOIL WAS NOT KNOWN PRIOR TO COVERING THE TANKS.
73-82	11/21/1973	RAIN AND ROTTING TIMBERS CAUSED SUBSIDENCE OF 216-B-12 CRIB, CRIB REMOVED FROM SERVICE.	DEGRADATION OF CRIB OVER TIME.
73-86	12/11/1973	EMPLOYEE ENTERED THE AREA OF AN OPEN 42" RISER ON 118-TX TANK WITHOUT RESPIRATOR OR LIFE BELT.	PERSONNEL FAILURE TO FOLLOW PROCEDURE CONCERNING ENTRANCE TO AREA WITH OPEN RISER.
74-9	02/15/1974	NEW LEVEL LIMITS ESTABLISHED FOR WASTE TANKS IN AUGUST, 1973, FOUND THAT THERE WERE 19 TANKS THAT EXCEEDED THE NEW LIMITS, 8 TANKS STILL EXCEEDED THE LIMIT ON 2/15/74.	EVAPORATOR OUTAGES HAVE PREVENTED EMPTYING THE TANKS AS RAPIDLY AS SCHEDULED.
74-16	03/09/1974	LARGE AMOUNT OF FOAM (FROM SLUDGE ACIDIFICATION) IN 244-AR VAULT TANK 001 MIGRATED INTO TANKS 002, 004 AND TO THE VESSEL VENT HEADER, WHICH FAILED THE HEPA FILTER.	INCREASED FOAM DEVELOPED DUE TO A RISE IN pH DURING ACIDIFICATION.
74-21	03/27/1974	UNEXPLAINED DECREASE OF 0.3 INCHES IN WASTE TANK 105-S.	UNKNOWN.
74-22	03/24/1974	UNEXPLAINED DECREASE OF 0.45 INCHES IN WASTE TANK 112-S.	UNKNOWN.
74-23	04/03/1974	UNEXPLAINED DECREASE OF 1 1/2 INCHES IN WASTE TANK 110-TX.	UNKNOWN.
74-26	04/08/1974	UNEXPLAINED DECREASE OF 0.30 INCHES IN WASTE TANK 112-BX.	UNKNOWN.
74-27	04/05/1974	UNEXPLAINED DECREASE OF LEVEL IN WASTE TANK 107-BY.	UNKNOWN.
74-28	04/10/1974	UNEXPLAINED DECREASE OF 3 1/2 INCHES IN WASTE TANK 102-TX.	UNKNOWN.
74-29	04/07/1974	WASTE TANK 109-TX EXCEEDED TEMPERATURE INCREASE LIMIT OF 22oC (40oF) IN EIGHT DAY PERIOD.	RESTART OF EVAPORATOR FEED TO THIS TANK AND INADEQUATE RESPONSE TIME DID NOT ALLOW MIXING PHENOMENA TO DEVELOP.

Table D3.2-2. Summary of Occurrences. (33 sheets)

74-30	03/31/1974	FAILURE TO OBTAIN MONTHLY SAMPLES FROM TANK 102-AY, THE SPARE BOILING WASTE TANK IN 200 EAST AREA	PERSONNEL ERROR, FAILURE TO FOLLOW ADMINISTRATIVE CONTROLS.
74-31	04/13/1974	FAILURE TO OBTAIN FIC GAUGE READINGS IN 241-T FARM AS REQUIRED.	MECHANICAL FAILURE. ELECTRICAL SHORT AND RESULTING MCC FIRE (CAUSED BY BIRD NEST IN MCC ENCLOSURE) PREVENTED TAKING TANK LIQUID LEVEL READINGS.
74-32	04/18/1974	INSTRUMENT POWER OUTAGE IN 241-S TANK FARM CAUSED BY PERSONNEL AUGURING A TEST HOLE TO FIND A PIPING LEAK.	PERSONNEL FAILURE. EMPLOYEE FAILED TO HAND DIG PRIOR TO USING THE AUGER. CABLES WERE NOT IN THE LOCATION INDICATED ON THE TANK FARM DRAWING.
74-37	05/03/1974	DURING A TRANSFER THE LEVEL IN 102-BY DROPPED 10 INCHES, INCREASED 10 3/4 INCHES IN TANK 111-BX. LEVEL IN 111-BX EVENTUALLY DROPPED 3/4 INCH (CONSIDERED SIGNIFICANT LEVEL DECREASE).	LEVEL DECREASE BELIEVED TO BE CAUSED BY STABILIZATION OF THE CRUST SURFACE AFTER TRANSFER.
74-38	05/03/1974	SIGNIFICANT RADIATION READINGS IN A LEAK DETECTION LATERAL BELOW TANK 111-SX.	APPARENT TANK LEAK, TANK SALTWELL PUMPED AFTER LEAK INDICATED.
74-41	05/19/1974	244-AR VAULT VESSEL VENT SECONDARY HEPA FILTERS FOUND WET AND PERFORATED AFTER REPLACEMENT OF PRIMARY FILTERS.	ASSUMED DEPOSITION OF AMMONIUM NITRATE ON FILTERS FROM B PLANT DAMAGED FILTERS.
74-43	05/27/1974	3800 GALLONS OF PUREX ACIDIFIED SLUDGE MISTRANSFERRED FROM 244-AR VAULT TO 106-A TANK INSTEAD OF TO CR VAULT.	PERSONNEL FAILURE. DIVERTER SETTINGS INCORRECT.
74-44	05/27/1974	150 GALLONS OF NITRIC ACID ADDED TO TANK 002 AT 244-AR VAULT INSTEAD OF TANK 001. ADDED TO 10,500 GALLONS OF SLUDGE SLURRY.	PERSONNEL ERROR. OPENED WRONG VALVE OUT OF CHEMICAL MAKEUP TANK.
74-88	06/13/1974	INCREASED ACTIVITY IN TANK 106-TY DRY WELL INDICATES TANK LEAK.	MECHANICAL FAILURE. TANK DEGRADATION OVER TIME. (SUSPECTED LEAKER IS 105-TY)
74-101	06/25/1974	INCREASED ACTIVITY IN DRY WELLS BY TANK 103-TY.	ASSUMED TANK LEAKAGE, DEGRADATION OVER TIME.
74-102	06/26/1974	INCREASED ACTIVITY IN TANK 105-TY DRY WELL INDICATES TANK LEAK.	TANK LEAKAGE, DEGRADATION OVER TIME.
74-103	06/27/1974	SUSPECTED DEFORMED TANK LINER IN TANK 201-B.	CORRODED BAFFLE DROPPED INTO TANK BELOW A RISER, CONJECTURED TO BE A LINER DEFORMATION.
74-104	06/27/1974	INCREASED ACTIVITY IN TANK 101-BX DRY WELL INDICATES TANK LEAK.	TANK LEAKAGE, DEGRADATION OVER TIME.
74-106	07/01/1974	INCREASED ACTIVITY IN TANK 103-BY DRY WELL INDICATES TANK LEAK.	TANK LEAKAGE, DEGRADATION OVER TIME.
74-108	07/07/1974	INCREASED ACTIVITY IN DRY WELL AND TANK 109-T LEVEL DROP INDICATES TANK LEAK.	TANK LEAKAGE, DEGRADATION OVER TIME.
74-112	07/18/1974	INCREASED ACTIVITY IN TANK 110-B DRY WELL INDICATES TANK LEAK.	TANK LEAKAGE, DEGRADATION OVER TIME.
74-117	08/07/1974	INCREASED ACTIVITY IN TANK 105-BY DRY WELL INDICATES TANK LEAK.	TANK LEAKAGE, DEGRADATION OVER TIME.
74-120	08/13/1974	INCREASED ACTIVITY IN DRY WELLS BETWEEN TANKS 104-C AND 105-C INDICATES POSSIBLE TANK LEAK.	ASSUMED FROM OTHER INDICATIONS THAT THESE TANKS ARE SOUND, NO LEAKAGE. LEAK INDICATION COULD BE FROM EARLIER LEAK IN SPARE FILL LINE TO 105-C.
74-121	08/16/1974	RADIOACTIVE LIQUID LEAKED FROM SAMPLE CUP RISER IN TANK 001-AR AT 244-AR VAULT DURING pH METER STANDARDIZATION.	CAUSE WAS NOT DETERMINED.

Table D3.2-2. Summary of Occurrences. (33 sheets)

74-123	08/16/1974	INCREASED ACTIVITY IN TANK 102-BY DRY WELL INDICATES TANK LEAK.	ASSUMED FROM OTHER INDICATIONS THAT THIS TANK IS SOUND. READINGS COULD BE FROM LATERAL MIGRATION OF SOIL CONTAMINATION.
74-127	08/26/1974	CONTAMINATION SPREAD DURING CLEANUP OF 154-B DIVERSION BOX.	CONTAMINATION SPREAD DUE TO WIND-CARRY OF PARTICULATE.
74-129	09/04/1974	INCREASED ACTIVITY IN TANKS 113 AND 114-TX DRYWELL INDICATE TANK LEAK.	ACTIVITY ASSUMED TO BE FROM TANK LEAKAGE OR SOIL CONTAMINATION MIGRATION.
74-130	09/16/1974	CONTAMINATION SPREAD DURING TRANSFER OF 53 FOOT LONG TUBE BUNDLE HEAT EXCHANGER FROM TANK 104-A TO 101-A.	PERSONNEL ERROR/PROCEDURE.
74-132	09/24/1974	UNEXPLAINED DECREASE OF 1 INCH OF LIQUID LEVEL IN TANK 110-SX.	UNKNOWN.
74-134	10/09/1974	SPILL OF 1 1/2 GALLONS OF RADIOACTIVE LIQUID WHEN OPENING A STRAINER TO ISOLATE A STEAM COIL FOR MAINTENANCE IN 241-A FARM.	PERSONNEL ERROR/PROCEDURE. PIPEFITTER ASSUMED GAUGE WAS INCORRECT WHEN IT SHOWED 20 PSIG REMAINING IN STRAINED AFTER DRAIN OPENED. THEN PLUG UNPLUGGED.
74-141	10/28/1974	INCREASED ACTIVITY IN TANK 101-B DRY WELL INDICATES TANK LEAK.	TANK LEAKAGE, DEGRADATION OVER TIME.
74-144	11/05/1974	CONTAMINATION SPREAD FROM OPEN PUMP PIT ON TANK 106-A DURING REMOVAL OF A FAILED JUMPER. THE JUMPER WAS DROPPED AND CONTAMINATION SPLASHED UP OVER THE PIT WALL.	PROCEDURE, NOT SUFFICIENT CONTAINMENT PROVIDED WHILE PUMP PIT OPEN.
74-148	11/22/1974	INCREASED ACTIVITY BETWEEN TANKS 108-C AND 109-C.	ASSUMED MIGRATION OF SOIL CONTAMINATION.
74-151	12/02/1974	LIQUID LEVEL IN TANK 102-SX DECREASED 1 INCH AFTER A TRANSFER INTO TANK.	ASSUMED TANK SETTLING TOOK LONGER THAN USUAL.
74-152	12/05/1974	LIQUID LEVEL IN TANK 112-TX DECREASED 4 1/2 INCHES AFTER A FLUSH OF MANUAL LIQUID LEVEL TAPE.	ASSUMED A DEPRESSION FORMED IN TANK CRUST AS A RESULT OF WATER FLUSHING THROUGH MANUAL TAPE.
74-153	12/13/1974	INCREASED ACTIVITY IN TANK 107-BY DRY WELLS.	ASSUMED MIGRATION OF SOIL CONTAMINATION.
74-154	12/11/1974	MISROUTING OF WASTE DURING TRANSFER FILLED 241-EW VENT STATION CATCH TANK FROM 18.75 INCHES TO 73.75 INCHES.	PERSONNEL ERROR. TFO PLANNER-SCHEDULER ERRED IN NOZZLE CONNECTION PROCEDURE INSTRUCTIONS.
74-159	12/30/1974	UNDERGROUND ELECTRICAL CABLE POWERING 244-AR VAULT COOLING WATER EFFLUENT DIVERSION VALVE BROKEN BY BACKHOE EXCAVATION.	PERSONNEL ERROR. BACKHOE OPERATOR CLEARED TRENCH WITHOUT HAND DIGGING TAKING PLACE.
75-02	01/06/1975	INCREASED ACTIVITY BETWEEN TANKS 105-T AND 108-T.	ASSUMED THAT TANK 105-T IS SOUND, AND 108-T IS QUESTIONABLE DUE TO OTHER MEASUREMENTS.
75-03	01/06/1975	244-AR VAULT HAD AN ACTIVATION OF EMERGENCY VENTILATION SYSTEM, AND VESSEL VENT SYSTEM SHUTDOWN.	MECHANICAL FAILURE, OVERHEATED CIRCUIT BREAKER IN ELECTRICAL SUPPLY TO AIR COMPRESSOR.
75-04	01/07/1975	INCREASED ACTIVITY BETWEEN TANKS 110-SX AND 111-SX.	UNKNOWN.
75-05	01/08/1975	ACTIVATION OF 244-AR EMERGENCY VENTILATION SYSTEM SEVERAL TIMES IN MORNING.	HIGH WINDS CAUSED DIFFERENTIAL PRESSURE FLUCTUATIONS THAT TRIPPED EMERGENCY SYSTEM.
75-09	01/31/1975	241-U FARM TANK DOME LOADING INDICATES THE SOIL COVER OVER THE TANKS IS ONE FOOT HIGHER THAN AS-BUILT DRAWINGS, POTENTIAL OVERLOAD.	DRAWINGS WERE INCORRECT, BUT DOME LOADINGS ARE WITHIN LIMITS.
75-15	02/13/1975	SPILL OF CONTAMINATION TO GROUND DURING OVERGROUND TRANSFER FROM TANK 105-BY.	PERSONNEL ERROR, MATERIAL FAILURE. PLASTIC WRAPPED JOINTS ON OVERGROUND LINE DID NOT HOLD THE LEAK.

Table D3.2-2. Summary of Occurrences. (33 sheets)

75-16	02/13/1975	RELEASE OF CONTAMINATION OUTSIDE 244-AR VAULT WHEN WASHING CANYON FLOOR AND WATER PUDDLED UNDER DOOR. A LOSS OF BUILDING NEGATIVE PRESSURE ALLOWED CONTAMINATION OUTSIDE.	PERSONNEL ERROR. FLOOR WASHED DURING PLANNED USE OF EMERGENCY GENERATOR, WHICH CAUSED A TEMPORARY LOSS OF BUILDING NEGATIVE PRESSURE.
75-17	02/18/1975	DECREASE IN LIQUID LEVEL IN TANK 101-T AFTER TRANSFER INTO TANK.	ASSUMED STABILIZATION OF SURFACE AFTER TRANSFER.
75-19	02/18/1975	DECREASE IN LIQUID LEVEL IN TANK 112-BY.	ASSUMED TANK CRUSTING IS ERRATIC.
75-29	03/21/1975	FAILURE OF SECONDARY FILTERS IN 244-AR VAULT VESSEL VENT SYSTEM, FILTERS WERE WET AND WARPED.	UNKNOWN. (ALSO SEE 74-41 OCCURRENCE)
75-33	03/31/1975	244-AR VAULT COOLING WATER DIVERSION VALVE DIVERTED AFTER RADIATION ALARM IN CANYON.	RADIATION ALARMS ATTRIBUTED TO WELDING IN AREA.
75-35	04/04/1975	EMPLOYEE FORCED A SAMPLER INTO TANK AFTER THE SAMPLER HAD REACHED THE BOTTOM OF TANK. SAMPLER BOWED, WHICH CAUSED IT TO BE DIFFICULT TO REMOVE THRU RISER, BREAKING THE SAMPLE WIRE.	PERSONNEL ERROR, DEVIATION FROM PROCEDURE.
75-36	04/06/1975	OVERFILLED TANK 002-CR IN 271-CR, TANK LIMIT IS 13,000 GALLONS, FILLED WITH 16,947 GALLONS.	PERSONNEL ERROR. OPERATOR PUSHED PUMP BUTTON INSTEAD OF AGITATOR BUTTON.
75-38	04/09/1975	TANK 101-BY LIQUID LEVEL EXCEEDED LEVEL LIMIT.	UNCONTROLLED WATER ADDITIONS DURING PUMP INSTALLATION, TESTING AND FLUSHING.
75-39	04/08/1975	LEAKAGE FROM TANK 104-A, AS NOTED IN LATERALS BENEATH TANK.	MECHANICAL FAILURE, TANK LINER FAILED.
75-41	04/08/1975	LIQUID LEVEL IN TANK 107-U DECREASED .80 INCHES.	ASSUMED TRANSFER INTO TANK CAUSED FOAMING WHICH HAD TO STABILIZE.
75-42	04/09/1975	TRANSFER OF WASTE WITH pH OF 4.2 FROM 244-AR TO TANK 107-U. pH LIMIT SHOULD BE GREATER THAN 9.	ASSUMED PERSONNEL ERROR.
75-44	04/08/1975	LIQUID LEVEL IN TANK 104-TX DECREASED .70 INCHES.	ASSUMED LEVEL DECREASE DUE TO ADDITION OF HOT WASTE AND THE RESULTING EVAPORATION VIA EXHAUSTER OPERATION.
75-47	04/09/1975	INCREASED ACTIVITY IN TANK 104-AX DRY WELL.	ASSUME THAT ACTIVITY IS DUE TO SHALLOW CONTAMINATION FROM EARLIER FAILED TRANSFER LINES, SURFACE SPILLS, OR OTHER DIRECT BURIED FACILITY FAILURES.
75-51	04/18/1975	LIQUID LEVEL IN TANK 108-T DECREASED .60 INCHES.	UNKNOWN.
75-54	04/17/1975	INCREASED RADIATION ACTIVITY IN LATERAL BENEATH TANK 112-SX.	ASSUMED THAT THE ACTIVITY IS DUE TO PRE-EXISTING CONTAMINATION.
75-56	04/18/1975	INCREASED ACTIVITY IN TANK 107-BY DRY WELLS.	UNKNOWN, COULD BE TANK LEAK OR REDISTRIBUTION OF SOIL CONTAMINATION.
75-57	04/25/1975	LIQUID LEVEL IN TANK 107-TX DECREASED .80 INCHES.	ASSUME LEVEL DECREASE DUE TO INCREASED EVAPORATION FROM EXHAUSTER OPERATION.
75-58	04/30/1975	INCREASED ACTIVITY IN TANK 101-B DRY WELL.	UNKNOWN, COULD BE TANK LEAK OR MIGRATION OF SOIL CONTAMINATION.
75-60	05/16/1975	INCREASED ACTIVITY IN TANK 102-AX DRY WELL.	UNKNOWN.
75-61	05/23/1975	HIGH dP ACROSS TANK 118-TX EXHAUSTER HEPA FILTERS.	PERSONNEL ERROR. FAILURE TO RESPOND TO INCREASING dP INDICATION AND CHANGE FILTERS.
75-64	06/07/1975	LIQUID LEVEL IN TANK 106-TX DECREASED 5 1/2 INCHES.	UNKNOWN.
75-67	06/26/1975	LIQUID LEVEL IN TANK 110-U DECREASED .50 INCHES.	TANK DECLARED A LEAKER ON 7/9/75.

Table D3.2-2. Summary of Occurrences. (33 sheets)

75-68	06/25/1975	INCREASED ACTIVITY IN LATERAL BENEATH TANK 112-SX.	TANK IS A LEAKER, INCREASED ACTIVITY COULD BE DUE TO SHIFT IN SOIL CONDITIONS.
75-69	06/25/1975	INCREASED ACTIVITY IN LATERAL BENEATH TANK 115-SX.	LIMITED CHANGE, READINGS TAKEN WITH A NEW, MORE SENSITIVE INSTRUMENT.
75-78	07/16/1975	JUMPER CONNECTOR FAILURE DURING WASTE TRANSFER FROM 107-TX TO 103-U. JUMPER LOCATED IN 153-TXR DIVERSION BOX.	MECHANICAL FAILURE OF FLEX JUMPER, THREADS STRIPPED.
75-82	07/29/1975	VEHICLE ACCIDENT IN 241-U TANK FARM, STRUCK AN 8-INCH WELL CASING THAT PROTRUDED UP 18-INCHES. PICKUP TRUCK HAD TO BE LIFTED OFF THE CASING.	PERSONNEL ERROR. CUT A TURN SHORT, NON-ESSENTIAL TANK FARM TRAFFIC NEEDS TO BE ELIMINATED.
75-87	07/31/1975	INCREASED ACTIVITY IN TANK 101-B DRY WELL.	UNKNOWN, COULD BE FROM PREVIOUS SOIL CONTAMINATION.
75-85	08/05/1975	EXCESSIVE LIQUID LEVEL IN TANK 105-A, LIMIT EXCEEDED BY 4 1/2 INCHES.	PERSONNEL ERROR, ACCIDENTAL RAW WATER DISCHARGE TO TANK.
75-86	07/24/1975	MINOR INJURY WHILE LIFTING A COVER PLATE WITH CRANE AT 104-TX PUMP PIT.	PERSONNEL ERROR. WORK BEGUN PRIOR TO CRANE LOAD BEING SECURED.
75-89	08/15/1975	SHARP DECREASE IN TANK 103-SX LEVEL FOLLOWING TRANSFER FROM 106-SX.	ASSUMED TRANSFER OF 100,000 GALLONS OF DILUTE 242-S FEED BROKE DOWN THE HEAVY CRUST FORMATION IN TANK.
75-90	08/17/1975	INCREASED ACTIVITY IN TANK 102-AX DRY WELL.	ASSUMED MIGRATION OF SOIL CONTAMINANTS.
75-92	08/20/1975	244-AR VAULT VESSEL VENT SYSTEM SHUTDOWN DUE TO HIGH dP ACROSS FILTER.	PERSONNEL ERROR. TANK 001-AR pH EXCEEDED LIMITS CAUSING FOAM THAT CARRIED OVER TO VENTILATION SYSTEM.
75-94	06/18/1975	WASTE DRUM CONTAINING GREATER THAN 200 GRAMS OF PLUTONIUM STORED AT THE ASPHALT STORAGE PAD.	PERSONNEL ERROR. FAILURE TO FOLLOW ADMINISTRATIVE PROCEDURE.
75-97	08/22/1975	UNPLANNED WASTE TRANSFER FROM 102-A TANK TO 101-A TANK.	PERSONNEL ERROR. INADVERTENT ENERGIZING OF 102-A PUMP INSTEAD OF 101-A PUMP.
75-98	08/15/1975	EXCESSIVE DOME LOADING IN TANK FARMS A, AX, AY, AZ, BX, BY, AND TX.	PERSONNEL ERROR. IDENTIFIED BY TOPOGRAPHIC SURVEYS.
75-101	08/09/1975	LIQUID LEVEL DECREASE OF .70 INCHES IN TANK 107-TX FOLLOWING TRANSFER OUT OF TANK.	ASSUMED LEVEL DECREASE DUE TO EVAPORATION VIA EXHAUSTER.
75-102	09/17/1975	BURIAL OF SIX DRUMS OF POTENTIALLY EXPLOSIVE MATERIAL IN BURIAL TRENCH.	PERSONNEL ERROR. FAILURE TO FOLLOW DISPOSAL PROCEDURES.
75-108	09/29/1975	LIQUID LEVEL LIMIT EXCEEDED IN TANK 110-S, INCREASED 9 INCHES IN FIVE MONTHS.	SUSPECTED UNKNOWN CHEMICAL PHENOMENON CAUSING TANK CONTENTS GROWTH.
75-109	09/30/1975	LIQUID LEVEL LIMIT EXCEEDED IN TANK 111-S, INCREASED 10 INCHES IN FIVE MONTHS.	SUSPECTED UNKNOWN CHEMICAL PHENOMENON CAUSING TANK CONTENTS GROWTH.
75-110	10/02/1975	RADIATION ALARM IN 101-AY "B" LEAK DETECTION PIT AFTER TRANSFER FROM 152-AX DIVERTER STATION CATCH TANK.	UNKNOWN, TRANSFER PIPELINE MAY HAVE LEAKED.
75-111	10/03/1975	2200 GALLON WASTE TRANSFER THROUGH OPEN JUMPER NOZZLE FLOWED VIA PUMP PIT DRAIN INTO INCORRECT TARGET TANK.	PERSONNEL ERROR. JUMPER NOT INSTALLED FOR TRANSFER, ROUTE NOT CHECKED.
75-115	10/11/1975	SMALL, SLOW, LEAK OCCURRED IN OVERGROUND TRANSFER LINE BETWEEN 108-C AND 103-C.	MECHANICAL FAILURE. LEAK AT CONNECTOR HEAD TO TRANSFER PUMP.
75-116	10/11/1975	LIQUID LEVEL DECREASE IN TANK 102-SX AFTER 242-S SLURRY TRANSFER IN.	SUSPECTED SLURRY BUILDUP AT ENTRANCE TO TANK, THEN SLOWLY FLOWED OUT OVER WASTE SURFACE.
75-117	10/09/1975	LIQUID LEVEL DECREASE IN TANK 110-BY AFTER TRANSFER IN.	INTRODUCTION OF STEAM AND HOT WATER TRANSFER LINE FLUSH SEEMS TO CAUSE A LEVEL DROP IN TANK.

Table D3.2-2. Summary of Occurrences. (33 sheets)

75-118	10/12/1975	LIQUID LEVEL INCREASE IN TANK 110-SX AFTER TRANSFER OUT.	SUSPECT A DEPRESSED AREA AROUND PUMP OCCURRED DURING TRANSFER IS SLOWLY FILLING IN.
75-119	10/14/1975	401-SX BUILDING VESSEL VENTILATION CONDENSATE COOLING WATER EXCEEDED RADIONUCLIDE SPECIFICATIONS.	UNKNOWN, BUT SUSPECTED FAILED CONDENSER.
75-127	11/09/1975	MISROUTING OF TRANSFER INTO TANK 102-AY INSTEAD OF 103-A.	PERSONNEL ERROR. USED WRONG PROCEDURE FOR SECOND PHASE OF TRANSFER.
75-130	11/14/1975	CONTAMINATION SPREAD IN PARKING AREA NEAR A FARM VENTILATION BUILDING. EXHAUSTS A, AX, AY, AND AZ FARMS.	UNKNOWN, ASSUME SOURCE IS A FARM VENTILATION STACK.
75-132	11/10/1975	LIQUID LEVEL IN TANK 111-BY DECREASED 1 INCH OVER FOUR DAYS.	SUSPECT LEVEL LOST VIA EVAPORATION, AND PROBLEM WITH DIFFICULTY IN READING TANK LEVEL.
75-134	11/21/1975	MISROUTED WASTE TRANSFER FROM 104-SX TO 101-SX PIT.	PERSONNEL ERROR. OPERATOR CHANGED VALVE SETTINGS WHILE WALKING THROUGH A PROCEDURE.
75-135	10/31/1975	A FARM PROCESS CONDENSATE pH TOO LOW.	SUSPECT pH PROBLEM FROM 102-AY STEAM COIL CONDENSATE.
75-141	12/02/1975	SIGNIFICANT MATERIAL BALANCE DISCREPANCY AFTER TRANSFER FROM TANK 102-C TO 103-C.	UNKNOWN, SUSPECT LEVEL GAUGE ANOMALIES A RESULT OF THE CHARACTER OF THE MATERIAL SURFACE IN TANK 102-C.
75-145	12/19/1975	POSSIBLE TRANSFER PIPING LEAKAGE DURING TRANSFER FROM TANK 103-B TO 110-SX.	UNKNOWN, MATERIAL BALANCE PROBLEM WAS NOT RESOLVED.
75-146	12/26/1975	LIQUID LEVEL IN TANK 114-TX DECREASED 11.25 INCHES.	SUSPECT A SHIFT IN SURFACE BEING CONTACTED BY THE LEVEL PROBE.
75-147	12/30/1975	INCREASED ACTIVITY IN TANK 101-T DRY WELL.	SUSPECT ACTIVITY IS FROM A MIGRATION OF SOIL CONTAMINATION.
76-04	01/09/1976	SIGNIFICANT RADIATION READINGS IN AN EXCAVATION SITE WHERE PERSONNEL WERE WORKING DUE TO A WASTE TRANSFER NEARBY.	PERSONNEL ERROR. RISK TO PERSONNEL FROM WASTE TRANSFER NOT ADEQUATELY CONSIDERED.
76-05	01/16/1976	LIQUID LEVEL IN TANK 101-S DECREASED MORE THAN 1 INCH.	SUSPECT A COLLAPSE OF FOAM AFTER A RECENT TRANSFER INTO TANK.
76-06	01/17/1976	LIQUID LEVEL DECREASE IN TANK 106-TX FOLLOWING A FLUSH OF THE LEVEL MONITORING TAPE.	SUSPECT A BUILDUP OF CRUST ON THE MANUAL TAPE PLUMB.
76-08	01/20/1976	INCREASED ACTIVITY IN TANK 104-AX DRY WELL.	ASSUMED MIGRATION OF SOIL CONTAMINATION.
76-14	01/29/1976	LIQUID LEVEL IN TANK 109-C DECREASED .90 INCHES.	ASSUME LEVEL CHANGE INDICATION DUE TO BUILDUP OF SOLIDS ON TAPE PLUMMET.
76-15	01/27/1976	CROSS-COUNTRY TRANSFER LINE PLUGGED DURING TRANSFER FROM 107-S TO 109-B AFTER PUMP SHUTDOWN DUE TO POWER LOSS.	PLUG DUE TO CUTTING DILUTION WATER DURING TRANSFER.
76-21	02/18/1976	WIND SWEPT TUMBLEWEEDS FORCED A VALVE OPEN SPILLING RAW WATER INTO 241-TX-155 DIVERSION BOX, AND SEVERAL CATCH TANKS AND INTO 20 OPEN NOZZLES. SPILLED 35,000 GALLONS.	ASSUME THAT WIND SWEPT TUMBLEWEEDS FORCED OPEN AN L-SHAPED VALVE HANDLE.
76-22	02/17/1976	RAW WATER SPILL (UOR 76-21) CAUSED LIQUID LEVEL INCREASE BEYOND LIMIT IN TANK 103-TY, A KNOWN LEAKER.	LEVEL INCREASE CAUSED BY OVERFLOW FROM CATCH TANK TX-302-B.
76-23	02/17/1976	LIQUID LEVEL DECREASE IN DIVERSION BOX 155-TX AND CATCH TANK TX-302-B AFTER RAW WATER SPILL (UOR 76-21).	ASSUME WATER LEVEL DECREASE DUE TO LEAKS IN DIVERSION BOX-CATCH TANK STRUCTURE.
76-24	02/23/1976	STEAM USED INSTEAD OF AIR AFTER TRANSFER LINE FLUSH.	PERSONNEL ERROR. FAILURE TO FOLLOW PROCEDURE.
76-25	02/26/1976	OPERATOR INJURED HIS FOOT WHEN HE SLIPPED AS A CAISSON WAS BEING LIFTED OUT OF THE GROUND AT 241-BX TANK FARM.	PERSONNEL ERROR. OPERATOR TRIED TO PULL FALLEN WOODEN BARRICADE FROM HOLE, AND SLIPPED INTO HOLE.
76-30	03/10/1976	LIQUID LEVEL INDICATION DECREASED FOR 152-AX DIVERTER STATION CATCH TANK DURING WASTE TRANSFER.	MECHANICAL FAILURE. APPARENT FAILURE OF LEVEL INSTRUMENTATION.
76-31	03/17/1976	LIQUID LEVEL IN TANK 112-BY DECREASED 2 1/2 INCHES.	ASSUMED CRUST HAS SHIFTED CAUSING LEVEL DECREASE INDICATION.

Table D3.2-2. Summary of Occurrences. (33 sheets)

76-36	03/23/1976	LIQUID LEVEL IN TANK 102-BY DECREASED 1 INCH.	ASSUMED CRYSTAL BUILDUP ON LEVEL PLUMMET CAUSED LEVEL INDICATION CHANGE.
76-38	03/26/1976	LIQUID LEVEL IN TANK 108-TX DECREASED 1 INCH.	ASSUMED SALT BUILDUP ON FIC PLUMMET.
76-39	03/22/1976	LIQUID LEVEL IN TANK 108-SX INCREASED, EXCEEDING THE .50 INCH CRITERIA.	UNKNOWN. TANK IS OUT-OF-SERVICE, A KNOWN LEAKER.
76-40	03/23/1976	LIQUID LEVEL IN TANK 105-SX INCREASED 2.1 INCHES.	ASSUMED SLURRY GROWTH, TYPICAL OF 242-S SLURRIES.
76-41	02/29/1976	RADIATION INCREASE IN 102-AX LEAK DETECTION PIT.	WATER IN LEAK DETECTION PIT EVAPORATED, RADIATION INDICATION INCREASED AS PIT BOTTOM WAS EXPOSED.
76-42	03/23/1976	LIQUID LEVEL IN TANK 111-C INCREASED, EXCEEDING .50 INCH CRITERIA.	UNKNOWN, ASSUME ERRATIC LEVEL READINGS DUE TO PROBLEM WITH OBTAINING GOOD CONTACT WITH SURFACE.
76-45	03/31/1976	LIQUID LEVEL IN TANK 110-S INCREASED 2.3 INCHES.	ASSUMED SLURRY GROWTH, TYPICAL OF 242-S SLURRIES.
76-46	03/29/1976	103-AX PUMP RUN WITHOUT FLOW TO BEARINGS DUE TO MISVALVING OF COOLING WATER TO 101-AX PUMP.	PERSONNEL ERROR, FAILURE TO FOLLOW VALVING PROCEDURE.
76-47	04/07/1976	TANK 115-TX REUSED AS A SALT WELL LIQUOR RECEIVER AFTER BEING DECLARED REMOVED-FROM-SERVICE.	PERSONNEL ERROR. FAILURE TO FOLLOW TANK IN-SERVICE ADMINISTRATIVE CONTROLS.
76-48	04/12/1976	DURING JUMPER INSTALLATION IN 241-A TANK FARM, RADIATION MONITOR RECOMMENDED WORK HALT DUE TO WIND, OPERATIONS SUPERVISOR DIRECTED THAT ONE MORE CONNECTOR HEAD BE INSTALLED TO FINISH THE JOB.	PERSONNEL, POLICY CONFLICT OF ASSIGNED AUTHORITY.
76-49	04/14/1976	LIQUID LEVEL IN TANK 105-TY INCREASED 32 INCHES.	LEVEL INDICATION INCREASE DUE TO REPLACING THE ROD PLUMMET WITH A DOUGHNUT PLUMMET.
76-50	04/19/1976	LIQUID LEVEL IN TANK 114-TX INCREASED 2.25 INCHES.	ASSUME LEVEL CHANGE DUE TO DRAINBACK OF LIQUID ON SALTCAKE AT HIGHER ELEVATIONS.
76-51	04/14/1976	LIQUID LEVEL IN TANK 113-SX INCREASED 1.5 INCHES.	SUSPECT THE LEVEL PLUMMET IS CONTACTING AN OLD LEVEL TAPE.
76-52	03/24/1976	LIQUID LEVEL IN TANK 105-S INCREASE EXCEEDED CRITERIA.	ASSUME SLURRY GROWTH, TYPICAL OF 242-S SLURRIES.
76-53	04/14/1976	LIQUID LEVEL IN TANK 102-TX INCREASED 2 INCHES.	ASSUME MATERIAL GROWTH ON TAPE PLUMMET.
76-55	04/08/1976	TRANSFER TO 244-AR MADE OF MATERIAL WITH HIGH H+ CONCENTRATION.	PERSONNEL ERROR. MISINTERPRETATION OF SPECIFICATION, FAILURE TO FOLLOW PROCEDURE.
76-56	04/09/1976	RADIATION ACTIVITY INCREASE IN TANK 106-T DRY WELL EXCEEDS CRITERIA.	MIGRATION OF CONTAMINATION FROM PREVIOUS TANK LEAK.
76-59	04/20/1976	RADIATION ACTIVITY INCREASE IN TANK 104-AX DRY WELL EXCEEDS CRITERIA.	MIGRATION OF CONTAMINATION FROM PREVIOUS EXHAUST HEADER LEAK.
76-60	04/20/1976	INCREASED ACTIVITY IN TANK 107-T DRY WELL.	ASSUME DISPERSION MECHANISM IN SOIL OF PREVIOUS CONTAMINATION.
76-61	04/25/1976	SPILLED 500 GALLONS OF WATER WHEN OVERGROUND LINE FROM 104-TX TO 108-TX PUMP PIT CONNECTION FAILED.	MECHANICAL. HOSE CONNECTION FAILED.
76-62	04/26/1976	LIQUID LEVEL IN TANK 105-U INCREASED 2.4 INCHES.	ASSUME SLURRY GROWTH, TYPICAL OF 242-S SLURRIES.
76-64	04/29/1976	CONTAMINATION RELEASE WHEN A PILOT HOLE WAS DRILLED IN A FLUSHED OUT TRANSFER PIPE, BEING READIED FOR REROUTING.	TRAPPED AIR IN THE HEAT TRACED LINE PUSHED OUT LIQUID WHEN THE HOLE WAS DRILLED IN THE PIPE.
76-66	05/05/1976	LIQUID LEVEL IN TANK 106-TX INCREASED GREATER THAN CRITERIA.	LEVEL TAPE WAS FLUSHED AND A CRUSTED ICICLE WAS REMOVED, LEVEL WAS THEN NORMAL.
76-67	05/05/1976	LIQUID LEVEL IN TANK 109-U INCREASED GREATER THAN CRITERIA.	ASSUME THAT SLUDGE IS FORMING ON TANK LIQUID SERVICE.

Table D3.2-2. Summary of Occurrences. (33 sheets)

76-68	04/20/1976	RADIATION ACTIVITY INCREASE IN TANK 101-BX DRY WELL EXCEEDED CRITERIA.	MIGRATION OF CONTAMINATION FROM PREVIOUS LEAK FROM PUMP CASING.
76-69	03/30/1976	CHANGE IN SURFACE LEVEL READING IN TANK 117-TX EXCEEDS CRITERIA.	CHANGING AREA OF MEASUREMENT. LEVEL PLUMMET HAD BEEN STRIKING MOUND OF DIATOMACEOUS EARTH IN THE CENTER OF THE TANK, NEW READINGS WERE TAKEN IN A DIFFERENT LOCATION.
76-70	05/10/1976	LIQUID LEVEL IN TANK 101-S DECREASE EXCEEDED CRITERIA.	ASSUME THE SURFACE LEVEL IS TOO DRY TO GET AN ACCURATE READING, FLUSHES OF TAPE PLUMMET HAVE WASHED OUT A DEPRESSION IN WASTE SURFACE.
76-71	05/10/1976	LIQUID LEVEL IN TANK 203-T INCREASED 1.25 INCHES.	ASSUME THAT THE INCREASE WAS A TEMPORARY PHENOMENON WHICH FOLLOWED A SALT WELL TRANSFER.
76-72	05/07/1976	PERSONNEL ENTERED BX TANK FARM WITHOUT USING PROTECTIVE CLOTHING.	PERSONNEL ERROR. FAILURE TO FOLLOW TANK FARM ENTRANCE PROCEDURE.
76-73	05/05/1976	MONITORING OF 101-A DRY WELL NOT PERFORMED ON SCHEDULE.	PERSONNEL ERROR. A DRILLING RIG WAS IN THE WAY SO THAT THE SURVEILLANCE COULD NOT BE MADE.
76-74	05/17/1976	RADIATION ACTIVITY INCREASE IN TANK 110-U DRY WELL.	ASSUME MIGRATION OF PREVIOUS SOIL CONTAMINATION.
76-76	05/22/1976	LIQUID LEVEL IN TANK 204-T INCREASED 1.25 INCHES.	INCREASE FOLLOWED A SALT WELL TRANSFER, ASSUME A DRAIN DOWN FROM OUTLYING WASTE SURFACES.
76-77	05/24/1976	LIQUID LEVEL IN TANK 106-U INCREASED 1.10 INCHES.	ASSUME A BUILDUP OF CRUST OVER TIME.
76-80	05/27/1976	LIQUID LEVEL IN TANK 108-U INCREASED 1.05 INCHES.	ASSUME INCREASE IS DUE TO DRAINAGE FROM EXHAUST SYSTEMS CONDENSATE.
76-81	05/28/1976	LIQUID LEVEL IN TANK 107-S DECREASED 0.5 INCHES.	DECREASE IN LEVEL IS APPARENTLY DUE TO EVAPORATIVE LOSS AND DROP IN TEMPERATURE OF THE LIQUID WASTE.
76-83	06/02/1976	LIQUID LEVEL IN TANK 103-SX INCREASED 2.10 INCHES.	ASSUME LEVEL INCREASE IS TYPICAL OF 242-S SLURRY SALT CAKE BEHAVIOR.
76-85	06/08/1976	LIQUID LEVEL IN TANK 104-SX INCREASED 2.10 INCHES.	ASSUME LEVEL INCREASE IS TYPICAL OF 242-S SLURRY SALT CAKE BEHAVIOR.
76-87	06/13/1976	LIQUID LEVEL IN TANK 111-TX INCREASED 1.25 INCHES.	LEVEL INCREASE DUE TO IN-LEAKAGE FROM A STEAM LEAK INTO A FLUSH PIT.
76-89	06/21/1976	LIQUID LEVEL IN TANK 105-U DECREASE EXCEEDED CRITERIA.	ASSUME LEVEL DECREASE IS DUE TO A BREAKDOWN OR PENETRATION OF FLOATING MATERIAL ON TANK WASTE SURFACE.
76-90	06/28/1976	SURFACE LEVEL IN TANK 110-U INCREASED 1.0 INCH.	ASSUME A SURFACE ANOMALY OR TEMPORARY MATERIAL BUILDUP ON THE GAUGE PLUMMET.
76-91	06/29/1976	LIQUID LEVEL IN TANK 110-SX DECREASED 0.75 INCHES.	ASSUME DECREASE DUE TO EVAPORATION AND ERRATIC READINGS USING MANUAL TAPE.
76-94	07/20/1976	LIQUID LEVEL IN TANK 108-C DECREASED 0.50 INCHES.	ASSUME SURFACE LEVEL SETTLING FOLLOWING SALT WELL PUMPING.
76-95	07/23/1976	LIQUID LEVEL IN TANK 101-S DECREASED 1.10 INCHES.	ASSUME DECREASE DUE TO EVAPORATION AND ERRATIC READINGS DUE TO SURFACE CONDITION.
76-96	07/28/1976	LIQUID LEVEL IN TANK 103-SX DECREASED 1.6 INCHES.	ASSUME DECREASE IS DUE TO LIQUEFACTION OF THE CRUST AFTER A 60,000 GALLON TRANSFER FROM 110-SX.
76-97	07/08/1976	LIQUID LEVEL IN TANK 106-TX INCREASED 1.25 INCHES.	ASSUME INCREASE IS DUE TO BUILDUP ON THE GAUGE PLUMMET.
76-98	07/08/1976	LIQUID LEVEL IN TANK 102-S INCREASED 1.20 INCHES.	ASSUME INCREASE IS DUE TO SLUDGE FORMATION TYPICAL OF 242-S FEED.

Table D3.2-2. Summary of Occurrences. (33 sheets)

76-99	07/08/1976	LIQUID LEVEL IN TANK 115-TX INCREASED 1.25 INCHES.	UNKNOWN.
76-100	07/13/1976	RADIATION ACTIVITY INCREASE IN TANK 104-A LATERALS.	ASSUME MIGRATION OF PREVIOUSLY LEAKED WASTE.
76-101	07/16/1976	LIQUID LEVEL IN TANK 114-TX INCREASE EXCEEDED CRITERIA.	INCREASE DUE TO GAUGE CONTINUITY REPAIR.
76-102	07/20/1976	LIQUID LEVEL IN TANK 109-TX DECREASED, POSSIBLY EXCEEDING CRITERIA.	DECREASE IS DUE TO EVAPORATION AND TEMPERATURE DROP OF LIQUID WASTE.
76-103	07/20/1976	LIQUID LEVEL IN TANK 104-TX DECREASED 0.55 INCHES.	ASSUME LEVEL DECREASE IS DUE TO WASTE TEMPERATURE DROP.
76-109	07/28/1976	SURFACE LEVEL IN TANK 102-BX EXCEEDED LEVEL LIMIT.	LEVEL READINGS ARE ERRATIC DUE TO SURFACE IRREGULARITIES.
76-115	08/24/1976	PERSONNEL AND EQUIPMENT CONTAMINATION DURING PUMP REMOVAL FROM TANK 103-A.	PERSONNEL AND PROCEDURE ERRORS. PUMP BASE NOT SUPPORTED SO IT MOVED DURING TRANSFER, CONTAMINATION WAS DISLODGED.
76-118	08/31/1976	CROSS-COUNTRY TRANSFER LINE V361 ENCASEMENT SWAB RISERS HAD ACTIVITY INCREASE.	POSSIBLE MIGRATION OF PREVIOUS CONTAMINATION.
76-119	08/31/1976	RADIATION ACTIVITY IN TANK 107-SX DRY WELL INCREASED.	ASSUME INCREASED ACTIVITY DUE TO MIGRATION OF SOIL CONTAMINATION.
76-124	09/14/1976	MAXIMUM LEVEL LIMIT IN TANK 105-A EXCEEDED.	PERSONNEL, PROCEDURE ERRORS. ADDED TOO MUCH WATER TO TANK DURING SPRINKLING OPERATION.
76-125	09/21/1976	SURFACE LEVEL IN TANK 104-SX INCREASED 3.05 INCHES.	ASSUME INCREASE DUE TO FLOTATION AND GROWTH OF SALT CRUST FOLLOWING SLURRY RECEPTION.
76-126	09/21/1976	LIQUID LEVEL IN TANK 106-S INCREASED 3.0 INCHES.	SUSPECTED TRANSFER LINE VALVE IN-LEAKAGE IN SA VALVE PIT.
76-128	09/25/1976	APPARENT MAXIMUM LEVEL LIMIT EXCEEDED IN 002-AR SUMP.	LEVEL READINGS CHANGED WHEN THE ZIPCORD LEVEL GAUGE WAS REPLACED WITH A MANUAL TAPE REEL.
76-129	09/25/1976	APPARENT MAXIMUM LEVEL LIMIT EXCEEDED IN 003-UR SUMP.	LEVEL READINGS CHANGED WHEN THE ZIPCORD LEVEL GAUGE WAS REPLACED WITH A MANUAL TAPE REEL.
76-131	09/27/1976	RADIOACTIVE WASTE SPILL DURING JUMPER DISCONNECTION IN 105-U PUMP PIT.	MECHANICAL FAILURE. WASTE TRANSFER ONGOING IN ADJACENT TANK PRESSURIZED JUMPER DUE TO PARTIAL FAILURE OF A CLOSED VALVE.
76-132	09/21/1976	RADIATION INCREASE IN TANK 101-AY ANNULUS EXHAUST AIR.	ASSUME PROCESS CONDENSATE PASSING THROUGH CROSS-TIE BETWEEN ANNULUS VENT SYSTEM AND THE VESSEL VENT SYSTEM.
76-136	10/05/1976	RADIOACTIVE LIQUID SPRAYED FROM A CHECK VALVE UNDER REPAIR ONTO THREE PERSONNEL IN BX TANK FARM.	PERSONNEL ERROR. PREPARATIONS FOR THE REPAIR WERE INADEQUATE.
76-137	10/06/1976	LIQUID LEVEL IN TANK 108-TX DECREASE EXCEEDED CRITERIA.	ASSUME MANUAL TAPE PLUMMET IS CONTACTING A MOUND OF SALT IN THE TANK RESULTING IN ERRONEOUS READINGS.
76-138	10/04/1976	LIQUID LEVEL IN TANK 102-AY DECREASED 2.5 INCHES.	DECREASE IN TANK VOLUME DUE TO SHUTTING OFF STEAM TO HEATING COIL AND HIGH TEMPERATURES CAUSING EVAPORATION.
76-139	10/07/1976	INCREASED ACTIVITY IN CROSS-COUNTRY TRANSFER LINE V361 SWAB RISERS.	ASSUME CONTAMINATION IS FROM PREVIOUS LEAKS.
76-142	10/16/1976	LIQUID LEVEL IN TANK 108-BY INCREASED 3.5 INCHES.	ASSUME SURFACE SHIFT FROM SALT WELL PUMPING. ALSO, TAPE PLUMMET IS NESTLED IN A SWIRL OF OLD TAPE.
76-143	10/04/1976	APPARENT LEAK DETECTION PIT LEVEL INCREASES FOR TANK 102-AZ.	INSTRUMENT AIR VALVED OFF SOME INSTRUMENTS AND FAULTY TRANSMITTER. TANK NOT IN SERVICE AT TIME OF ANOMALIES.
76-146	10/25/1976	SURFACE LEVEL INDICATION IN TANK 108-SX INCREASED WHEN NEW MANUAL TAPE INSTALLED.	NEW TAPE NOT CALIBRATED CORRECTLY ACCORDING TO SYSTEM REFERENCE DRAWING.

Table D3.2-2. Summary of Occurrences. (33 sheets)

76-148	10/28/1976	LIQUID LEVEL IN TANK 102-AY BELOW MINIMUM LIMIT.	PROCEDURE. TANK PUMPED DOWN TO MINIMUM, THEN MAINTENANCE ON LEVEL TAPE OCCURRED, RESULTING IN LEVEL INDICATION BELOW MINIMUM LIMIT.
76-153	11/04/1976	LIQUID LEVEL IN TANK 105-C DECREASE EXCEEDED CRITERIA.	ASSUME LEVEL DECREASE DUE TO EVAPORATION.
76-155	11/08/1976	LIQUID LEVEL IN TANK 113-SX INCREASE EXCEEDED CRITERIA.	ASSUME LEVEL GAUGE PLUMMET MANIPULATION EFFECTS LEVEL INDICATION.
76-156	11/12/1976	LIQUID LEVEL IN TANK 115-TX INCREASED 3.0 INCHES.	ASSUME LIQUID DRAINING FROM SURROUNDING AREA OR SALT HAS SLUMPED INTO POOL AFTER TANK PUMPOUT.
76-163	12/03/1976	RADIATION ACTIVITY IN TANK 107-SX DRY WELL INCREASED.	ASSUME PREVIOUS LEAK CONTAMINATION IS MIGRATING.
76-164	12/03/1976	RADIATION ACTIVITY IN TANK 114-TX DRY WELL INCREASED.	ASSUME ACTIVITY IS DUE TO MIGRATION OF SOIL CONTAMINATION.
76-165	12/03/1976	WATER USED FOR 102-AX PUMP PIT WASH DOWN VAPORIZED AND CONTAMINATED THE GROUND AND VEHICLES NEAR THE PIT.	PERSONNEL ERROR. PERSONNEL DID NOT ANTICIPATE THE WATER FLASHING TO STEAM DUE TO COLD AMBIENT TEMPERATURE (22oF) AND LOW HUMIDITY.
76-172	12/15/1976	LIQUID LEVEL IN TANK 105-SX INCREASED 3.0 INCHES.	ASSUME SLURRY GROWTH TYPICAL OF 242-S EVAPORATOR SLURRIES.
76-174	12/21/1976	LIQUID LEVEL IN TANK 106-U DECREASED 0.5 INCHES.	UNKNOWN. ASSUME TANK IS SOUND.
76-175	12/28/1976	RADIATION ACTIVITY IN TANK 105-T DRY WELL INCREASED.	ASSUME LATERAL MIGRATION OF SOIL CONTAMINATION.
76-176	12/28/1976	RADIATION ACTIVITY IN TANK 101-T DRY WELL INCREASED.	ASSUME FURTHER MIGRATION OF PREVIOUS SOIL CONTAMINATION.
	01/03/1977	LIQUID LEVEL IN 001-TXR SUMP DECREASED 2.0 INCHES.	ASSUME RAINWATER DRAINAGE OR ZIPCORD LOCATION WAS THE CAUSE OF LEVEL INDICATION CHANGE.
77-01	01/10/1977	LIQUID LEVEL IN TANK 104-TX DECREASED .60 INCHES.	ASSUME LEVEL DECREASE ATTRIBUTABLE TO TEMPERATURE DROP.
77-06	01/14/1977	RADIOACTIVE ACTIVITY IN TANK 114-TX DRY WELL INCREASED.	ASSUME MIGRATION OF SOIL CONTAMINATION.
77-07	01/13/1977	LIQUID LEVEL IN TANK 102-SX INCREASED 3.0 INCHES.	ASSUME LEVEL CHANGE TYPICAL OF SLURRIES FROM 242-S EVAPORATOR.
77-08	01/13/1977	LIQUID LEVEL IN TANK 103-SX INCREASED 3.0 INCHES.	ASSUME LEVEL CHANGE TYPICAL OF SLURRIES FROM 242-S EVAPORATOR.
77-11	01/17/1977	LIQUID LEVEL IN TANK 101-S DECREASED .70 INCHES.	ASSUME CRUST MOVEMENT OR SURFACE DRYING COULD CAUSE LEVEL INDICATION CHANGES.
77-17	01/27/1977	SURFACE LEVEL IN TANK 104-SX INCREASED 3.01 INCHES.	ASSUME LEVEL INCREASE DUE TO FLOTATION AND GROWTH OF SALT CRUST.
77-18	01/27/1977	LIQUID LEVEL IN TANK 115-TX INCREASED 3.75 INCHES.	MECHANICAL FAILURE. BROKEN WATER VALVE IN FLUSH PIT DRAINING TO 115-TX.
77-19	01/31/1977	LIQUID LEVEL IN TANK 104-AX DECREASED 1.20 INCHES.	ASSUME LEVEL DECREASE DUE TO INCREASED EVAPORATION WITH INSTALLATION OF AN INLET AIR FILTER.
77-20	02/01/1977	LIQUID LEVEL IN TANK 107-TX DECREASED .40 INCHES.	ASSUME LEVEL DECREASE DUE TO REACTIVATING THE EXHAUSTER.
77-22	02/03/1977	TRANSFER PIPELINE EXPOSED AND STRUCK DURING EXCAVATION NEAR 244-AR VAULT.	PERSONNEL ERROR. PIPELINE LOCATION NOT NOTED ON EXCAVATION PERMIT.
77-23	02/07/1977	WATER LEAKAGE FROM 108-BX FLUSH PIT DRAINED TO TANK 108-BX.	MECHANICAL FAILURE. WATER VALVE BONNET BLEW OFF DURING FLUSH OF LINE BETWEEN 110-BY AND 105-BX.
77-25	02/08/1977	RADIATION ACTIVITY IN TANK 110-U DRY WELL INCREASED.	ASSUME MIGRATION OF SOIL CONTAMINATION.
77-29	02/22/1977	LIQUID LEVEL IN TANK 106-SX INCREASED 3 INCHES.	ASSUME LEVEL INCREASE TYPICAL OF WASTE SLURRIES RECEIVED FROM 242-S EVAPORATOR.
77-30	02/27/1977	LIQUID LEVEL IN TANK 111-U DECREASED .65 INCHES.	ASSUME LEVEL DECREASE DUE TO VOLUME CHANGES FROM TEMPERATURE DECREASE.

Table D3.2-2. Summary of Occurrences. (33 sheets)

77-31	02/28/1977	004-AR WEIGHT FACTOR REFERENCE LINE PLUGGED DURING TRANSFER, CAUSING OVERFILLING OF TANK AND AUTOMATIC SHUTDOWN OF VESSEL VENT SYSTEM.	MATERIAL. PLUGGED WEIGHT FACTOR REFERENCE LINE.
77-33	03/06/1977	LIQUID LEVEL IN TANK 103-SX INCREASED 3 INCHES.	ASSUME LEVEL INCREASE TYPICAL OF WASTE SLURRIES RECEIVED FROM 242-S EVAPORATOR.
77-34	03/02/1977	RADIATION ACTIVITY IN TANK 107-SX DRY WELL INCREASED.	ASSUME MIGRATION OF SOIL CONTAMINATION.
77-35	03/08/1977	LIQUID LEVEL IN TANK 202-C INCREASED >2.25 INCHES.	UNKNOWN. POSSIBLE RAW WATER IN-LEAKAGE CAUSE FOR LEVEL INCREASE.
77-36	03/10/1977	LIQUID LEVEL IN TANK 101-AX DECREASED >.50 INCHES.	ASSUME TANK INVENTORY OF WARM WASTE INCREASED EVAPORATIVE LOSS.
77-37	03/13/1977	LIQUID LEVEL IN TANK 102-SX INCREASED >3 INCHES.	ASSUME LEVEL INCREASE TYPICAL OF WASTE SLURRIES RECEIVED FROM 242-S EVAPORATOR.
77-43	03/25/1977	LIQUID LEVEL IN TANK 103-SX EXCEEDED MAXIMUM OPERATING LIMIT.	ASSUME LEVEL INCREASE DUE TO SALT CAKE GROWTH.
77-46	03/31/1977	LIQUID LEVEL IN 002-BXR-SUMP INCREASED >2 INCHES.	ASSUME LEVEL INCREASE DUE TO DRAINAGE OF RAINWATER.
77-52	04/12/1977	RADIOACTIVE CONDENSATE DRIPPING ONTO GROUND FROM 102-SY VENTILATION EXHAUST LINE.	MECHANICAL FAILURE. LEAKS DEVELOPED WITHIN THREE DAYS OF STARTING TO FILL NEW TANK.
77-53	04/15/1977	LIQUID LEVEL IN TANK 103-SX DECREASED >.5 INCHES.	ASSUME LATERAL MOVEMENT OF CRUST AFTER TRANSFER OUT OF TANK.
77-54	04/17/1977	RADIOACTIVE ACTIVITY ON 102-SY ANNULUS AIR SAMPLING FILTER FOLLOWING TRANSFER INTO TANK.	ASSUME RADIOACTIVE AEROSOL TRAVELED FROM TANK UP THROUGH PUMP PIT DRAIN AND INTO ANNULUS THROUGH ANNULUS PUMP PIT DUE TO NEGATIVE PRESSURE.
77-55	04/22/1977	LIQUID LEVEL IN TANK 107-TX INCREASED AND THEN DECREASED FOLLOWING CRANE WORK IN AREA.	UNKNOWN.
77-58	04/23/1977	LIQUID LEVEL IN 240-S-302 CATCH TANK DECREASED >2 INCHES.	ASSUME INCREASED EVAPORATION DUE TO NEGATIVE PRESSURE APPLIED TO TANK FROM THE REDOX PLANT.
77-59	04/24/1977	LIQUID LEVEL IN 002-UR TANK DECREASED 0.25 INCHES.	UNKNOWN.
77-60	04/26/1977	LIQUID LEVEL IN TANK 105-U DECREASED 1.35 INCHES.	ASSUME LEVEL INCREASE DUE TO SURFACE MATERIAL MOVEMENT OR SLOUGHING OFF OF MATERIAL COLLECTED ON FIC PLUMMET.
77-64	04/30/1977	MISROUTED WASTE TRANSFER INTO TANKS 101-SY, 103-SY, AND 103-SY LEAK DETECTION PIT, DURING TRANSFER FROM 111-U TO 102-SY.	PERSONNEL ERROR. TRANSFER MISROUTED.
77-65	04/29/1977	LIQUID LEVEL IN TANK TX-302-A CATCH TANK DECREASED >2 INCHES.	UNKNOWN.
77-66	05/04/1977	LIQUID LEVEL IN TANK 12-BX DECREASED >.5 INCHES.	FAILURE TO READJUST THE BASELINE FOLLOWING MAINTENANCE ON FIC PLUMMET.
77-68	05/10/1977	OVERFILLED TANK 103-S DURING TRANSFER FROM 242-S EVAPORATOR AND DIVERSION OF STEAM CONDENSATE.	PERSONNEL ERROR. STEAM CONDENSATE WAS INADVERTENTLY VALVE TO WASTE TANK INSTEAD OF CRIB.
77-69	05/10/1977	LIQUID LEVEL IN TANK 106-BY INCREASED 2 INCHES.	ASSUME FAILURE OF MANUAL LIQUID LEVEL MEASURING DEVICE.
77-70	05/11/1977	LIQUID LEVEL IN TANK 108-TX SHOWED DISCREPANCY OF 24 INCHES BETWEEN FIC AND THE MANUAL TAPE.	FIC TAPE WAS FABRICATED INCORRECTLY.
77-71	05/13/1977	LIQUID LEVEL IN TANK 102-SX DECREASED 2.95 INCHES AFTER TRANSFER FROM 103-S.	ASSUME MIXING SALT CAKE AND DILUTE WASTE IN TRANSFER CAUSED LEVEL DECREASE. NO CAUSE WAS CERTAIN.

Table D3.2-2. Summary of Occurrences. (33 sheets)

77-73	05/20/1977	LIQUID LEVEL IN TANK 106-U DECREASED 1.7 INCHES.	UNKNOWN. TANK CONTENTS ORDERED TRANSFERRED.
77-74	05/23/1977	LIQUID LEVEL IN TANK 105-SX DECREASED >.5 INCHES.	ASSUME THE FIC INSTRUMENT IS NOT IN CONTACT WITH LIQUID, EXPECTED TO VARY.
77-76	05/25/1977	LIQUID LEVEL IN TANK 110-BX DECREASED 1.25 INCHES.	ASSUME INACCURATE INSTRUMENT READING OF THE LIQUID LEVEL.
77-77	05/24/1977	LIQUID LEVEL IN TANK 107-BY INCREASED 2.25 INCHES.	ASSUME LEVEL INDICATION CHANGE DUE TO UNEVEN SURFACE OF WASTE.
77-78	05/25/1977	LIQUID LEVEL IN 151-AX DIVERTER STATION CATCH TANK EXCEEDED MAXIMUM LIMIT.	OVERFLOW TO CATCH TANK WAS ANTICIPATED, BUT EXCEEDED THE LEVEL LIMIT WAS NOT. PROCEDURE PROBLEM.
77-79	05/24/1977	OPERATIONS PERSONNEL CONTAMINATED WHILE INSERTING A NEW MANUAL TAPE IN TANK 106-SX.	PERSONNEL AND PROCEDURE ERROR. SHOULD HAVE WORN WATER PROOF GLOVES.
77-81	05/25/1977	LIQUID LEVEL IN TANK 103-B EXCEEDED REUSE CRITERION.	PERSONNEL AND PROCEDURE ERROR. EMPLOYEE FAILED TO USE REUSE PROCEDURE AND PROCEDURE HAD INADEQUATE APPROVAL FORM.
77-82	05/29/1977	LIQUID LEVEL IN TANK 106-SX INCREASED >3 INCHES.	ASSUME INCREASE DUE TO WASTE VOLUME EXPANSION, AND ACCUMULATION OF MATERIAL ON FIC LEVEL DEVICE.
77-84	05/31/1977	PERSONNEL CONTAMINATION WHILE REMOVING A SLUDGE WEIGHT FROM TANK 104-AX RISER.	PERSONNEL ERROR. IMPROPER REMOVAL OF PROTECTIVE CLOTHING.
77-87	06/06/1977	LIQUID LEVEL IN 002-TXR SUMP EXCEEDED LIMIT.	INCREASE DUE TO RAINWATER SEEPING INTO SUMP.
77-91	06/10/1977	RAW WATER LINE BREAK NEAR TANKS 112-SX AND 115-SX CAUSING 100 SQUARE FOOT PUDDLE.	MECHANICAL FAILURE. RAW WATER LINE BREAK.
77-92	06/09/1977	LIQUID LEVEL IN TANK 101-SY INCREASED 2.95 INCHES.	ASSUME WASTE EXPANSION IN TANK. RECEIVER OF 242-S EVAPORATOR CRYSTALLIZER.
77-93	06/11/1977	LIQUID LEVEL IN TANK 103-BX DECREASED .6 INCHES.	ASSUME REDISTRIBUTION OF SLUDGE FOLLOWING TRANSFER OF 46 INCHES.
77-100	06/21/1977	LIQUID LEVEL IN 011-BXR TANK DECREASED 1.25 INCHES.	UNKNOWN.
77-101	06/21/1977	LIQUID LEVEL 002-BXR SUMP INCREASED 2.25 INCHES.	ASSUME LEVEL INCREASE MAY BE DUE TO RAINWATER DRAINAGE.
77-103	12/07/1977	MANY INSTANCES OF RADIATION ACTIVITY IN TANK 103-TX DRY WELLS.	ASSUME MANY CAUSES OF INCREASED ACTIVITY: TANK LEAK, TANK OVERFILL, TRANSFER LINE LEAKAGE, MIGRATION OF SOIL CONTAMINATION, OR CONTAMINATION CARRIED BY MATERIAL CHANNELING.
77-105	06/29/1977	TANK 111-U OVERFILLED DURING A TRANSFER FROM 107-TX AND 102-U.	PERSONNEL ERROR. FAILURE TO NOTE LEVEL LIMIT, AND FAILURE TO RESPOND TO HIGH LEVEL ALARM.
77-107	06/30/1977	LIQUID LEVEL IN TANK 102-TX DECREASED 7 INCHES.	HOT WATER FLUSH OF LEVEL TAPE AND PLUMMET CAUSED LEVEL INDICATION CHANGE.
77-108	06/30/1977	LIQUID LEVEL IN TANK 106-A DECREASED 1 INCH.	ASSUME INCREASED EVAPORATION CAUSED LEVEL DECREASE.
77-109	07/05/1977	LIQUID LEVEL IN TANK 105-TX DECREASED 2.5 INCHES.	UNKNOWN.
77-114	05/06/1977	LIQUID LEVEL IN TANK 109-B DECREASED 3.5 INCHES.	ASSUME LEVEL INDICATION CHANGE CAUSED BY EROSION OF SALT CRUST UNDER THE PLUMMET CAUSED BY A FLUSH.
77-115	07/06/1977	LIQUID LEVEL IN TANK 107-TX DECREASED .5 INCHES.	LEVEL CHANGE CAUSED BY OPERATION OF A SUBMERSIBLE PUMP.
77-116	07/09/1977	LIQUID LEVEL IN TANK 102-TY DECREASED .8 INCHES.	ASSUMED SLUMPING OF SLUDGE FOLLOWING TANK PUMPING CAUSED THE LEVEL CHANGE.
77-117	07/07/1977	PIPEFITTERS WERE WORKING IN A FLUSH PIT THAT HAD A BACK UP OF PROCESS SOLUTION IN THE FLUSH LINE.	PERSONNEL ERROR. HPT THOUGHT THE WORK WOULD BE DONE IN A CLEAN PIT.

Table D3.2-2. Summary of Occurrences. (33 sheets)

77-118	07/13/1977	TANK 101-S OVERFILLED TO STANDARD LIMIT, WHICH IS 3 INCHES ABOVE THE OPERATING LIMIT.	PERSONNEL ERROR. PERSONNEL FAILED TO REALIZE THAT LEVEL WAS CLOSE TO THE LIMIT.
77-120	07/15/1977	LIQUID LEVEL IN TANK 108-U INCREASED 3.2 INCHES.	FAILURE TO RESET BASELINE AFTER FLUSH TRANSFERRED TO TANK, AND APPARENT TYPICAL GROWTH OF SLURRY FROM 242-S EVAPORATOR.
77-122	07/19/1977	RADIOACTIVE MATERIAL ON AIR SAMPLE FILTERS FROM TANKS 101-AZ AND 102-AZ.	APPARENT COLLECTION OF NATURALLY OCCURRING RADIONUCLIDES FROM A THORIUM SERIES.
77-125	07/21/1977	LIQUID LEVEL IN TANK 101-A DECREASED .7 INCHES.	APPARENT HIGHER RATE OF EVAPORATION DUE TO INCREASED TEMPERATURE FROM SLURRY ADDITION.
77-132	08/03/1977	OPERATION OF 002-BXR PUMP IN STRONG ACID SOLUTION.	PERSONNEL ERROR. ACID WAS TO HAVE BEEN NEUTRALIZED BEFORE PLACING PUMP IN SOLUTION.
77-133	08/03/1977	LIQUID LEVEL IN TANK 105-SX INCREASED 3.2 INCHES.	ASSUME LEVEL INCREASE DUE TO TYPICAL GROWTH OF 242-S SLURRIES.
77-136	08/06/1977	LIQUID LEVEL IN TANK 103-SX INCREASED 3.1 INCHES.	ASSUME LEVEL INCREASE DUE TO TYPICAL GROWTH OF 242-S SLURRIES.
77-137	08/08/1977	2200 GALLONS MISROUTED TO TANK 109-TX DURING 102-TY TO 105-TX TRANSFER.	VALVE IN 109-TX PIT COULD NOT BE COMPLETELY CLOSED DUE TO INTERFERENCE FROM JUMPER.
77-138	08/13/1977	LIQUID LEVEL IN TANK 114-TX INCREASED 2.25 INCHES.	ASSUME LIQUID IS SEEPING INTO DEPRESSION LEFT BY SALT WELL PUMPING.
77-139	08/13/1977	LIQUID LEVEL IN TANK 101-AX DECREASED 1 INCH.	UNKNOWN.
77-140	08/14/1977	LIQUID LEVEL IN TANK 109-U INCREASED 3.1 INCHES.	ASSUME LEVEL INCREASE DUE TO TYPICAL GROWTH OF 242-S SLURRIES.
77-141	08/15/1977	LIQUID LEVEL IN TANK 103-A DECREASED .9 INCHES.	ASSUME DISSOLUTION OF A FOAM WHICH HAD BEEN OBSERVED DURING LAST SLURRY TRANSFER.
77-144	08/18/1977	RADIATION ACTIVITY IN TANKS 110-TX AND 114-TX DRY WELL.	ASSUME MIGRATION OF SOIL CONTAMINATION.
77-146	08/24/1977	241-SY EXHAUSTER MOISTURE SEPARATOR LEAKED EXTERNALLY, SPREADING CONTAMINATION ONTO CONCRETE PAD.	MECHANICAL FAILURE. APPARENT WELD LEAKS.
77-147	08/24/1977	LIQUID LEVEL IN TANK 101-S DECREASED .7 INCHES.	LEVEL CHANGE IS APPARENT TRANSIENT PHENOMENA ASSOCIATED WITH 242-S EVAPORATOR TRANSFER.
77-148	08/25/1977	LIQUID LEVEL IN TANK 101-TY INCREASED 4.1 INCHES.	ASSUME LEVEL INDICATION CHANGE IS DUE TO LEVEL DEVICE MOVING OVER A DISCARDED FIC TAPE.
77-150	08/30/1977	LIQUID LEVEL IN TANK 105-TX DECREASED 6.75 INCHES.	APPARENT CAUSE OF LEVEL INDICATION CHANGE IS LATERAL MOVEMENT OF THE FIC PLUMMET OVER RAPIDLY CHANGING TERRAIN.
77-151	09/02/1977	LIQUID LEVEL IN TANK 101-B INCREASED 1.15 INCHES.	ASSUME LEVEL INDICATION CHANGE CAUSED BY A RAINWATER ACCUMULATION UNDER LEVEL MEASUREMENT TAPE.
77-152	09/04/1977	LIQUID LEVEL IN TANK 111-S INCREASED 3.1 INCHES.	LEVEL INCREASE CHANGE CAUSED BY REDISTRIBUTION OF LIQUID PRESENT IN THE SALT CAKE AND SLUDGE.
77-155	09/08/1977	EXCEEDED MAXIMUM LEVEL LIMIT IN 002-TXR TANK BY 4.25 INCHES.	PERSONNEL ERROR. TANK OVERFILLED WHEN FLUSHING LINE FROM 155-TX DIVERSION BOX TO 002-TXR TANK.
77-156	09/12/1977	LIQUID LEVEL IN TANK 105-U INCREASED 3.1 INCHES.	ASSUME LEVEL CHANGE DUE TO EXPANSION OF SLURRY MATERIAL IN TANK.
77-158	09/12/1977	EXCEEDED MAXIMUM LEVEL LIMIT IN 002-TXR SUMP.	FLUSH OF LINE BETWEEN TANKS 103-TX AND 102-SY OCCURRED, THE LINE BROKE IN 151-TXR DIVERSION BOX WHICH OVERFILLED THE SUMP.
77-160	09/14/1977	LIQUID LEVEL IN TANK 114-TX EXCEEDED MAXIMUM OPERATING LIMIT.	APPARENT CAUSE OF LEVEL INCREASE IS DUE TO WATER ENTERING THE TANK FROM PRESSURE TESTING A LINE INTO THE TANK.

Table D3.2-2. Summary of Occurrences. (33 sheets)

77-161	09/15/1977	LIQUID LEVEL IN TANK 106-BY INCREASED 1.25 INCHES.	APPARENT CAUSE OF LEVEL INCREASE IS SHIFTING OF THE UNEVEN SALT CRUST.
77-163	09/19/1977	LIQUID LEVEL IN TANK 102-BY INCREASED 1.25 INCHES.	APPARENT CAUSE OF LEVEL INCREASE IS REDISTRIBUTION OF LIQUID AFTER A SALT WELL TRANSFER.
77-168	09/23/1977	LIQUID LEVEL IN TANK 111-U INCREASED 2.1 INCHES.	APPARENT CAUSE OF LEVEL INCREASE ID DRAINAGE FROM U-C AND U-D VALVE PITS AND FLUSH PITS.
77-169	09/23/1977	LIQUID LEVEL IN TANK 115-TX DECREASED 2.25 INCHES.	ASSUME LEVEL CHANGE IS DUE TO SETTLING OF SLUDGE FOLLOWING SALT WELL PUMPING.
77-171	09/29/1977	PUREX SUMP WASTE JETTED TO TANK 104-C INSTEAD OF TANK 102-A.	PERSONNEL AND PROCEDURE ERRORS. PROCEDURE CHANGES HAD NOT BEEN COMPLETED.
77-172	09/29/1977	LIQUID LEVEL IN TANK 201-C INCREASED 2.25 INCHES.	ASSUME LEVEL INCREASE DUE TO NATURALLY OCCURRING PRECIPITATION.
77-174	10/03/1977	LIQUID LEVEL IN TANK 102-U INCREASED 2.05 INCHES.	ASSUME LEVEL INCREASE DUE TO EXPANSION OF SLURRY IN TANK.
77-175	10/04/1977	LIQUID LEVEL IN TANK 101-SY INCREASED 2.05 INCHES.	ASSUME LEVEL INCREASE DUE TO EXPANSION OF SLURRY IN TANK.
77-177	10/10/1977	LIQUID LEVEL IN TANK 202-B DECREASED 1 INCH.	ASSUME LEVEL DECREASE DUE TO SLUDGE SETTLING FOLLOWING PUMPING OF THE TANK.
77-178	10/11/1977	LIQUID LEVEL IN TANK 111-BY DECREASED 1 INCH.	ASSUME LEVEL CHANGE DUE TO TAPE PLUMMET TOUCHING UNEVEN SURFACE CRUST.
77-182	10/12/1977	LIQUID LEVEL IN TANK 105-TX DECREASED 36.75 INCHES.	LEVEL CHANGE DUE TO MOVEMENT OF LEVEL TAPE PLUMMET INTO A HOLE IN THE TANK SURFACE LEFT AFTER SALT WELL PUMPING.
77-184	10/15/1977	LIQUID LEVEL IN TANK 105-SX INCREASED 4.2 INCHES.	ASSUME LEVEL INCREASE DUE TO EXPANSION OF THE SLURRY IN THE TANK.
77-186	10/18/1977	LIQUID LEVEL IN TANK 108-T INCREASED .75 INCHES.	ASSUME LEVEL INCREASE IS DUE TO ACCUMULATION OF MATERIAL ON THE TAPE PLUMMET.
77-188	10/20/1977	LIQUID LEVEL IN TANK 104-SX INCREASED 3.55 INCHES.	ASSUME LEVEL INCREASE IS DUE TO EXPANSION OF THE SLURRY IN THE TANK.
77-189	10/19/1977	RADIOACTIVE ACTIVITY ON 102-SY ANNULUS AIR FILTER.	MECHANICAL FAILURE. FAILURE OF BLANK BETWEEN TANK PUMP PIT AND LEAK DETECTION PIT. FLOW IS THEN THROUGH AN UNDERGROUND LINE.
77-190	10/23/1977	LIQUID LEVEL IN TANK 106-SX INCREASED 3.1 INCHES.	ASSUME LEVEL INCREASE DUE TO RECEIPT OF CONDENSATE FROM OTHER SX TANKS.
77-191	11/02/1977	LIQUID LEVEL IN TANK 102-S INCREASED 7 INCHES.	ASSUME CAUSE OF LEVEL INCREASE IS DUE TO DRAINAGE FROM SA AND SB VALVE PITS.
77-193	11/05/1977	LIQUID LEVEL IN TANK 105-U DECREASED .55 INCHES.	ASSUME DECREASE DUE TO SETTLING OF TANK MATERIAL FOLLOWING TRANSFER.
77-194	11/06/1977	LIQUID LEVEL IN TANK 109-U INCREASED 3.05 INCHES.	ASSUME LEVEL INCREASE DUE TO GROWTH OF CRUST ON TANK SURFACE.
77-196	11/08/1977	RADIATION ACTIVITY IN TANK 105-T DRY WELL INCREASED.	ASSUME ACTIVITY DUE TO REDISTRIBUTION OF TANK 106-T LEAK PLUME.
77-199	11/12/1977	LIQUID LEVEL IN TANK 104-TX DECREASED .9 INCHES.	ASSUME LEVEL DECREASE IS DUE TO MOVEMENT OF A PATCH OF CRUST FROM THE VICINITY OF THE TAPE PLUMMET.
77-200	11/15/1977	DURING PRESSURE TEST OF 001-AR TANK UPPER COIL, CONTAMINATION RELEASED IN A VALVE PIT AND THE PIT THAT RECEIVES ALL COOLING WATER FROM THE AR VAULT.	PROCEDURE ERROR. PROCEDURE INCORRECT TO PREVENT SPREAD OF CONTAMINATION, AND LACK OF WARNINGS IN PROCEDURE FOR PERSONNEL.

Table D3.2-2. Summary of Occurrences. (33 sheets)

77-201	11/18/1977	LIQUID LEVEL IN TANK 112-T DECREASED 1 INCH.	ASSUME LEVEL DECREASE IS DUE TO LEVEL TAPE PLUMMET MOVEMENT OVER AN IRREGULAR SURFACE.
77-202	11/22/1977	RADIATION ACTIVITY IN TANK 104-AX DRY WELL INCREASED.	SEVERAL CAUSES ARE CONSIDERED FOR THIS EVENT. CONTAMINATION FROM PREVIOUS COUPLING LEAK, FROM EXHAUST SYSTEM, FROM NEARBY PROCESS PIPING, OR FROM TANK LEAK.
77-205	12/06/1977	SPRAY LEAK FROM 111-S PUMP PIT DURING LEAK CHECK OF SALT WELL PUMP AND JUMPER.	PROCEDURE ERROR AND MECHANICAL FAILURE. LEAK CHECK SHOULD BE DONE WITH COVER BLOCKS INSTALLED, AND FAILED GASKET AT PUMP INLET FLANGE.
77-206	12/08/1977	LIQUID LEVEL IN TANK 101-S INCREASED 2.35 INCHES.	ASSUME CRYSTAL GROWTH IN THE SLURRY IN THE TANK.
77-207	12/08/1977	LIQUID LEVEL IN TANK 101-SY INCREASED 2.9 INCHES.	ASSUME CRYSTAL GROWTH IN THE SLURRY IN THE TANK.
77-208	12/10/1977	LIQUID LEVEL IN TANK 106-TX DECREASED 2.25 INCHES.	ASSUME LEVEL INDICATION DECREASE DUE TO DEPRESSION IN SURFACE CRUST CAUSED BY MANUAL TAPE PLUMMET.
77-210	12/20/1977	LIQUID LEVEL IN TANK 203-T DECREASED 2.5 INCHES.	ASSUME LEVEL DECREASE IS DUE TO SETTLING OF THE SLUDGE FOLLOWING SALT WELL PUMPING.
77-211	12/23/1977	LIQUID LEVEL IN TANK 101-SX DECREASED 1.1 INCHES.	ASSUME LEVEL DECREASE CAUSED BY DISSOLUTION OF SALT CRYSTALS FOLLOWING WATER ADDITION.
77-212	12/23/1977	LIQUID LEVEL IN TANK 103-TX DECREASED .6 INCHES.	ASSUME LEVEL DECREASE CAUSED BY MOVEMENT OF FOAM OR SLUDGE UNDER THE TAPE PLUMMET.
78-1	01/02/1978	LIQUID LEVEL IN TANK 101-A INCREASED 3.1 INCHES.	ASSUME LEVEL INCREASE DUE TO MATERIAL ON THE TAPE PLUMMET.
78-2	01/02/1978	WASTE MISROUTED FROM 004-AR TO TANK 102-A RATHER THAN TANK 106-A.	PERSONNEL AND PROCEDURE ERRORS. SUPERVISOR SIGNED INCOMPLETE DATA SHEET WITHOUT PROPER REVIEW, AND PROCEDURE LACKS ADEQUATE CHECKS AND APPROVALS.
78-3	01/06/1978	LIQUID LEVEL IN TANK 103-SX DECREASED 1 INCH.	ASSUME LEVEL DECREASE DUE TO FIC MOVING OVER IRREGULAR FISSURED CRUST.
78-4	01/08/1978	LIQUID LEVEL IN TANK 101-S DECREASED .6 INCHES.	UNKNOWN.
78-6	01/10/1978	BACKFLOW OF CONTAMINATION INTO RAW WATER SYSTEM IN 241-TX TANK FARM.	PERSONNEL ERROR/PROCEDURE. CHECK VALVE ON FLUSH PIPING INSTALLED IN THE INVERTED POSITION, MANUAL FLUSH VALVE LEFT PARTIALLY OPEN.
78-13	01/23/1978	UNDETECTED FILLING OF A-40 RETENTION BASIN AT 244-AR VAULT WITH 200,000 GALLONS.	MECHANICAL FAILURES. RADIATION ALARM FAILED CAUSING DIVERTER VALVE TO DIVERT. VALVE STEM WAS BINDING AND THE VALVE DID NOT CLOSE COMPLETELY, INDICATING LIGHT SHOWED VALVE CLOSED.
78-14	01/20/1978	CONTAMINATED LIQUID SPRAYED FROM HOLE DRILLED IN TOP OF TRANSFER LINE V453 WHEN PREPARING TO CUT LINE.	PROCEDURE ERROR. NO CONTAINMENT USED WHEN DRILLING INTO LINE. (SIMILAR TO 76-64)
78-15	01/23/1978	LIQUID LEVEL IN TANK 103-A DECREASED .75 INCHES.	ASSUME LEVEL DECREASE INDICATION DUE TO FIC PLUMMET MOVEMENT OVER IRREGULAR SURFACE.
78-16	01/23/1978	LIQUID LEVEL IN TANK 101-SY INCREASED 3.05 INCHES.	ASSUME LEVEL INCREASE DUE TO EXPANSION OF THE TANK MATERIAL.
78-18	02/09/1978	LIQUID LEVEL IN TANK 111-BY DECREASED 1.25 INCHES.	ASSUME LEVEL DECREASE DUE TO COMPACTION OF THE SURFACE BY THE TAPE PLUMMET, OR TO CONTACT WITH A DISCARDED TAPE LYING ON THE WASTE SURFACE.
78-24	02/23/1978	UNDERGROUND RAW WATER LINE BREAK RELEASED 60,000 GALLONS IN 241-A TANK FARM AND CAUSED CAVE-IN BETWEEN 102-A AND 105-A. HOLE READ 1R/HR DUE TO WATER FLOW THROUGH A BURIED UNUSED DE-ENTRAINER.	MECHANICAL FAILURE. RAW WATER LINE M5a RUPTURE.

Table D3.2-2. Summary of Occurrences. (33 sheets)

78-26	03/02/1978	ELECTRICIAN ENTERED A 15 R/HR RADIATION FIELD IN 244-AR CANYON.	PERSONNEL ERROR. FAILURE OF TEAM IN CANYON TO RECOGNIZE THE RADIATION HAZARD.
78-30	03/22/1978	LIQUID LEVEL IN TANK 106-SX DECREASED .7 INCHES.	ASSUME LEVEL DECREASE DUE TO SLUDGE SETTLING FOLLOWING PUMP OUT.
78-39	04/17/1978	LIQUID LEVEL IN TANK 109-B DECREASED .55 INCHES.	ASSUME LEVEL DECREASE IS DUE TO SLIPPAGE OF THE FIC PLUMMET DOWN SLOPE IN CRUST.
78-44	04/25/1978	RAW WATER LINE LEAK OF 5000 GALLONS BETWEEN 241-S AND 241-SX TANK FARMS.	MECHANICAL FAILURE OF A BELL AND SPIGOT JOINT IN THE RAW WATER LINE.
78-47	05/08/1978	RADIOACTIVE DISCHARGE TO 216-A-8 CRIB EXCEEDED LIMITS.	ASSUME VENT HEADER EXTENSION SEAL LOOP CONDENSATE FOR A, AX, AY, AND AZ FARMS DRAINED INTO LINE.
78-49	05/15/1978	RADIATION ACTIVITY IN TANK 105-A DRY WELL INCREASED.	ASSUME TWO CAUSES: ADDING COOLING WATER TO THIS KNOWN LEAKING TANK, EARLIER RAW WATER SPILL IN 241-A FARM.
78-53	05/23/1978	LIQUID LEVEL IN TANK 103-SX DECREASED .55 INCHES.	ASSUME LEVEL DECREASE DUE TO PLUMMET MOVEMENT OVER IRREGULAR SURFACE.
78-54	05/19/1978	LIQUID LEVEL IN TANK 111-U DECREASED .7 INCHES.	ASSUME LEVEL DECREASE DUE TO FOAM MATERIAL UNDER THE FIC PLUMMET.
78-60	06/09/1978	RADIATION ACTIVITY IN TANK 108-T DRY WELL INCREASED.	ASSUME ACTIVITY INCREASE DUE TO 106-T LEAK PLUME.
78-64	06/21/1978	ROAD GRADER STRUCK TRANSFER LINES HSW-202-M8 AND HSW-203-M8, LINE 202 ENCASEMENT WAS BENT AND PARTIALLY CRUSHED.	PERSONNEL ERROR. RESPONSIBLE PARTY WAS NOT FOLLOWING THE ROAD GRADING WORK, TRANSFER LINES WERE WELL MARKED AND BERMED.
78-69	07/05/1978	HIGH LEVEL WASTE LODGED STUCK IN CAISSON CHUTE WHILE BEING UNLOADED INTO FACILITY.	PROCEDURE ERROR AND DESIGN INADEQUATE. CASK AND CAISSON CHUTE DO NOT MATE PROPERLY AND UNLOADING PROCEDURAL CONTROL INADEQUATE.
78-73	06/12/1978	VACUUM TEST OF FIBERGLASS REINFORCED PLASTIC AND WOOD BOXES RESULTED IN STRUCTURAL FAILURE OF THE BOXES. SUSPECT THAT ALREADY BURIED BOXES ALSO WOULD FAIL.	DESIGN PROBLEMS OF THE BURIAL BOXES.
78-76	07/26/1978	MINOR LEAK IN 4-INCH RAW WATER LINE NEAR 241-TX TANK FARM.	MECHANICAL FAILURE OF A BELL AND SPIGOT JOINT IN LINE.
78-78	07/25/1978	RADIOGRAPHY CREW LEFT THE JOB SITE IN 241-TX FARM DUE TO AN UNDERGROUND TRANSFER IN PROGRESS.	PERSONNEL ERROR. PROBLEMS IN SCHEDULING AND MANAGING PERSONNEL.
78-80	07/27/1978	PROCESS TRANSFER LINE EXPOSED DURING HAND EXCAVATION, OVER-EXPOSURE OF PERSONNEL.	PROCEDURE ERROR. PERSONNEL NOT MADE AWARE OF THE PRESENCE OF THE UNDERGROUND LINE.
78-83	08/10/1978	MISTRANSFER OF WASTE FROM TANK 101-A TO TANK 104-BX INSTEAD OF 102-A.	PERSONNEL ERROR. VALVING CHANGED IN AA VALVE PIT INSTEAD OF AB VALVE PIT DURING TRANSFER.
78-87	08/17/1978	TWO 55-GALLON DRUMS ON 4-C ALPHA PAD APPEAR DISTORTED. DRUMS CONTAIN PLUTONIUM IN SOLUTION.	ASSUME THE CONTAINERS ARE PRESSURIZING AS A RESULT OF CHEMICAL REACTIONS OF THEIR CONTENTS.
78-88	08/22/1978	TRANSFER LINE BETWEEN TANK 107-S AND 105-BX PLUGGED DURING TRANSFER.	PLUGGAGE APPEARS TO BE CAUSED BY SOLIDS SETTLED IN LINE WHEN POWER WAS LOST TO 107-S TRANSFER PUMP.
78-89	08/24/1978	RADIATION ACTIVITY IN DRY WELL BETWEEN TANK 104-U AND 105-U INCREASED.	APPARENT SOURCE OF INCREASED ACTIVITY IS TANK 104-U WHICH IS A LEAKER.
78-90	08/26/1978	FRACTURED 6" SANITARY WATER LINE AND 8" RAW WATER LINE NEAR 275-EA BUILDING. AFFECTED WATER SUPPLY TO 244-AR FACILITY.	APPARENT CAUSE OF BROKEN PIPES WAS FROM HEAVY WEIGHT OF A CRANE UNLOADING PLATES FROM A RAILROAD CAR FOR USE AT 241-AW TANK FARM.

Table D3.2-2. Summary of Occurrences. (33 sheets)

78-98	09/12/1978	PERSONNEL WIPING OFF POLE USED TO RELOCATE JUMPER IN 152-A DIVERSION BOX INGESTED RADIOACTIVE MATERIAL AND SUFFERED SKIN CONTAMINATIONS.	PERSONNEL ERROR. FAILURE TO FOLLOW PROCEDURE OR WEAR APPROPRIATE PROTECTIVE CLOTHING.
78-117	10/30/1978	UNDETECTED FAILURE OF LEAK DETECTORS IN 241-SA AND 241-SB VALVE PITS DURING CROSS-COUNTRY TRANSFER.	MECHANICAL PROBLEM. COMMON DRAIN FOR BOTH VALVE PITS BLOCKED.
78-121	11/15/1978	LIQUID LEVEL IN TANK 106-B DECREASED .6 INCHES.	UNKNOWN.
78-129	12/04/1978	LIQUID LEVEL IN CATCH TANK TX-302-A DECREASED 2.25 INCHES.	UNKNOWN.
78-130	12/02/1978	CONTAMINATED VAPOR VENTING FROM TANK 105-BX AIR INLET RISER AND 104-BX CENTER PIT.	TRANSFER INTO TANK DISPLACED WARM VAPORS OUT THIS TANK'S OPENINGS. TANK IS NOT EXHAUSTED.
79-02	01/02/1979	RAW WATER LEAK OF 37,500 GALLONS LEAKED FROM 241-S/SX SERVICE PIT.	PERSONNEL AND MECHANICAL FAILURES. HOUSING ON PIT WATER METER FAILED, AND PERSONNEL DID NOT VALVE OUT RAW WATER SUPPLY AS REQUIRED.
79-17	02/02/1979	LIQUID LEVEL IN TANK 103-SY DECREASED 2.8 INCHES.	ASSUME LEVEL DECREASE DUE TO COLLAPSE OF SURFACE CRUST.
79-20	02/07/1979	LIQUID LEVEL IN TANK 110-U INCREASED .2 INCHES.	LEVEL INCREASE ATTRIBUTED TO WATER INTRUSION THROUGH PUMP PIT.
79-22	02/08/1979	RADIATION ACTIVITY IN DRY WELL NEAR TANKS 103-TX AND 107-TX INCREASED.	APPARENT MIGRATION OF CONTAMINATION IN SOIL.
79-25	02/12/1979	IMPROPER VALVE LINE-UP DURING WASTE TRANSFER OR SUBSEQUENT FLUSHING CONTAMINATED RAW WATER HOSE BIB IN 241-S FLUSH PIT.	PERSONNEL ERROR. IMPROPER VALVING IN FLUSH PIT OR VALVE PIT.
79-26	02/17/1979	MISROUTING OF TRANSFER FROM TANK 102-S TO TANK 103-SX INSTEAD OF TANK 106-SX.	PERSONNEL ERROR. IMPROPER VALVING IN 241-SX-A VALVE PIT.
79-29	01/31/1979	CONTAMINATED VAPOR VENTED FROM TANK 118-TX #1 RISER WHICH CONTAINS THE LIQUID LEVEL REEL.	UNKNOWN CAUSE AT TIME OF REPORT.
79-31	03/21/1979	LIQUID LEVEL IN TANK 110-TX DECREASED 2.5 INCHES.	UNKNOWN.
79-34	03/22/1979	CONTAMINATED VAPOR VENTED FROM TANK 106-U RISER #9, WHICH CONTAINS THE LIQUID LEVEL REEL.	NOT REPORTED.
79-35	03/22/1979	CORE DRILL STRING CONTACT WITH BOTTOM OF TANK 107-BX, WHICH BROKE THE DRILL ROD.	PROCEDURE ERROR. INADEQUATE ADMINISTRATIVE CONTROL OF DOCUMENTATION OF DRILL ROD SEGMENTS.
79-37	03/28/1979	RADIATION ACTIVITY IN TANK 107-BY DRY WELL INCREASED.	UNKNOWN.
79-38	03/28/1979	LIQUID LEVEL IN TANK 102-S EXCEEDED LIMIT.	PERSONNEL ERROR. INATTENTION BY CASS OPERATORS TO LEVEL ALARMS.
79-39	03/29/1979	LIQUID LEVEL IN 103-AX LEAK DETECTION PIT INCREASED.	ASSUME SNOW MELT INTRUSION THROUGH DRAIN BELLOWS ASSEMBLY.
79-60	05/23/1979	CONTAMINATED SWALLOW NESTS FOUND AT 244-AR VAULT.	BIRDS PICKED UP CONTAMINATED MUD FROM 216-A-40 RETENTION BASIN. BLADDER TYPE BAGS AT RETENTION BASIN HAVE LEAKS.
79-61	05/25/1979	SLURRY LINE SL-113 LEAKED IN 241-S FARM WHEN BEING READIED FOR A PRESSURE TEST.	MECHANICAL FAILURE OF 2-INCH CARBON STEEL LINE.
79-65	06/06/1979	WASTE TANK SURVEILLANCE SIGNALS LOST WHEN LINES CUT BY BACKHOE NEAR 241-B AND BX TANK FARMS.	PERSONNEL ERROR. PROCEDURE INDICATED HAND DIGGING IN THIS AREA INSTEAD OF BACKHOE USE.
79-68	07/11/1979	LIQUID LEVEL IN TANK 001-TXR DECREASED 1.25 INCHES.	UNKNOWN. TANK INTEGRITY IS QUESTIONABLE.
79-70	07/13/1979	LIQUID LEVEL IN 011-BXR VAULT TANK DECREASED 1.25 INCHES. ALSO TANK CELL HAS STRUCTURAL ANOMALIES.	LEVEL DECREASE CAUSE UNKNOWN. CELL STRUCTURAL ANOMALIES DUE TO PREVIOUS CELL OVERFILLING.

Table D3.2-2. Summary of Occurrences. (33 sheets)

79-73	07/23/1979	RAW WATER LEAK IN 241-C TANK FARM RESULTED IN LARGE PUDDLE WHICH PARTIALLY COVERED TANKS 111-C AND 112-C.	MECHANICAL FAILURE OF "STOP AND WASTE" VALVE SUPPLYING 241-C FARM.
79-75	06/09/1978	RADIATION ACTIVITY IN TANK 108-T DRY WELL INCREASED.	ASSUME INCREASED ACTIVITY DUE TO MIGRATION OF TANK 106-T LEAK PLUME.
79-80	08/17/1979	MISROUTING OF 13,000 GALLONS OF CROSS-COUNTRY LINE LEAK CHECK WATER TO TANK 103-S.	PERSONNEL ERROR. FAILURE TO REALIGN VALVE IN 241-SA VALVE PIT.
79-81	08/20/1979	BOXES IN BURIAL GROUND 3A-TRENCH 17 EXCEEDED CRITICALITY LIMITS.	PERSONNEL ERROR. IT APPEARS THAT THREE BOXES WERE PUT IN THE BURIAL TRENCH WITHOUT PROPER SPACING.
79-100	10/10/1979	LIQUID LEVEL IN TANK 102-S EXCEEDED LIMIT.	PERSONNEL ERROR. FAILURE TO MAINTAIN CONTROL WHILE 242-S EVAPORATOR STEAM TURBINE PRESSURE REGULATING VALVE WAS CYCLED.
79-104	10/21/1979	WASTE TRANSFER FROM TANK 106-SX TO 101-SX MISROUTED TO TANK 102-S.	PERSONNEL ERROR. VALVE ALIGNMENT IN 241-SA VALVE PIT FOR OTHER TRANSFER REROUTED THIS TRANSFER.
79-113	10/10/1979	INADVERTENT FLOW ROUTING TO INACTIVE CRIB 216-A-24.	PERSONNEL ERROR. TWO SETS OF ROUTING VALVES WERE MISALIGNED.
79-118	11/29/1979	LIQUID LEVEL IN TANK 103-A DECREASED 4 INCHES.	ASSUME LEVEL DECREASE DUE TO SLUMPING OF THE TANK SURFACE.
79-125	12/15/1979	LIQUID LEVEL IN TANK 105-SX DECREASED 2.3 INCHES.	ASSUME LEVEL DECREASE DUE TO PLUMMET/TANK MATERIAL INTERACTION.
79-126	12/18/1979	25-TON CRANE BOOM POSITIONED OVER WORKERS ON TOP OF 241-SA VALVE PIT AND TESTED, VIOLATING SAFE OPERATING PRACTICES.	PERSONNEL ERROR. WILLFUL VIOLATION OF CRANE OPERATION PROCEDURES.
80-4	01/13/1980	LIQUID LEVEL IN TANK 110-BX INCREASED 2.5 INCHES.	SNOW MELT CHANNELED INTO PUMP PIT AND DIRECTLY INTO TANK.
80-5	01/15/1980	LIQUID LEVEL IN TANK 108-BY INCREASED 3 INCHES.	RAPID SNOW MELT RAN INTO PUMP PIT THROUGH THE PIT DRAIN DIRECTLY INTO TANK.
80-6	01/15/1980	LIQUID LEVEL IN TANK 103-BY INCREASED 1.25 INCHES.	RAPID SNOW MELT RAN INTO PUMP PIT THROUGH THE PIT DRAIN DIRECTLY INTO TANK.
80-7	01/17/1980	LIQUID LEVEL IN TANK 103-SX DECREASED 1.1 INCHES.	ASSUME LEVEL DECREASE DUE TO FIC PLUMMET MEASURING IRREGULAR SURFACE.
80-8	01/18/1980	MISROUTED 2000 GALLONS INTO TANK 102-AY FROM TANK 103-A INSTEAD OF INTO TANK 101-AY.	PERSONNEL ERROR. MISVALVING THE SLURRY DISTRIBUTOR VALVE IN TANK 102-AY 02A VALVE PIT.
80-9	01/16/1980	CROSS-COUNTRY TRANSFER LINE FROM TANK 107-S TO 105-BX PLUGGED DURING TRANSFER OF TERMINAL LIQUOR SOLUTION.	PLUG DUE TO INADEQUATE DILUTION OF WASTE, DILUTION WATER METER FAILED.
80-25	02/20/1980	UNUSUAL LIQUID LEVEL DECREASE IN TANK 103-SX FOLLOWING TRANSFER IN.	LEVEL DECREASE CAUSED BY MIXING LARGE AMOUNT OF LOW DENSITY LIQUID INTO TANK OF SOLIDS.
80-26	02/21/1980	LINE LEAK IN SLURRY LINE SL 126 BETWEEN 241-SD VALVE PIT AND TANK 107-S CROSS-SITE PUMP PIT.	ASSUME LINE LEAKS DUE TO UNANTICIPATED CORROSION.
80-32	03/05/1980	CASS TRANSMISSION CABLE FROM 241-A TANK FARM CRUSHED DURING REMOVAL OF A FLUME IN 241-AZ TANK FARM. NOTIFICATION TO TANK FARM OPERATIONS WAS NOT INITIATED IMMEDIATELY AS REQUIRED.	PERSONNEL ERRORS. DAMAGE DURING CONSTRUCTION ACTIVITIES.
80-36	03/14/1980	CRITICALITY PREVENTION SPECIFICATION VIOLATIONS IN ALPHA-1 CAISSON OCCURRED BETWEEN 1970 AND 1973.	PROCEDURE ERRORS.
80-37	04/03/1980	HIGH VACUUM (-4.0"W.G. FOR 3 1/2 DAYS WHEN SUPPLY FAN WAS OFF, COULD HAVE BEEN AS HIGH AS -6.25" W.G.) IN TANK 102-AY ANNULUS.	PERSONNEL AND DESIGN PROBLEMS. UNEXPECTED SHUTDOWN OF ANNULUS SUPPLY FAN COUPLED WITH THE LACK OF PRESSURE SWITCH TO SHUT DOWN EXHAUST FAN.

Table D3.2-2. Summary of Occurrences. (33 sheets)

80-50	05/16/1980	PARTIAL MISTRANSFER OF 4125 GALLONS INTO TANK 101-AY FROM TANK 103-A. TRANSFER WAS TO GO TO TANK 102-AY.	MECHANICAL FAILURE. 3-WAY SDV VALVE IN 241-AY-02A VALVE PIT SPLIT FLOW BETWEEN TWO TANKS. BALL VALVE ORIENTATION WITHIN VALVE BODY DID NOT CORRESPOND TO PAINTED FLOW DIAGRAM ON PROCESS PIT COVER BLOCK
80-51	05/31/1980	4120 GALLONS MISROUTED TO TANKS 101-AY AND 102-AY FROM 244-A CATCH TANK. INTENDED RECEIVER TANK WAS 102-A.	PERSONNEL ERROR. INSTALLED JUMPER WAS MISALIGNED IN 241-A-02C PIT.
80-53	06/07/1980	LIQUID LEVEL IN TANK 201-T INCREASED 2.25 INCHES.	ASSUME LEVEL INCREASE INDICATION DUE TO SOLIDS MOVEMENT IN VICINITY OF PLUMMET.
80-58	05/12/1980	LIQUID LEVEL MEASUREMENT TAPE IN TANK 107-BY CUT AND REMOVED WITHOUT PERMISSION.	PERSONNEL ERROR. CONSTRUCTION EMPLOYEE REMOVED TAPE AND GAUGE WITHOUT PERMISSION.
80-60	05/08/1980	PHOTOGRAPHIC SURVEY OF TX-302-C CATCH TANK REVEALED LIQUID LEVEL ABOVE MAXIMUM LIMIT.	MANUAL TAPE READINGS INDICATED LEVEL WITHIN LIMITS. TANK RISER EXTENDED 3' PREVIOUSLY AND NO REFERENCE TO ELEVATION CHANGE MADE TO DRAWINGS.
80-64	07/11/1980	LIQUID LEVEL IN TANK 112-TX INCREASED 1.75 INCHES.	LEVEL INCREASE DUE TO INTRUSION FROM A STEAM LINE LOCATED IN AN ASSOCIATED VALVE PIT.
80-66	07/21/1980	PLUGGED DEENTRAINER MINIMIZED FLOW THROUGH 241-SY EXHAUSTER, CAUSING 102-SY ANNULUS EXHAUST SYSTEM TO PULL CONTAMINATED AIR THROUGH AIR SAMPLER FILTER.	PERSONNEL ERROR. DEENTRAINER dP INSTRUMENT INSTALLED BACKWARDS, GIVING FALSE INDICATION OF GOOD OPERATION.
80-73	07/10/1980	MISROUTED 2200 GALLONS TO TANK 103-TX FROM 118-TX, INTENDED RECEIVER TANK WAS 106-SX.	PERSONNEL ERROR. FAILURE TO CLOSE VALVE IN 241-152-TXR DIVERSION BOX.
80-80	07/23/1980	WHILE TRANSPORTING A SALT WELL PUMP FOR BURIAL THE PLASTIC COVERING THE PUMP WAS PUNCTURED AND TWO GALLONS OF RADIOACTIVE LIQUID SPILLED ON THE GROUND.	PERSONNEL ERROR. IMPROPER RIGGING OF PUMP FOR BURIAL.
80-81	08/26/1980	SPRAY LEAK IN 241-AW-05A CENTRAL PUMP PIT DURING SLURRY TRANSFER TO TANK 105-AW.	PERSONNEL AND DESIGN ERROR. WORKER UNABLE TO TIGHTEN CONNECTION BETWEEN JUMPER AND DISTRIBUTOR SUFFICIENTLY.
80-82	09/04/1980	LIQUID LEVEL IN TANK 103-A DECREASED 3.3 INCHES.	ASSUME LEVEL DECREASE IS DUE TO MIXING OF DISSIMILAR SOLIDS WITHIN THE TANK.
80-84	09/08/1980	WORKER EXCEEDED WEEKLY EXPOSURE WHILE WORKING IN A TRENCH IN 241-SY FARM DURING WASTE TRANSFER.	PROCEDURE ERROR. TRANSFER NOT COMMUNICATED TO CONSTRUCTION WORKERS.
80-87	10/02/1980	5775 GALLONS MISTRANSFERRED INTO TANK 103-AX FROM TANK 101-AX. INTENDED RECEIVER TANK WAS 103-AW.	PERSONNEL ERROR. VALVE MISPOSITIONED IN AX-A VALVE PIT.
80-88	10/17/1980	9625 GALLONS MISTRANSFERRED TO TANK 102-AY FROM 101-A. INTENDED RECEIVER TANK WAS 102-A.	PERSONNEL ERROR. CORRECT TRANSFER ROUTE NOT SET UP.
80-90	11/11/1980	SLURRY LINE SL 176 LEAKED DURING TRANSFER FROM 242-S EVAPORATOR TO TANK 103-SY.	MECHANICAL FAILURE. ASSUME CORROSION OF CARBON STEEL TRANSFER LINE.
81-02	11/19/1980	LIQUID LEVEL IN TANK 106-SX INCREASED 3 INCHES.	MECHANICAL FAILURE. INTRUSION FROM A LEAKING STEAM COIL AND FAILURE OF A VALVE TO THE STEAM COIL.
81-03	01/13/1981	RADIATION ACTIVITY IN TANK 101-A DRY WELL INCREASED.	ACTIVITY INCREASE DUE TO LEACHING DOWN OF A PREVIOUS SOIL CONTAMINATION AROUND 241-A-01B PIT.
81-04	01/14/1981	LIQUID LEVEL IN TANK 110-BX INCREASED 1.25 INCHES.	LIQUID LEVEL INCREASE DUE TO INTRUSION OF RAINWATER.
81-24	03/02/1981	20-40 GALLONS/DAY LEAK IN 4" RAW WATER LINE FEEDING 244-UR PROCESS VAULT.	MECHANICAL FAILURE. RAW WATER LINE DEVELOPED LEAKS AND CLOSED DISCHARGE LINE VALVES LEAKED THROUGH.
81-25	03/30/1981	LIQUID LEVEL IN TANK 103-T EXCEEDED LIMIT.	ASSUME LEVEL INCREASE DUE TO PRECIPITATION ENTERING TANK VIA PUMP PITS.

Table D3.2-2. Summary of Occurrences. (33 sheets)

81-36	05/20/1981	LIQUID LEVEL IN TANK 103-TY EXCEEDED LIMIT BY 5.1 INCHES.	LEVEL INCREASE CAUSED BY WATER INTRUSION VIA AN OPEN WATER LINE IN 103-TY WATER FLUSH PIT. WATER RAN INTO PIT AND INTO THE TANK VIA THE PIT DRAIN.
81-48	07/10/1981	FIC BOX NEAR 118-TX VALVE PIT DAMAGED BY CRANE BACKING UP.	APPARENT ACCIDENT CAUSED BY ERROR IN JUDGMENT BY FLAGMAN, CONGESTION IN TANK FARM, AND EXTREMELY ROUGH TERRAIN.
81-52	08/17/1981	WASTE TRANSFER FROM 101-AY TO 104-AW MISROUTED TO 102-AY.	MECHANICAL FAILURE. MISROUTING CAUSED BY FAILURE OF 3-WAY DISCHARGE VALVE IN TK-AY-102-02D TO BE POSITIONED AGAINST MECHANICAL STOP.
81-55	09/03/1981	CONTAMINATION RELEASE IN 204-S UNLOADING STATION WHILE HOOKING UP RAILROAD CAR FOR UNLOADING.	MECHANICAL FAILURE. FAULTY SPRAY RING VALVE ON TOP OF CAR.
81-58	09/15/1981	FIRE IN 241-AN TANK FARM K1-2-1 CABINET ELECTRIC BLAST HEATER POWER COMPONENTS.	PERSONNEL ERROR AND MECHANICAL FAILURE. CURRENT ALARM SWITCH SHORTED OUT, SWITCH WAS REDUNDANT AND SHOULD HAVE BEEN REMOVED DURING CONSTRUCTION.
81-61	09/08/1981	RADIOACTIVE FLUSH WATER PUMPED TO TANK 102-SY THROUGH TRANSFER LINE THAT GOES THROUGH S-FARM WHERE WORKERS WERE EXCAVATING.	PERSONNEL ERROR. COMMUNICATION FAILURE, AND FAILURE TO FOLLOW LOCK AND TAG PROCEDURE.
81-82	12/07/1981	LIQUID LEVEL IN 011-BXR TANK DECREASED 2.5 INCHES.	MECHANICAL FAILURE. LEVEL DECREASED WHEN TANK WALL BUCKLED WHICH CAUSED LEAKS.
82-01	01/06/1982	RADIATION ACTIVITY IN TANK 109-C DRY WELL INCREASED.	ASSUME ACTIVITY INCREASE IS CAUSED BY MIGRATION OF SOIL CONTAMINATION.
82-02	01/05/1982	FAILURE OF PROCESS LINE V-402 DURING TX-FARM SALT WELL PUMPING.	MECHANICAL FAILURE. LINE FAILURE CONFIRMED BY PRESSURE TEST.
82-12	03/24/1982	LOSS OF EMERGENCY POWER TO 204-AR UNLOADING STATION AND 242-A EVAPORATOR.	MECHANICAL FAILURE. APPARENT LOSS OF BACK-UP POWER DUE TO DIRT IN RELAY CONTACTS, FAILURE OF MANUAL/AUTOMATIC SWITCH, AND FAILURE IN AUTOMATIC START CONTROL CIRCUIT MODULE.
82-21	05/15/1982	FAILURE OF PROCESS LINE BETWEEN 241-TX-155 AND 241-U-151, V-398.	MECHANICAL FAILURE OF INNER PROCESS LINE.
83-1	01/22/1983	FAILURE OF PUREX 36" CHEMICAL SEWER LINE DISCOVERED BY CRANE TIRE CAUSING CAVE-IN IN 241-AP TANK FARM.	MECHANICAL FAILURE. BELLS OF VITRIFIED CLAY PIPE WERE BROKEN AND LEAKING.
83-07	04/11/1983	WASTE TRANSFER INTO AY TANK WITHOUT VENTILATION ON RECEIVER TANK. NORMAL VENTILATION SYSTEM WAS OUT-OF-SERVICE, PORTABLE EXHAUSTER STARTED, BUT OPERATOR FAILED TO OPEN THE EXHAUSTER INLET VALVE.	PERSONNEL ERROR, FAILURE TO FOLLOW PROCEDURE. OPERATOR OPENED VALVE ONE QUARTER TURN INSTEAD OF 15 1/2 TURNS.
83-09	03/25/1983	WHILE CORE DRILLING IN 241-AX-152 DIVERTER STATION A 2" ENCASEMENT DRAIN LINE WAS HIT AND BREACHED.	DESIGN PROBLEM. ENCASEMENT DRAIN LINE WAS NOT ON CONSTRUCTION DRAWINGS OR DRILL PERMIT.
83-11	03/19/1983	LIQUID LEVEL IN TANK 201-T INCREASED 2.25 INCHES.	UNKNOWN.
83-16	07/11/1983	TANK 102-T LIQUID LEVEL INCREASE. TANK INTERIM STABILIZED, ASSUMED INTRUSION OF RAIN/SNOW MELT.	WEATHER. RAIN/SNOW MELT INTRUSION INTO TANK. 241-TR-153 BOOSTER PUMP PIT DRAINED WAS SEALED, LEVEL INCREASE HAS STOPPED.
83-22	11/16/1983	INCREASE IN ACTIVITY IN DRYWELL ADJACENT TO TANK 107-TX. APPARENT RAINFALL INTRUSION INTO INACTIVE, QUESTIONABLE INTEGRITY TANK CAUSED INCREASED ACTIVITY IN ASSOCIATED DRYWELL.	MECHANICAL/WEATHER. TANK INTEGRITY QUESTIONABLE, RAINFALL INTRUSION THROUGH COVERBLOCKS ASSUMED. TANK 107-TX PUMPED.

Table D3.2-2. Summary of Occurrences. (33 sheets)

83-28	11/07/1983	STEAM RELEASE FROM 107-AN PUMP PIT. AN FARM VENT FAN SHUT DOWN DURING WASTE TRANSFER TO TANK 107-AN. TANK VACUUM LOST, STEAM ESCAPED FROM 107-AN PUMP PITS.	MECHANICAL. STACK SAMPLER MALFUNCTION CAUSED INTERLOCK TO SHUTDOWN VENT FAN, PRIOR TO TRANSFER BEING STOPPED.
83-31	11/16/1983	TANKS 102,101,104 AND 106-AW PRESSURIZED WHEN HOT WATER (123oF) DUMPED INTO TANK 102-AW FROM 242-A EVAPORATOR.	RAPID EXPANSION OF TANK VAPORS OVERWHELMED THE EXHAUST AIR FLOW.
83-33	11/06/1983	MULTIPLE PRESSURIZATIONS OF TANK 103-AW WHEN RECEIVING PUREX E-5 WASTE.	PRESSURIZATION DUE TO VAPORIZATION OF THE THERMALLY HOT WASTE AS IT IS DUMPED INTO A COOLER TANK.
83-34	12/12/1983	SMEARABLE CONTAMINATION IN 200-EAST ARE CLEAN OUT BOXES (COBs).	ASSUME DETERIORATION OF PLUG SEALS ON THE CENTER RISER OF THE COBs.
84-02	01/08/1984	50-70' BREACH IN B-POND DIKE BETWEEN EAST AND WEST EXPANSION PONDS.	APPARENT CAUSE OF DIKE BREACH IS EROSION UNDER THE FABRIFORM LINER OF THE SPILLWAY.
84-06	10/27/1983	RELEASE OF RADIOACTIVE EFFLUENT TO THE 216-A-8 CRIB IN EXCESS OF CONCENTRATION GUIDELINES.	APPARENT SOURCE OF CONTAMINATION WAS A DEACTIVATED 16" WASTE COOLING WATER LINE THAT ENTERS THE A-08 SAMPLE PIT.
84-17	04/13/1984	FAILURE OF THERMOCOUPLES NEAR AIR LIFT CIRCULATORS IN AGING WASTE TANK 101-AZ.	MECHANICAL FAILURE OF UNKNOWN TYPE.
84-19	03/21/1984	FIRE IN FUEL DELIVERY TRUCK IN 200-WEST AREA.	PINHOLE LEAK IN POWER STEERING LINE CAUSED FLUID TO SPRAY ONTO THE MANIFOLD OF THE TRUCK. FLUID FLASHPOINT IS 375 °F, MANIFOLD TEMPERATURE WAS 800-900 °F.
84-21	03/28/1984	2800 GALLONS OF PUREX WASTE ROUTED TO TANK 102-AZ INSTEAD OF TANK 101-AZ.	PERSONNEL ERROR. DIVERTER VALVE IN 152-AX DIVERTER STATION NOT RETURNED TO NORMAL POSITION AFTER TRANSFER TO NEARBY WASTE TANK.
84-27	04/30/1984	SAMPLE OF GABLE MOUNTAIN POND FOUND HIGH LEVELS OF STRONTIUM 90 EXCEEDING LIMITS.	HIGH STRONTIUM LEVELS DUE TO ACCIDENTAL RELEASE IN 1964.
84-34	05/31/1984	LIQUID LEVEL IN TANK 203-C DECREASED 2 INCHES.	CAUSE OF TANK LEVEL DECREASE NOT REPORTED.
84-71	11/19/1984	TRANSFER LINE BETWEEN B-PLANT AND 244-A LIFT STATION (SN-233) LEAKED TO ENCASEMENT.	MECHANICAL FAILURE OF TRANSFER LINE.
84-81	12/18/1984	BACKUP EXHAUSTER FOR 241-AY AND AZ FARMS FAILED AFTER STARTING. AGING WASTE FARM TANKS WERE WITHOUT VENTILATION FOR 20 MINUTES.	MECHANICAL FAILURE. EXHAUSTER CIRCUIT BREAKER TRIPPED AT FAN START.
85-34	04/12/1985	UNNEUTRALIZED TANK F-18 (PUREX) TRANSFER RESULTED IN PIPE DAMAGE IN LINE BETWEEN 241-AW-A VALVE PIT AND 241-101-AW DISTRIBUTOR.	PERSONNEL ERROR.FAILURE TO NEUTRALIZE BATCH PRIOR TO TRANSFER.
85-48	05/23/1985	TRANSFER BETWEEN PUREX AND 101-AZ TANK RESULTED IN EXPOSURE TO PERSONNEL IN EXCAVATION NEAR 241-AY FARM.	PERSONNEL ERROR. FAILURE TO COMMUNICATE A DELAY IN TRANSFER TIME TO PERSONNEL IN EXCAVATION.
85-55	06/26/1985	FLASH FIRE IN 153-AX DIVERSION BOX.	FIRE CAUSED BY ACTUATING AN ELECTRIC TOOL IN DIVERSION BOX AFTER USING A CONTAMINATION SEALANT IN THE DIVERSION BOX FOLLOWED BY A METHYL ALCOHOL FLUSH.
85-98	12/18/1985	FAILURE TO REPLACE BREATHER FILTERS WHEN REQUIRED BY SAR FOR WASTE TANKS 102-BX, 103-C, AND 108-C.	PERSONNEL ERRORS. FILTERS NOT REPLACED IN TIME DUE TO MANPOWER PROBLEMS.
86-45	08/06/1986	FOUR OPERATIONAL SAFETY REQUIREMENTS NOT COMPLETED AS REQUIRED. PREVENTATIVE MAINTENANCE ACTIVITIES WERE NOT CARRIED OUT AS REQUIRED.	ADMINISTRATIVE. TANK FARM PROD CONTROL DID NOT SCHEDULE THE PMs. COVERED 241-A-702 AIR MONITOR, 241-AR-151 LEAK DETECTOR, AY & AZ LEAK DETECTOR, AREA EFFLUENT IN-LINE RADIATION MONITOR
RHO-UOR-87-04	03/13/1987	ALL OPERATIONAL SAFETY REQUIREMENTS REVIEWED, FOUND THAT FOR 9 OF THEM, POSITIVE COMPLIANCE COULD NOT BE VERIFIED.	ADMINISTRATIVE. SAFETY ANALYSIS REPORTS HAD TO BE CHANGED TO REFLECT THE REAL SITUATION.

Table D3.2-2. Summary of Occurrences. (33 sheets)

87-05	03/30/1987	I-129 EMISSIONS FROM 241-AW FARM PRIMARY EXHAUSTER EXCEEDED OPERATIONS ADMINISTRATIVE CONTROL VALUE	OPERATIONAL. PUREX FLUSHED A SILVER REACTOR TO THE AW FARM IN JUNE, 1986. I-129 LEVELS WENT UP TO 4 TIMES THE LIMIT. LEVELS STARTED DECREASING IN JULY, BACK TO NORMAL IN DECEMBER.
WHC-UO-87-010-PUREX-01	08/30/1987	PUREX CLADDING REMOVAL IN PROGRESS, DISCHARGE MADE TO 216-A-36B CRIB. PUREX STACKS, CRIB, AND AW TANK FARM EXHAUST EXCEEDED LIMITS OF (AMMONIUM HYDROXIDE) NH4OH AND AMMONIA (NH3).	PROCEDURE/PERSONNEL ERROR. AMMONIA CONTAINING DISCHARGE SHOULD HAVE BEEN TO A WASTE TANK INSTEAD OF CRIB. INSUFFICIENT ATTENTION TO ENVIRONMENTAL DISCHARGE LIMITS.
WHC-UO-88-028-TF-03	07/13/1988	241-SX-104 EXCEEDED THE LEVEL DECREASE CRITERIA OF 0.3 FOOT DECREASE.	MECHANICAL. TANK ASSUMED TO LEAK. INITIATED STABILIZATION AND ISOLATION ACTIVITIES.
WHC-UO-88-029-TF-04	07/26/1988	241-AX-102 EXCEEDED THE 1.00 INCH DECREASE CRITERIA.	MECHANICAL. TANK ASSUMED TO LEAK. PUMPED TANK OUT IN AUGUST, 1988.
WHC-UO-88-034-TF-05	10/11/1988	241-C-103 SHOWS DECREASING LEVEL TREND OF 0.5" SINCE DECEMBER, 1984. NO LIMITS EXCEEDED.	MECHANICAL. NO LIMITS EXCEEDED. TANK WILL BE STABILIZED ON SCHEDULE.
WHC-UO-89-03-TF-01	01/09/1989	OPERATING AGING WASTE FACILITY USING DOE UNAPPROVED SAFETY ANALYSIS REPORT (2 YEARS). REPORT WAS APPROVED BY CONTRACTOR AND "OFFICIALLY RELEASED". DOE HAD NOT APPROVED THE SAR REVISION.	ADMINISTRATIVE. SAR APPROVAL PROCESS BREAKDOWN.
WHC-UO-89-04-TF-02	01/06/1989	SURVEILLANCE NON-CONFORMANCE, FAILURE TO TAKE TEMPERATURE READINGS EVERY 45 DAYS ON HIGH-HEAT TANKS (101, 102, 103, 104, 105, AND 106-SX)	ADMINISTRATIVE/PERSONNEL ERROR. NO ADMINISTRATIVE PROCEDURE TO ENSURE ALL OSRs AND STATUS OF MONITORING. DATA TAKING REQUIREMENTS NOT FOLLOWED.
WHC-UO-89-009-TF-03	01/31/1989	LEVEL DECREASE IN 241-A-102. EXCEEDED THE 1.00 INCH LEVEL DECREASE CRITERIA.	MECHANICAL. TANK ASSUMED LEAKER. EXPEDITED PUMPING OF TANK.
WHC-UO-89-014-TF-04	03/07/1989	SURFACE LEVEL MEASUREMENT DECREASE IN 241-A-302-B CATCH TANK. LEVEL READINGS HAVE SHOWN WIDE FLUCTUATIONS.	MECHANICAL. MEASURING DEVICE SHORTING OUT. TANK INTERIM STABILIZED.
WHC-UO-89-023-TF-05	05/18/1989	LEVEL DECREASE IN 241-AX-102. LEVEL CONTINUED TO DECREASE AFTER TANK PUMP DOWN. EXCEEDED 1.00" LEVEL DECREASE CRITERIA.	LEVEL DECREASE ATTRIBUTED TO TANK CONTENTS SETTLING.
WHC-UO-89-030-SAHP-01	05/24/1989	RAILROAD WASTE TANK CAR SHIPPED FROM 340 FACILITY IN 300-AREA TO 204-AR FACILITY WITH SMEARABLE CONTAMINATION IN EXCESS OF LIMITS.	PERSONNEL ERROR. FAILURE TO COMMUNICATE THE REQUIREMENTS OF DEPT. OF TRANSPORTATION IN SAFETY ANALYSIS REPORT FOR PACKAGING (SARP) AND THE HEALTH PHYSICS PROCEDURE.
WHC-UO-89-043-TF-06	09/05/1989	TANK FARM AMMONIA RELEASES EXCEEDING CERCLA LIMITS.	TRAINING. THE REQUIREMENTS CHANGED FOR AMMONIA RELEASES, PLANT OPERATING AND ENGINEERING STAFF WERE NOT AWARE OF THE SIGNIFICANCE OF THESE CHANGES, PROCEDURES TO BE CHANGED.
WHC-UO-89-044-TF-07	08/16/1989	241-C TANK FARM VAPOR RELEASE INHALED BY EMPLOYEE.	OPERATION OF TANK FARM. SUSPECT AMMONIA SMELL FROM TANK 241-C-102 THROUGH BREATHER FILTER. INSTALLED ACTIVATED CARBON SYSTEM TO FILTERS.
WHC-UO-89-059-TF-08	11/28/1989	AUTOMATIC TRANSFER OF ELECTRIC POWER FAILED TO TRANSFER TO DIESEL GENERATED POWER ON LOSS OF NORMAL POWER TO 242-A EVAPORATOR.	MECHANICAL. MALFUNCTION OF AUTOMATIC EMERGENCY TRANSFER SWITCH.
WHC-UO-89-062-SSS-01	12/22/1989	ERROR FOUND IN COMPUTER CODE GENII USED TO CALCULATE ENVIRONMENTAL IMPACTS OF EMISSIONS ON HANFORD SITE.	PERSONNEL, PROCEDURE ERROR. WIND DIRECTIONS USED IN MODELLING ARE OFF BY 180 DEGREES.
WHC-UO-89-065-TF-09	12/25/1989	PORTABLE POWER TRANSFORMER FAILED WHILE NORMAL POWER OUT OF SERVICE FOR SCHEDULED MAINTENANCE, 200-EAST TANK FARMS.	MECHANICAL. PORTABLE TRANSFORMER FAILED DUE TO A BURNT CABLE.

Table D3.2-2. Summary of Occurrences. (33 sheets)

RL-WHC-TANKFARM-1990-0014	09/04/1990	RELEASE OF RADIONUCLIDE MATERIAL FROM TANK 105-A PORTABLE EXHAUSTER SEAL POT AND ONTO SOIL. APPROX 3 SQUARE FEET OF THE SOIL SURFACE WAS CONTAMINATED.	ADMINISTRATIVE/MECHANICAL. FAULTY SEAL POT DISCOVERED APRIL, 1990, FAULTY SEAL POT NOT REPLACED, FAILED IN SEPTEMBER, 1990
RL-WHC-TANKFARM-1990-0056	09/16/1990	RELEASE OF RADIONUCLIDE MATERIAL FROM TANK 105-A PORTABLE EXHAUSTER FILTER HOUSING ONTO SOIL. TWO SPOTS WERE CONTAMINATED, 8000 D/M IN 1 FT IN DIAMETER AREA, 600 D/M IN AN 8 INCH IN DIAMETER AREA	ADMINISTRATIVE. LOCK AND TAG PROCEDURE FOR MAINTENANCE DID NOT LOCK OUT THE DRAIN VALVES DURING MAINTENANCE.
RL-WHC-TANKFARM-1990-0082	09/26/1990	OSR NON-CONFORMANCE ON ADMINISTRATIVE CONTROLS FOR UNDERGROUND STORAGE TANK 241-U-103. MAINTENANCE FAILED TO USE SPARK RESISTANT TOOLS DURING BREATHER FILTER MAINTENANCE.	ADMINISTRATIVE. WORK PACKAGE NOT PROPERLY PREPARED, NO PERSON-IN-CHARGE.
RL-WHC-TANKFARM-1990-0087	09/27/1990	UNCONTROLLED ACCESS TO HIGH RADIATION AREAS, IMPROPER ACCESS TO S/SX/SY FARMS DUE TO NO CONTROL BEING PROVIDED	PERSONNEL ERROR. NOT TRAINED PROPERLY IN ACCESS CONTROL REQUIREMENTS.
RL-WHC-TANKFARM-1990-0117	10/05/1990	LOSS OF 105-A PORTABLE EXHAUSTER EFFLUENT MONITORING CAPABILITIES. FAILURE OF CAM AND RECORD SAMPLER, WHILE EXHAUSTER WAS OPERATING.	MECHANICAL. KNIFE SWITCH NOT FULLY ENGAGED.
RL-WHC-TANKFARM-1990-0145	10/14/1990	LOSS OF POWER TO A SECTION OF HANFORD 230 KV LINE. LINE FAULT CAUSED POWER LOSS AT 100-B, 100-KE, 100-KW, AND 100-N.	MECHANICAL. CONTAMINATED INSULATOR CAUSED POWER POLE FIRE.
RL-WHC-TANKFARM-1990-0186	10/30/1990	241-A-105 UNEXPLAINED TEMPERATURE INCREASE DURING EXHAUSTER OPERATION AND FAILURE TO NOTIFY DOE IN A TIMELY MANNER. SOIL TEMPERATURE UNDER THE WASTE TANK READ 297oF, LIMIT IS 300oF. NO SPECIFICATIONS OR REQUIREMENTS WERE VIOLATED.	MECHANICAL/PERSONNEL ERROR. UNDERGROUND THERMOCOUPLE WIRE HAD DETERIORATED. OPERATIONS FAILED TO REPORT INCREASING TEMPERATURE AS REQUIRED.
RL-WHC-TANKFARM-1990-0319	12/12/1990	INADVERTENT SHUTDOWN OF 241-SY PRIMARY EXHAUSTER, OPERATOR OPENED INCORRECT CIRCUIT BREAKER.	PERSONNEL ERROR. BREAKERS WAS NOT LABELED, OPERATOR DID NOT VERIFY CORRECT CIRCUIT BREAKER.
RL-WHC-TANKFARM-1990-0386	12/26/1990	STEAM COIL LEAK AT 242-S EVAPORATOR RESULTS IN ACTIVATION OF FIRE SPRINKLER SYSTEM. SPRINKLER WAS LOCATED IN THE HVAC FILTER SYSTEM PLENUM.	MECHANICAL/ADMINISTRATIVE. FAILED STEAM COIL, ROOT CAUSE WAS FAILURE TO REPLACE COILS WHEN NOTIFIED OF REPLACEMENT NEED IN JUNE, 1989.
RL-WHC-TANKFARM-1991-0003	01/03/1991	DISABLING OF AUDIBLE ALARM ANNUNCIATOR, ALARM PANEL "A", 242-S EVAPORATOR. ALARM PANEL "ACKNOWLEDGE" BUTTON WAS HELD IN WITH WEDGED PAPER CLIP, PREVENTING SIX ALARMS FROM SOUNDING.	ADMINISTRATIVE. PROCEDURE VIOLATION.
RL-WHC-TANKFARM-1991-0011	01/06/1991	FREEZING OF 241-A-401 COOLING TOWER SPRAY LINE RESULTS IN UTILIZATION OF BACKUP SYSTEM.	PERSONNEL ERROR/WEATHER CONDITIONS. TWO VALVES HAD BEEN LEFT CLOSED PREVENTING THE COOLING TOWER PIPING FROM DRAINING. THE WATER FROZE AND RENDERED THE PIPING INOPERABLE.
RL-WHC-TANKFARM-1991-0061	01/18/1991	242-T ALPHA CONTINUOUS AIR MONITOR DISABLED, OSR VIOLATION. VACUUM PUMP WAS INTENTIONALLY UNPLUGGED BY A HEALTH PHYSICS TECHNICIAN.	PROCEDURE VIOLATION. EMPLOYEE INDICATED THE NOISE FROM THE PUMP RESULTED IN A HEADACHE.
RL-WHC-TANKFARM-1991-0079	01/25/1991	LOSS OF ACCOUNTABILITY OF RADIOACTIVE SOURCES.	ADMINISTRATIVE. SOURCE LOCATIONS NOT UPDATED, MULTIPLE SERIAL NUMBERS ON SOURCES, LACK OF TRAINING, REQUIREMENTS AND MANAGEMENT EXPECTATIONS NOT EASILY DERIVED.
WHC-91-0096-TFARM	01/16/1991	ADDITION OF TWO TANKS, 241-T-107 AND 241-TY-104, TO THE LIST OF UNREVIEWED SAFETY QUESTION TANKS CONTAINING FERROCYANIDE.	FURTHER REVIEW OF HISTORICAL RECORDS INDICATED THESE TANKS SHOULD BE ADDED TO THE LIST OF 22 FERROCYANIDE TANKS.

Table D3.2-2. Summary of Occurrences. (33 sheets)

RL-WHC-TANKFARM-1991-0099	01/31/1991	LOSS OF 244-CR RECORD SAMPLER, DUE TO LOW FLOW CAUSED BY A HIGH DIFFERENTIAL PRESSURE ACROSS THE PRE-FILTERS.	ADMINISTRATIVE. DATA SHEET SPECIFICATIONS DID NOT AGREE WITH OSD REQUIREMENTS. SYSTEM REACTED AS DESIGNED.
RL-WHC-TANKFARM-1991-0103	02/01/1991	DAMAGED HEAT TRACE LINE CAUSES ELECTRICAL SHOCK.	MECHANICAL. DAMAGED HEAT TRACE LINE ALLOWED DRAIN PIPE TO BE ENERGIZED. WORKED CONTACTED PIPE AND RECEIVED ELECTRICAL SHOCK.
RL-WHC-TANKFARM-1991-0192	03/06/1991	242-S PUMP ROOM FLOODED (7 FT) BY DAMAGED FIRE SYSTEM PIPING, CAUSED BY FREEZING CONDITIONS.	WEATHER CONDITIONS/PROCEDURE ERROR. FIRE SYSTEM OUT OF SERVICE FOR REPAIR, PROCEDURE DID NOT INCLUDE PUMP ROOM OR EVAPORATOR ROOM.
RL-WHC-TANKFARM-1991-0200	03/21/1991	POTENTIAL DISTURBANCE OF 241-SY-101 TANK CRUST. WHILE RAISING A RISER COVER TO INSTALL VAPOR SPACE PROBES, AN UNEXPECTED CABLE WAS DISCOVERED, ATTACHED TO THE RISER COVER. ASSUMED THE WORK DISTURBED THE CRUST.	ADMINISTRATIVE. CONFIGURATION CONTROL PROBLEM, SLUDGE WEIGHT CABLE LOCATION WAS UNKNOWN PRIOR TO WORK.
RL-WHC-TANKFARM-1991-1001	04/01/1991	LOSS OF TANK PRESS. INDICATION IN 241-SY TANK FARM, OPERATIONAL SAFETY REQUIREMENT VIOLATION. RELAY FAILURE CAUSED LOSS OF BOTH AIR COMPRESSORS, AIR MONITORING AND ALARM CAPABILITIES.	MECHANICAL/ADMINISTRATIVE. RELAY FAILURE. AIR DRYER IN 242-S OUT OF SERVICE FOR TWO YEARS, LOSS OF AIR COMPRESSORS ALLOWED MOISTURE IN LINES CAUSING FLUCTUATING READINGS AND WATER IN ROTAMETERS.
RL-WHC-TANKFARM-1991-1002	04/04/1991	MISSED PROGRAMMATIC MILESTONE FOR 242-A EVAPORATOR RE-START.	ADMINISTRATIVE. ADDITIONAL WORK TAKEN ON WITHOUT CHANGING THE MILESTONE DATE. FAILURE TO USE A FORMALIZED CHANGE CONTROL SYSTEM.
RL-WHC-TANKFARM-1991-1008	04/18/1991	DIESEL FUEL SPILL FROM THE EMERGENCY GENERATOR AT 241-SY TANK FARM.	PERSONNEL ERROR. THE FUEL TANK WAS OVERFILLED, WHEN HEATED UP DO TO WARM WEATHER, THE FUEL EXPANDED AND OVERFLOWED.
RL-WHC-TANKFARM-1991-1012	05/05/1991	244-AR VAULT PORTABLE COMPRESSOR FUEL LEAK DUE TO FUEL FILTER SEAL RUPTURE.	ADMINISTRATIVE. MAINTENANCE NOTED THAT THE SEAL NEEDED TO BE CHANGED BUT TWO COMPRESSORS HAD BEEN OUT OF SERVICE FOR A YEAR, IT COULD NOT BE SHUT DOWN.
RL-WHC-TANKFARM-1991-1021	06/21/1991	TANK 241-C-104 CORE SAMPLE EXCEEDED CRITICALITY SPECIFICATIONS. THIS INFRACTION WAS DECLARED FIVE YEARS AFTER THE SAMPLE WAS TAKEN, AN ERROR IN THE LABORATORY DATA TRANSMITTAL WAS DISCOVERED. NO INFRACTION ACTUALLY OCCURRED.	ADMINISTRATIVE. LACK OF ADMINISTRATIVE CONTROL IN REVIEWING DATA.
RL-WHC-TANKFARM-1991-1030	07/24/1991	POTENTIAL LOCK AND TAG PROCEDURE VIOLATION AT 216-A 29-A DIVERSION BOX. CHAIN WHICH HAD LOCKED VALVE 216-A-29-A-1, APPEARED TO HAVE BEEN CUT AND THE VALVE PARTIALLY OPENED.	MALICIOUS OR CRIMINAL INTENT.
RL-WHC-TANKFARM-1991-1050	10/02/1991	UNPLANNED LIQUID LEVEL INCREASE IN TANK 241-AW-102. LEVEL INCREASED ONE INCH OVER ONE SHIFT. EYEWASH UNIT WAS LEFT ON, OR LEAKED, AND DRAINED INTO TANK.	MANAGEMENT PROBLEM, IMPROPER RESOURCE ALLOCATION.
RL-WHC-TANKFARM-1991-1053	10/18/1991	241-TX LOCK AND TAG VIOLATION, A BREAKER WAS IN THE ON POSITION WITH A TAG INDICATING IT WAS LOCKED IN THE OFF POSITION.	ADMINISTRATIVE/PERSONNEL ERROR. PROCEDURE DID NOT INDICATE THE BREAKER COULD BE CHANGED, CUSTODIAN DID NOT TELL TAG INSTALLER TO CHANGE POSITION.
RL-WHC-TANKFARM-1991-1056	10/25/1991	SUSPECT SINGLE SHELL TANK pH LEVELS. INFORMATION WAS PRESENTED AT A DNFSB MEETING WHICH INDICATED pH LEVELS OF SIX TO EIGHT IN THE 1940s AND 1950s.	MANAGEMENT DECISION. IN CONSIDERATION OF TANK SPACE PRESERVATION.
RL-WHC-TANKFARM-1991-1058	11/07/1991	LOSS OF 241-AN VENTILATION SYSTEM. THE PRIMARY EXHAUSTER TRIPPED ON LOW DIFFERENTIAL PRESSURE DURING A PRE-FILTER INSPECTION, THE BACKUP SYSTEM WAS TAGGED OUT FOR MAINTENANCE. NO VENTILATION SYSTEM FOR 12 MINUTES.	PLANNING DEFICIENCY. POTENTIAL FOR SYSTEM SHUTDOWN DURING PRE-FILTER INSPECTION, NO BACKUP SYSTEM AVAILABLE.

Table D3.2-2. Summary of Occurrences. (33 sheets)

RL-WHC-TANKFARM-1991-1063	11/16/1991	LOSS OF POWER TO 200 WEST TANK FARMS. LOST VENTILATION TO 241-SY FARM AND 242-T EVAPORATOR. POWER OFF FOR ONE MINUTE.	SUSPECT THAT A SMALL ANIMAL CAUSED THE OUTAGE.
RL-WHC-TANKFARM-1991-1064	11/22/1991	LOSS OF 241-AY/AZ TANK FARM BACKUP VENTILATION SYSTEM CLASS A EQUIPMENT DURING TROUBLESHOOTING.	MECHANICAL/PERSONNEL ERROR. MOTOR RESET CIRCUIT FAULT TRIGGERED AN ELECTRICAL CHAIN REACTION. RESET BUTTON SHOULD NOT HAVE BEEN PRESSED.
RL-WHC-TANKFARM-1991-1073	05/24/1991	MISSED PROGRAMMATIC MILESTONE FOR 242-A EVAPORATOR RE-START.	WORK STOPPAGE DUE TO FUNDING LIMITATIONS. LACK OF ABILITY TO HOLD THE CONSTRUCTION CONTRACTOR ACCOUNTABLE.
RL-WHC-TANKFARM-1991-1076	12/16/1991	LOCK AND TAG VIOLATION AT 241-C TANK FARM, WORK WAS DONE ON A HEAT TRACE LINE WITH NO LOCK AND TAG IN PLACE.	ADMINISTRATIVE. LOCK AND TAG CLEARED WITHOUT TESTING, PAPERWORK NOT COMPLETED.
RL-WHC-TANKFARM-1991-1079	12/23/1991	MISSED TRI-PARTY AGREEMENT MILESTONE M-05-03 FOR INTERIM STABILIZATION. COULD NOT PUMP THE TANKS AS ASSIGNED.	ADMINISTRATIVE. FAILURE TO GET OFFICIAL DETERMINATION OF IMPACTS OF INTERIM STABILIZATION ACTIVITIES.
RL-WHC-TANKFARM-1992-0007	01/22/1992	TANK FARM INTERNAL ASSESSMENTS UNCOVERED DEFICIENCIES IN SOLID WASTE COMPLIANCE ISSUES DUE TO LACK OF PROGRAMMATIC DIRECTION.	INSUFFICIENT STAFFING, TRAINING, INADEQUATE IMPLEMENTATION OF INTERNAL ENVIRONMENTAL COMPLIANCE OVERSIGHT PROGRAMS.
RL-WHC-TANKFARM-1992-0011	01/28/1992	PERSONNEL EXPOSURE TO UNKNOWN VAPORS AT B-COMPLEX RESULT IN SYMPTOMS REQUIRING MEDICAL EVALUATION.	BATTERY BOILED OVER INSIDE RADIOLOGICAL CONTROLLED AREA.
RL-WHC-TANKFARM-1992-0012	01/31/1992	OPERATIONAL SAFETY REQUIREMENT NONCONFORMANCE. DAILY READINGS COULD NOT BE OBTAINED DUE TO TANK FARM ENTRY LIMITATIONS AFTER BATTERY BOILOVER.	ADMINISTRATIVE. APPROPRIATE PERSONAL PROTECTIVE EQUIPMENT NOT AVAILABLE TO MAKE TANK FARM ENTRIES FOR SURVEILLANCE.
RL-WHC-TANKFARM-1992-0019	02/29/1992	LOSS OF PRIMARY VENTILATION IN AP-FARM. THE PRIMARY FAN TRIPPED DUE TO DIFFERENTIAL PRESSURE PROBLEMS, AND THE BACKUP FAN ATTEMPTER, BUT FAILED, TO START.	MECHANICAL.
RL-WHC-TANKFARM-1992-0022	02/28/1992	LOSS OF CONFIGURATION CONTROL IN THE 241-SY PRIMARY LEAK DETECTION SYSTEM DUE TO AN INACCURATE PROCEDURE. CONDUCTIVITY PROBE SETTINGS INCORRECT FOR 101-SY AND 103-SY.	ADMINISTRATIVE. PROCEDURES HAD NOT BEEN UPDATED TO REFLECT MODIFICATIONS IN LEAK DETECTION CONFIGURATION.
RL-WHC-TANKFARM-1992-0028	03/16/1992	200 EAST/200 WEST POWER OUTAGE. TWO BACKUP POWER SYSTEMS FAILED TO START DURING OUTAGE.	MECHANICAL. 204-AR DIESEL GENERATOR AND 241-SY TANK FARM DIESEL GENERATOR FAILED TO START WHEN REQUIRED.
RL-WHC-TANKFARM-1992-0033	04/23/1992	OSR SURVEILLANCE REQUIREMENT NOT MET, EQUIPMENT OUT OF CALIBRATION DUE TO LACK OF ADMINISTRATIVE CONTROL.	ADMINISTRATIVE. CALIBRATION CARDS FOR LOW FLOW ALARMS AT AY AND AZ TANKS WERE INACTIVATED IN 1989. CHANGES TO PISCES SYSTEM NOW REQUIRES OUTSIDE REVIEW.
RL-WHC-TANKFARM-1992-0037	04/30/1992	UNREVIEWED SAFETY QUESTION REGARDING CRITICALITY SAFETY OF TANK FARMS. SARs STATE A CRITICALITY IN WASTE TANKS IS INCREDIBLE. WE CAN NOT PROVE THIS.	ADMINISTRATIVE. INADEQUATE CHARACTERIZATION, AND LACK OF DATA ON MATERIAL DISTRIBUTION IN THE TANKS.
RL-WHC-TANKFARM-1992-0038	05/02/1992	241-A-702 STACK CONTINUOUS AIR MONITOR FAILURE.	MECHANICAL.
RL-WHC-TANKFARM-1992-0051	06/28/1992	ELECTRICAL STORM DISRUPTS 200 WEST POWER.	WEATHER CONDITIONS.

Table D3.2-2. Summary of Occurrences. (33 sheets)

RL-WHC-TANKFARM-1992-0055	07/20/1992	15 MINUTE LOSS OF VENTILATION IN 241-AP TANK FARM DUE TO PLUGGED SENSING LINE LEADING TO DIFFERENTIAL PRESSURE INDICATING SWITCH. BACKUP FAN ATTEMPTED TO START BUT TRIPPED DUE TO VALVE FAILING TO OPEN.	MECHANICAL. SENSING LINE PLUG AND INLET VALVE FAILURE.
RL-WHC-TANKFARM-1992-0066	09/15/1992	BOMB THREAT RESULTS IN 241-SY EVACUATION.	MALICIOUS INTENT OR PART OF A TRAINING EXERCISE. UNKNOWN.
RL-WHC-TANKFARM-1992-0069	09/21/1992	FLOATING LIQUID ORGANIC LAYER IN 241-C-103 DETERMINED TO BE AN UNREVIEWED SAFETY QUESTION.	ADMINISTRATIVE. FLOATING ORGANIC LAYER IS NOT ADDRESSED IN THE SAFETY ANALYSIS REPORT.
RL-WHC-TANKFARM-1992-0073	09/18/1992	DECREASE IN LIQUID LEVEL IN TANK 241-T-101. ASSUMED LEAKER.	DEFECTIVE OR FAILED MATERIAL.
RL-WHC-TANKFARM-1992-0074	10/01/1992	LEAKAGE FROM CONTAINMENT CASK CONTAINING AN AIR LANCE TAKEN FROM TANK 241-SY-101. SOIL CONTAMINATED.	DEFECTIVE OR INADEQUATE DESIGN. NEEDED A GASKET IN THE LOCKING ASSEMBLY.
RL-WHC-TANKFARM-1992-0082	11/04/1992	LOSS OF LEAK DETECTION CAPABILITIES FOR TANK 241-SY-102. ANNULUS FLAKE BOX LEAK DETECTOR PROBE FAILED. ANNULUS CAM WAS NOT FUNCTIONAL DUE TO PREVIOUS FAILURE. RESULTING LCO NONCONFORMANCE.	MECHANICAL. LEAK DETECTOR FAILURE, CAM OUT OF SERVICE DUE TO VACUUM PUMP FAILURE.
RL-WHC-TANKFARM-1993-0005	01/12/1993	MISSED SURVEILLANCE ON TK-105-C AND TK-106-C RESULT IN OSR NONCONFORMANCE.	WEATHER CONDITION. SNOW DRIFTS WAIST HIGH AND HIGH WINDS CAUSED READINGS TO BE 12 HOURS BEYOND THE LIMIT.
RL-WHC-TANKFARM-1993-0009	01/18/1993	LOSS OF PRIMARY TANK VENTILATION IN 241-AN TANK FARM. VENTILATION FAN SHUT OFF FOR UNKNOWN REASON. BACKUP FAN FAILED TO START DUE TO INCORRECT SWITCH POSITION SETTING THE FAN IN STANDBY.	MECHANICAL/PERSONNEL ERROR. SUSPECT INSTRUMENT NOISE CAUSED PRIMARY FAN FAILURE, SWITCH MISPOSITION CAUSED BACKUP FAN FAILURE TO START.
RL-WHC-TANKFARM-1993-0011	01/21/1993	TEMPORARY LOSS OF 241-AY/AZ PRIMARY TANK VENTILATION DUE TO PERSONNEL ERROR. THE TWO BACKUP FANS WERE OUT FOR MAINTENANCE.	PERSONNEL ERROR. INATTENTION TO DETAIL, ELECTRICIAN BUMPED MAGNETIC MOTOR STARTER FOR ISOLATED FAN, TRIPPING THE OPERATING FAN.
RL-WHC-TANKFARM-1993-0012	01/22/1993	AMMONIA-LIKE ODOR AFTER REMOVING 1" DRAIN PLUG FROM AIR LANCE RECEIVER.	WEATHER CONDITIONS. TEMPERATURE WARMING CONTRIBUTED TO PRESSURIZATION OF AIR IN AIR LANCE PACKAGE, WHEN PLUG WAS REMOVED, PRESSURE WAS RELIEVED.
RL-WHC-TANKFARM-1993-0023	02/11/1993	ALPHA CAM VACUUM PUMP FAILED ON EXHAUST STACK MONITOR AT 242-T EVAPORATOR. PUMP WAS UNPLUGGED FOR ROUTINE TESTING OF FLOW ALARM, PUMP FAILED TO RE-START WHEN PLUGGED BACK IN.	MECHANICAL. DEFECTIVE OR FAILED COMPONENT.
RL-WHC-TANKFARM-1993-0027	03/05/1993	TANK 101-AN LIQUID INDICATING TRANSMITTER FAILURE, SURVEILLANCE MISSED. OSR VIOLATION.	MECHANICAL/TRAINING. COMPONENT FAILURE. DELAY IN SURVEILLANCE DUE TO MAINTENANCE STAFF UNFAMILIAR WITH JOB.
RL-WHC-TANKFARM-1993-0028	03/05/1993	WASTE TRANSFER STOPPED DUE TO FAULTY AIR VALVE, LEAK BY ON BALL VALVE ALLOWED 700 GALLON TRANSFER TO 102-SY.	MECHANICAL. AIR VALVE FAILURE, BALL VALVE LEAK BY, LEAK DETECTORS FAILED TO ALARM.
RL-WHC-TANKFARM-1993-0035	03/23/1993	SINGLE SHELL TANK 241-BX-111 ASSUMED LEAKER. LEVEL DECREASE IN TANK CHANGED FROM 0.5 INCH DECREASE OVER 7 YEARS, TO ONE INCH DECREASE IN THREE MONTHS.	MECHANICAL/ADMINISTRATIVE. ASSUMED CORROSION CAUSED LEAK. TANK SERVICE LONG PAST DESIGN LIFE.

Table D3.2-2. Summary of Occurrences. (33 sheets)

RL-WHC-TANKFARM-1993-0043	03/05/1993	NON-CONFORMANCE TO STATE REQUIREMENTS CONCERNING STORING HAZARDOUS WASTE CONTAINERS.	ADMINISTRATIVE/FAILURE TO FOLLOW PROCEDURE. RESULTED IN A BACKLOG OF WASTE CONTAINERS ACCUMULATED.
RL-WHC-TANKFARM-1993-0044	05/06/1993	LIQUID OBSERVATION WELL IN TANK 241-SX-102 INDICATES LIQUID LEVEL DECREASE OF 0.4 FEET. ASSUMED LEAKER.	DEFECTIVE OR FAILED MATERIAL.
RL-WHC-TANKFARM-1993-0045	05/08/1993	WASTE CONTAINERS FOUND WITHOUT CORRECT PAPERWORK. INVENTORY OF TANK FARMS FOUND 26 OUT OF COMPLIANCE WASTE CONTAINERS (NO ACCUMULATION DATES, NO INVENTORIES, OR IMPROPER STORAGE)	ADMINISTRATIVE. LACK OF EFFECTIVE PROCEDURE TO CONTROL WASTE CONTAINERS ACCORDING TO POLICIES AND REGULATIONS.
RL-WHC-TANKFARM-1993-0057	06/22/1993	CRANE ACTIVITIES IN 241-SY TANK FARM, WIRE ROPE SEVERED, BLOCK FALLING TO GROUND.	PERSONNEL ERROR/LACK OF PROPER EQUIPMENT. INATTENTION BY CRANE OPERATOR, LACK OF ANTI TWO-BLOCKING ALARM ON CRANE MAIN HOIST.
RL-WHC-TANKFARM-1993-0063	07/15/1993	PACKAGING DISCREPANCIES OF SOLID WASTE CONTAINERS AT 241-SX FARM. LOW LEVEL WASTE BOXES CONTAINED DANGEROUS WASTE.	PROCEDURE VIOLATION.
RL-WHC-TANKFARM-1993-0069	08/04/1993	INADVERTENT START OF 241-SY-101 HYDROGEN MITIGATION PUMP.	LACK OF TRAINING, INFORMATION TAG INFORMATION INCOMPLETE.
RL-WHC-TANKFARM-1993-0072	08/11/1993	LOSS OF POWER TO AP, AW, AND AN TANK FARMS RESULTING IN LOSS OF PRIMARY EXHAUST FANS IN AP, AW, AN, AND C TANK FARMS.	POWER LOSS DUE TO LARGE BIRD LANDING ON POWER POLE AT GABLE MOUNTAIN.
RL-WHC-TANKFARM-1993-0090	10/08/1993	CALCULATION ERROR FOR AMMONIA RELEASE MECHANISM AT 241-SY-101, GENERATES USQ.	PERSONNEL ERROR IN COMPUTER INPUT FOR TANK BURN ACCIDENT CALCULATION.
RL-WHC-TANKFARM-1993-0105	12/02/1993	METHANE GAS IN SY-101 DISCOVERED TO ADD 10% MORE ENERGY TO THE BURN ANALYSIS RESULTS. NEW DATA ANALYSIS METHOD DISCOVERED DISCREPANCY.	LESS THAN EFFECTIVE MANAGEMENT METHODS. LACK OF FORMAL REPORTING METHODS BETWEEN LOS ALAMOS NATIONAL LAB AND WHC.
RL-WHC-TANKFARM-1993-0107	12/04/1993	241-SY TANK FARM ENTRANCE DURING MIXER PUMP OPERATION.	PROCEDURE VIOLATION. OPERATORS REMOVED EXCLUSION AREA BARRIERS AND ENTERED AREA WITHOUT VERIFYING PUMP TEST COMPLETION.
RL-WHC-TANKFARM-1993-0117	12/15/1993	INCORRECT SAFETY PRECAUTIONS USED DURING MAINTENANCE ACTIVITIES ON EXHAUSTER SYSTEM OF FLAMMABLE WATCHLIST TANK.	PERSONNEL ERROR. ERRONEOUS INFORMATION ON DRAWING AND INCORRECT INTERPRETATION OF DRAWING.
RL-WHC-TANKFARM-1994-0002	01/11/1994	SOIL COVER DEPTH OVER 241-SY TANKFARM TANKS EXCEEDS SPECIFICATIONS.	ROOT CAUSE ANALYSIS TO BE PERFORMED.
RL-WHC-TANKFARM-1994-0009	02/23/1994	DECREASE IN LIQUID LEVEL IN TANK 241-T-111. DECLARED ASSUMED LEAKER IN 1984.	TANK ASSUMED TO LEAK, FAILED MATERIAL, PROBABLY DUE TO CORROSION.
RL-WHC-TANKFARM-1994-0035	06/14/1994	POTENTIAL VIOLATION OF 241-AP TANKFARM DOME LOADING REQUIREMENTS. ENGINEERING REVIEW OF CONSTRUCTION DOCUMENTATION FOUND THAT DOME LOADING WAS BASED ON 110 LBS. PER CUBIC FOOT, WETTED SOIL DENSITY IS 121 LBS. PER CUBIC FOOT.	ROOT CAUSE ANALYSIS TO BE PERFORMED.

Table D3.2-2. Summary of Occurrences. (33 sheets)

RL-WHC-TANKFARM-1994-0036	07/01/1994	SURVEILLANCE ANOMALY IN 241-C-106. CYCLIC TEMPERATURE VARIATIONS OCCURRED ON ONE OF TWO THERMOCOUPLE TREES IN TANK. INCONSISTENT DATA WITH HISTORICAL DATA. EXCEEDED OPERATING SPECIFICATION OF 20 DEGREES PER DAY VARIATION.	DESIGN PROBLEM. ENERGY BUILDUP DURING TESTING WAS NOT DETECTED UNTIL AFTER THE TEST WHEN WATER ADDITION TO TANK PUSHED HOT SLUDGE UP AGAINST THE THERMOCOUPLE.
RL-WHC-TANKFARM-1994-0063	11/14/1994	MISSED SURVEILLANCE REQUIREMENTS DURING WASTE TRANSFER. COVERS ON CLEAN-OUT BOXES, PITS, AND BOXES ARE TO BE VERIFIED IN POSITION ONCE EVERY 72 HOURS DURING TRANSFER.	PERSONNEL ERROR, VIOLATION OF PROCEDURE. COVER BLOCKS WERE NOT INSPECTED AS REQUIRED.
RL-WHC-TANKFARM-1994-0070	12/12/1994	SPILL OF ONE GALLON OF WASTE AT C-110 SALTWELL AFTER FLUSH OF C-110 AND C-107.	PROCEDURE PROBLEM/MECHANICAL. SALTWELL FLUSH WATER BACKPRESSURE CAUSED WASTE WATER INTO RAW WATER FEED LINE WHERE IT LEAKED OUT OF DEFECTIVE QUICK DISCONNECTS.
RL-WHC-TANKFARM-1995-0010	01/26/1995	PERSONAL CLOTHING CONTAMINATION AT W-030 PROJECT CHANGE TRAILER. KEH PIPEFITTER HAD CONTAMINATED OVERALLS. NUCLEAR PROCESS OPERATOR BAGGED THE CLOTHING AND RELEASED THE PIPEFITTER TO GO HOME. MANAGEMENT NOT NOTIFIED.	MANAGEMENT PROBLEM. NUCLEAR PROCESS OPERATOR DID NOT NOTIFY RADIOLOGICAL CONTROL OR SHIFT MANAGER.
RL-WHC-TANKFARM-1995-0063	07/25/1995	FAILURE TO COMPLY WITH WATCHLIST CONTROLS WHEN SAMPLES FROM C-105, C-202, AND C-204, WERE TAKEN AND FORWARDED TO OPERATIONS WITHOUT HAVING WATCHLIST CONTROLS IMPOSED.	PROCEDURE VIOLATION. SHIFT MANAGER DID NOT IMPOSE WATCHLIST CONTROLS FOR SAMPLES.
RL-WHC-TANKFARM-1995-0088	10/16/1995	RECENT STUDY INDICATES 23 TANKS SHOULD BE ADDED TO FLAMMABLE GAS UNREVIEWED SAFETY QUESTION. PNL IDENTIFIED 59 TANKS WITH POSSIBLE TRAPPED GAS, BASED ON LEVEL FLUCTUATIONS. 21 OF THESE TANKS ARE MONITORED AND CONTROLLED AS WATCHLIST TANKS.	TO BE DETERMINED.
RL-WHC-TANKFARM-1996-0007	01/16/1996	OSD VIOLATION, 244-TX DCRT HYDROXIDE LEVELS NOT SUFFICIENT. SHOULD HAVE HAD 0.1178 MOLES/LITER, ONLY HAD 0.0025 MOLES/LITER. HYDROXIDE LEVEL NOT ADJUSTED AFTER SALTWELL WASTE AND FLUSH WATER TRANSFER FROM SST T-107.	IMPROPER CHEMICAL ADJUSTMENT AFTER WASTE TRANSFER.
WHC-TANKFARM-1996-0026	03/15/1996	Helicopter operated by Bechtel Nevada Corporation performing aerial radiological surveys flew over 241-A, AX, AY, AW, and C Tank Farm and was not authorized.	Although flights directly over tankfarms is prohibited, it was not recognized by personnel that this was true. Personnel error.
WHC-TANKFARM-1996-0029	03/26/1996	Cover block inspections not specified for pump pit 241-S-107-A which had waste transfer passing through it.	Inadequate procedure. It did not call for cover block inspection of this pit.
WHC-TANKFARM-1996-0032	04/08/1996	An unplanned shutdown of the 241-SY-K1-4-1 primary tank exhauster occurred. Exhauster was restarted after investigation of cause.	No cause was found.
WHC-TANKFARM-1996-0038	06/04/1996	An assessment team reviewing the "Double-shell Tank Composition Status - Quarterly Report" discovered a potential low hydroxide concern with Tank 101-AZ.	The Root Cause and Direct Cause of this event was Procedure Problem/Defective or Inadequate Procedure.
WHC-TANKFARM-1996-0044	07/01/1996	Electrical power was lost at 241-AN/AW/AP/AZ, 272-AW, and 244-AR.	A piece of foil backed paper, caught in a whirlwind shorted 2 phases on the power line west of AY Farm.
WHC-TANKFARM-1996-0047	07/07/1996	Lock and Tag placed on wrong valve on cross-site transfer line. Valve was in 153-ER and the correct valve was in 152-ER.	No mention in procedure was made to geographical location and no mention of location was discussed during the pre-job briefing prior to installing the lock out. Human Error
WHC-TANKFARM-1996-0050	07/15/1996	During excavation of Tank C-104, riser #14, it was found that no flange was covering access to tank. Instead, a piece of lead shielding was covering the opening.	The exact cause of this event cannot be determined. It is evident that the riser did not have a cover flange installed when it was backfilled.

Table D3.2-2. Summary of Occurrences. (33 sheets)

WHC-TANKFARM-1996-0056	08/02/1996	During preparation to install video camera in Tank 241-A-101 a spark occurred when the electrician attached the bonding wire to the bonding bus bar.	A deficiency existed in the Tank 241-A-101 air lift circulator building electrical system. The cause of the spark was traced to wiring in the receptacles used to supply 120 VAC power due to cross-connected ground and neutral wires.
WHC-TANKFARM-1996-0066	09/04/1996	Tank C-106 dummy jumper dropped during removal from pump pit.	The grapple assembly control box fell off cabinet resulting in grapple assembly opening and the jumper twisting and tilting over.
WHC-TANKFARM-1996-0067	09/17/1996	Ninety seven gallons of water spilled into containment tent at tank C-106 pump pit.	Operator commenced water addition without verifying the lineup and without connecting the fill hose to the fill adapter as required by procedure.
WHC-TANKFARM-1996-0072	09/24/1996	Unsafe use of non-sparking tools during tank intrusive work. Use of crescent wrench combination resulted in potential for worker injury and spark creation.	Correct tools not available at the job site caused by schedule pressures. This caused the craft personnel to improvise.
PHMC-TANKFARM-1996-0002	10/08/1996	Loss of ventilation in AN Tank Farm.	During checking phase rotation of the SHMS sample pump the wrong breakers were opened. The breakers for the ventilation fans and the SHMS are directly above each other.
PHMC-TANKFARM-1996-0006	10/18/1996	241-A-A intrinsically safe leak detector does not meet design requirements of the authorization basis.	Personnel error due to inattention to detail.
PHMC-TANKFARM-1996-0010	10/29/1996	Discovery declared on authorization basis deficiency at 209-E facility. No authorization basis was found to include for the 209-E facility.	Inadequate administrative control.
PHMC-TANKFARM-1996-0016	11/26/1996	Dump truck bed contacted and broke overhead local area network cable.	Procedure not used. Human error.
PHMC-TANKFARM-1996-0018	12/11/1996	Procedure misinterpretation discovered in tankfarm operating specification document. Requirement was interpreted that there was no replacement time limit for filter replacement on a cascaded tank if its HEPA filter failed its aerosol test. The requirement actually specifies that a 7 day period is permitted for replacement.	Personnel error in interpreting this requirement.
PHMC-TANKFARM-1997-0001	01/03/97	Liquid level in 244-AR sump #1 increased from 3% to 51.5%.	During the weeks leading up; to the level increase, an unusual increase in the outside temperature resulted in a sudden and large amount of snow melt. In addition to the snow melt, an above average amount of precipitation fell during this time period. Two paths are available to cell1. One is the drain line on the concrete encasement line from 151-AR diversion box. The other is the drain line located at the bottom of the failed equipment storage containers.
PHMC-TANKFARM-1997-0002	01/07/97	Ruptured sanitary water line causes flooding in wet grout facility, Module G3.	The facility was left in an "abandon as is" condition and the sanitary water was not secured to the eye wash station. No freeze protection was provided and the line froze and broke when the outside temperature went below freezing. The root cause is failure to recognize hazards for abandoned facilities.
PHMC-TANKFARM-1997-0003	12/27/1996	241-SY primary exhauster unexpectedly shut down.	Frozen pressure sensor line due to water accumulation coupled with low ambient temperatures. Inadequate design of the sensor line.

Table D3.2-2. Summary of Occurrences. (33 sheets)

PHMC-TANKFARM-1997-0004	12/30/1996	Unplanned loss of ventilation at 242-S Building.	An electrical short due to motor bearing failure permitting armature to contact stator winding caused the exhauster motor to fail.
PHMC-TANKFARM-1997-0006	01/09/1997	102-AZ primary tank pressurization alarm received after maintenance on the service water system in AZ Tankfarm.	A worker left a wrong valve open during testing of a repair of an instrument line leak. This resulted in the tank ventilation system seal loop filling. The valve was mislabeled.
PHMC-TANKFARM-1997-0007	01/17/1997	106-AN transfer pump operated for 4 hours with the Tankfarm Master Pump Shutdown (MPS) alarm activated.	Multiple personnel errors in communication and recognition of an undesirable condition. Procedures not used or used incorrectly. Inattention to detail. Ground in adjacent fused grounding panel allowed pump relay to remain energized even though the MPS was tripped.
PHMC-TANKFARM-1997-0008	01/19/1997	241-SY Primary exhauster shut down during troubleshooting activities. (Backup P-28 exhauster manually started)	Inadvertent cycling of the main breaker to the CAM cabinet resulted in CAM high radiation alarm relay being de-energized immediately causing exhauster shutdown. Procedure not used or used incorrectly. Violation of administrative procedure.
PHMC-TANKFARM-1997-0009	01/23/1997	241-SY Tank farm primary exhauster shutdown resulting in activation of pressurization alarm. Exhauster was restarted within 1 minute of shutting down.	Inadequate design resulted in an erroneous signal of high vacuum in header to occur when panel door was shut.
PHMC-TANKFARM-1997-0011	01/23/1997	244-AR Sump #2 water intrusion due to ruptured sanitary water line outside the facility.	Two water lines broke outside the 244-AR facility. Water flowed toward the facility, entered the control room, flowed around the north east side of the facility and entered the ground near the seal pot manhole. Current drawings do not show a potential leak path, but the rapid rise in sump level was concurrent with the water line breakage.
PHMC-TANKFARM-1997-0013	01/28/1997	Liquid levels in 240-S-302 Catch tank and 240-S-151 Diversion box showed a marked increase in liquid level.	Rain water and snow melt accumulated in an area that permits drainage to the diversion box. The tape used to augment the cover block seals had deteriorated from exposure to the elements. The cover block seals do not make a water tight seal.
PHMC-TANKFARM-1997-0023	02/20/1997	Loss of AW Tankfarm ventilation system results in a pressurization alarm.	Electrician was installing the cover on EDS-DP-203 when it slipped down causing the main breaker and adjacent breaker to turn off. Per work package, the crew did not attempt to reset the breakers, but finished the panel installation. Human error.
PHMC-TANKFARM-1997-0029	03/17/1997	Electrical line severed during excavation. A buried electrical conduit was severed by a backhoe during excavation activities for the W-058 Cross Site Transfer Line Project.	The excavation permit issued for this work was less than adequate. A recent project had installed perimeter lighting around the 241-SY Tank Farm. The as-built drawings for this installation were not reviewed during the preparation stage of the excavation permit.
PHMC-TANKFARM-1997-0033	03/27/1997	Unanticipated shutdown of the P-28 backup exhauster for the 241-SY Tank Farm. Shutdown was discovered when personnel responded to tank farm high pressure alarm. 45 minutes later the primary exhauster was started.	Cause is unknown.
PHMC-TANKFARM-1997-0035	04/02/1997	Unexpected loss of 242-S K1-5-3 exhauster. Approximately one half hour later the exhauster was restarted.	An electrician performing de-winterization opened circuit breaker #5 inside the K1-5-3 CAM enclosure. When the breaker was opened the exhauster shutdown. The winterization procedure was inadequate in providing direction on how heat trace was to be shutoff.

Table D3.2-2. Summary of Occurrences. (33 sheets)

PHMC-TANKFARM-0036	04/06/1997	Tank 105-AN experienced a gas release event (GRE)	Gas generation in tank coupled with changing weather conditions.
PHMC-TANKFARM-0037	04/07/1997	Unexplained decrease in 244-AR Sump #2 level. The surface level in the 244-AR decreased 2.57 inches in the prior 4 weeks.	Cause unknown.
PHMC-TANKFARM-0048	05/30/1997	An Apollo-owned Grove 30 Ton hydraulic crane tipped while lifting trench box components.	Operator failed to extend all outriggers. Operator mis-estimated actual load and crane capacity. Human error.
PHMC-TANKFARM-1997-0049	05/31/1997	Momentary power loss at 200 west tank farms causes exhauster to unexpectedly shutdown.	Unexplained momentary power loss.
PHMC-TANKFARM-1997-0055	06/29/1997	Momentary power loss at 200 west tank farms causes exhauster s to unexpectedly shutdown.	Momentary power loss may be connected with dust devil activity.
PHMC-TANKFARM-1997-0064	08/06/1997	Loss of tank farm ventilation power to 241-SY, 244-TX, 242-T, 241-SX exhausters, and the S and T CASS substations. The power surge also caused the 204-AR Backup Generator to start and come on line.	Tank & Toilet service contractor inadvertently caught crane hook on utility pole guy wire and caused pole to be pulled to the ground breaking the wire. Human error.
PHMC-TANKFARM-1997-00065	08/10/1997	Unplanned shutdown of the 296-S-15 "Sludge Cooler" exhauster in the 241-SX tank farm. At 0050 hrs CASS operator reported a 241-SX loss of ventilation alarm. Exhauster restarted at 0110 hrs and shutdown after 5 minutes. Operators switched to South fan and restarted at 0120 hrs. Fan shutdown at 0154 hrs and trouble shooting went on for 90 minutes unsuccessfully. Electricians were dispatched for trouble shooting and could find nothing wrong. Exhauster was started and operated normally.	The direct cause was determined to be electrical or instrument signal noise.
PHMC-TANKFARM-1997-0070	08/22/1997	Unexpected shutdown of the 241-SY P-28 Portable exhauster.	The direct cause was determined to be electrical or instrument signal noise.
PHMC-TANKFARM-1997-0072	08/26/1997	101-SY mixer pump computer system not updating temperature data. On August 25, 1997 it was confirmed that tank 101-SY temperature data had not been updating the DACS system since August 6, 1997.	The cause of this event was a design problem. There was an inadequate man-machine interface. The original design of the DACS software did not include a method of alerting operators that the thermocouples had lost communications with the DACS.
PHMC-TANKFARM-1997-0073	09/08/1997	While transferring waste from Tank 101-AY to Tank 102-AW, a level increase was detected in tank 102-AY.	A three way valve on the transfer route located in the 102-AY, 02A pit was allowing waste to leak by the valve and through a drop leg into tank 102-AY. The leaking valve was part of a jumper assembly that had recently been installed by Project W-320. Although a hydrostatic test had been performed on the jumper to test welds and piping integrity, no testing had been done on the valves to ensure they did not leak through.
PHMC-TANKFARM-1997-0074	09/11/1997	Approximately 250 gallons of water which contained 20 gallons of dilute citric acid water was potentially spilled from 241-BY transfer line SN-200. The line is a direct buried pipe which is foam encapsulated. The addition of the liquid was part of an attempt to clear a blockage in the line.	The blockage occurred due to the line being inactive for an extended period of time. Corrosion of the line caused the leak.

Table D3.2-2. Summary of Occurrences. (33 sheets)

PHMC-TANKFARM-1997-0079	10/06/1997	Loss of compressed air to 244-TX dip tubes. The dip tube system is utilized to determine level and specific gravity in the DCRT. It also provides purge air to minimize the potential for flammable gas buildup in the DCRT.	An air leak developed in the air system causing the compressor to run continuously, which eventually led to a tripped breaker.
PHMC-TANKFARM-1997-0083	10/08/1997	Loss of 241-SY 296-S-15 "Sludge Cooler" exhauster.	The direct and root causes of this event have been determined to be electrical/instrument noise.
PHMC-TANKFARM-1997-0086	10/30/1997	The 241-SY Tank farm primary ventilation system unexpectedly shut down.	Inadequate/defective design caused event. High winds experienced on the Hanford site caused the 2400 Vac regulated line to come in contact with the 13.8 kv line resulting in a momentary power loss.
PHMC-TANKFARM-1997-0092	11/17/1997	Non-intrinsically safe leak detectors were discovered not to be isolated from tank 101-AN. The pit drain and drain seal designs did not adequately isolate the pit from the tank dome space during a time waste disturbing operations were occurring.	The root cause of this event was determined to be personnel error/inattention to detail. The design of the drain seal was not adequate to identify that it did not provide adequate isolation from the tank dome.
PHMC-TANKFARM-1997-0095	11/20/1997	The 241-SY primary exhauster shutdown causing the SY Farm pressurization alarm to activate.	Maintenance procedure not used or used incorrectly resulted in CAM set point not being changed as prescribed by procedure, allowing a check source to activate the CAM's interlock shutting down the exhauster.
PHMC-TANKFARM-1997-0108	12/31/1997	The 241-T-104 waste transfer pump shut down due to activation of a service water system high pressure switch.	The waste transfer line plugged during transfer and the waste solution leaked by a 3-way valve into the service water (flush) system. The valve failed to remain leak tight at the pressure of the deadheaded system. Defective component.
PHMC-TANKFARM-1998-0009	01/24/1998	A pressurization alarm was received at the CASS indicating the 241-SY double-shell tank's primary exhauster had shutdown.	No abnormal conditions were discovered to indicate what caused the shutdown. Evaluation of changes in design will be considered to prevent high winds from affecting exhauster operation.
PHMC-TANKFARM-1998-0020	03/05/1998	When nozzle E was loosened to drain a rigid jumper in 241-A-A valve pit to permit removal an unexpected amount of water drained to A-350 catch tank. The level in the tank exceeded 77 inches, beyond the range of the instrumentation.	The work package used to accomplish the work did not have proper details describing how much water, if any, should be allowed to drain to the A-A valve pit. This was a result of personnel error/inattention to detail as the cognizant engineer did not take into account several aspects of the job.
PHMC-TANKFARM-1998-0032	03/27/1998	Worker in area around 241-AZ evaporative cooling towers noticed odor of chlorine.	Cause not specified
PHMC-TANKFARM-1998-0034	03/29/1998	Unscheduled shutdown of C-106 exhaust fan.	Personnel performing routine efficiency checks of the CAM caused fan shutdown on high radiation alarm while performing the cam efficiency check.
PHMC-TANKFARM-1998-0036	03/31/1998	Inadvertent shutdown of 241-SX exhauster.	Personnel performing maintenance on the exhauster CAM inadvertently moved the interlock set point control knob, causing the exhauster to shut down.
PHMC-TANKFARM-1998-0037	04/01/1998	Loss of ventilation in tank 101-AZ.	Valve K1-2 was found shut. Cause unspecified.

Table D3.2-2. Summary of Occurrences. (33 sheets)

PHMC-TANKFARM-1998-0038	04/02/1998	Addition of soil to catch tank exclusion area results in near miss violation of technical safety requirements administrative control. Clean backfill was spread in the area above an SST underground tank just east of 221-U. Administrative controls for the catch tank area associated with tank dome loading prohibit any additional loads to be added to the catch tank dome without engineering concurrence.	Interface requirements between contractors inadequate to prevent this event.

This page intentionally left blank.

Table D3.2-3. Hazard Analysis Cause Groups and Associated Occurrences.

CAUSE GROUPS/RELATED OCCURRENCES	
ITEM	NUMBER OF OCCURRENCES
CRITICALITY	4 occurrences
FIRE/EXPLOSION	14 occurrences
TANK DOME COLLAPSE	8 occurrences
RELEASE	156 occurrences
HUMAN ERROR RELEASE	59 occurrences
NON-RELEASES / OCCUPATIONAL	0 occurrences

This page intentionally left blank.

Table D3.2-4. Occurrences Not Included in the Hazard Analysis. (4 sheets)

ITEM	OCCURRENCE	NUMBER OF OCCURRENCES	COMMENTS
1	Occupational injury (or potential)	20	Occupational. Not an official part of the study, these events were included when discovered.
2	Ventilation heater failure	2	Ventilation heater failure. This event does not cause a release of radioactive or toxic material.
3	Rotten timbers-crib subsidence	1	Rotten timbers, crib subsidence. Potential contamination spread. However, this event did not cause a release of radioactive or toxic material.
4	No protective equipment	7	No protective equipment. Included as failure to follow administrative controls in the control section of the study. This event does not cause a release of radioactive or toxic material.
5	Tank exceeds level limit	27	Tank exceeds level limit. No release from this event.
6	Waste tank level decrease	121	Waste tank level decrease. No release from these events.
7	Waste tank level increase	93	Waste tank level increase. This event does not cause a release of radioactive or toxic material.
8	Tank temperature increase	3	Tank temperature increase. This event does not cause a release of radioactive or toxic material.
9	Sampling/ surveillance failure	10	Sampling/surveillance failure. Included as the failure to follow administrative controls, in the control section of the study.
10	Instrument failure-due to auguring	1	Instrument failure-due to auguring. If this event resulted in a release, it would be included as an intrusive activity.
11	Increased radiation readings	52	Increased radiation readings. Generally, these events were a result of the migration of soil contamination in laterals or dry wells associated with waste tanks.
12	Radioactive/ toxic liquid spill	11	Radioactive/toxic spill. These events are included in the study as leaks and/or contamination spread.
13	Radiation alarm due to welding	1	Radiation alarm due to welding. This event does not cause a release, an alarm was triggered.
14	Waste tank sampler, break, rupture	2	Waste tank sampler break, rupture. Breaking a sampler does not cause a release. It is an operational problem.
15	High dP across filters	3	High dP across filters. High dP does not cause a release, filter plugging can be a precursor to filter rupture.
16	Vehicle collision in tank farm, nothing broken	3	Vehicle collision in farm, nothing broken. These events did not cause a rupture, or release.
17	Process condensate pH too low	1	Process condensate pH too low. This event entails clean water, it does not cause a release.
18	High radiation in excavation	4	High radiation in excavation. These events included personnel exposure because they were in an excavation in the tank farms. They were an occupational problem, they did not involve a release.
19	Transfer line plug	4	Transfer line plug. These events did not cause a release.
20	Steam used instead of air	1	Steam used instead of air. This event caused no release, it was an operational problem.

Table D3.2-4. Occurrences Not Included in the Hazard Analysis. (4 sheets)

ITEM	OCCURRENCE	NUMBER OF OCCURRENCES	COMMENTS
21	Indicator failure	21	Indicator failure. These events are covered in the study concerning engineered controls.
22	Pump run w/o cooling water, too acidic	2	Pump run without cooling water. This event caused no release.
23	Re-used o.o.s. waste tank	1	Re-use of out-of-service waste tank. This event is a violation of administrative controls, it did not cause a release.
24	Intentional violation of admin. controls	8	Intentional violations of administrative controls. Included in the administrative control section of the study.
25	Water spill	11	Water spill. These events involved clean water, no release.
26	Encasement contamination	2	Encasement contamination. This event involved a leak into a pipe encasement, which prevented a spill.
27	Instrument air off, inaccurate instr. readings	2	Instrument air off: inaccurate instrument readings. This event is included in the failure to follow administrative controls. This event does not cause a release, it is an operational problem.
28	Tank level below minimum limit	3	Tank level below minimum limit. This is an operational problem, a violation of administrative controls. No release.
29	Rad. activity on filters	3	Radiation activity on filters. This event does not cause a release. The filters did their job, buildup on the filters is an operational problem.
30	Personnel contamination or over-exposure	16	Personnel contamination or over exposure. The study scope did not include these events, they were noted when discovered in the analysis. Does not include a release.
31	Undetected basin filling	1	Undetected basin filling. This was an operational problem in that the process was not detected, and it caused a large volume of slightly contaminated water to have to be added to the waste tank inventory. No release.
32	Rad. discharge to crib exceeded limits	3	Radiation discharge to crib exceeded limits. This event is a violation of administrative controls, but does not result in a release.
33	Waste stuck in caisson	1	Waste stuck in caisson. This event is an operational problem, but does not result in a release.
34	Burial box failure	1	Burial box failure. This event is a potential for a spread of contamination, but did not result in a release.
35	Loss of emergency power	3	Loss of emergency power. These events did not result in a release, they are an operational, administrative, problems.
36	Pond rad. exceeded limits	1	Pond radiation exceeded limits. This event is a violation of administrative controls, but does not result in a release.
37	Violation of admin. controls	70	Violation of administrative controls. These are operational problems, and included in the controls section of the study, but these violations did not result in a release.
38	Error in computer for safety calculations	2	Error in computer for safety calculations. Errors in computer codes do not cause a release. These codes are to help understand the behaviors of emissions.
39	Loss of electric power	12	Loss of electric power. This event was covered in the What If Analysis, and was found to not be a significant contributor to a release.

Table D3.2-4. Occurrences Not Included in the Hazard Analysis. (4 sheets)

ITEM	OCCURRENCE	NUMBER OF OCCURRENCES	COMMENTS
40	Activation of fire system	1	Activation of fire system. This is an operational problem, does not cause a release.
41	Loss of accountability of rad. sources	1	Loss of accountability of radiation sources. This is a failure to maintain administrative controls, but does not cause a release.
42	Ferrocyanide USQ	1	Ferrocyanide USQ. This event does not cause a release, it is an administrative process.
43	Unknown cable attached to riser	1	Unknown cable attached to riser. This event was not looked at specifically, it did not cause a release or spread of contamination.
44	Missed milestone	5	Missed milestones. These events are administrative milestones, no release mechanism is involved.
45	Tank contents, extremely low pH	3	Tank contents, extremely low pH. The tanks involved in these events are small, not the large waste tanks. The potential for causing a release due to pH is small. These events did not cause a release.
46	Criticality USQ-SSTs	1	Criticality USQ.
47	Bomb threat	1	Bomb threat. This is an administrative and operational problem. No release is involved.
48	Organic layer, C-103 USQ	1	Organic layer, C-103 USQ. There is no release involved with this event.
49	Pressurized air lance package	1	Pressurized air lance package. The results of this event were considered as a contamination spread or spray leak.
50	Stack monitor failure	2	Stack monitor failure. This event does not cause a release, it results in a failure to follow administrative controls if not repaired.
51	Waste packaging violations	2	Waste packaging violations. These violations did not cause a release, they are a violation of administrative controls which were included in the control section of the study.
52	Flammable gas USQ	1	Flammable gas USQ.
53	Improper chemical adjustment	1	Improper chemical adjustment. This event is included in the administrative controls section of the study, the solution did not cause a release.
54	Diesel generator failure	1	Diesel generator failure. this event was considered in the What If Analysis, it is not a significant contributor to a release.
55	Tank pressurized	21	Tank pressurized. Waste tank pressurization was considered in the Hazard Analysis. It is not a significant problem unless accompanying a filter breach.
56	Oil line ruptured, smoked	1	Oil line ruptured, smoked. This event is a potential for fire in a contaminated location.
57	Air compressor failure	6	Air compressor failure. This event was considered in the What If Analysis and is not a significant contributor to a release.
58	Inadvertent flow to crib	1	Inadvertent flow to crib. This event involved steam condensate flow to a crib. It is not a release, like a raw water spill, but a failure to follow administrative controls.
59	Human error tripped alarms	3	Human error tripped alarm. These events did not involve a release, but were operational problems.

Table D3.2-4. Occurrences Not Included in the Hazard Analysis. (4 sheets)

ITEM	OCCURRENCE	NUMBER OF OCCURRENCES	COMMENTS
60	Removal of thermocouple tree, bent and broken	1	Removal of thermocouple tree, bent and broken. This was an operational problem, not a release.
61	Riser not symmetrical	1	Riser not symmetrical. This was an operational problem, not a release.
62	Raw water usage unexplained	2	Raw water usage unexplained. These events did not result in a release, but were a control problem.
63	Sludge cooler high vacuum	1	Sludge cooler high vacuum. This was an operational problem, not a potential release.
64	Pipe discovered w/in buffer zone of tank farm	1	Pipe found within tank farm buffer zone. No release, problem with controlled drawings.
65	Core sample USQ	1	Core sample USQ. Core sample containing reactive components, inadvertent addition of aggravating material.
66	Carbon monoxide trip due to operating truck	1	Carbon monoxide trip due to operating truck. This event was an operational problem, not a release.
67	Steam trap failure	1	Steam trap failure. This event creates an industrial hazard due to leak temperature, but it does not result in a release.
68	MUST tanks-unknown status	1	MUST tanks-unknown status. MUST tanks were included in the study.
69	Rotary Mode Core Sampler operated out-of-specs	5	Rotary Mode Core Sampler operating out-of-specifications. These are administrative control problems, they do not result in a release.
70	Wrong length auger rod	1	Wrong length auger rod. Operational problem, this event did not cause a release.
71	RMCS over energized	1	Rotary Mode Core Sampler over-energized. Operational and industrial safety problem, no release.
72	Discovery of drug paraphernalia	1	Discovery of drug paraphernalia. This event indicates a personnel problem, does not result in a release.
73	Soil contamination far deeper than expected	1	Soil contamination deeper than expected. This event was considered as the spread of contamination, section 8.5.

Table D3.3-1. Analyzed Accidents. (4 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
ANALYZED ACCIDENT: Nuclear Criticality								
A-1-a	I-PFP-1-AGT-A	Fission product gasses and aerosols from receiver tank.	Release of fission product gasses and aerosols from receiver tank due to: Potential for solids to collect in D-5 If mixed later, potential for composition of next batch to exceed Criticality Prevention Specifications (CPS). Potential "Criticality Issue".	Human Error or Agitator fails results in criticality	F3	S2	A05	01
ANALYZED ACCIDENT: In-Tank Fuel Fire/Deflagration								
A-1-a	EE-05-a	Contents of SST tank, fires and possible explosions	Release of radioactive or hazardous materials from SST tank due to external fires	Run-away vehicle or truck shears off one or more risers, ruptures gasoline tank	F3	S3	B25	02A
A-1-a	EE-05-b	Contents of DST tank, fires and possible explosions	Release of radioactive or hazardous materials from DST tank due to external fires	Run-away vehicle or truck shears off one or more risers, ruptures gasoline tank	F3	S3	B25	02B
ANALYZED ACCIDENT: Mixing of Incompatible Material - Tank Pressurization								
B-1-a	I-222S-1-RXN-A	Aerosols and/or toxic vapors from receiver tank	Release of aerosols and/or toxic vapors from receiver tank due adverse chemical reactions from incompatible waste.	Transfer of incompatible waste	F3	S2	D01	03
ANALYZED ACCIDENT: Flammable Gas Deflagrations - DST								
A-1-a	ITK-10-b	DST tank inventory	Release of radioactive material from in-tank fire or explosion due to intrusive activity (Dome Collapse)	Spark from equipment or tools	F3	S3	B04	04
ANALYZED ACCIDENT: Flammable Gas Deflagrations - SST								
A-1-a	XS-01-FLOW03	SST and DCRT tank contents	Release of liquids, solids, and-or vapors from single shell tank due to dome collapse and DCRT pressurization caused by flammable gas explosion/fire propagating from DCRT to single shell tank	Pipeline connecting single shell tank and DCRT fills with flammable gas; loss of ventilation flow in DCRT so that a flammable gas atmosphere is ignited by the ventilation outlet heater	F2	S3	B07	05
ANALYZED ACCIDENT: HEPA Filter Failure - Exposure to High Temperature or Pressure								
A-1-a	106C-10J	Tank atmosphere and surface contamination on HEPA filters	Release of radioactive and/or hazardous material from C-106 tank due to tank structural damage, HEPA damage caused by high temperature	Fire in or around ventilation system	F2	S2	B09	06

Table D3.3-1. Analyzed Accidents. (4 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
ANALYZED ACCIDENT: Fire in Contaminated Area								
A-1-a	CRN-05	Pits and risers inventory	Release of radioactive and/or toxic materials from pits and risers due to fuel tank fire in crane or support vehicle (see In-Tank Equipment Installation for tank fires)	Human error in positioning crane load	F3	S2	B26	07
ANALYZED ACCIDENT: Waste Transport Vehicle Accident								
A-1-a	VEH-03	Sample transport cask	Release of radioactive or toxic material from cask due to damage to transport casks during a high wind/tornado	High wind/tornado	F2	S2	D20	08
ANALYZED ACCIDENT: Organic Solvent Fire/Organic Salt-Nitrate Reaction								
A-1-a	I-222S-1-CMP-E	Aerosols from receiver tank or 244-S	Release of radioactive aerosols to the atmosphere from 244-S or receiver tank due to over pressurization of tank caused by organic fire.	Human Error - Upset of 222-S Lab operations	F3	S3	B01	09
ANALYZED ACCIDENT: Natural Phenomena - High Wind								
A-1-a	CRN-13-a	Tank Inventory	Release of radioactive or toxic material from tank/equipment damage and dome collapse due to boom failure	High wind	F3	S3	D20	10
ANALYZED ACCIDENT: Natural Phenomena - Lightning								
A-1-a	NP-03	Headspace inventories and combustion products from tank fire	Radioactive and hazardous material releases from tanks due to fire in tanks	Lightning strikes riser in tank farm	F2	S2	B21	11
ANALYZED ACCIDENT: Tank Failure Due to Excessive Loads								
B-1-a	CRN-03	Tank inventory	Release of radioactive and/or toxic materials from tank due to dome collapse	Human error results in excessive weight on dome	F3	S3	C10	12A
B-1-a	CRN-04	Tank inventory.	Release of radioactive and/or toxic materials from tank due to dome collapse	Crane or rigging failures drop load resulting in large impact to dome	F3	S3	C10	12B
B-1-a	CRN-11	Tank inventory	Radioactive or toxic material release from tank due to boom failure and tank/equipment damage and dome collapse	Human error: improper load assembly, rigging, crane overloaded	F3	S3	C10	12C
ANALYZED ACCIDENT: Tank Failures Due to Vacuum or Degradation								
B-1-a	114SX-06.a.3	Radioactive material contained in the tank (this tank has a dry crust which may be composed of easily disturbed dusty material)	Release of radioactive aerosols from Tank SX-114 waste to the atmosphere due to dome collapse as a result of loss of strength due to aging	Long term aging resulting in tank degradation	F1	S3	C12	13

Table D3.3-1. Analyzed Accidents. (4 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
ANALYZED ACCIDENT: Natural Phenomena - Seismic								
B-1-a	NP-07	Multiple tanks and ventilation systems inventories, 204-AR tanker spill	Radioactive and hazardous material releases from tanks and ventilation systems due to seismic event	Earthquake collapses domes	F1	S3	D18	14
ANALYZED ACCIDENT: Spray Leak in Structure or from Overground Waste Transfer Lines								
B-1-a	XS-06-FLOW02	DCRT waste being transferred to 102-SY	Release of liquid radioactive waste from DCRT transfer piping to 102-SY due to spray leak in DCRT pump pit	Pipe failure in DCRT pump pit causing spray leak	F2	S3	D12	15
ANALYZED ACCIDENT: Spray Leak from Underground Waste Transfer Lines								
B-1-a	EE-16	Material leaked from transfer line	Release of radioactive and hazardous material from transfer line spray leak due to excavation error	Excavation into waste transfer line during a transfer	F3	S3	D22	16
ANALYZED ACCIDENT: Caustic Spray Leak								
B-1-a	107AN-02-PRES	Contents of caustic truck	Release of caustic aerosol from caustic truck transfer piping due to spray leak	Piping/hose leak initiated by various causes	F3	S2	D12	17
ANALYZED ACCIDENT: Tank Bump								
B-1-a	102AW-02-TEMP02	DST tank vapors/aerosols	Release of radioactive aerosols from tank 102-AW due to tank bump	High heat waste combined with loss of ventilation contributes to tank bump	F2	S2	D01	18A
ANALYZED ACCIDENT: Unfiltered Release								
B-1-a	114SX-04.c.2.a	Radioactive aerosols contained in the tank headspace	Radioactive aerosols released from Tank SX-114 headspace to atmosphere due to exhauster HEPA filter seal failure	HEPA filter seal failure	F3	S2	D07	18B
ANALYZED ACCIDENT: Subsurface Leak Resulting in Pool								
B-3-b	XS-07-FLOW02	Liquid radioactive waste transferred out of DCRT	Release of radioactive waste to soil from transfer piping out of 244-TX DCRT due to leak in primary pipe and encasement	Corrosion of inner and outer pipe	F3	S2	D16	21A
B-3-b	XS-07-FLOW06	Liquid radioactive waste transferred out of DCRT	Release of radioactive waste to soil from transfer pipe out of 244-TX-DCRT due to leak in primary pipe and encasement	Water hammer causes failure of primary pipe and encasement	F3	S2	D17	21B
ANALYZED ACCIDENT: Evaporator Dump								
C-1-a	102AW-02-PRES%102 AW-02-TEMP	DCRT tank vapor/aerosols	Release of radioactive aerosols from 102-AW due to pressurization	Evaporator dump when intrusive activity is occurring which causes pressurization	F3	S2	D01	22

Table D3.3-1. Analyzed Accidents. (4 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
ANALYZED ACCIDENT: Mixing of Incompatible Material - Toxic Vapor Generation								
C-1-a	XS-26-PRES%XS-26-TEMP	DST vapor/aerosols	Release of toxic vapors from 102-SY due to chemical reaction	Mistransfer of incompatible waste causes chemical reaction	F3	S2	E06	23
ANALYZED ACCIDENT: Leak from Rail Car/Tank Trailer								
B-2-b	204AR-01H	20,000 gallons of liquid radioactive waste from the rail car	Release of airborne and waterborne contaminates outside building on track spur, and potential contamination in unloader room from rail car due to spilling rail car contents	Rail car rupture due to collision with other or a derailment	F2	S2	D25	25
ANALYZED ACCIDENT: Surface Leak Resulting in Pool								
C-2-b	W058-PRES01	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (Pool)	Water hammer plus mitigative features failure	F3	S2	D17	26
ANALYZED ACCIDENT: Unplanned Excavation/Drilling in Pond/Crib/Ditch								
C-2-c	CDP-10	Portion of radioactive material present in crib, ditch, or pond	Release of radioactive contamination to soil surface from excavation or drilling in cribs, ditches, or ponds that disturbs radioactive material	Excavation or drilling	F3	S2	D22	28
ANALYZED ACCIDENT: Subsurface Leak Remaining Subsurface								
B-3-b	102S-01.b3	Radioactive/hazardous material contained in pumpable liquids from S-102.	Radioactive liquid released to the soil subsurface from leaks in transfer Lines SL-140, SN-242. (Plume)	Line leak during saltwell pumping (corrosion)	F3	S2	D12	29
ANALYZED ACCIDENT: Sodium Fire								
A-1-a	2727W-06	Building inventory	Release of hazardous materials from 2727W due to sodium-water reactions	High wind or tornado destroys building with rain/snow	F2	S2	D20	30
ANALYZED ACCIDENT: Above Ground Structure Failure								
B-1-a	ITK-FR-08	DST & SST tank liquid held in flex receiver	Release of radioactive aerosols/vapors from flex receiver due to structural failure	High winds tear flex receiver bag	F3	S2	D20	31
ANALYZED ACCIDENT: Steam Intrusion from Interfacing Systems								
B-1-a	I-242A-6-CMP-A	Aerosols and particulates entrained in steam from feed tank TK-AW-102.	Release (steam) of aerosols to the atmosphere through unsealed cracks in the cover blocks due to over pressurization of the receiver tank.	Human error - Steam block valve inadvertently left opened.	F3	S3	E01	32

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
ANALYZED ACCIDENT: Nuclear Criticality								
A-1-a	I-PFP-1-AGT-A	Fission product gases and aerosols from receiver tank	Release of fission product gases and aerosols from receiver tank due to potential for solids to collect in D-5, If mixed later, potential for composition of next batch to exceed Criticality Prevention Specifications (CPS); potential "Criticality Issue"	Human error or agitator fails results in criticality	F3	S2	A05	01
HAZARDOUS CONDITIONS								
A-1-a	102AW-08-COMP02	DST tank contents	Release of fission product gases and aerosols from Tank 241-AW-102 due to criticality	Misrouting of waste creates critical mass	F1	S2	A06	01X
A-1-a	102AW-08-COMP02A	DST tank contents	Release of fission product gases and aerosols from Tank 241-AW-102 due to criticality	Human error - addition of excess fissile material to Tank 241-AW-102 creates critical mass	F1	S2	A01	01X
A-1-a	102AW-08-COMP03	DST tank contents	Release of fission product gases and aerosols from Tank 241-AW-102 due to criticality	Non-uniform distribution of fissile material (horizontally) creates critical mass	F1	S2	A02	01X
A-1-a	102AW-08-COMP04	DST tank contents	Release of fission product gases and aerosols from Tank 241-AW-102 due to criticality	Non-uniform distribution of fissile material (vertically) due to addition of "rich" layer	F1.	S2	A02	01X
A-1-a	102AW-08-COMP05	DST tank contents	Release of fission product gases and aerosols from Tank 241-AW-102 due to criticality	Over concentration of waste creates critical mass	F0	S2	A03	01X
A-1-a	102S-04.e4	Tank waste/vapor space	Release of radioactive gases and aerosols from Tank 241-S-102 vapor space to atmosphere due to criticality	Criticality (misrouting)	F1	S2	A06	01X
A-1-a	106C-01N	Tank inventory	Release of radioactive and/or hazardous material from Tank 241-C-106 due to high temperature in tank	Criticality in waste tank	F1	S2	A05	01X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
A-1-a	114SX-05.c.2c	Radioactive aerosols created by criticality event	Release pf radioactive gases and aerosols as well as direct radiation from Tank SX-114 due to criticality	Criticality (difficult to achieve concentration needed and difficult to obtain configuration required)	F1	S2	A05	01X
A-1-a	244AR-03.a.09	Fission product gases generated by the criticality	Release of radioactive aerosols created by criticality to the cell atmosphere	Criticality in waste	F1	S2	A05	01X
A-1-a	I-PFP-1-CMP-B	Fission product gases and aerosols from receiver tank	Release of fission product gases and aerosols from receiver tank due to, potential for localized concentration of fissile materials in receiver tank from failure to add ferric nitrates; potential "Criticality Issue"	Failure to add ferric nitrates, results in criticality	F3	S2	A01	01X
A-1-a	I-PFP-1-CMP-D	Fission product gases and aerosols from receiver tank	Release of fission product gases and aerosols from receiver tank due to excess fissile material in waste, potential to exceed criticality prevention specification requirements for shipment; potential "Criticality Issue"	Excess fissile content added to waste results in criticality	F3	S2	A01	01X
B-1-a	I-PUREX-3-CMP-E	Fission product gases and aerosols from receiver tank	Release of fission product gases and aerosols from receiver tank due to criticality caused by exceeding Criticality Prevention Specifications for shipment from PUREX	Transfer of L Cell sump water to Tank F-18 and eventually to the Tank Farms	F3	S2	A01	01X
A-1-a	ITK-06	Radionuclides from criticality plus tank wastes	Release of radioactive and/or hazardous material from point of in-tank access (non-fire, non-explosion) due to criticality	Intrusive activity causes critical mass	F1	S2	A04	01X
A-1-a	ITK-06-I	Material inside MISF	Release of radioactive and/or hazardous material from point of in-facility access due to criticality within the in-facility waste during intrusive activity (non-fire, non-explosion)	Criticality from intrusive activity	F1	S2	A04	01X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
A-1-a	XS-03-LEVE02 XS-21-LEVE (244-S DCRT)	DCRT tank contents	Release of fission product gases and aerosols from 244-TX DCRT due to criticality	Evaporation of DCRT contents with increased solids settling on DCRT bottom creates critical mass	F3	S2	A02	01X
A-1-a	XS-03-TEMP02 XS-21-TEMP (244-S-DCRT)	DCRT tank contents	Release of fission product gases and aerosols from 244-TX DCRT due to criticality	Transfer of material into tank that violates criticality specification	F3	S2	A01	01X
A-1-a	XS-06-FLOW01	DCRT tank contents	Release of fission product gases and aerosols from 244-TX DCRT due to criticality	Transfer of inadequately recirculated waste from tank due to failure to appropriately balance flow between recirculation and transfer line causing buildup of solids creating critical mass	F3	S2	A06	01X
A-1-a	XS-13-PRES04	Catch tank contents	Release of fission product gases and aerosols from catch tank 241-U-301B due to criticality	Transfer of excess fissile material to catch tank creates critical mass	F1	S2	A01	01X
A-1-a	XS-20-FLOW05	Catch tank/DCRT tank contents	Release of fission product gases and aerosols from 244-S DCRT (not designated solids receiver) due to criticality	Transfer of waste from 244-TX DCRT due to improper valve lineup creates critical mass	F1	S2	A06	01X
A-1-a	XS-26-PRES XS-26-TEMP 102-AW-TEMP (FOR TK-102-AW)	DST tank contents	Release of fission product gases and aerosols from Tank 241-SY-102 due to criticality	Transfer of critical mass of fissile material and achievement of critical geometry	F1	S2	A01	01X
ANALYZED ACCIDENT: In-Tank Fuel fire/Deflagration								
A-1-a	EE-05-a	Contents of SST tank, fires and possible explosions	Release of radioactive or hazardous materials from SST tank due to external fires	Run-away vehicle or truck shears off one or more risers, ruptures gasoline tank	F3	S3	B25	02A

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
A-1-a	EE-05-b	Contents of DST tank, fires and possible explosions	Release of radioactive or hazardous materials from DST tank due to external fires	Run-away vehicle or truck shears off one or more risers, ruptures gasoline tank	F3	S3	B25	02B
			HAZARDOUS CONDITIONS					
A-1-a	102AW-03-TEMP01	DST tank contents	Release of liquids, solids and/or vapors from Tank 241-AW-102 due to dome collapse caused by an fire/explosion in the annulus	Fire/ Explosion of flammable liquid spilled into annulus via a riser	F2	S3	B09	02X
A-1-a	102AW-09-COMP02	DST tank contents	Release of radioactive waste aerosols from Tank 241-AW-102 due to fire in fuel spilled in waste tank causing dome collapse	Spill of fuel from external source plus fuel reaching flash point or being aerosolized plus ignition source	F2	S3	B09	02X
A-1-a	102S-03.b4	Tank contents	Release of radioactive aerosols to atmosphere from Tank 241-S-102 due to burning fuel flowing into waste tank causing dome collapse	Vehicle drives into open riser puncturing gas tank + Ignition + Flammable organic vapors in tank	F3	S3	B25	02X
A-1-a	EE-04-a	SST tank contents	Release of radioactive and hazardous materials from SST tank due to external fires	Vehicle accident involving propane, diesel or gasoline delivery	F2	S3	B25	02X
A-1-a	EE-04-b	DST tank contents	Release of radioactive and hazardous materials from DST tank due to external fires	Vehicle accident involving propane, diesel or gasoline delivery	F2	S3	B25	02X
A-1-a	LDUA 2-2	Aerosols and other radioactive material in single shell tank	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of hydraulic fluid	Structural failure of hydraulic system	F2	S3	B09	02X
A-1-a	102AW-03-TEMP02	DST tank contents	Release of radioactive aerosols from Tank 241-AW-102 due to fire/explosion in annulus damaging primary tank	Flammable concentration of gases in annulus vapor space due to spill of fuel into annulus and spark source	F2	S2	B09	02X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
A-1-a	102S-03.b3	Tank contents	Release of radioactive aerosols to atmosphere from Tank 241-S-102 due to burning fuel flowing into waste tank due to ignition of fuel from ruptured gas tank.	Vehicle drives into open riser puncturing gas tank + Ignition	F2	S2	B25	02X
A-1-a	VEH-07-I	Material in MISF	Release of radioactive or toxic material from MISF due to riser being sheared off and possibly vehicle gas tank ruptured and fire	Vehicle moving near facility risers	F3	S2	B25	02X
ANALYZED ACCIDENT: Mixing of Incompatible Material - Tank Pressurization								
B-1-a	I-222S-1-RXN-A	Aerosols and/or toxic vapors from receiver tank	Release of aerosols and/or toxic vapors from receiver tank due adverse chemical reactions from incompatible waste	Transfer of incompatible waste	F3	S2	D01	03
HAZARDOUS CONDITIONS								
C-1-a	102AW-02-TEMP 102AW-08-TEMP	DST tank vapor/aerosols	Release of radioactive aerosols from Tank 241-AW-102 due to positive pressure	Chemical reaction heating up and/or agitating tank causes positive pressure in tank	F2	S2	E15	03X
B-1-a	102AW-02-TEMP01	DST tank vapor/aerosols	Release of radioactive aerosols from Tank 241-AW-102 due to boiling waste	High heat waste causing boiling	F2	S2	D01	03X
B-1-a	106C-01G	Tank atmosphere	Release of radioactive and/or hazardous material from Tank 241-C-106 tank, due to waste reaction causing local discharge of contamination through blown HEPAs or out cover blocks	Addition of acid to tank	F2	S2	E01	03X
C-1-a	106C-01H	Tank atmosphere, residual filter surface contamination	Release of radioactive and/or hazardous material from Tank 241-C-106, through blown HEPAs or out cover blocks due to tank boiling with vent path blocked or failed	Tank boiling with lack of vent path	F2	S2	D07	03X
B-1-a	106C-01M	Tank inventory	Release of radioactive and/or hazardous material from Tank 241-C-106, due to high temperature in the waste tank	Exothermic, chemical reaction in tank due to inadvertent addition to tank	F2	S2	E01	03X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
C-1-a	106C-12F	Tank inventory	Release of radioactive and/or hazardous material from Tank 241-C-106 tank due to waste reaction in tank	Added chemicals to tank instead of normal water addition	F2	S2	E01	03X
C-1-a	107AN-02-FLOW01	Contents of DST	Release of radioactive aerosols from Tank 241-AN-107 due to surface chemical reaction	Transfer of incompatible chemical to tank via chemical addition system due to vendor or paperwork error	F3	S2	E01	03X
C-1-a	107AN-02-FLOW02	Contents of DST	Release of toxic vapors from Tank 241-AN-107 due to surface chemical reaction	Transfer of incompatible chemical to tank via chemical addition system due to vendor or paperwork error	F3	S2	E01	03X
B-1-a	CCF-01	Head space inventories from actively ventilated tanks	Radioactive and hazardous release from tanks due to extended loss of ventilation (over 6 months)	Sustained loss of offsite power	F1	S2	D07	03X
B-1-a	CCF-20	Contents of two tanks	Release of radioactive and hazardous aerosols/vapors from tanks due to chemical reactions between waste and added materials	Reactive chemical additions to two tanks	F2	S2	D01	03X
B-1-a	I-222S-2-FLW-C	Aerosols and/or toxic vapors from receiver tank	Release of aerosols and/or toxic vapors from receiver tank due adverse chemical reactions from incompatible waste	Human error - incorrect valve line up	F2	S2	E06	03X
B-1-a	I-BPLANT-2-FLW-D	Receiver tank waste	Release of aerosols and/or toxic vapors from receiver tank due to transfer of incompatible waste from B Plant	Human error - communication error between B Plant and TWRS causes transfer of incompatible waste	F3	S2	E01	03X
C-1-a	XS-02-FLOW03	DCRT tank vapors/aerosols	Release of toxic gases (oxides of nitrogen) from DCRT due to chemical reaction	Chemical reaction between sodium nitrite (DCRT) and nitric acid (PFP transfer) due to failure to adjust waste pH prior to transfer	F2	S2	E01	03X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
B-1-a	XS-03-TEMP01	DCRT tank contents	Release of radioactive aerosols from 244-TX DCRT headspace due to positive pressure	Chemical reaction in DCRT causes positive pressure	F2	S2	D01	03X
C-1-a	XS-13-PRES01	Liquid radioactive waste contents of catch tank	Release of radioactive aerosols from 241-U-301B catch tank due to chemical reaction	Draining of incompatible chemicals to catch tank	F3	S2	D01	03X
C-1-a	XS-20-FLOW01	DCRT tank vapor/aerosols	Release of radioactive aerosols from 244-TX DCRT due to chemical reaction	Transfer of incompatible waste to 244-TX DCRT due to improper valve lineup	F3	S2	E06	03X
B-1-a	XS-20-FLOW03	DCRT tank contents	Release of radioactive aerosols from 244-TX DCRT due to positive pressure caused by chemical reaction	Chemical reaction of 244-S material with contents of 244-TX caused by misrouting	F2	S2	B06	03X
C-1-a	XS-26-PRES01	DST tank vapor/aerosols	Release of radioactive aerosols from Tank 241-SY-102 due to chemical reaction	Mis-transfer of incompatible waste causes chemical reaction	F3	S2	E06	03X
ANALYZED ACCIDENT: Flammable Gas Deflagrations - DST								
A-1-a	ITK-10-b	DST tank inventory	Release of radioactive material from in-tank fire or explosion due to intrusive activity (dome collapse)	Spark from equipment or tools	F3	S3	B04	04
HAZARDOUS CONDITIONS								
A-1-a	102AW-02-PRES01	DST tank contents	Release of radioactive aerosols from Tank 241-AW-102 due to fire/explosion in waste tank (Dome Collapse)	Flammable concentration of gases in tank vapor space with spark source	F2	S3	B08	04X
A-1-a	I-242A-1-FLW-A	Aerosols and other radioactive material from Tank 241-AW-102	Release of radioactive material from Feed Tank 241-AW-102 due to fire/explosion caused by igniting hydrogen gas when pump is damaged and possibly becomes an ignition source from dead heading	Valves fail to regulate (closed position) which fails pump and creates ignition source, sufficient hydrogen accumulation for fire/explosion.	F2	S3	B08	04X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
A-1-a	I-242A-1-FLW-B	Aerosols and other radioactive material from Tank 241-AW-102	Release of radioactive material from Feed Tank 241-AW-102 due to fire/explosion caused by igniting hydrogen gas when pump is damaged and possibly becomes an ignition source	Feed pump fails and causes ignition source, sufficient hydrogen accumulation for fire/explosion	F2	S3	B08	04X
A-1-a	I-242A-1-FLW-C	Aerosols and other radioactive material from Tank 241-AW-102	Release of radioactive material from Feed Tank 241-AW-102 due to fire/explosion caused by igniting hydrogen gas when pump is damaged and possibly becomes an ignition source from dead heading	Plugged line which fails pump and causes ignition source, sufficient hydrogen accumulation for fire/explosion	F2	S3	B08	04X
A-1-a	I-242A-1-FLW-D	Aerosols and other radioactive material from Tank 241-AW-102	Release of radioactive material from Feed Tank 241-AW-102 due to fire/explosion caused by igniting hydrogen gas when pump is damaged and possibly becomes an ignition source	Pump plugged which fails pump and causes ignition source, sufficient hydrogen accumulation for fire/explosion	F2	S3	B08	04X
A-1-a	I-242A-1-FLW-E	Aerosols and other radioactive material from Tank 241-AW-102	Release of radioactive material from Feed Tank 241-AW-102 due to fire/explosion caused by igniting hydrogen gas when pump is damaged and possibly becomes an ignition source from pump cavitation	Empty feed tank which fails pump and causes ignition source, sufficient hydrogen accumulation for fire/explosion	F2	S3	B08	04X
A-1-a	ITK-11	Tank Inventory	Release of radioactive material from in-tank fire or explosion due to intrusive activity (dome collapse)	Lightning, range fire, or seismic event ignites tank vapors	F2	S3	B09	04X
A-1-a	XS-26-PRES02	DST tank contents	Release of radioactive aerosols from Tank 241-SY-102 due to flammable gas fire/explosion (dome collapse)	Accumulation of flammable gases in vapor space and spark source	F2	S3	B08	04X
A-1-a	102AW-03-LEVE01	DST tank contents	Release of radioactive aerosols from Tank 241-AW-102 due to fire/explosion in annulus	Flammable concentration of gases in annulus vapor space due to waste leak into annulus and spark source	F2	S2	B12	04X
A-1-a	102AW-03-LEVE02	Liquid radioactive waste leaked into Tank 241-AW-102 annulus	Release of radioactive aerosols from Tank 241-AW-102 due to fire/explosion in annulus	Flammable concentration of gases in annulus vapor space due to waste mis-transfer into annulus and spark source	F2	S2	B06	04X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
A-1-a	ITK-FR-13	DST & SST tank liquid held in flex receiver	Release of radioactive aerosols/vapors from flex receiver due to buildup and ignition of flammable gas in receiver	Hydrogen gas buildup in tank/riser that travels into receiver with ignition source (spark from herculite or equipment)	F1	S2	B08	04X
ANALYZED ACCIDENT: Flammable Gas Deflagrations - SST								
A-1-a	XS-01-FLOW03	SST and DCRT tank contents	Release of liquids, solids and/or vapors from single shell tank due to dome collapse and DCRT pressurization caused by flammable gas fire/explosion propagating from DCRT to single shell tank	Pipeline connecting single shell tank and DCRT fills with flammable gas; loss of ventilation flow in DCRT so that a flammable gas atmosphere is ignited by the ventilation outlet heater	F2	S3	B07	05
HAZARDOUS CONDITIONS								
A-1-a	102AW-01-FLOW 102AW-02-PRES	DST tank contents	Release of liquids, solids and/or vapors from Tank 241-AW-102 due to dome collapse caused by chemical reaction of incompatible wastes	Misrouting to destination other than intended creates chemical incompatibility	F0	S3	B06	05X
A-1-a	102S-04.e3	Tank contents	Release of radioactive aerosols contained in Tank 241-S-102 vapor space to atmosphere due to generation of excessive heat leading to dome collapse	Addition of incompatible waste/chemical (misroute)	F0	S3	B06	05X
A-1-a	106C-01I	Tank inventory	Release of radioactive and/or hazardous material from Tank 241-C-106 due to possible dome collapse caused by tank high pressure	Fire in waste tank	F2	S3	B08	05X
A-1-a	106C-01J	Tank inventory	Release of radioactive and/or hazardous material from Tank 241-C-106 due to high pressure in tank and possible dome collapse	Fire/explosion in waste tank	F2	S3	B08	05X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
A-1-a	106C-01Na	Tank inventory	Release of radioactive and/or hazardous material from Tank 241-C-106 due to flammable gas fire/explosion in tank caused by high temperature (dome collapse)	Chemical reaction in tank	F2	S3	B01	05X
A-1-a	106C-02A	Tank inventory	Release of radioactive and/or hazardous material from Tank 241-C-106 due to dome collapse caused by ignition of high flammable gas content in tank	High waste temperature	F2	S3	B08	05X
A-1-a	106C-02B	Tank inventory	Release of radioactive and/or hazardous material from Tank 241-C-106 due to ignition of high flammable gas content in tank and possible dome collapse	Ventilation system failure	F2	S3	B07	05X
A-1-a	106C-02C	Tank inventory	Release of radioactive and/or hazardous material from Tank 241-C-106 due to dome collapse caused by ignition of high flammable gas content in tank	Tank burp, release of trapped gas	F2	S3	B08	05X
A-1-a	106C-04A	Tank inventory	Release of radioactive and/or hazardous material from Tank 241-C-106 due to tank damage caused by flammable gas fire/explosion because of high flammable gas content in the tank (dome collapse)	High flammable gas content due to chemical reaction in sludge layer	F2	S3	B01	05X
A-1-a	106C-04B	Tank inventory	Release of radioactive and/or hazardous material from Tank 241-C-106 due to fire/explosion caused by ignition of flammable gas released from radiolysis in tank sludge	Radiolysis in sludge layer allows release of trapped gas to vapor space	F2	S3	B08	05X
A-1-a	106C-13A	Tank inventory	Release of radioactive and/or hazardous material from Tank 241-C-106 due to possible dome collapse, tank damage caused by high temperature	Fire in Tank 241-C-105 propagates into Tank 241-C-106	F2	S3	B09	05X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
A-1-a	114SX-04.b.3b	Radioactive aerosols contained in tank head space	Release of radioactive aerosols from head space of Tank 241-SX-114 to atmosphere through exhaust HEPA filter due to flammable gas ignition in the headspace (dome collapse)	Flammable gas fire/explosion in Tank 241-SX-114 (Note: Tank 241-SX-114 is NOT currently identified as a Flammable Gas Watch List Tank) Requires spark to be present	F1	S3	B08	05X
A-1-a	114SX-05.b.1	Radioactive material contained in the tank (this tank has a dry crust which may be composed of easily disturbed dusty material)	Release of radioactive aerosols from Tank 241-SX-114 waste to atmosphere due to flammable gas ignition resulting in dome collapse	Radiolysis creating bubbles of gases in waste	F2	S3	B08	05X
A-1-a	114SX-06.a.1b	Radioactive material contained in the tank (this tank has a dry crust which may be composed of easily disturbed dusty material)	Release of radioactive aerosols from Tank 241-SX-114 waste to atmosphere as a result of a dome collapse	Deflagration of H2 (Implies gas generation with spark)	F1	S3	B08	05X
A-1-a	CP-MSP-05	Tank inventory	Release of radioactive or toxic material to atmosphere from waste tank due to flammable gas deflagration	Human error AND Flammable gas is present in tank AND Mechanical failure of the pipe and probe (ignition source)	F1	S3	B09	05X
A-1-a	CP-MSP-06	Tank inventory	Release of radioactive or toxic material to atmosphere due to flammable gas deflagration caused by puncture and ignition of flammable gas in transfer line which propagates to the waste tank	Human error AND Flammable gas is present in transfer pipe AND Spark from probe tip (ignition source)	F1	S3	B09	05X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
A-1-a	ITK-08	Tank inventory	Release of radioactive material from in-tank fire or explosion due to intrusive activity (dome collapse)	Exothermic reaction of incompatible materials in tank	F3	S3	B04	05X
A-1-a	ITK-09	Tank inventory	Release of radioactive material from in-tank fire or explosion due to intrusive activity (dome collapse)	Failure to bond components or incorrect bonding	F3	S3	B08	05X
A-1-a	ITK-10-a	SST tank inventory	Release of radioactive material from in-tank fire or explosion due to intrusive activity (dome collapse)	Spark from equipment or tools	F3	S3	B04	05X
A-1-a	LDUA 1-25	Aerosols and other radioactive material in single shell tank	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of flammable gas	Fire (electrical, lighting)	F2	S3	B04	05X
A-1-a	LDUA 1-32	Aerosols and other radioactive material in single shell tank	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of flammable gas	During planned intrusive activities, sampling triggers GRE	F3	S3	B04	05X
A-1-a	LDUA 1-33	Aerosols and other radioactive material in single shell tank	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of flammable gas	Non-arm end effectors (OVS, OSVS) dropped down riser	F2	S3	B04	05X
A-1-a	LDUA 2-20	Aerosols and other radioactive material in single shell tank	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of flammable gas	Combustible source of gas located near the compressor intake.	F3	S3	B04	05X
A-1-a	LDUA 2-51	Aerosols and other radioactive material in single shell tank	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of flammable gas	Supervisor error - arm in wrong mode, Electric remains on after air purge fault, flammable gas enters arm, spark ignites gas	F1	S3	B04	05X
A-1-a	LDUA 5-45	Aerosols and other radioactive material in single shell tank	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of flammable gas	Helicopter/airplane crash	F1	S3	B23	05X

B-1-a	106C-01C	Tank inventory	Release of radioactive and/or hazardous material from Tank 241-C-106, structural damage, and dome collapse due to tank low pressure	Exhauster damper positioned incorrectly	F0	S3	C07	13X
B-1-a	106C-01D	Tank inventory	Release of radioactive and/or hazardous material from Tank 241-C-106, structural damage and dome collapse due to tank low pressure	Wrong sized portable exhauster	F0	S3	C13	13X
B-1-a	106C-01E	Tank inventory	Release of radioactive and/or hazardous material from Tank 241-C-106, structural damage and dome collapse due to tank low pressure	Subcooling of tank vapor space due to water addition of flushing	F2	S3	C11	13X
B-1-a	114SX-04.a.2	Radioactive material contained in the tank (this tank has a dry crust which may be composed of easily disturbed dusty material)	Radioactive aerosols released from failed tank dome due to vacuum produced by valving error.	Human error: Valve out flammable watch list (Tank 241-SX-109) butterfly valve	F0	S3	C07	13X
B-1-a	114SX-04.a.3	Radioactive material contained in the tank (this tank has a dry crust which may be composed of easily disturbed dusty material)	Release of radioactive aerosols from Tank 241-SX-114 to atmosphere due to high temperatures causing dome concrete strength loss	No ventilation flow High ambient temperature conditions Resulting in tank degradation	F1	S3	C12	13X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
B-1-a	114SX-04.b.1.a.2	Radioactive material contained in the tank (this tank has a dry crust which may be composed of easily disturbed dusty material)	Release of radioactive material from Tank 241-SX-114 to atmosphere due to high temperature in the dome leading to dome collapse (long term closure of butterfly valve)	Human error: Closure of Tank 241-SX-114 exhaust butterfly valve isolating tank from exhaust plenum Resulting in tank degradation	F1	S3	C07	13X
B-1-a	114SX-04.b.1.b.2a	Radioactive material contained in the tank (this tank has a dry crust which may be composed of easily disturbed dusty material)	Release of radioactive aerosols to atmosphere from Tank 241-SX-114 waste due to heat induced tank dome collapse	Ducting failure due to bad welds	F1	S3	C12	13X
B-1-a	114SX-04.b.1.c.2	Radioactive material contained in the tank (this tank has a dry crust which may be composed of easily disturbed dusty material)	Release of radioactive aerosols to atmosphere from Tank 241-SX-114 waste due to dome collapse	Exhauster failure Fan failure Filter rupture (low differential pressure shutdown) Resulting in tank degradation	F0	S3	C07	13X
B-1-a	114SX-04.b.1.d.2	Radioactive material contained in the tank (this tank has a dry crust which may be composed of easily disturbed dusty material)	Release of radioactive aerosols from Tank 241-SX-114 waste to atmosphere due to dome collapse	Filter plugging results in lack of heat removal with high temperatures degrading dome strength	F1	S3	C07	13X
B-1-a	114SX-05.b.3	Radioactive material contained in the tank (this tank has a dry crust which may be composed of easily disturbed dusty material)	Release of radioactive aerosols from Tank 241-SX-114 waste to atmosphere due to dome collapse caused by sudden vacuum in tank	Quenching (adding cold liquid to hot tank contents) creating a vacuum	F0	S3	C11	13X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
A-1-a	114SX-05.c.2b	Radioactive material contained in the tank (this tank has a dry crust which may be composed of easily disturbed dusty material)	Release of radioactive aerosols from Tank 241-SX-114 waste to atmosphere due to dome collapse	Chemical reaction caused by addition of chemical/solution. Resulting in tank degradation	F1	S3	C01	13X
B-1-a	CCF-17	Contents of tank	Release of radioactive and hazardous materials from tank due to dome collapse	Corrosion of rebar in concrete SST domes	F1	S3	C12	13X
ANALYZED ACCIDENT: Natural Phenomena - Seismic								
B-1-a	NP-07	Multiple tanks and ventilation systems inventories, 204-AR tanker spill	Radioactive and hazardous material releases from tanks and ventilation systems due to seismic event	Seismic event collapses domes	F1	S3	D18	14
HAZARDOUS CONDITIONS								
B-1-a	102S-05.a2	Tank contents	Release of radioactive aerosols from Tank 241-S-102 to atmosphere due to dome collapse	Seismic event (common mode failure)	F1	S3	D18	14X
B-1-a	114SX-04.b.1.b.2b	Radioactive material contained in the tank (this tank has a dry crust which may be composed of easily disturbed dusty material)	Release of radioactive aerosols to atmosphere from Tank 241-SX-114 waste due to heat induced tank dome collapse	Ducting failure due to seismic activity coupled with failure to respond Resulting in tank degradation	F1	S3	D18	14X
B-1-a	244AR-02.a.14	Radioactive material contained in the four tanks and facility	Release of radioactive aerosols from waste contained in tanks (4) and building due to earthquake	Seismic event collapses building and four tanks	F1	S3	D18	14X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
B-1-a	CCF-18	Contents of tanks, products of combustion	Release of radioactive and hazardous materials from tanks due to dome collapses	Fire in tank propagates to connecting tank and both tanks collapse during cooldown from negative tank pressure	F0	S3	C11	14X
B-1-a	CCF-19	Contents of tanks, products of combustion	Release of radioactive and hazardous materials from tanks due to dome collapses	Fire in tank causes pressure transient that leads to GRE in connecting tank with subsequent fire and tank collapses from negative tank pressure	F0	S3	C11	14X
B-1-a	CRN-13-b	Tank Inventory	Release of radioactive or toxic material from tank/equipment damage and dome collapse due to boom failure	Seismic event	F1	S3	D18	14X
B-1-a	NP-13	Tank head space inventories and splash from dome collapse	Radioactive and hazardous material releases from tanks due to excessive weight on dome	Accumulations of heavy snow followed by heavy rain	F2	S3	C10	14X
B-1-a	244AR-05.a.02	Total amount of radioactive material contained in facility	Release of radioactive material from facility due to seismic event which causes building collapse without cell collapse	Seismic event damages facility structure	F2	S2	D18	14X
ANALYZED ACCIDENT: Spray Leak in Structure of from Overground Waste Transfer Lines								
B-1-a	XS-06-FLOW02	DCRT waste being transferred to Tank 241-SY-102	Release of liquid radioactive waste from DCRT transfer piping to Tank 241-SY-102 due to spray leak in DCRT pump pit	Pipe failure in DCRT pump pit causing spray leak	F2	S3	D12	15
HAZARDOUS CONDITIONS								
B-1-a	102AW-01-FLOW 102AW-04-PRES	Liquid radioactive waste being transferred to DST from DCRT	Release of radioactive aerosol from transfer pipe which runs from DCRT to Tank 241-AW-102 due to spray leak into open underground structure	Piping leak due to thermal stress of transferring hot solution in cold pipe	F3	S3	D01	15X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
B-1-a	102AW-01-FLOW01	Liquid radioactive waste being transferred to DST from DCRT	Release of liquid radioactive waste aerosols from transfer pipe to Tank 241-AW-102 due to spray leak into open underground structure	Piping leak due to corrosion caused by transferring high temperature waste	F2	S3	D01	15X
B-1-a	102AW-13-FLOW01	Radioactive waste being pumped from SST to DCRT	Release of radioactive waste aerosols due to spray leak of waste from flush pit	Backflow of waste to flush pit with valve or pipe leak and cover block off	F1	S3	D12	15X
B-1-a	COB-01	Transfer inventory	Release of radioactive and/or hazardous material from COB due to spray leak	Flange, gasket or valve, spray leak with COB lid removed	F3	S3	D12	15X
B-1-a	OGT-EXT3-01A	DST & SST tank inventory	Release of radioactive or hazardous aerosols from the primary pipe due to spray leak caused by truck crash into piping system	Human error, line struck by truck	F3	S3	E25	15X
B-1-a	OGT-FLOW1-03A	DST & SST tank inventory	Release of radioactive or hazardous aerosols from the primary pipe due to spray leak caused by misdirected flow	Spray leak caused by JR-1 (3-way valve) mispositioned to flush, two check valves fail, flush disconnect fails (check valve), reverse flow to external flush fixture and release to the environment	F1	S3	E06	15X
B-1-a	OGT-FLOW2-02	DST & SST tank inventory	Release of radioactive or hazardous aerosols from the primary pipe due spray leak caused by over-rated pump	Installation of incorrect pump and failure of inner pipe, failure of weld on flange of outer pipe, isolation valves closed on secondary pipe drains and no concrete shield in place	F2	S3	E13	15X
B-1-a	OGT-NP3-01	DST & SST tank inventory	Release of radioactive or hazardous aerosols from the primary pipe due spray leak caused by seismic event	Failure of line and concrete shielding during seismic event	F1	S3	D18	15X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
B-1-a	OGT-NP3-02	DST & SST tank inventory	Release of radioactive or hazardous aerosols from the primary pipe due to leak caused by high wind	Pipe is blown off supports and no concrete shielding in place	F1	S3	D20	15X
B-1-a	W058-FLOW15	Amount of slurry transferrable through a limited size orifice	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak	Computer failure or human error causing misrouting of material when flow path is not completely connected	F2	S3	E06	15X
B-1-a	W058-FLOW16	Amount of slurry transferrable through a limited size orifice	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak	External leak of valve or valves to the valve pit	F2	S3	D12	15X
B-1-a	W058-FLOW17a	Amount of slurry transferrable through a limited size orifice	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak	Failure of jumper due to misalignment (human error) plus mitigative features failure	F2	S3	E06	15X
B-1-a	W058-FLOW17b	Amount of slurry transferrable through a limited size orifice	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak	Failure of jumper due to gasket failure plus mitigative features failure	F2	S3	D12	15X
B-1-a	W058-FLOW17c	Amount of slurry transferrable through a limited size orifice	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak	Failure of jumper due to corrosion plus mitigative features failure	F2	S3	D16	15X
B-1-a	W058-FLOW18	Amount of supernate transferrable through a limited size orifice	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak	Computer failure or human error causing misrouting of material when flow path is not completely connected	F2	S3	E06	15X
B-1-a	W058-FLOW19	Amount of supernate transferrable through a limited size orifice	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak	External leak of valve or valves to the valve pit plus mitigative features failure	F2	S3	D12	15X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
B-1-a	W058-FLOW20a	Amount of supernate transferrable through a limited size orifice	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak	Failure of jumper due to misalignment (human error) plus mitigative features failure	F2	S3	E06	15X
B-1-a	W058-FLOW20b	Amount of supernate transferrable through a limited size orifice	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak	Failure of jumper due to gasket failure plus mitigative features failure	F2	S3	D12	15X
B-1-a	W058-FLOW20c	Amount of supernate transferrable through a limited size orifice	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak	Failure of jumper due to corrosion plus mitigative features failure	F2	S3	D16	15X
B-1-a	W058-INTEG32	Amount of supernate or slurry aerosol that could be released through a small orifice	Release of radioactive supernate or slurry aerosols to the atmosphere due to a spray leak from test risers located near SY-A and SY-B valve pits	Failure of primary piping and path for spray leak from test riser plus mitigative features failure	F2	S3	D12	15X
B-1-a	W058-INTEG34	Amount of slurry transferrable through a limited size orifice	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak	External event (airplane crash, etc)	F1	S3	D23	15X
B-1-a	W058-INTEG35	Amount of slurry transferrable through a limited size orifice	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak	Seismic event	F1	S3	D18	15X
B-1-a	W058-INTEG36	Amount of supernate transferrable through a limited size orifice	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak	External event (airplane crash, etc)	F1	S3	D23	15X
B-1-a	W058-INTEG37	Amount of supernate transferrable through a limited size orifice	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak	Seismic event	F1	S3	D18	15X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
B-1-a	XS-06-FLOW03	Radioactive waste being transferred from PFP to DCRT	Release of liquid radioactive waste from transfer piping from PFP to DCRT due to spray leak in DCRT pump pit	Pipe failure in DCRT pump pit causing spray leak	F2	S3	D12	15X
B-1-a	204AR-07A	Aging waste DST tank contents	Release of liquid radioactive waste and high airborne in unloading room from the Tank 241-AY-102 due to reverse pumping of Tank 241-AY-102 contents back to 204-AR	Pump in pit 02D starts and pumps back to the 204-AR building through the transfer piping and leaks	F2	S2	E06	15X
B-1-b	I-222S-1-CMP-C	222-S lab waste from Tank 219-S-102 (capacity 4000 gal)	Release (potential spray leak) of 222-S lab waste to atmosphere in diversion box or 244-S Pump Pit due to increased corrosion from failure to add sodium hydroxide	Human error - failure to add sodium hydroxide	F3	S2	E01	15X
B-1-b	I-222S-2-LEK-B	222-S lab waste from Tank 219-S-102 (capacity 4000 gal)	Release of 222-S lab waste to the atmosphere due to spray leak at the diversion box or pump pit, caused by corrosion in the pipe	Corrosion in pipe line	F1	S2	D16	15X
B-1-b	I-222S-2-LEK-E	222-S lab waste from Tank 219-S-102 (capacity 4000 gal)	Release of 222-S lab waste to the atmosphere due to spray leak at the diversion box or pump pit, caused by rupture at pipe connections from a seismic event	Seismic event	F2	S2	D18	15X
B-1-b	I-242A-1-LEK-B	Liquid waste from Tank 241-AW-102	Release of waste from Feed Tank 241-AW-102 to the atmosphere due to spray leak at the diversion box or pump pit, caused by corrosion in the pipe	Corrosion in pipe line	F1	S2	D16	15X
B-1-b	I-242A-1-LEK-E	Liquid waste from Tank 241-AW-102	Release of waste from Feed Tank 241-AW-102 to the atmosphere due to spray leak at the diversion box or pump pit, caused by rupture at pipe connections	Seismic event causes spray leak	F2	S2	D18	15X
B-1-b	I-242A-2-LEK-B	Slurry from the evaporator	Release of slurry tank waste to the atmosphere due to spray leak at the diversion boxes or pump pit, caused by corrosion in the pipe	Corrosion in pipe line	F1	S2	D16	15X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

C-2-b	W058-PRES01	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	Water hammer plus mitigative features failure	F3	S2	D17	26
			HAZARDOUS CONDITIONS					
C-2-b	102AW-01-FLOW10	Liquid radioactive waste involved in transfer	Release of liquid radioactive waste from Tank 241-AW-102 due to overflow	Misrouting of waste from reverse flow caused by the combination of an incorrectly wired pump and a full transfer pipe	F2	S2	E06	26X
C-2-b	102AW-01-FLOW11	Liquid radioactive waste involved in transfer	Release of liquid radioactive waste to the ground surface from Tank 241-AW-102 due to overflow of Tank 241-AW-102 or underground structure	Misrouting to destination other than intended causes overflow	F3	S2	E06	26X
C-2-b	102AW-01-TEMP01	Liquid radioactive waste being transferred to DST	Release of liquid radioactive waste from transfer pipe to Tank 241-AW-102 due to leaks overflowing from underground structure	Piping leak due to corrosion caused by transferring high temperature waste	F2	S2	D01	26X
C-2-b	102AW-01-TEMP01A	Liquid radioactive waste being transferred to DST	Release of liquid waste from transfer pipe to Tank 241-AW-102 due to leaks overflowing from underground structure	Piping leak due to thermal stress of transferring hot solution in cold pipe	F2	S2	D01	26X
C-2-b	102AW-01-TEMP02	Liquid radioactive waste being transferred to DST	Release of liquid radioactive waste from transfer pipe to Tank 241-AW-102 due to leaks overflowing from underground structure	Piping leak due to exceeding the design temperature of the pipe by transferring high temperature waste	F2	S2	D01	26X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
C-2-b	102AW-02-LEVE03	DST contents	Release of radioactive liquid from Tank 241-AW-102 due to overfilling	Failure to stop transfer causes overfilling of tank	F3	S2	E06	26X
C-2-b	102AW-02-LEVE04	DST contents	Release of radioactive liquid from Tank 241-AW-102 due to overfilling	Misrouting causes overfilling of tank	F3	S2	E06	26X
C-2-b	102AW-02-LEVE05	DST contents	Release of radioactive liquid from Tank 241-AW-102 to the soil column due to gross overfilling of tank (Pool)	Misrouting causes overfilling of tank	F3	S2	E06	26X
C-2-b	102AW-13-FLOW02	Liquid waste being transferred from DST	Release of radioactive liquid from transfer piping out of Tank 241-AW-102 due to backflow of radioactive material into flush pit and subsequent overflow (Pool)	Multiple valving errors and failure of backflow prevention devices dumps to pit as designed	F3	S2	E06	26X
C-2-b	102S-01.a1	Radioactive/hazardous material contained in pumpable liquids from various S Farm Tanks.	Radioactive/hazardous liquid released to soil surface from tank diversion box/access pit to the ground surface due to misrouting a transfer.	Human error (jumper/blank installation) + Mistransfer to Tank 241-S-102 (450-600 Kgal) overfills tank	F2	S2	E06	26X
C-2-b	102S-01.b2	Radioactive/hazardous material contained in pumpable liquids from Tank 241-S-102.	Radioactive liquid released to soil surface from Tank 241-S-102 pump pit due to leak in jumpers connecting tank transfer lines SL-140, SN-242 during saltwell pumping.	Jumper failure + Drain plugged	F2	S2	D12	26X
B-2-b	114SX-02.b	Radioactive material contained in pumpable liquid	Radioactive liquid released from tank pump pit to the ground surface due to inadvertent pumping activity (pool)	Human error (not normal activity)	F1	S2	E06	26X
C-2-b	204AR-09A	Up to 20,000 of liquid radioactive waste from rail car	Release of airborne and waterborne contamination from the sump pit due to ruptured piping during transfer.	Rupture of transfer piping section above the sump pit	F2	S2	D12	26X
C-1-a	244AR-02.a.07	Radioactive material contained in vessel	Release of radioactive aerosols from vessel headspace to building atmosphere with eventual release outside facility due to overfilling of sump causing tank failure	Rain or snow water intrusion	F1	S2	D01	26X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
C-2-b	CCF-07	Overflow of tank contents	Release of radioactive and hazardous materials from tank due to overfill	Disabled or unavailable staff to terminate transfer	F3	S2	E06	26X
C-2-b	COB-04	Transfer inventory	Release of radioactive and/or hazardous material from COB lid due to overflow of COB during transfer (pool)	Leak into COB with floor drain plugged, leak detector failed	F3	S2	D12	26X
C-2-b	COB-08	Transfer inventory	Release of radioactive and/or hazardous material from COB due to over filling of COB (pool)	Transfer pipe or riser rupture, backfilling lower part of COB then filling COB via the floor drain	F3	S2	D12	26X
C-2-b	CRN-11-IC	Contents of facility	Release of radioactive and/or toxic materials from facility due to containment top collapse damage by boom failure (pool)	Human error: improper load assembly, rigging, crane overloaded	F3	S2	E10	26X
C-2-b	CRN-12-IC	Contents of facility	Release of radioactive and/or toxic materials from facility due to containment top collapse by boom failure (pool)	Mechanical failure: corrosion, faulty materials	F2	S2	D10	26X
C-3-b	EE-11	Contents of affected tank	Release of radioactive and hazardous materials from tank due to overfilling	Water line breaks and overfills tank	F2	S2	D12	26X
C-2-b	I-242A-6-FLW-B	Aerosols and liquid waste from Tank 241-AW-102 diluted with raw water from the evaporator	Release of diluted high level tank waste from Feed Tank 241-AW-102 caused by overfilling Tank 241-AW-102 and annulus, aggravated by an uncontrolled evaporator dump when a raw water leak occurs in evaporator condenser room	Rupture of raw water line in condenser/pump room	F3	S2	D12	26X
C-2-b	I-242S-2-FLW-A	Contaminated fire water and other liquid waste in Tank 241-SY-102	Release of tank waste diluted with contaminated fire water to the soil due to flooding the pump room from a fire main break and pumping the water to Tank 241-SY-102 which overfills the tank and floods pit through risers	Break in fire main	F1	S2	D12	26X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
C-2-b	I-242S-2-FLW-E	High level waste from tank farms	Release of high level waste to the ground outside the 242-S building due to unmitigated reverse flow to the pump room from Tank 241-SY-102	Human error - incorrect valve line up	F2	S2	E06	26X
C-2-b	I-242S-4-FLW-C	High level waste from tank farms	Release of high level waste to the ground outside the 242-S building due to unmitigated reverse flow to the condenser room	Human error - incorrect valve line up	F2	S2	E06	26X
C-2-b	I-242S-4-FLW-D	Contaminated fire water and other waste in Tank 241-SY-102	Release of tank waste diluted with contaminated water to the soil due to flooding the condenser room which is pumped to Tank 241-SY-102 and overfills the tank and floods pit through risers	Break in fire main	F1	S2	D12	26X
C-2-b	I-PUREX-4-FLW-B	High level tank waste diluted with flush water	Release (ground surface) of high level tank waste diluted with flush water from the receiver tank due to overfilling from sending excess water	Block valve on flush water inadvertently left opened or leaking	F3	S2	D06	26X
C-2-b	I-UPLANT-1-LEK-B	Contaminated rain water from U Plant stack	Release of low level waste to the ground at the rupture of the line	Inadvertent excavation of line	F1	S2	D22	26X
B-2-b	OGT-EXT3-01B	DST & SST tank inventory	Release of radioactive or hazardous material from the primary pipe due to leak caused by truck crash into piping system	Human error, line struck by truck	F2	S2	E25	26X
C-2-b	OGT-FLOW1-02	DST & SST Tank inventory	Release of radioactive or hazardous material from pit overflow due to primary pipe leak caused by over-rated pump	Incorrect pump installed creates excessive flow and pressure on OGT system eroding EPDM pipe causing leak to secondary pipe with drain in pit plugged	F2	S2	E13	26X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
B-2-b	OGT-FLOW1-03B	DST & SST tank inventory	Release of radioactive or hazardous material from the primary pipe due to misdirected flow of waste through flush line	JR-1 (3-way valve) mispositioned to flush, two check valves fail, flush disconnect fails (check valve), and reverse flow to water truck, drum or onto ground	F1	S2	E06	26X
B-2-b	OGT-FLOW1-04	DST & SST Tank Inventory	Release of radioactive or hazardous material from the primary pipe due to valve failure resulting in misdirected flow of waste through flush line to flush water supply truck	JR-1 leak (bleed-by), two check valves fail, and flush disconnect fails and pump started causing reverse flow to flush water truck tank	F1	S2	D06	26X
C-2-b	OGT-FLOW1-06	DST & SST tank inventory	Release of radioactive or hazardous material from the DCRT due to overflow	Exceed volume available in DCRT/insufficient volume available, condition goes unnoticed until overflow occurs	F2	S2	E06	26X
B-2-b	OGT-FLOW2-01B	DST & SST Tank Inventory	Release of radioactive or hazardous material from the primary pipe due to leak caused by incorrect pump installed	Incorrect pump installed creates excessive flow and isolation valve closed on secondary pipe, erosion of EPDM and pressurization of secondary pipe causing leaks from flanges gasket within concrete shield	F2	S2	E13	26X
B-2-b	OGT-FLOW2-03B	DST & SST tank inventory	Release of radioactive or hazardous material from the primary pipe due leak caused by incorrect pump installed	Installation of incorrect pump, failure of inner pipe and isolation valves closed on secondary pipe drains causing leak from failed welds on flange within the concrete shield	F1	S2	E13	26X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
C-2-b	OGT-PRES1-01	DST & SST tank inventory	Release of radioactive or hazardous material from overflow of pit due to leak caused by high pressure	Heat up of hydro test by heat tape or high ambient temperature, high pressure results from captive fluid heat up, inner pipe damaged, leaks to secondary pipe and drains back to pits and insufficient drainage in pit	F1	S2	D05	26X
C-2-b	OGT-REAC1-01	DST & SST tank inventory	Release of radioactive or hazardous material from overflow of pit due to primary pipe leak cause by chemical reaction	Pumping from multiple tanks to single OGT, potential for adverse chemical reactions in pipeline damaging inner pipe, leaks to secondary pipe and drains back to pits and insufficient drainage in pit	F1	S2	D01	26X
C-2-b	OGT-TEMP1-03	DST & SST tank inventory	Release of radioactive or hazardous material from overflow of pit due to leak caused by high temperature	High temperature flush water fails inner pipe causing leak to secondary pipe, drain to pit with insufficient drainage in pit	F1	S2	E01	26X
C-2-b	TFS-1	Waste from Tank 241-SY-102	Release of radioactive or hazardous waste liquid from overflow of 244-S vault to the 244-S pump pit due to syphon effect on Tank 241-SY-102 (pump does not overflow)	Human Error - failure to close isolation valve (or valve malfunction) following waste transfer which allows flow to continue (syphon) when pump is stopped	F3	S2	E06	26X
C-2-b	W058-FLOW01	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	Computer failure or human error causing misrouting of material when flow path is not completely connected plus mitigative features failure	F3	S2	E06	26X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
C-2-b	W058-FLOW03	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	External leak of valve or valves to the valve pit plus mitigative features failure	F2	S2	D12	26X
C-2-b	W058-FLOW05a	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	Failure of jumper due to misalignment (human error) plus mitigative features failure	F3	S2	E06	26X
C-2-b	W058-FLOW05b	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	Failure of jumper due to gasket failure plus mitigative features failure	F2	S2	D12	26X
C-2-b	W058-FLOW05c	Amount of slurry transferred (20,000 to 1,000,000 gallons)	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	Failure of jumper due to corrosion plus mitigative features failure	F2	S2	D12	26X
C-2-b	W058-FLOW07	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	Computer failure or human error causing misrouting of material when flow path is not completely connected plus mitigative features failure	F3	S2	E06	26X
C-2-b	W058-FLOW09	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	External leak of valve or valves to the valve pit plus mitigative features failure	F2	S2	D12	26X
C-2-b	W058-FLOW11a	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	Failure of jumper due to misalignment (human error) plus mitigative features failure	F3	S2	E06	26X
C-2-b	W058-FLOW11b	Amount of supernate transferred (20,000 to 1,000,000 gallons)	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	Failure of jumper due to gasket failure plus mitigative features failure	F2	S2	D12	26X

C-2-b	XS-20-FLOW08	Liquid radioactive waste in catch tank and DCRT	Release of radioactive waste from 244-TX DCRT to surface due to overflow	Transfer of excess waste to 244-TX DCRT due to improper valve lineup causes overflow	F3	S2	E06	26X
C-2-b	XS-20-FLOW09	Liquid radioactive waste in catch tank and DCRT	Release of radioactive waste from 244S DCRT to surface due to overflow	Transfer of waste from 244-TX DCRT due to improper valve lineup causes overflow	F3	S2	E06	26X
C-2-b	XS-35-FLOW02	Liquid radioactive waste from cross-site transfer	Release of radioactive waste to surface from 242-S Evaporator sump due to backflow to and overflow	Human error of leaving open flow path after emptying the sump and backflow and subsequent overflow	F3	S2	E06	26X
C-2-b	XS-37-FLOW01	Liquid waste involved in cross-site transfer	Release of radioactive liquid waste from catch tank to surface due to overfilling (pool)	Leak of transfer piping with drainage to catch tank causes overflow	F3	S2	D12	26X
C-2-b	XS-41A-FLOW01	Liquid radioactive waste from cross-site transfer	Release of radioactive waste from vent station nozzle pit to surface due to overflow	Catastrophic failure of vent piping causes overflow of nozzle pit	F3	S2	D12	26X
C-2-b	XS-41A-FLOW02	Liquid radioactive waste from cross-site transfer	Release of radioactive waste to surface from vent station nozzle pit due to overflow	Vent valve left open or leaking during transfer causes overflow	F3	S2	E06	26X
C-2-b	XS-41B-LEVE03	Liquid radioactive waste in vent station catch tank and waste being transferred	Release of radioactive waste to surface from vent station nozzle pit due to overflow	Failure to empty catch tank, causing overflow of tank and pit due to transfer failure	F3	S2	E06	26X
C-2-b	XS-52-FLOW02	Liquid radioactive waste transfer to DST	Release of radioactive waste from Tank 244-CR-003 to surface due to overflow (pool)	Mis-valving or valve failure during cross-site transfer causes overflow	F3	S2	E06	26X
ANALYZED ACCIDENT: Unplanned Excavation/Drilling in Pond/Crib/Ditch								
C-2-c	CDP-10	Portion of radioactive material present in crib, ditch or pond	Release of radioactive contamination to soil surface from excavation or drilling in cribs, ditches or ponds that disturbs radioactive material	Excavation or drilling	F3	S2	D22	28

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
			HAZARDOUS CONDITIONS					
C-1-a	EE-17	Materials in inactive equipment	Radioactive and hazardous material release from inactive equipment due to excavation error	Excavation into abandoned or inactive equipment	F3	S2	D22	28X
			ANALYZED ACCIDENT: Subsurface Leak Remaining Subsurface					
B-3-b	102S-01.b3	Radioactive/hazardous material contained in pumpable liquids from Tank 241-S-102.	Radioactive liquid released to the soil subsurface from leaks in transfer lines SL-140, SN-242. (Plume)	Line leak during saltwell pumping (corrosion)	F3	S2	D12	29
			HAZARDOUS CONDITIONS					
C-3-b	102AW-04-STRU04	Radioactive waste transfer through DST central pump pit	Release of liquid radioactive waste from Tank 241-AW-102 central pump pit due to leak to soil	Piping leak and leak from pump pit due to equipment drop	F2	S2	D10	29X
C-3-b	102AW-04-STRU05	Radioactive waste transfer through DST central pump pit	Release of liquid radioactive waste from Tank 241-AW-102 central pump pit due to leak to soil	Piping leak and leak from pump pit due to seismic event	F1	S2	D18	29X
B-3-b	XS-01-FLOW07	Saltwell liquor being transferred to DCRT	Release of liquid radioactive waste to the soil from transfer piping from SST to DCRT due to leakage (plume)	Pipe failure from various causes	F3	S2	D12	29X
B-3-b	XS-02-FLOW04	PFP waste being transferred to DCRT	Release of liquid radioactive waste to soil from transfer pipe (non-pool) subsurface plume	Failure to adjust waste pH prior to transfer causes leak	F2	S2	E01	29X
C-3-b	XS-37-FLOW02	Liquid waste involved in cross-site transfer	Release of radioactive liquid waste to soil from transfer piping due to leak of liquid waste from concrete encasement (subsurface plume)	Leak of transfer piping with encasement leak or blocked drain to catch tank (liquid oozes out concrete encasement)	F3	S2	D12	29X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
B-3-b	XS-48-FLOW	Liquid waste transferred from B-Plant to diversion box	Release of liquid waste to soil from transfer piping between B-Plant and 241-ER-152 diversion box due to leak (plume)	Piping failure from various causes	F3	S2	D12	29X
ANALYZED ACCIDENT: Sodium Fire								
A-1-a	2727W-06	Building inventory	Release of hazardous materials from 2727-W due to sodium-water reactions	High wind or tornado destroys building with rain/snow	F2	S2	D20	30
HAZARDOUS CONDITIONS								
A-1-a	2727W-02	Building inventory	Release of hazardous material from 2727-W due to sodium fire	Vehicle crashes into building and ignites sodium	F1	S2	B25	30X
A-1-a	2727W-03	Building inventory	Release of hazardous material from 2727-W due to sodium fire	Lightning	F2	S2	B21	30X
A-1-a	2727W-04	Building inventory	Release of hazardous material from 2727-W due to sodium fire	Overhead power line falls through building	F1	S2	B09	30X
A-1-a	2727W-05	Building inventory	Release of hazardous material from 2727-W due to sodium fire	Nitrogen tank overpressurizes sodium tank, ignites sodium	F3	S2	B01	30X
ANALYZED ACCIDENT: Above Ground Structure Failure								
B-1-a	ITK-FR-08	DST & SST tank liquid held in flex receiver	Release of radioactive aerosols/vapors from flex receiver due to structural failure	High winds tear flex receiver bag	F3	S2	D20	31
HAZARDOUS CONDITIONS								
B-1-a	CRN-11-IB	Contents of equipment	Release of radioactive and/or toxic materials from facility due to equipment damage by boom failure	Human error: improper load assembly, rigging, crane overloaded	F3	S2	E10	31X
B-1-a	CRN-12-IB	Contents of equipment	Release of radioactive and/or toxic materials from facility due to equipment damage by boom failure	Mechanical failure: corrosion, faulty materials	F2	S2	D10	31X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
B-1-a	CRN-13-IB	Contents of equipment	Release of radioactive and/or toxic materials from above ground facility due to equipment damage by boom failure	High wind or seismic event	F2	S2	D05	31X
B-1-a	CRN-18	Contaminates on above ground equipment	Release of radioactive or toxic material from above ground tank equipment due to dropping crane load	Human error: improper load assembly, rigging, crane overloaded	F3	S2	D10	31X
B-1-a	CRN-18-I	Material in aboveground facility equipment	Release of radioactive or toxic material from aboveground facility equipment due to dropping crane load	Human error: improper load assembly, rigging, crane overloaded	F3	S2	E10	31X
B-1-a	CRN-19-I	Material in aboveground facility equipment	Release of radioactive or toxic material from aboveground facility equipment due to dropping crane load	Mechanical failure: corrosion, faulty materials	F2	S2	D10	31X
B-1-a	CRN-20-I	Material in aboveground facility equipment	Release of radioactive or toxic material from aboveground facility equipment due to dropping crane load	High wind or seismic event	F2	S2	D05	31X
B-1-a	CRN-23-IB	Contents of facility	Release of radioactive or toxic materials from aboveground facility bottom due to loss of vertical load control, dropping crane load into facility	High wind or seismic event	F2	S2	D05	31X
C-2-b	CRN-25-IB	Material in aboveground facility or equipment	Release of radioactive or toxic material from aboveground MISF due to swinging load into equipment caused by loss of lateral load control	Human error: improper load assembly, rigging, positioning error	F3	S2	E26	31X
C-2-b	CRN-26-IB	Material in aboveground facility or equipment	Release of radioactive or toxic material from aboveground MISF due to swinging load into equipment caused by loss of lateral load control	Mechanical failure: corrosion, faulty materials, hydraulics, outriggers in soft soil	F2	S2	D26	31X
C-2-b	CRN-27-IB	Material in aboveground facility or equipment	Release of radioactive or toxic material from aboveground MISF due to swinging load into equipment caused by loss of lateral load control	Mechanical failure: corrosion, faulty materials, hydraulics, outriggers in soft soil	F2	S2	D10	31X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
C-1-a	ITK-FR-03	DST & SST tank inventory	Release of radioactive aerosols from tank and/or receiver due to equipment jam in riser	Equipment becomes lodged in riser, efforts to remove pull riser out of tank causing breach of tank & receiver containment	F1	S2	E05	31X
C-1-a	ITK-FR-22	DST & SST tank liquid held in flex receiver	Release of radioactive aerosols from flex receiver due to tank gas release	Tank gas release pressurizes bag and causes bag to rupture	F1	S2	D01	31X
B-1-a	LDUA 5-40	Radioactive aerosols in single shell tank headspace	Release of contamination from TRIC and tank riser due to damage during wind storm	High winds	F3	S2	D14	31X
A-1-a	NP-05	Head space inventories, ventilation system inventories, surface contaminates, 209-E inventory, tanker spill at 204-AR	Radioactive and hazardous material release from tanks, nearby ground surfaces, and ventilation systems due to above grade disturbances	High winds	F1	S2	D20	31X
ANALYZED ACCIDENT: Steam Intrusion from Interfacing Systems								
B-1-a	I-242A-6-CMP-A	Aerosols and particulates entrained in steam from Tank 241-AW-102	Release (steam) of aerosols to the atmosphere through unsealed cracks in the cover blocks due to over pressurization of the receiver tank	Human error - steam block valve inadvertently left opened	F3	S3	E01	32
HAZARDOUS CONDITIONS								
B-1-a	I-222S-1-LVL-A	Aerosols and particulates from 244-S entrained in the steam	Release (steam) of aerosols and entrained particulates to atmosphere through ventilation due to over pressurization of 244-S DCRT caused by sending just steam to tank farm	Human error - failing to shut off steam after Tank 219-S-102 is empty	F3	S2	E01	32X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
B-1-a	I-222S-2-PRS-A	Aerosols and particulates from 244-S entrained in the steam	Release (steam) of aerosols and particulates to atmosphere through ventilation due to over pressurization of 244-S DCRT caused by sending just steam to tank farm	Steam reducer valve fails open	F3	S2	D01	32X
B-1-a	I-242A-2-CMP-B	Aerosols and particulates entrained in steam from receiver tank	Release to the atmosphere through unsealed cracks in the cover blocks due to over pressurization of the receiver tank	Steam block valves inadvertently opened or left open	F2	S3	E01	32X
B-1-a	I-PFP-2-TMP-B	Steam release of aerosols and entrained particulates from 244-TX	Release (steam) of aerosols and entrained particulate from 244-TX ventilation system due to saturating HEPAs with steam sending higher pressure steam to steam jet, gassing it out	Failure of steam reducer	F2	S2	D01	32X
B-1-a	I-PUREX-1-LVL-A	Aerosols from Tank 241-AW-105	Release of aerosols from Tank 241-AW-105 through cracks in the cover block due to pressurizing tank from transfer of steam	Human error - failure to shut off steam jet when U-3 is empty	F3	S2	E01	32X
B-1-a	I-PUREX-2-PRS-A	Aerosols and particulates entrained in steam from receiver tank	Release (steam) of aerosols and particulates through cracks in the cover block from the receiver tank due to tank pressurization which gases out the steam jet	Steam reducer fails	F2	S2	D01	32X
B-1-a	I-PUREX-3-LVL-A	Aerosols from Tank 241-AW-105	Release of aerosols from Tank 241-AW-105 through cracks in the cover block due to pressurizing tank from transfer of steam	Human error - failure to shut off steam jet when U-3 is empty	F3	S2	E01	32X
B-1-a	I-PUREX-4-PRS-A	Aerosols and particulates entrained in steam from receiver tank	Release of aerosols and particulates through cracks in the cover block from the receiver tank due to tank pressurization which gases out the steam jet	Steam reducer fails	F2	S2	D01	32X
B-1-a	I-TPLANT-2-CMP-A	Aerosols and particulates from 244-S entrained in the steam	Release (steam) of aerosols and entrained particulates to atmosphere through ventilation due to over pressurization of 244-S DCRT caused by sending just steam to the tank farm	Human error - steam block valve inadvertently opened or failure to close valve when Tank 15-1 is low	F3	S2	E01	32X

Table D3.3-2. Analyzed Accidents and the Represented Hazardous Conditions.[1] (68 sheets)

BIN	ID	Material at Risk	Hazardous Condition	Cause	Freq NC	Safety Cons NC	Cause Grp	Rep Acc
B-1-a	XS-02-FLOW02	DCRT filter inventory	Release of aerosols and particulate from DCRT ventilation filter due to transfer of steam from PFP steam jet into DCRT headspace	Human error (failure to shut off steam jet at completion of transfer) which causes DCRT ventilation filter failure	F3	S2	E01	32X

[1]This table was generated from a relational database of hazards information. Changes from the previous revision of this table have been independently reviewed, but are not highlighted in Redline.

Table D3.4-1. Hazardous Conditions With Potential Significant Offsite Consequences (S3).[1] (11 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
102AW-01-FLOW 102AW-02-PRES	Release of liquids, solids and/or vapors from Tank 241-AW-102 due to dome collapse caused by chemical reaction of incompatible wastes	Misrouting to destination other than intended creates chemical incompatibility	F0	E3
102AW-01-FLOW 102AW-04-PRES	Release of radioactive aerosol from transfer pipe which runs from DCRT to Tank 241-AW-102 due to spray leak into open underground structure	Piping leak due to thermal stress of transferring hot solution in cold pipe	F3	E2
102AW-01-FLOW01	Release of liquid radioactive waste aerosols from transfer pipe to Tank 241-AW-102 due to spray leak into open underground structure	Piping leak due to corrosion caused by transferring high temperature waste	F2	E2
102AW-01-TEMP	Release of liquid radioactive waste aerosols from transfer pipe to Tank 241-AW-102 due to spray leak of liquid waste from transfer pipe leak	Piping leak due to exceeding the design temperature of the pipe by transferring high temperature waste	F1	E3
102AW-02-PRES01	Release of radioactive aerosols from Tank 241-AW-102 due to fire/explosion in waste tank (Dome Collapse)	Flammable concentration of gases in tank vapor space with spark source	F2	E2
102AW-02-PRES03	Release of liquids, solids and/or vapors from Tank 241-AW-102 due to dome collapse caused by excessive vacuum	Blocked ventilation inlet causes excessive vacuum leading to dome collapse	F0	E3
102AW-02-PRES04	Release of liquids, solids and/or vapors from Tank 241-AW-102 due to dome collapse caused by excessive vacuum	Condensation of vapors causes excessive vacuum leading to dome collapse	F0	E3
102AW-02-PRES05	Release of liquids, solids and/or vapors from Tank 241-AW-102 due to dome collapse caused by excessive vacuum	Sub-cooling of vapor during equipment flushing causes excessive vacuum leading to dome collapse	F0	E3
102AW-02-PRES06	Release of liquids, solids and/or vapors from Tank 241-AW-102 due to dome collapse caused by excessive vacuum	Ventilation imbalance causes excessive vacuum leading to dome collapse	F0	E3
102AW-02-PRES07	Release of liquids, solids and/or vapors from Tank 241-AW-102 due to dome collapse caused by excessive vacuum	Wrong size portable ventilator chosen for support work causes excessive vacuum leading to dome collapse	F0	E3
102AW-03-LEVE03	Release of liquids, solids and/or vapors from Tank 241-AW-102 due to dome collapse caused by floating the primary tank within the annulus	Misrouting of liquid waste to the annulus causes floating of primary tank and subsequent dome collapse	F1	E3
102AW-03-TEMP01	Release of liquids, solids and/or vapors from Tank 241-AW-102 due to dome collapse caused by an fire/explosion in the annulus	Fire/ Explosion of flammable liquid spilled into annulus via a riser	F2	E3
102AW-04-STRU01A	Release of liquids, solids and/or vapors from Tank 241-AW-102 due to dome collapse caused by excessive dome loading	Equipment drop during crane work causes excessive dome loading	F3	E3
102AW-04-STRU02	Release of liquids, solids and/or vapors from Tank 241-AW-102 due to dome collapse caused by excessive dome loading	Violation of limits on dome loading	F3	E3

Table D3.4-1. Hazardous Conditions With Potential Significant Offsite Consequences (S3).[1] (11 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
102AW-09-COMP01	Release of combustion product aerosols from Tank 241-AW-102 due to fire in separable organic layer in waste tank causing dome collapse	Organic reaching flash point or being aerosolized plus ignition source	F2	E3
102AW-09-COMP02	Release of radioactive waste aerosols from Tank 241-AW-102 due to fire in fuel spilled in waste tank causing dome collapse	Spill of fuel from external source plus fuel reaching flash point or being aerosolized plus ignition source	F2	E3
102AW-13-FLOW01	Release of radioactive waste aerosols due to spray leak of waste from flush pit	Backflow of waste to flush pit with valve or pipe leak and cover block off	F1	E3
102S-03.b4	Release of radioactive aerosols to atmosphere from Tank 241-S-102 due to burning fuel flowing into waste tank causing dome collapse	Vehicle drives into open riser puncturing gas tank + Ignition + Flammable organic vapors in tank	F3	E3
102S-04.c	Release of radioactive aerosols contained in Tank 241-S-102 vapor space to atmosphere due to ignition of flammable gas in tank vapor space	Concentration of H2 or Ammonia (or other flammable gasses) above LFL + Ignition source	F1	E3
102S-04.d1	Release of radioactive aerosols contained in Tank 241-S-102 vapor space to the atmosphere due to low pressure causing dome collapse	Misoperation of exhauster during saltwell pumping	F0	E3
102S-04.e3	Release of radioactive aerosols contained in Tank 241-S-102 vapor space to atmosphere due to generation of excessive heat leading to dome collapse	Addition of incompatible waste/chemical (misroute)	F0	E3
102S-05.a1a	Release of radioactive aerosols from Tank 241-S-102 to atmosphere due to dome collapse	Excess gravel overburden	F3	E3
102S-05.a1aa	Release of radioactive aerosols from Tank 241-S-102 to atmosphere due to dome collapse	Large vehicle traffic over tank	F3	E3
102S-05.a2	Release of radioactive aerosols from Tank 241-S-102 to atmosphere due to dome collapse	Seismic event (common mode failure)	F1	E3
102S-05.a3	Release of radioactive aerosols from Tank 241-S-102 to atmosphere due to dome collapse	Past thermocycling of tank	F1	E3
102S-05.a3a	Release of radioactive aerosols from Tank 241-S-102 to atmosphere due to dome collapse	Long term aging	F1	E3
106C-01A	Release of radioactive and/or hazardous material from Tank 241-C-106, structural damage and dome collapse due to tank low pressure	Air inlet plugged due to icing/dust	F0	E3
106C-01B	Release of radioactive and/or hazardous material from Tank 241-C-106, structural damage and dome collapse due to tank low pressure	Inlet air valve closed	F0	E3

Table D3.4-1. Hazardous Conditions With Potential Significant Offsite Consequences (S3).[1] (11 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
106C-01C	Release of radioactive and/or hazardous material from Tank 241-C-106, structural damage, and dome collapse due to tank low pressure	Exhauster damper positioned incorrectly	F0	E3
106C-01D	Release of radioactive and/or hazardous material from Tank 241-C-106, structural damage and dome collapse due to tank low pressure	Wrong sized portable exhauster	F0	E3
106C-01E	Release of radioactive and/or hazardous material from Tank 241-C-106, structural damage and dome collapse due to tank low pressure	Subcooling of tank vapor space due to water addition of flushing	F2	E3
106C-01I	Release of radioactive and/or hazardous material from Tank 241-C-106 due to possible dome collapse caused by tank high pressure	Fire in waste tank	F2	E3
106C-01J	Release of radioactive and/or hazardous material from Tank 241-C-106 due to high pressure in tank and possible dome collapse	Fire/explosion in waste tank	F2	E3
106C-01Ma	Release of radioactive and/or hazardous material from Tank 241-C-106 due to flammable gas fire/explosion in tank caused by high temperature (dome collapse)	Chemical reaction in tank	F2	E2
106C-01X	Release of radioactive and/or hazardous material from Tank 241-C-106, dome structural damage and/or personnel injury due to overload of tank dome	Overweight vehicles over top of tank	F3	E3
106C-01Y	Release of radioactive and/or hazardous material from Tank 241-C-106, dome structural damage and/or personnel injury due to overload of tank dome	Flooding over top of tank	F2	E3
106C-02A	Release of radioactive and/or hazardous material from Tank 241-C-106 due to dome collapse caused by ignition of high flammable gas content in tank	High waste temperature	F2	E3
106C-02B	Release of radioactive and/or hazardous material from Tank 241-C-106 due to ignition of high flammable gas content in tank and possible dome collapse	Ventilation system failure	F2	E3
106C-02C	Release of radioactive and/or hazardous material from Tank 241-C-106 due to dome collapse caused by ignition of high flammable gas content in tank	Tank burp, release of trapped gas	F2	E3
106C-04A	Release of radioactive and/or hazardous material from Tank 241-C-106 due to tank damage caused by flammable gas fire/explosion because of high flammable gas content in the tank (dome collapse)	High flammable gas content due to chemical reaction in sludge layer	F2	E2
106C-04B	Release of radioactive and/or hazardous material from Tank 241-C-106 due to fire/explosion caused by ignition of flammable gas released from radiolysis in tank sludge	Radiolysis in sludge layer allows release of trapped gas to vapor space	F2	E3

Table D3.4-1. Hazardous Conditions With Potential Significant Offsite Consequences (S3).[1] (11 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
106C-13A	Release of radioactive and/or hazardous material from Tank 241-C-106 due to possible dome collapse, tank damage caused by high temperature	Fire in Tank 241-C-105 propagates into Tank 241-C-106	F2	E3
114SX-04.a.2	Radioactive aerosols released from failed tank dome due to vacuum produced by valving error.	Human error: Valve out flammable watch list (Tank 241-SX-109) butterfly valve	F0	E3
114SX-04.a.3	Release of radioactive aerosols from Tank 241-SX-114 to atmosphere due to high temperatures causing dome concrete strength loss	No ventilation flow High ambient temperature conditions Resulting in tank degradation	F1	E3
114SX-04.b.1.a.2	Release of radioactive material from Tank 241-SX-114 to atmosphere due to high temperature in the dome leading to dome collapse (long term closure of butterfly valve)	Human error: Closure of Tank 241-SX-114 exhaust butterfly valve isolating tank from exhaust plenum Resulting in tank degradation	F1	E3
114SX-04.b.1.b.2a	Release of radioactive aerosols to atmosphere from Tank 241-SX-114 waste due to heat induced tank dome collapse	Ducting failure due to bad welds	F1	E3
114SX-04.b.1.b.2b	Release of radioactive aerosols to atmosphere from Tank 241-SX-114 waste due to heat induced tank dome collapse	Ducting failure due to seismic activity coupled with failure to respond Resulting in tank degradation	F1	E3
114SX-04.b.1.c.2	Release of radioactive aerosols to atmosphere from Tank 241-SX-114 waste due to dome collapse	Exhauster failure Fan failure Filter rupture (low differential pressure shutdown) Resulting in tank degradation	F0	E3
114SX-04.b.1.d.2	Release of radioactive aerosols from Tank 241-SX-114 waste to atmosphere due to dome collapse	Filter plugging results in lack of heat removal with high temperatures degrading dome strength	F1	E3
114SX-04.b.3b	Release of radioactive aerosols from head space of Tank 241-SX-114 to atmosphere through exhaust HEPA filter due to flammable gas ignition in the headspace (dome collapse)	Flammable gas fire/explosion in Tank 241-SX-114 (Note: Tank 241-SX-114 is NOT currently identified as a Flammable Gas Watch List Tank) Requires spark to be present	F1	E2
114SX-05.b.1	Release of radioactive aerosols from Tank 241-SX-114 waste to atmosphere due to flammable gas ignition resulting in dome collapse	Radiolysis creating bubbles of gases in waste	F2	E3

Table D3.4-1. Hazardous Conditions With Potential Significant Offsite Consequences (S3).[1] (11 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
114SX-05.b.3	Release of radioactive aerosols from Tank 241-SX-114 waste to atmosphere due to dome collapse caused by sudden vacuum in tank	Quenching (adding cold liquid to hot tank contents) creating a vacuum	F0	E3
114SX-05.c.2b	Release of radioactive aerosols from Tank 241-SX-114 waste to atmosphere due to dome collapse	Chemical reaction caused by addition of chemical/solution. Resulting in tank degradation	F1	E3
114SX-06.a.1a	Release of radioactive aerosols from Tank 241-SX-114 waste to atmosphere due to dome collapse	Gravel overburden Large vehicle	F3	E3
114SX-06.a.1b	Release of radioactive aerosols from Tank 241-SX-114 waste to atmosphere as a result of a dome collapse	Deflagration of H2 (Implies gas generation with spark)	F1	E3
114SX-06.a.3	Release of radioactive aerosols from Tank 241-SX-114 waste to the atmosphere due to dome collapse caused by loss of strength due to aging	Long term aging resulting in tank degradation	F1	E3
244AR-02.a.14	Release of radioactive aerosols from waste contained in tanks (4) and building due to earthquake	Seismic event collapses building and four tanks	F1	E3
CCF-17	Release of radioactive and hazardous materials from tank due to dome collapse	Corrosion of rebar in concrete SST domes	F1	E3
CCF-18	Release of radioactive and hazardous materials from tanks due to dome collapses	Fire in tank propagates to connecting tank and both tanks collapse during cooldown from negative tank pressure	F0	E3
CCF-19	Release of radioactive and hazardous materials from tanks due to dome collapses	Fire in tank causes pressure transient that leads to GRE in connecting tank with subsequent fire and tank collapses from negative tank pressure	F0	E3
COB-01	Release of radioactive and/or hazardous material from COB due to spray leak	Flange, gasket or valve, spray leak with COB lid removed	F3	E2
CP-GRT-02	Release of radioactive or toxic material to soil surface (pool) from transfer line due to puncture of line during transfer	Human error AND Mechanical failure of push pipe integrity inside the transfer line	F1	E3
CP-MSP-05	Release of radioactive or toxic material to atmosphere from waste tank due to flammable gas deflagration	Human error AND Flammable gas is present in tank AND Mechanical failure of the pipe and probe (ignition source)	F1	E3

Table D3.4-1. Hazardous Conditions With Potential Significant Offsite Consequences (S3).[1] (11 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
CP-MSP-06	Release of radioactive or toxic material to atmosphere due to flammable gas deflagration caused by puncture and ignition of flammable gas in transfer line which propagates to the waste tank	Human error AND Flammable gas is present in transfer pipe AND Spark from probe tip (ignition source)	F1	E3
CP-RMV-03	Release of radioactive or toxic material from transfer line through the push pipe during removal activities	Human error	F1	E3
CP-SET-04	Release of radioactive or toxic material from waste tank due to dome collapse	Excessive weight on tank dome (static load of platform)	F2	E3
CP-SET-05	Release of radioactive or toxic material from waste tank due to dome collapse caused by load drop	Mechanical failure of equipment causes load drop	F2	E3
CP-SET-06	Release of radioactive or toxic material from waste tank due to dome collapse caused by load drop	Human error causes load drop	F3	E3
CP-SSP-01	Release of radioactive or toxic material to soil surface (pool) from transfer line due to puncture of line during transfer	Human error caused puncture to transfer line during push operations.	F1	E3
CP-SSP-16	Release of radioactive or toxic material to soil surface (pool) from transfer line due to puncture of line during transfer	Human error AND Mechanical failure of push pipe integrity inside the transfer line	F1	E3
CRN-03	Release of radioactive and/or toxic materials from tank due to dome collapse	Human error results in excessive weight on dome	F3	E3
CRN-04	Release of radioactive and/or toxic materials from tank due to dome collapse	Crane or rigging failures drop load resulting in large impact to dome	F3	E3
CRN-11	Radioactive or toxic material release from tank due to boom failure and tank/equipment damage and dome collapse	Human error: improper load assembly, rigging, crane overloaded	F3	E3
CRN-12	Radioactive or toxic material release from tank due to boom failure and tank/equipment damage and dome collapse	Mechanical failure: corrosion, faulty materials	F3	E3
CRN-13-a	Release of radioactive or toxic material from tank/equipment damage and dome collapse due to boom failure	High wind	F3	E3
CRN-13-b	Release of radioactive or toxic material from tank/equipment damage and dome collapse due to boom failure	Seismic event	F1	E3
EE-01	Release of radioactive and toxic materials from tanks due to external force and fire	Aircraft crash	F1	E3
EE-04-a	Release of radioactive and hazardous materials from SST tank due to external fires	Vehicle accident involving propane, diesel or gasoline delivery	F2	E3
EE-04-b	Release of radioactive and hazardous materials from DST tank due to external fires	Vehicle accident involving propane, diesel or gasoline delivery	F2	E3

Table D3.4-1. Hazardous Conditions With Potential Significant Offsite Consequences (S3).[1] (11 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
EE-05-a	Release of radioactive or hazardous materials from SST tank due to external fires	Run-away vehicle or truck shears off one or more risers, ruptures gasoline tank	F3	E3
EE-05-b	Release of radioactive or hazardous materials from DST tank due to external fires	Run-away vehicle or truck shears off one or more risers, ruptures gasoline tank	F3	E3
EE-16	Release of radioactive and hazardous material from transfer line spray leak due to excavation error	Excavation into waste transfer line during a transfer	F3	E2
I-222S-1-CMP-E	Release of radioactive aerosols to the atmosphere from 244-S or receiver tank due to over pressurization of tank caused by organic fire	Human error - upset of 222-S Lab operations	F3	E3
I-242A-1-FLW-A	Release of radioactive material from Feed Tank 241-AW-102 due to fire/explosion caused by igniting hydrogen gas when pump is damaged and possibly becomes an ignition source from dead heading	Valves fail to regulate (closed position) which fails pump and creates ignition source, sufficient hydrogen accumulation for fire/ explosion.	F2	E3
I-242A-1-FLW-B	Release of radioactive material from Feed Tank 241-AW-102 due to fire/explosion caused by igniting hydrogen gas when pump is damaged and possibly becomes an ignition source	Feed pump fails and causes ignition source, sufficient hydrogen accumulation for fire/explosion	F2	E3
I-242A-1-FLW-C	Release of radioactive material from Feed Tank 241-AW-102 due to fire/explosion caused by igniting hydrogen gas when pump is damaged and possibly becomes an ignition source from dead heading	Plugged line which fails pump and causes ignition source, sufficient hydrogen accumulation for fire/explosion	F2	E3
I-242A-1-FLW-D	Release of radioactive material from Feed Tank 241-AW-102 due to fire/explosion caused by igniting hydrogen gas when pump is damaged and possibly becomes an ignition source	Pump plugged which fails pump and causes ignition source, sufficient hydrogen accumulation for fire/explosion	F2	E3
I-242A-1-FLW-E	Release of radioactive material from Feed Tank 241-AW-102 due to fire/explosion caused by igniting hydrogen gas when pump is damaged and possibly becomes an ignition source from pump cavitation	Empty feed tank which fails pump and causes ignition source, sufficient hydrogen accumulation for fire/explosion	F2	E3
I-242A-2-CMP-B	Release to the atmosphere through unsealed cracks in the cover blocks due to over pressurization of the receiver tank	Steam block valves inadvertently opened or left open	F2	E3
I-242A-4-TMP-A	Release of radioactive material from Tank 241-AW-102 caused by ignition of organics in Tank 241-C-100 which pressurizes the drain line and propagates the fire down the line to Feed Tank 241-AW-102	Faulty control of vacuum to CA-1 vessel causing pot to boil with organic layer available	F0	E3
I-242A-6-CMP-A	Release (steam) of aerosols to the atmosphere through unsealed cracks in the cover blocks due to over pressurization of the receiver tank	Human error - steam block valve inadvertently left opened	F3	E3

Table D3.4-1. Hazardous Conditions With Potential Significant Offsite Consequences (S3).[1] (11 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
I-BPLANT-1-CMP-E	Release of tank waste due to fire in receiver tank from transferring organics from B Plant	Human error - tank containing organics in B Plant rupture and spills organics to the drains which eventually end up in Tank 24-1 and an inadvertent transfer to tank farms	F1	E3
I-PFP-1-CMP-E	Release of high level waste from receiver tank due to fire from organics transferred from PFP	Excess organic material added to waste results in fire	F2	E3
ITK-08	Release of radioactive material from in-tank fire or explosion due to intrusive activity (dome collapse)	Exothermic reaction of incompatible materials in tank	F3	E2
ITK-09	Release of radioactive material from in-tank fire or explosion due to intrusive activity (dome collapse)	Failure to bond components or incorrect bonding	F3	E2
ITK-10-a	Release of radioactive material from in-tank fire or explosion due to intrusive activity (dome collapse)	Spark from equipment or tools	F3	E2
ITK-10-b	Release of radioactive material from in-tank fire or explosion due to intrusive activity (dome collapse)	Spark from equipment or tools	F3	E2
ITK-11	Release of radioactive material from in-tank fire or explosion due to intrusive activity (dome collapse)	Lightning, range fire, or seismic event ignites tank vapors	F2	E2
ITK-FR-04	Release of radioactive aerosols from tank due to tank collapse	Equipment becomes lodged in riser, efforts to remove pull riser out of tank causing loss of structural integrity leading to tank collapse	F1	E3
ITK-FR-19	Release of radioactive aerosols from tank due to dome collapse	Hydraulic jacks on assembly stand are operated while assembly is bolted to flange tearing out riser and destroying tank integrity leading to dome collapse	F1	E3
LDUA 1-25	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of flammable gas	Fire (electrical, lighting)	F2	E3
LDUA 1-32	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of flammable gas	During planned intrusive activities, sampling triggers GRE	F3	E3
LDUA 1-33	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of flammable gas	Non-arm end effectors (OVS, OSVS) dropped down riser	F2	E3
LDUA 2-2	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of hydraulic fluid	Structural failure of hydraulic system	F2	E3

Table D3.4-1. Hazardous Conditions With Potential Significant Offsite Consequences (S3).[1] (11 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
LDUA 2-20	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of flammable gas	Combustible source of gas located near the compressor intake.	F3	E3
LDUA 2-51	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of flammable gas	Supervisor error - arm in wrong mode, Electric remains on after air purge fault, flammable gas enters arm, spark ignites gas	F1	E3
LDUA 5-43	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of flammable gas	Lightning strikes VPM in raised position	F2	E3
LDUA 5-45	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of flammable gas	Helicopter/airplane crash	F1	E3
LDUA 6-24	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of flammable gas	Wrong setting on safety interlock for electric shutdown on loss of purge air	F3	E3
LDUA/EREE 1-22	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of flammable gas	Electrical Short in LDUA Lighting short	F2	E3
LDUA/EREE 1-28	Release of aerosolized waste to the atmosphere from headspace of single shell tank due to ignition of flammable gas	Electrical Short in LDUA/ EREE Lighting short	F3	E3
NP-07	Radioactive and hazardous material releases from tanks and ventilation systems due to seismic event	Seismic event collapses domes	F1	E3
NP-08	Radioactive and hazardous material releases from transfer pipes due to seismic event (possible spray leak)	Seismic event shears pipes and encasements during transfer	F2	E2
NP-11	Radioactive and hazardous material releases from tank farms due to lava flow	Eruption of molten lava from fissures	F0	E3
NP-13	Radioactive and hazardous material releases from tanks due to excessive weight on dome	Accumulations of heavy snow followed by heavy rain	F2	E3
OGT-EXT3-01A	Release of radioactive or hazardous aerosols from the primary pipe due to spray leak caused by truck crash into piping system	Human error, line struck by truck	F3	E3
OGT-FLOW1-03A	Release of radioactive or hazardous aerosols from the primary pipe due to spray leak caused by misdirected flow	Spray leak caused by JR-1 (3-way valve) mispositioned to flush, two check valves fail, flush disconnect fails (check valve), reverse flow to external flush fixture and release to the environment	F1	E3

Table D3.4-1. Hazardous Conditions With Potential Significant Offsite Consequences (S3).[1] (11 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
OGT-FLOW2-02	Release of radioactive or hazardous aerosols from the primary pipe due spray leak caused by over-rated pump	Installation of incorrect pump and failure of inner pipe, failure of weld on flange of outer pipe, isolation valves closed on secondary pipe drains and no concrete shield in place	F2	E2
OGT-NP3-01	Release of radioactive or hazardous aerosols from the primary pipe due spray leak caused by seismic event	Failure of line and concrete shielding during seismic event	F1	E2
OGT-NP3-02	Release of radioactive or hazardous aerosols from the primary pipe due to leak caused by high wind	Pipe is blown off supports and no concrete shielding in place	F1	E2
W058-FLOW15	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak	Computer failure or human error causing misrouting of material when flow path is not completely connected	F2	E3
W058-FLOW16	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak	External leak of valve or valves to the valve pit	F2	E3
W058-FLOW17a	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak	Failure of jumper due to misalignment (human error) plus mitigative features failure	F2	E3
W058-FLOW17b	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak	Failure of jumper due to gasket failure plus mitigative features failure	F2	E3
W058-FLOW17c	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak	Failure of jumper due to corrosion plus mitigative features failure	F2	E3
W058-FLOW18	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak	Computer failure or human error causing misrouting of material when flow path is not completely connected	F2	E3
W058-FLOW19	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak	External leak of valve or valves to the valve pit plus mitigative features failure	F2	E3
W058-FLOW20a	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak	Failure of jumper due to misalignment (human error) plus mitigative features failure	F2	E3
W058-FLOW20b	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak	Failure of jumper due to gasket failure plus mitigative features failure	F2	E3

Table D3.4-1. Hazardous Conditions With Potential Significant Offsite Consequences (S3).[1] (11 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
W058-FLOW20c	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak	Failure of jumper due to corrosion plus mitigative features failure	F2	E3
W058-INTEG32	Release of radioactive supernate or slurry aerosols to the atmosphere due to a spray leak from test risers located near SY-A and SY-B valve pits	Failure of primary piping and path for spray leak from test riser plus mitigative features failure	F2	E3
W058-INTEG34	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak	External event (airplane crash, etc)	F1	E3
W058-INTEG35	Release of radioactive slurry aerosols to the atmosphere caused by spray leak of slurry from the SY-A or SY-B valve pit due to piping system leak	Seismic event	F1	E3
W058-INTEG36	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak	External event (airplane crash, etc)	F1	E3
W058-INTEG37	Release of radioactive supernate aerosols to the atmosphere caused by spray leak of supernate from the SY-A or SY-B valve pit due to piping system leak	Seismic event	F1	E3
XS-01-FLOW02	Release of liquids, solids and/or vapors from single shell tank due to dome collapse caused by flammable gas burn	Loss of pump prime results in overheated pump that ignites flammable gas	F2	E3
XS-01-FLOW03	Release of liquids, solids and/or vapors from single shell tank due to dome collapse and DCRT pressurization caused by flammable gas fire/explosion propagating from DCRT to single shell tank	Pipeline connecting single shell tank and DCRT fills with flammable gas; loss of ventilation flow in DCRT so that a flammable gas atmosphere is ignited by the ventilation outlet heater	F2	E3
XS-06-FLOW02	Release of liquid radioactive waste from DCRT transfer piping to Tank 241-SY-102 due to spray leak in DCRT pump pit	Pipe failure in DCRT pump pit causing spray leak	F2	E3
XS-06-FLOW03	Release of liquid radioactive waste from transfer piping from PFP to DCRT due to spray leak in DCRT pump pit	Pipe failure in DCRT pump pit causing spray leak	F2	E3
XS-13-PRES02	Release of radioactive aerosols from 241-U-301B catch tank due to fire/explosion of flammable gas	Buildup of flammable gas in catch tank and spark source	F2	E2
XS-26-PRES02	Release of radioactive aerosols from Tank 241-SY-102 due to flammable gas fire/explosion (dome collapse)	Accumulation of flammable gases in vapor space and spark source	F2	E2

[1]This table was generated from a relational database of hazards information. Changes from the previous revision of this table have been independently reviewed, but are not highlighted in Redline.

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
102AW-01-FLOW02	Release of radioactive waste to soil from transfer piping which runs to Tank 241-AW-102 due to leak from primary pipe and encasement	Excavation accident fails primary pipe and encasement	F3	E2
102AW-01-FLOW03	Release of radioactive waste to soil from transfer pipe to Tank 241-AW-102 due to leak of radioactive waste from primary pipe and encasement	Corrosion of inner and outer pipe cause failure of primary pipe and encasement	F3	E2
102AW-01-FLOW04	Release of radioactive waste to soil from transfer pipe to Tank 241-AW-102 due to leak of radioactive waste from primary pipe and encasement	High structural loading from traffic or cranes fails primary pipe and encasement	F3	E2
102AW-01-FLOW05	Release of radioactive waste to soil from transfer piping to Tank 241-AW-102 due to leak from primary pipe and encasement	Seismic event fails primary pipe and encasement	F2	E2
102AW-01-FLOW06	Release of radioactive waste to soil from transfer pipe to Tank 241-AW-102 due to leak of radioactive waste from primary pipe and encasement	Undermining due to leak of nearby pipes cause failure of primary pipe and encasement	F3	E2
102AW-01-FLOW07	Release of radioactive waste to soil from transfer pipe to Tank 241-AW-102 due to leak of radioactive waste from primary pipe and encasement	Water hammer cause failure of primary pipe and encasement	F3	E2
102AW-01-FLOW10	Release of liquid radioactive waste from Tank 241-AW-102 due to overflow	Misrouting of waste from reverse flow caused by the combination of an incorrectly wired pump and a full transfer pipe	F2	E2
102AW-01-FLOW11	Release of liquid radioactive waste to the ground surface from Tank 241-AW-102 due to overflow of Tank 241-AW-102 or underground structure	Misrouting to destination other than intended causes overflow	F3	E2
102AW-01-TEMP01	Release of liquid radioactive waste from transfer pipe to Tank 241-AW-102 due to leaks overflowing from underground structure	Piping leak due to corrosion caused by transferring high temperature waste	F2	E2
102AW-01-TEMP01A	Release of liquid waste from transfer pipe to Tank 241-AW-102 due to leaks overflowing from underground structure	Piping leak due to thermal stress of transferring hot solution in cold pipe	F2	E2
102AW-01-TEMP02	Release of liquid radioactive waste from transfer pipe to Tank 241-AW-102 due to leaks overflowing from underground structure	Piping leak due to exceeding the design temperature of the pipe by transferring high temperature waste	F2	E2
102AW-02-LEVE01	Release of toxic gases from Tank 241-AW-102 due to accumulations of gases	Slurry growth	F1	E1
102AW-02-LEVE03	Release of radioactive liquid from Tank 241-AW-102 due to overfilling	Failure to stop transfer causes overfilling of tank	F3	E2
102AW-02-LEVE04	Release of radioactive liquid from Tank 241-AW-102 due to overfilling	Misrouting causes overfilling of tank	F3	E2
102AW-02-LEVE05	Release of radioactive liquid from Tank 241-AW-102 to the soil column due to gross overfilling of tank (Pool)	Misrouting causes overfilling of tank	F3	E2

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
102AW-02-PRES 102AW-02-TEMP	Release of radioactive aerosols from Tank 241-AW-102 due to pressurization	Evaporator dump when intrusive activity is occurring which causes pressurization	F3	E2
102AW-02-PRES02	Release of toxic gases from Tank 241-AW-102 due to chemical reaction in waste	Transfer of incompatible waste to Tank 241-AW-102 causes tank gas accumulation	F3	E2
102AW-02-PRES08	Release of radioactive aerosols from Tank 241-AW-102 due to positive pressure	Evaporator dump of hot liquid generates aerosols and pressurizes the tank	F3	E1
102AW-02-PRES09	Release of radioactive aerosols from head space of Tank 241-AW-102 due to positive pressure (lower energy than tank bump)	Loss of fan with airlift circulators running, generating aerosols and pressurizing the tank	F3	E1
102AW-02-TEMP 102AW-08-TEMP	Release of radioactive aerosols from Tank 241-AW-102 due to positive pressure	Chemical reaction heating up and/or agitating tank causes positive pressure in tank	F2	E1
102AW-02-TEMP01	Release of radioactive aerosols from Tank 241-AW-102 due to boiling waste	High heat waste causing boiling	F2	E2
102AW-02-TEMP02	Release of radioactive aerosols from Tank 241-AW-102 due to tank bump	High heat waste combined with loss of ventilation contributes to tank bump	F2	E2
102AW-03-LEVE01	Release of radioactive aerosols from Tank 241-AW-102 due to fire/explosion in annulus	Flammable concentration of gases in annulus vapor space due to waste leak into annulus and spark source	F2	E2
102AW-03-LEVE02	Release of radioactive aerosols from Tank 241-AW-102 due to fire/explosion in annulus	Flammable concentration of gases in annulus vapor space due to waste mis-transfer into annulus and spark source	F2	E2
102AW-03-TEMP02	Release of radioactive aerosols from Tank 241-AW-102 due to fire/explosion in annulus damaging primary tank	Flammable concentration of gases in annulus vapor space due to spill of fuel into annulus and spark source	F2	E2
102AW-04-STRU03	Release of radioactive particulate from Tank 241-AW-102 central pump pit due to re-suspension	Equipment drop during crane work	F2	E1
102AW-04-STRU04	Release of liquid radioactive waste from Tank 241-AW-102 central pump pit due to leak to soil	Piping leak and leak from pump pit due to equipment drop	F2	E2
102AW-04-STRU05	Release of liquid radioactive waste from Tank 241-AW-102 central pump pit due to leak to soil	Piping leak and leak from pump pit due to seismic event	F1	E2
102AW-04-TEMP	Release of radioactive particulate from Tank 241-AW-102 central pump pit due to fire	Pump motor electrical fire	F1	E1
102AW-08-COMP02	Release of fission product gases and aerosols from Tank 241-AW-102 due to criticality	Misrouting of waste creates critical mass	F1	E2

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
102AW-08-COMP02A	Release of fission product gases and aerosols from Tank 241-AW-102 due to criticality	Human error - addition of excess fissile material to Tank 241-AW-102 creates critical mass	F1	E2
102AW-08-COMP03	Release of fission product gases and aerosols from Tank 241-AW-102 due to criticality	Non-uniform distribution of fissile material (horizontally) creates critical mass	F1	E2
102AW-08-COMP04	Release of fission product gases and aerosols from Tank 241-AW-102 due to criticality	Non-uniform distribution of fissile material (vertically) due to addition of "rich" layer	F1	E2
102AW-08-COMP05	Release of fission product gases and aerosols from Tank 241-AW-102 due to criticality	Over concentration of waste creates critical mass	F0	E2
102AW-09-TEMP	Release of aerosols from Tank 241-AW-102 vapor space due to pressurization	Transfer of hot solution from facility, generates aerosols and pressurizes the tank	F3	E1
102AW-09-TEMP01	Release of radioactive aerosols from Tank 241-AW-102 atmosphere due to tank bump	High heat waste plus loss of cooling and/or mixing pump (not yet installed) operation	F2	E2
102AW-13-FLOW02	Release of radioactive liquid from transfer piping out of Tank 241-AW-102 due to backflow of radioactive material into flush pit and subsequent overflow (Pool)	Multiple valving errors and failure of backflow prevention devices dumps to pit as designed	F3	E1
102S-01.a1	Radioactive/hazardous liquid released to soil surface from tank diversion box/access pit to the ground surface due to misrouting a transfer.	Human error (jumper/blank installation) + Mistransfer to Tank 241-S-102 (450-600 Kgal) overfills tank	F2	E2
102S-01.b2	Radioactive liquid released to soil surface from Tank 241-S-102 pump pit due to leak in jumpers connecting tank transfer lines SL-140, SN-242 during saltwell pumping.	Jumper failure + Drain plugged	F2	E2
102S-01.b3	Radioactive liquid released to the soil subsurface from leaks in transfer lines SL-140, SN-242. (Plume)	Line leak during saltwell pumping (corrosion)	F3	E2
102S-02.b1	Release of radioactive aerosols to atmosphere from Tank 241-S-102 pump pit due to flammable gas generated in pump pit igniting and burning paint off pump pit walls	Jumper leak + H2 evolution (or ammonia) + Spark	F2	E1
102S-02.b2	Release of radioactive aerosols to atmosphere from Tank 241-S-102 due to flammable gas from tank igniting in pump pit and burning paint off pump pit	H2 /Ammonia production migrates into pump pit + Spark (pumps not operating)	F2	E2
102S-02.d2	Release of radioactive aerosols to atmosphere from Tank 241-S-102 due to burning fuel flowing into pit ignited from ruptured gas tank.	Vehicle drives into pit cover puncturing gas tank + Ignition	F3	E0

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
102S-03.b3	Release of radioactive aerosols to atmosphere from Tank 241-S-102 due to burning fuel flowing into waste tank due to ignition of fuel from ruptured gas tank.	Vehicle drives into open riser puncturing gas tank + Ignition	F2	E2
102S-04.a3	Release of radioactive aerosols trapped in gases throughout Tank 241-S-102 waste to the atmosphere due to periodic release of toxic gases (lower energy than tank bump)	Waste growth (bump) due to chemistry within the waste coupled with crust movement	F3	E1
102S-04.e1b	Release of radioactive aerosols contained in Tank 241-S-102 vapor space to atmosphere due to due to ignition of flammable gas in tank vapor space	Concentration of H2 or Ammonia (or other flammable gasses) above LFL + Ignition source	F2	E2
102S-04.e4	Release of radioactive gases and aerosols from Tank 241-S-102 vapor space to atmosphere due to criticality	Criticality (misrouting)	F1	E1
106C-01F	Release of radioactive and/or hazardous material from Tank 241-C-106, blown out HEPA filters and/or discharge out cover blocks due to high tank pressure	Blockage of inlet, outlet and cascade lines	F2	E2
106C-01G	Release of radioactive and/or hazardous material from Tank 241-C-106 tank, due to waste reaction causing local discharge of contamination through blown HEPAs or out cover blocks	Addition of acid to tank	F2	E1
106C-01H	Release of radioactive and/or hazardous material from Tank 241-C-106, through blown HEPAs or out cover blocks due to tank boiling with vent path blocked or failed	Tank boiling with lack of vent path	F2	E1
106C-01M	Release of radioactive and/or hazardous material from Tank 241-C-106, due to high temperature in the waste tank	Exothermic, chemical reaction in tank due to inadvertent addition to tank	F2	E1
106C-01N	Release of radioactive and/or hazardous material from Tank 241-C-106 due to high temperature in tank	Criticality in waste tank	F1	E2
106C-04Aa	Release of radioactive and/or hazardous material from Tank 241-C-106 due to flammable gas content of the waste causing an exothermic reaction in waste tank	High flammable gas content in tank sludge layer due to chemical reaction	F2	E1
106C-06D	Release of contamination from Tank 241-C-106 pump pit and potential worker injury due to fire	Fire in or near pump pit due to vehicle fuel spill and burn	F2	E1
106C-06L	Release of contamination from Tank 241-C-106 pump pit due to fire/explosion affecting the structural integrity	Fire/explosion in pump pit	F2	E1
106C-10J	Release of radioactive and/or hazardous material from Tank 241-C-106 due to tank structural damage, HEPA damage caused by high temperature	Fire in or around ventilation system	F2	E3
106C-11E	Release of unfiltered tank atmosphere from Tank 241-C-106 due to damaged ductwork	Damage to ventilation ductwork upstream of filters	F3	E2
106C-11J	Release of radioactive and/or hazardous material from Tank 241-C-106 due to HEPA damage, beyond 200 F design	Exhauster heater overheat	F3	E1

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
106C-11K	Release of radioactive and/or hazardous material from Tank 241-C-106 due to HEPA filter damage, spread of contamination caused by high temperature in ventilation system	Fire in exhauster ductwork	F2	E1
106C-11L	Release of radioactive and/or hazardous material from Tank 241-C-106, through HEPA filter path, due to human error in installation of filter	Improper installation of HEPAs	F3	E1
106C-11M	Release of radioactive and/or hazardous material from Tank 241-C-106 due to damaged HEPA filters	Event that damages HEPAs	F3	E1
106C-110	Release of radioactive and/or hazardous material from Tank 241-C-106 due to loss of filtration	HEPA filter blowout	F2	E1
106C-12F	Release of radioactive and/or hazardous material from Tank 241-C-106 tank due to waste reaction in tank	Added chemicals to tank instead of normal water addition	F2	E2
107AN-01-LEVE01	Release of caustic material from truck tank due to leak (aerosol spray)	Open valve on truck with pressurized tank transfer.	F3	E2
107AN-01-LEVE02	Release of caustic material from truck tank due to leak (aerosol spray)	Truck tank leak	F2	E2
107AN-01-TEMP02	Spray release of caustic material from truck tank due to high temperature	Fire in gas tank	F1	E2
107AN-02-FLOW01	Release of radioactive aerosols from Tank 241-AN-107 due to surface chemical reaction	Transfer of incompatible chemical to tank via chemical addition system due to vendor or paperwork error	F3	E2
107AN-02-FLOW02	Release of toxic vapors from Tank 241-AN-107 due to surface chemical reaction	Transfer of incompatible chemical to tank via chemical addition system due to vendor or paperwork error	F3	E2
107AN-02-PRES	Release of caustic aerosol from caustic truck transfer piping due to spray leak	Piping/hose leak initiated by various causes	F3	E2
107AN-02-PRES02	Release of caustic material from transfer piping due to high pressure (aerosol spray)	Hose disconnect	F3	E1
114SX-02.b	Radioactive liquid released from tank pump pit to the ground surface due to inadvertent pumping activity (pool)	Human error (not normal activity)	F1	E2
114SX-04.b.1.b.1b	Release of radioactive aerosols from Tank 241-SX-114 head space to atmosphere due to failure of exhaust ducting from seismic event (mechanical disruption)	Ducting failure from seismic activity	F1	E1
114SX-04.c.1	Release or radioactive aerosols from Tank 241-SX-114 head space to atmosphere due to mechanical failure of exhauster HEPA filter	Plenum structure failure pierces filter	F2	E2
114SX-04.c.2.a	Release of radioactive aerosols from Tank 241-SX-114 head space to atmosphere due to exhauster HEPA filter seal failure	HEPA filter seal failure	F3	E2
114SX-04.c.2.b	Release of radioactive aerosols from Tank 241-SX-114 head space to atmosphere due to exhauster defective HEPA filter	Defective HEPA filter	F3	E2

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
114SX-04.c.2.c	Release of radioactive aerosols from Tank 241-SX-114 head space to atmosphere due to exhauster HEPA filter deterioration	Deteriorated HEPA filter	F3	E2
114SX-04.c.2.d	Release of radioactive aerosols from Tank 241-SX-114 head space to atmosphere due to exhauster HEPA filter installation errors	Improper installation (human error)	F2	E2
114SX-05.b.2	Release of radioactive aerosols from Tank 241-SX-114 head space to atmosphere due to sudden flashing of water added to tank for cooling	Flashing (adding cold liquid to hot tank contents)	F0	E2
114SX-05.c.2c	Release pf radioactive gases and aerosols as well as direct radiation from Tank SX-114 due to criticality	Criticality (difficult to achieve concentration needed and difficult to obtain configuration required)	F1	E1
114SX-05.d	Release of radioactive aerosols from Tank 241-SX-114 head space to atmosphere due to localized fire/explosion of flammable gas	Core Sampling through a pocket of gas large enough to exceed local LFL with ignition source (spark) creates local fire/explosion	F3	E1
204AR-01H	Release of airborne and waterborne contaminates outside building on track spur, and potential contamination in unloader room from rail car due to spilling rail car contents	Rail car rupture due to collision with other or a derailment	F2	E2
204AR-01I	Release of airborne and waterborne contaminates outside building on track spur, and potential contamination in unloader room from rail car due to leak	Rail car leak due to tanker corrosion or other degradation	F2	E2
204AR-02A	Release of liquid radioactive material and toxic chemicals outside and inside the 204AR building from the trailer due to collision which causes a spill	Tank trailer damage due to running into the building and causing the tank contents to spill	F2	E1
204AR-02B	Release of radioactive material and toxic chemicals from trailer due to structural degradation of trailer	Tank trailer damaged due to corrosion or other degradation	F2	E1
204AR-07A	Release of liquid radioactive waste and high airborne in unloading room from the Tank 241-AY-102 due to reverse pumping of Tank 241-AY-102 contents back to 204-AR	Pump in pit 02D starts and pumps back to the 204-AR building through the transfer piping and leaks	F2	E2
204AR-09A	Release of airborne and waterborne contamination from the sump pit due to ruptured piping during transfer.	Rupture of transfer piping section above the sump pit	F2	E2
204AR-09B	Release of airborne and radiation contamination in the unloader room from trailer or rail car leak due to high level in sump pit	Catastrophic leak from a large liquid source such as a trailer or rail car	F2	E2
204AR-09C	Release of airborne and radiation contamination in the unloader room from rail car due to gross overfilling of catch tank	Gross overfilling of catch tank either from large source such as the trailers or rail cars or continual pumping of transfer water through a leaky pipe	F2	E2

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
204AR-09D	Release of radioactive liquid waste in the unloader room from the rail car or trailer due to failed rail car or trailer	Failed tank car or rail car (initially full of liquid waste) overflowing the catch tank and sump pit	F2	E1
204AR-11F	Release of airborne radiological contamination through the ventilation stack from the unloader room atmosphere due to fire in ventilation ducting	Fire in ventilation ducting resulting in damage to the HEPA filters and release to the atmosphere	F2	E1
244AR-01.b.04	Release of radioactive aerosols from the facility exhaust stack due to filter failure	HEPA filter fails	F3	E1
244AR-01.c.09	Release of radioactive aerosols from vessel headspace into canyon atmosphere due to flammable gas ignition	Ignition of flammable gas that has collected in piping and tank dome	F2	E2
244AR-02.a.03	Release of radioactive liquid in the form of aerosols contained in a cell to the exterior of the 244-AR facility due to ignition of flammable gas	Fire/explosion from hydrogen buildup	F1	E2
244AR-02.a.07	Release of radioactive aerosols from vessel headspace to building atmosphere with eventual release outside facility due to overfilling of sump causing tank failure	Rain or snow water intrusion	F1	E2
244AR-03.a.04	Release of radioactive aerosols into cell due to ignition of flammable gas in 244-AR Vault tank headspace	Fire/explosion due to ignition of accumulated flammable gas	F2	E2
244AR-03.a.05	Release of radioactive aerosols from tanks headspace due to ventilation system blockage	Ventilation and risers blocked while jetting occurring	F2	E2
244AR-03.a.08	Release of radioactive aerosols created by boiling waste to the cell atmosphere	Steam being supplied to tank heating/cooling coils	F3	E2
244AR-03.a.09	Release of radioactive aerosols created by criticality to the cell atmosphere	Criticality in waste	F1	E2
244AR-05.a.02	Release of radioactive material from facility due to seismic event which causes building collapse without cell collapse	Seismic event damages facility structure	F2	E2
2727W-02	Release of hazardous material from 2727-W due to sodium fire	Vehicle crashes into building and ignites sodium	F1	E1
2727W-03	Release of hazardous material from 2727-W due to sodium fire	Lightning	F2	E1
2727W-04	Release of hazardous material from 2727-W due to sodium fire	Overhead power line falls through building	F1	E1
2727W-05	Release of hazardous material from 2727-W due to sodium fire	Nitrogen tank overpressurizes sodium tank, ignites sodium	F3	E1
2727W-06	Release of hazardous materials from 2727-W due to sodium-water reactions	High wind or tornado destroys building with rain/snow	F2	E1
BND-02	Release of radioactive aerosols from tank due to ignition of combustibles during preparation for bonding	Drilling holes for bonding attachments causes sparks when flammable gases or materials are present	F2	E1

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
CCF-01	Radioactive and hazardous release from tanks due to extended loss of ventilation (over 6 months)	Sustained loss of offsite power	F1	E2
CCF-07	Release of radioactive and hazardous materials from tank due to overfill	Disabled or unavailable staff to terminate transfer	F3	E2
CCF-20	Release of radioactive and hazardous aerosols/vapors from tanks due to chemical reactions between waste and added materials	Reactive chemical additions to two tanks	F2	E1
CDP-10	Release of radioactive contamination to soil surface from excavation or drilling in cribs, ditches or ponds that disturbs radioactive material	Excavation or drilling	F3	E2
COB-04	Release of radioactive and/or hazardous material from COB lid due to overflow of COB during transfer (pool)	Leak into COB with floor drain plugged, leak detector failed	F3	E2
COB-08	Release of radioactive and/or hazardous material from COB due to over filling of COB (pool)	Transfer pipe or riser rupture, backfilling lower part of COB then filling COB via the floor drain	F3	E2
CP-MSP-01	Release of radioactive or toxic material to soil surface (pool) from transfer line due to puncture of line during transfer	Human error caused puncture to transfer line during push operations	F1	E2
CP-MSP-08	Release of radioactive or toxic material to atmosphere from MISF Miscellaneous Inactive Storage Facilities due to flammable gas deflagration	Human error AND Mechanical failure of probe	F2	E2
CRN-03-IA	Release of radioactive and/or toxic materials from facility due to containment top collapse	Human error results in excessive weight on top of containment	F3	E1
CRN-03-IB	Release of radioactive and/or toxic materials from facility due to MISF containment collapse	Human error results in excessive weight on top of containment	F3	E2
CRN-04-IA	Release of radioactive and/or toxic materials from facility due to MISF containment collapse	Crane or rigging failures drop load resulting in large impact to top of containment	F2	E1
CRN-04-IB	Release of radioactive and/or toxic materials from facility due to MISF containment collapse	Crane or rigging failures drop load resulting in large impact to top of containment	F2	E2
CRN-05	Release of radioactive and/or toxic materials from pits and risers due to fuel tank fire in crane or support vehicle (see In-Tank Equipment Installation for tank fires)	Human error in positioning crane load	F3	E2
CRN-06	Release of radioactive and/or toxic materials from pits and risers due to fuel tank fire in crane or support vehicle (see In-Tank Equipment Installation for tank fires)	Mechanical failure in positioning crane load	F3	E2
CRN-07	Release of radioactive and/or toxic materials from pits and risers due to fuel tank fire in crane or support vehicle (see In-Tank Equipment Installation for tank fires)	Crane hits electrical lines/supplies	F3	E2

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
CRN-08	Release of radioactive and/or toxic materials from pits and risers due to fuel tank fire in crane or support vehicle (see In-Tank Equipment Installation for tank fires)	Lightning	F3	E2
CRN-09	Release of radioactive and/or toxic materials from ventilation system due to crane damage	Human error in positioning crane load	F3	E2
CRN-09-I	Release of radioactive and/or toxic materials from ventilation system due to damage caused by crane operation	Human error in positioning crane load	F3	E1
CRN-10	Release of radioactive and/or toxic materials from ventilation system due to crane damage	Mechanical failure in positioning crane load	F3	E2
CRN-10-I	Release of radioactive and/or toxic materials from ventilation system due to damage caused by crane operation	Mechanical failure in positioning crane load	F2	E1
CRN-11-IA	Release of radioactive and/or toxic materials from facility due to containment top collapse or equipment damage by boom failure	Human error: improper load assembly, rigging, crane overloaded	F3	E1
CRN-11-IB	Release of radioactive and/or toxic materials from facility due to equipment damage by boom failure	Human error: improper load assembly, rigging, crane overloaded	F3	E1
CRN-11-IC	Release of radioactive and/or toxic materials from facility due to containment top collapse damage by boom failure (pool)	Human error: improper load assembly, rigging, crane overloaded	F3	E2
CRN-12-IA	Release of radioactive and/or toxic materials from facility due to containment top collapse or equipment damage by boom failure	Mechanical failure: corrosion, faulty materials	F2	E1
CRN-12-IB	Release of radioactive and/or toxic materials from facility due to equipment damage by boom failure	Mechanical failure: corrosion, faulty materials	F2	E1
CRN-12-IC	Release of radioactive and/or toxic materials from facility due to containment top collapse by boom failure (pool)	Mechanical failure: corrosion, faulty materials	F2	E2
CRN-13-IA	Release of radioactive and/or toxic materials from below ground facility due to containment top collapse or equipment damage by boom failure	High wind or seismic event	F2	E1
CRN-13-IB	Release of radioactive and/or toxic materials from above ground facility due to equipment damage by boom failure	High wind or seismic event	F2	E1
CRN-13-IC	Release of radioactive and/or toxic materials from facility due to containment top collapse damage by boom failure	High wind or seismic event	F2	E2
CRN-18	Release of radioactive or toxic material from above ground tank equipment due to dropping crane load	Human error: improper load assembly, rigging, crane overloaded	F3	E1
CRN-18-I	Release of radioactive or toxic material from aboveground facility equipment due to dropping crane load	Human error: improper load assembly, rigging, crane overloaded	F3	E1

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
CRN-19	Release of radioactive or toxic material from above ground tank equipment due to dropping crane load	Mechanical failure: corrosion, faulty materials (filter crush)	F3	E1
CRN-19-I	Release of radioactive or toxic material from aboveground facility equipment due to dropping crane load	Mechanical failure: corrosion, faulty materials	F2	E1
CRN-20	Radioactive or toxic material release from pit or riser due to dropping crane load onto above ground tank equipment	High wind or seismic event (filter crush)	F3	E1
CRN-20-I	Release of radioactive or toxic material from aboveground facility equipment due to dropping crane load	High wind or seismic event	F2	E1
CRN-21-IB	Release of radioactive or toxic materials from aboveground facility bottom due to loss of vertical load control, dropping crane load into facility (surface pool)	Human error: improper load assembly, rigging, positioning error	F3	E2
CRN-22-IB	Release of radioactive or toxic materials from aboveground facility bottom due to loss of vertical load control, dropping crane load into facility (surface pool)	Mechanical failure: corrosion, faulty materials, hydraulics	F2	E2
CRN-23	Release of radioactive or toxic materials from tank due to loss of vertical load control, dropping crane load into tank, onto tank bottom (subsurface leak)	High wind or seismic event	F3	E3
CRN-23-IA	Release of radioactive or toxic materials from underground facility bottom due to loss of vertical load control, dropping crane load into facility (subsurface leak)	High wind or seismic event	F2	E1
CRN-23-IB	Release of radioactive or toxic materials from aboveground facility bottom due to loss of vertical load control, dropping crane load into facility	High wind or seismic event	F2	E2
CRN-25-IB	Release of radioactive or toxic material from aboveground MISF due to swinging load into equipment caused by loss of lateral load control	Human error: improper load assembly, rigging, positioning error	F3	E1
CRN-26-IB	Release of radioactive or toxic material from aboveground MISF due to swinging load into equipment caused by loss of lateral load control	Mechanical failure: corrosion, faulty materials, hydraulics, outriggers in soft soil	F2	E1
CRN-27-IB	Release of radioactive or toxic material from aboveground MISF due to swinging load into equipment caused by loss of lateral load control	Mechanical failure: corrosion, faulty materials, hydraulics, outriggers in soft soil	F2	E1
CVR-05	Release of radioactive or hazardous material through combustion or fire/explosion of materials in pit due to human error	Failure to sniff or improper sniffing	F3	E1
CVR-15-I	Release of radioactive or hazardous material from pit upon dropping or falling coverblocks or pieces of coverblocks	Coverblock hooks fail or pieces of degraded coverblock fall into pit	F3	E1
EE-11	Release of radioactive and hazardous materials from tank due to overfilling	Water line breaks and overfills tank	F2	E2

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
EE-17	Radioactive and hazardous material release from inactive equipment due to excavation error	Excavation into abandoned or inactive equipment	F3	E1
I-222S-1-CMP-C	Release (potential spray leak) of 222-S lab waste to atmosphere in diversion box or 244-S Pump Pit due to increased corrosion from failure to add sodium hydroxide	Human error - failure to add sodium hydroxide	F3	E2
I-222S-1-LVL-A	Release (steam) of aerosols and entrained particulates to atmosphere through ventilation due to over pressurization of 244-S DCRT caused by sending just steam to tank farm	Human error - failing to shut off steam after Tank 219-S-102 is empty	F3	E2
I-222S-1-RXN-A	Release of aerosols and/or toxic vapors from receiver tank due adverse chemical reactions from incompatible waste	Transfer of incompatible waste	F3	E2
I-222S-2-FLW-C	Release of aerosols and/or toxic vapors from receiver tank due adverse chemical reactions from incompatible waste	Human error - incorrect valve line up	F2	E2
I-222S-2-LEK-B	Release of 222-S lab waste to the atmosphere due to spray leak at the diversion box or pump pit, caused by corrosion in the pipe	Corrosion in pipe line	F1	E2
I-222S-2-LEK-C	Release of 222-S lab waste to the atmosphere due to spray leak at the rupture of the line	Inadvertent excavation of line	F2	E2
I-222S-2-LEK-E	Release of 222-S lab waste to the atmosphere due to spray leak at the diversion box or pump pit, caused by rupture at pipe connections from a seismic event	Seismic event	F2	E2
I-222S-2-PRS-A	Release (steam) of aerosols and particulates to atmosphere through ventilation due to over pressurization of 244-S DCRT caused by sending just steam to tank farm	Steam reducer valve fails open	F3	E2
I-242A-1-LEK-B	Release of waste from Feed Tank 241-AW-102 to the atmosphere due to spray leak at the diversion box or pump pit, caused by corrosion in the pipe	Corrosion in pipe line	F1	E2
I-242A-1-LEK-C	Release of waste from Feed Tank 241-AW-102 to the atmosphere due to spray leak at the rupture of the line	Inadvertent excavation of line causes spray leak	F2	E2
I-242A-1-LEK-E	Release of waste from Feed Tank 241-AW-102 to the atmosphere due to spray leak at the diversion box or pump pit, caused by rupture at pipe connections	Seismic event causes spray leak	F2	E2
I-242A-2-FLW-A	Release of aerosols to the atmosphere through unsealed cracks in the cover blocks due to over pressurization of the receiver tank and possible structural damage to the tank	Human error - pump is run at maximum speed	F3	E2
I-242A-2-FLW-B	Release of aerosols to the atmosphere through 12 inch opening in inlet station due to over pressurization of the receiver tank and possible structural damage to the tank	Human error - pump is run at maximum speed	F3	E2

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
I-242A-2-LEK-B	Release of slurry tank waste to the atmosphere due to spray leak at the diversion boxes or pump pit, caused by corrosion in the pipe	Corrosion in pipe line	F1	E2
I-242A-2-LEK-C	Release of slurry tank waste to the atmosphere due to spray leak at the rupture of the line	Inadvertent excavation of line causes spray leak	F2	E2
I-242A-2-LEK-E	Release of slurry tank waste to the atmosphere due to spray leak at the diversion box or pump pit, caused by rupture at pipe connections	Seismic event causes leak	F2	E2
I-242A-2-VSC-A	Release of aerosols in receiver tank due to tank burp from over concentration, potential to generate conditions similar to Tank 241-SY-101, "Tank Burp" due to hydrogen being trapped in thick solution (lower energy than tank bump)	Human error - over concentration of slurry at evaporator	F2	E2
I-242A-3-FLW-A	Release of aerosols to the atmosphere through unsealed cracks in the cover blocks due to over pressurization of the feed tank and possible structural damage to the tank	Uncontrolled pot dump at evaporator (loss of electricity or air)	F3	E2
I-242A-3-FLW-B	Release of aerosols to the atmosphere through 12 inch opening in inlet station due to over pressurization of the feed tank and possible structural damage to the tank	Uncontrolled pot dump at evaporator (loss of electricity or air)	F3	E2
I-242A-6-FLW-B	Release of diluted high level tank waste from Feed Tank 241-AW-102 caused by overfilling Tank 241-AW-102 and annulus, aggravated by an uncontrolled evaporator dump when a raw water leak occurs in evaporator condenser room	Rupture of raw water line in condenser/pump room	F3	E2
I-242A-7-FLW-A	Release of aerosols through the risers due to loss of instrument air which causes an uncontrolled evaporator dump and failure to detect changes in feed tank pressure	Compressor fails and 241-AW Tank Farm air supplied from 242-A	F1	E2
I-242A-7-FLW-B	Release of aerosols through the risers due to loss of instrument air which causes an uncontrolled evaporator dump and failure to detect changes in feed tank pressure	Valve inadvertently closed, 241-AW Tank Farm air supplied from 242-A	F1	E2
I-242A-7-FLW-C	Release of aerosols through the risers due to loss of instrument air which causes an uncontrolled evaporator dump and failure to detect changes in feed tank pressure	Filter plugged, 241-AW Tank Farm air supplied from 242-A	F1	E2
I-242S-2-FLW-A	Release of tank waste diluted with contaminated fire water to the soil due to flooding the pump room from a fire main break and pumping the water to Tank 241-SY-102 which overfills the tank and floods pit through risers	Break in fire main	F1	E2
I-242S-2-FLW-E	Release of high level waste to the ground outside the 242-S building due to unmitigated reverse flow to the pump room from Tank 241-SY-102	Human error - incorrect valve line up	F2	E2
I-242S-2-LEK-B	Release of contaminated water to the atmosphere due to spray leak at the diversion box or pump pit, caused by corrosion in the pipe	Corrosion in pipe line causes spray leak	F1	E2

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
I-242S-2-LEK-C	Release of contaminated water to the atmosphere due to spray leak at the rupture of the line from excavation	Inadvertent excavation of line causes spray leak	F2	E2
I-242S-2-LEK-E	Release of contaminated water to the atmosphere due to spray leak at the diversion box or pump pit, caused by rupture at pipe connections from seismic event	Seismic event	F2	E2
I-242S-4-FLW-C	Release of high level waste to the ground outside the 242-S building due to unmitigated reverse flow to the condenser room	Human error - incorrect valve line up	F2	E2
I-242S-4-FLW-D	Release of tank waste diluted with contaminated water to the soil due to flooding the condenser room which is pumped to Tank 241-SY-102 and overfills the tank and floods pit through risers	Break in fire main	F1	E2
I-242S-4-LEK-E	Release of contaminated water to the atmosphere due to spray leak at the diversion box or pump pit, caused by rupture at pipe connections from an seismic event	Seismic event causes spray leak	F2	E2
I-BPLANT-1-CMP-B	Release (spray leak) of low level waste at diversion box from transfer of low pH material resulting in increased corrosion in pipe	Human error - failure to add sodium hydroxide leads to corrosion and leak in pipe	F3	E2
I-BPLANT-2-FLW-D	Release of aerosols and/or toxic vapors from receiver tank due to transfer of incompatible waste from B Plant	Human error - communication error between B Plant and TWRS causes transfer of incompatible waste	F3	E2
I-BPLANT-2-LEK-B	Release of low level waste to the atmosphere due to spray leak at the diversion box or pump pit, caused by corrosion in the pipe	Corrosion in pipe line causes spray leak	F1	E2
I-BPLANT-2-LEK-C	Release of low level waste to the atmosphere due to spray leak at the rupture of the line from excavation	Inadvertent excavation of line causes spray leak	F2	E2
I-BPLANT-2-LEK-E	Release of low level waste to the atmosphere due to spray leak at the diversion box or pump pit, caused by rupture at pipe connections from seismic event	Seismic event causes spray leak	F2	E2
I-PFP-1-AGT-A	Release of fission product gases and aerosols from receiver tank due to potential for solids to collect in D-5, If mixed later, potential for composition of next batch to exceed Criticality Prevention Specifications (CPS); potential "Criticality Issue"	Human error or agitator fails results in criticality	F3	E2
I-PFP-1-CMP-B	Release of fission product gases and aerosols from receiver tank due to, potential for localized concentration of fissile materials in receiver tank from failure to add ferric nitrates; potential "Criticality Issue"	Failure to add ferric nitrates, results in criticality	F3	E2

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
I-PFP-1-CMP-D	Release of fission product gases and aerosols from receiver tank due to excess fissile material in waste, potential to exceed criticality prevention specification requirements for shipment; potential "Criticality Issue"	Excess fissile content added to waste results in criticality	F3	E2
I-PFP-2-LEK-B	Release of TRU mixed waste to the atmosphere due to spray leak at the diversion box or pump pit, caused by corrosion in the pipe	Corrosion in pipe line causes spray leak	F1	E2
I-PFP-2-LEK-C	Release of TRU mixed waste to the atmosphere due to spray leak at the rupture of the line	Inadvertent excavation of line	F2	E2
I-PFP-2-LEK-E	Release of TRU mixed waste to the atmosphere due to spray leak at the diversion box or pump pit, caused by rupture at pipe connections	Seismic event causes spray leak.	F2	E2
I-PFP-2-TMP-B	Release (steam) of aerosols and entrained particulate from 244-TX ventilation system due to saturating HEPAs with steam sending higher pressure steam to steam jet, gassing it out	Failure of steam reducer	F2	E2
I-PFP-3-LEK-B	Release of TRU mixed waste to the atmosphere due to spray leak at the diversion box or pump pit, caused by corrosion in the pipe	Corrosion in pipe line causes spray leak	F1	E2
I-PFP-3-LEK-C	Release of TRU mixed waste to the atmosphere due to spray leak at the rupture of the line	Inadvertent excavation of line	F2	E2
I-PFP-3-LEK-E	Release of TRU mixed waste to the atmosphere due to spray leak at the diversion box or pump pit, caused by rupture at pipe connections	Seismic event causes spray leak	F2	E2
I-PUREX-1-AGT-B	Release (spray leak) of TRU waste from PUREX at diversion box due to leak from increased corrosion caused by transfer of acidic waste	Human error or mechanical failure - agitator fails or is not turned on	F3	E2
I-PUREX-1-CMP-B	Release (spray leak) of TRU waste from PUREX at diversion box due to leak from increased corrosion caused by transfer of acidic waste	Human error - failure to add sodium hydroxide to low level waste results in corrosion and causes spray leak	F3	E2
I-PUREX-1-LVL-A	Release of aerosols from Tank 241-AW-105 through cracks in the cover block due to pressurizing tank from transfer of steam	Human error - failure to shut off steam jet when U-3 is empty	F3	E2
I-PUREX-2-LEK-B	Release of TRU waste from PUREX to the atmosphere due to spray leak at the diversion box or pump pit, caused by corrosion in the pipe	Corrosion in pipe line causes spray leak	F1	E2
I-PUREX-2-LEK-C	Release of TRU waste from PUREX to the atmosphere due to spray leak at the rupture of the line from inadvertent excavation	Inadvertent excavation of line causes spray leak	F2	E2
I-PUREX-2-LEK-E	Release of TRU waste from PUREX to the atmosphere due to spray leak at the diversion box or pump pit, caused by seismic event	Seismic event causes spray leak	F2	E2

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
I-PUREX-2-PRS-A	Release (steam) of aerosols and particulates through cracks in the cover block from the receiver tank due to tank pressurization which gases out the steam jet	Steam reducer fails	F2	E2
I-PUREX-3-AGT-B	Release (spray leak) of TRU waste from PUREX at diversion box due to leak from increased corrosion caused by transfer of acidic waste	Agitator fails or is not turned on results in corrosion and causes spray leak	F3	E2
I-PUREX-3-CMP-B	Release (spray leak) of TRU waste from PUREX at diversion box due to leak from increased corrosion caused by transfer of acidic waste	Human error - failure to add sodium hydroxide to low level waste results in spray leak	F3	E2
I-PUREX-3-CMP-E	Release of fission product gases and aerosols from receiver tank due to criticality caused by exceeding Criticality Prevention Specifications for shipment from PUREX	Transfer of L Cell sump water to Tank F-18 and eventually to the Tank Farms	F3	E2
I-PUREX-3-LVL-A	Release of aerosols from Tank 241-AW-105 through cracks in the cover block due to pressurizing tank from transfer of steam	Human error - failure to shut off steam jet when U-3 is empty	F3	E2
I-PUREX-4-FLW-B	Release (ground surface) of high level tank waste diluted with flush water from the receiver tank due to overfilling from sending excess water	Block valve on flush water inadvertently left opened or leaking	F3	E2
I-PUREX-4-LEK-B	Release of TRU waste from PUREX to the atmosphere due to spray leak at the diversion box or pump pit, caused by corrosion in the pipe	Corrosion in pipe line causes spray leak	F1	E2
I-PUREX-4-LEK-C	Release of TRU waste from PUREX to the atmosphere due to spray leak at the rupture of the line from excavation	Inadvertent excavation of line causes spray leak	F2	E2
I-PUREX-4-LEK-E	Release of TRU waste from PUREX to the atmosphere due to spray leak at the diversion box or pump pit, caused by rupture at pipe connections from seismic event	Seismic event causes spray leak	F2	E2
I-PUREX-4-PRS-A	Release of aerosols and particulates through cracks in the cover block from the receiver tank due to tank pressurization which gases out the steam jet	Steam reducer fails	F2	E2
I-TPLANT-1-CMP-B	Release (spray) of low level waste at diversion box from transfer of lower pH material resulting in increased corrosion in pipe	Human error - failure to add sodium hydroxide causes corrosion and associated spray leak	F3	E2
I-TPLANT-2-CMP-A	Release (steam) of aerosols and entrained particulates to atmosphere through ventilation due to over pressurization of 244-S DCRT caused by sending just steam to the tank farm	Human error - steam block valve inadvertently opened or failure to close valve when Tank 15-1 is low	F3	E2
I-TPLANT-2-LEK-B	Release of low level waste to the atmosphere due to spray leak at the diversion box or pump pit	Corrosion in pipe line causes spray leak	F1	E2
I-TPLANT-2-LEK-C	Release of low level waste to the atmosphere due to spray leak at the rupture of the line from excavation	Inadvertent excavation of line causes spray leak	F2	E2

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
I-TPLANT-2-LEK-E	Release of low level waste to the atmosphere due to spray leak at the diversion box or pump pit, caused by rupture at pipe connections from seismic event	Seismic event causes spray leak	F2	E2
I-UPLANT-1-LEK-B	Release of low level waste to the ground at the rupture of the line	Inadvertent excavation of line	F1	E2
ITK-05	Release of radioactive and/or hazardous material from point of in-tank access (non-fire, non-explosion) due to intrusive activity	Tank burps from intrusive activity	F2	E1
ITK-05-I	Release of radioactive and/or hazardous material from point of in-facility access due to gas release from in-facility waste during intrusive activity (non-fire, non-explosion)	Gas release from in-facility waste during intrusive activity	F2	E1
ITK-06	Release of radioactive and/or hazardous material from point of in-tank access (non-fire, non-explosion) due to criticality	Intrusive activity causes critical mass	F1	E2
ITK-06-I	Release of radioactive and/or hazardous material from point of in-facility access due to criticality within the in-facility waste during intrusive activity (non-fire, non-explosion)	Criticality from intrusive activity	F1	E2
ITK-08-I	Release of radioactive or toxic material from facility due to in-facility fire or explosion during intrusive activity	Exothermic reaction of incompatible materials in facility	F2	E2
ITK-09-I	Release of radioactive or toxic material from facility due to in-facility fire or explosion during intrusive activity	Failure to bond components or incorrect bonding	F2	E2
ITK-10-I	Release of radioactive or toxic material from facility due to in-facility fire or explosion during intrusive activity	Spark from equipment or tools provide an ignition source	F3	E2
ITK-11-I	Release of radioactive or toxic material from facility due to in-facility fire or explosion during intrusive activity	Lightning, range fire, or seismic event ignites facility vapors	F1	E2
ITK-FR-03	Release of radioactive aerosols from tank and/or receiver due to equipment jam in riser	Equipment becomes lodged in riser, efforts to remove pull riser out of tank causing breach of tank & receiver containment	F1	E2
ITK-FR-08	Release of radioactive aerosols/vapors from flex receiver due to structural failure	High winds tear flex receiver bag	F3	E2
ITK-FR-13	Release of radioactive aerosols/vapors from flex receiver due to buildup and ignition of flammable gas in receiver	Hydrogen gas buildup in tank/riser that travels into receiver with ignition source (spark from herculite or equipment)	F1	E2
ITK-FR-22	Release of radioactive aerosols from flex receiver due to tank gas release	Tank gas release pressurizes bag and causes bag to rupture	F1	E2
LDUA 5-40	Release of contamination from TRIC and tank riser due to damage during wind storm	High winds	F3	E1

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
NP-02	Radioactive and hazardous material releases from tanks and ventilation systems due to fire	Lightning strikes ventilation system	F2	E1
NP-03	Radioactive and hazardous material releases from tanks due to fire in tanks	Lightning strikes riser in tank farm	F2	E2
NP-05	Radioactive and hazardous material release from tanks, nearby ground surfaces, and ventilation systems due to above grade disturbances	High winds	F1	E2
NP-15	Radioactive and hazardous material release from isolated or abandoned equipment due to fire	Hydrogen producing chemical reactions in isolated or abandoned equipment	F3	E1
OGT-EXT3-01B	Release of radioactive or hazardous material from the primary pipe due to leak caused by truck crash into piping system	Human error, line struck by truck	F2	E2
OGT-FLOW1-02	Release of radioactive or hazardous material from pit overflow due to primary pipe leak caused by over-rated pump	Incorrect pump installed creates excessive flow and pressure on OGT system eroding EPDM pipe causing leak to secondary pipe with drain in pit plugged	F2	E2
OGT-FLOW1-03B	Release of radioactive or hazardous material from the primary pipe due to misdirected flow of waste through flush line	JR-1 (3-way valve) mispositioned to flush, two check valves fail, flush disconnect fails (check valve), and reverse flow to water truck, drum or onto ground	F1	E2
OGT-FLOW1-04	Release of radioactive or hazardous material from the primary pipe due to valve failure resulting in misdirected flow of waste through flush line to flush water supply truck	JR-1 leak (bleed-by), two check valves fail, and flush disconnect fails and pump started causing reverse flow to flush water truck tank	F1	E2
OGT-FLOW1-06	Release of radioactive or hazardous material from the DCRT due to overflow	Exceed volume available in DCRT/insufficient volume available, condition goes unnoticed until overflow occurs	F2	E2
OGT-FLOW2-01B	Release of radioactive or hazardous material from the primary pipe due to leak caused by incorrect pump installed	Incorrect pump installed creates excessive flow and isolation valve closed on secondary pipe, erosion of EPDM and pressurization of secondary pipe causing leaks from flanges gasket within concrete shield	F2	E2
OGT-FLOW2-03B	Release of radioactive or hazardous material from the primary pipe due leak caused by incorrect pump installed	Installation of incorrect pump, failure of inner pipe and isolation valves closed on secondary pipe drains causing leak from failed welds on flange within the concrete shield	F1	E2

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
OGT-PRES1-01	Release of radioactive or hazardous material from overflow of pit due to leak caused by high pressure	Heat up of hydro test by heat tape or high ambient temperature, high pressure results from captive fluid heat up, inner pipe damaged, leaks to secondary pipe and drains back to pits and insufficient drainage in pit	F1	E2
OGT-REAC1-01	Release of radioactive or hazardous material from overflow of pit due to primary pipe leak cause by chemical reaction	Pumping from multiple tanks to single OGT, potential for adverse chemical reactions in pipeline damaging inner pipe, leaks to secondary pipe and drains back to pits and insufficient drainage in pit	F1	E2
OGT-TEMP1-02	Release of radioactive or hazardous vapors/aerosols from the primary pipe due to spray leak caused by high temperatures	Vehicle accident above ground starts fire, melt the EPDM hose causing a leak to secondary pipe, pumping occurring, fire fails gasket and facilitates a release to atmosphere	F1	E2
OGT-TEMP1-03	Release of radioactive or hazardous material from overflow of pit due to leak caused by high temperature	High temperature flush water fails inner pipe causing leak to secondary pipe, drain to pit with insufficient drainage in pit	F1	E2
RSR-06-I	Release of radioactive or toxic material from facility due to in-facility fire or explosion during riser removal activity	Failure to bond components or incorrect bonding allows electrostatic spark	F2	E2
RSR-07-I	Release of radioactive or toxic material from facility due to in-facility fire or explosion during riser removal activity (chosen to represent all organic nitrate tanks)	Spark from failure to use non-sparking tools or sparks from welding, cutting, grinding, etc.	F3	E2
TFS-1	Release of radioactive or hazardous waste liquid from overflow of 244-S vault to the 244-S pump pit due to syphon effect on Tank 241-SY-102 (pump does not overflow)	Human Error - failure to close isolation valve (or valve malfunction) following waste transfer which allows flow to continue (syphon) when pump is stopped	F3	E2
VEH-01	Release of radioactive or toxic materials from cask due to fire caused by vehicle operation	Vehicle catches on fire	F3	E2
VEH-01-I	Release of radioactive or toxic materials from vehicle carrying MISF samples or contaminated equipment due to vehicle fire	Vehicle catches on fire	F2	E2
VEH-02	Release of radioactive or toxic material from cask due to damage to transport casks during seismic event	Seismic event	F1	E1
VEH-02-I	Release of radioactive or toxic material from MISF samples in transport casks due to seismic damage	Seismic event	F1	E1

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
VEH-03	Release of radioactive or toxic material from cask due to damage to transport casks during a high wind/tornado	High wind/tornado	F2	E2
VEH-03-I	Release of radioactive or toxic material from MISF samples in transport casks due to high wind/tornado damage	High wind/tornado	F2	E2
VEH-07-I	Release of radioactive or toxic material from MISF due to riser being sheared off and possibly vehicle gas tank ruptured and fire	Vehicle moving near facility risers	F3	E1
W058-FLOW01	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	Computer failure or human error causing misrouting of material when flow path is not completely connected plus mitigative features failure	F3	E2
W058-FLOW03	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	External leak of valve or valves to the valve pit plus mitigative features failure	F2	E2
W058-FLOW05a	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	Failure of jumper due to misalignment (human error) plus mitigative features failure	F3	E2
W058-FLOW05b	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	Failure of jumper due to gasket failure plus mitigative features failure	F2	E2
W058-FLOW05c	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	Failure of jumper due to corrosion plus mitigative features failure	F2	E2
W058-FLOW07	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	Computer failure or human error causing misrouting of material when flow path is not completely connected plus mitigative features failure	F3	E2
W058-FLOW09	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	External leak of valve or valves to the valve pit plus mitigative features failure	F2	E2
W058-FLOW11a	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	Failure of jumper due to misalignment (human error) plus mitigative features failure	F3	E2
W058-FLOW11b	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	Failure of jumper due to gasket failure plus mitigative features failure	F2	E2
W058-FLOW11c	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	Failure of jumper due to corrosion plus mitigative features failure	F2	E2
W058-FLOW13	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	Open path for pool leak from test riser	F3	E2

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
W058-INTEG01a	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak	Failure of primary and encasement piping due to corrosion plus mitigative features failure	F2	E2
W058-INTEG01b	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak	Failure of primary and encasement piping due to unrecognized material flaw plus mitigative features failure	F2	E2
W058-INTEG01c	Release of radioactive slurry to the soil surface from overflow of a diversion box due to piping system leak	Failure of primary and encasement piping due to corrosion plus mitigative features failure	F2	E2
W058-INTEG01d	Release of radioactive slurry to the soil surface from overflow of a diversion box due to piping system leak	Failure of primary and encasement piping due to unrecognized material flaw plus mitigative features failure	F2	E2
W058-INTEG03a	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak	Failure of primary and encasement piping due to external event (airplane crash, volcanism, etc)	F2	E2
W058-INTEG03b	Release of radioactive slurry to the soil surface from overflow of a diversion box due to piping system leak	Failure of primary and encasement piping due to external event (airplane crash, volcanism, etc)	F2	E2
W058-INTEG05a	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak	Failure of primary and encasement piping due to external event (excavation accident) plus mitigative features failure	F2	E2
W058-INTEG05b	Release of radioactive slurry to the soil surface from overflow of a diversion box due to piping system leak	Failure of primary and encasement piping due to external event (excavation accident) plus mitigative features failure	F3	E2
W058-INTEG07a	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak	Failure of primary and encasement piping due to external event (undermining from broken fluid transfer lines in vicinity) plus mitigative features failure	F3	E2
W058-INTEG07b	Release of radioactive slurry to the soil surface from overflow of a diversion box due to piping system leak	Failure of primary and encasement piping due to external event (undermining from broken fluid transfer lines in vicinity) plus mitigative features failure	F2	E2
W058-INTEG09a	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak	Failure of primary and encasement piping due to freezing	F1	E2
W058-INTEG09b	Release of radioactive slurry to the soil surface from overflow of a diversion box due to piping system leak	Failure of primary and encasement piping due to freezing	F1	E2

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
W058-INTEG11a	Release of radioactive slurry to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak	Failure of primary and encasement piping due to seismic event plus mitigative features failure	F1	E2
W058-INTEG11b	Release of radioactive slurry to the soil surface from overflow of a diversion box due to piping system leak	Failure of primary and encasement piping due to seismic event plus mitigative features failure	F1	E2
W058-INTEG13a	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak	Failure of primary and encasement piping due to corrosion plus mitigative features failure	F2	E2
W058-INTEG13b	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak	Failure of primary and encasement piping due to unrecognized material flaw plus mitigative features failure	F2	E2
W058-INTEG13c	Release of radioactive supernate to the soil surface from overflow of a diversion box due to piping system leak	Failure of primary and encasement piping due to corrosion plus mitigative features failure	F2	E2
W058-INTEG13d	Release of radioactive supernate to the soil surface from overflow of a diversion box due to piping system leak	Failure of primary and encasement piping due to unrecognized material flaw plus mitigative features failure	F2	E2
W058-INTEG14a	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak	Failure of primary and encasement piping due to external event (airplane crash, volcanism, etc) plus mitigative features failure	F2	E2
W058-INTEG14b	Release of radioactive supernate to the soil surface from overflow of a diversion box due to piping system leak	Failure of primary and encasement piping due to external event (airplane crash, volcanism, etc) plus mitigative features failure	F2	E2
W058-INTEG16a	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak	Failure of primary and encasement piping due to external event (excavation accident) plus mitigative features failure	F3	E2
W058-INTEG16b	Release of radioactive supernate to the soil surface from overflow of a diversion box due to piping system leak	Failure of primary and encasement piping due to external event (excavation accident) plus mitigative features failure	F3	E2
W058-INTEG18a	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak	Failure of primary and encasement piping due to external event (undermining from broken fluid transfer lines in vicinity) plus mitigative features failure	F2	E2
W058-INTEG18b	Release of radioactive supernate to the soil surface from overflow of a diversion box due to piping system leak	Failure of primary and encasement piping due to external event (undermining from broken fluid transfer lines in vicinity) plus mitigative features failure	F2	E2

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
W058-INTEG20a	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak	Failure of primary and encasement piping due to freezing	F1	E2
W058-INTEG20b	Release of radioactive supernate to the soil surface from overflow of a diversion box due to piping system leak	Failure of primary and encasement piping due to freezing	F1	E2
W058-INTEG22	Release of radioactive supernate to the soil surface from the underground piping between the SY-A or SY-B valve pit and a diversion box due to piping system leak	Failure of primary and encasement piping due to seismic event plus mitigative features failure	F1	E2
W058-INTEG24	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak	External event (airplane crash, etc)	F1	E2
W058-INTEG26	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak	Seismic event plus mitigative features failure	F1	E2
W058-INTEG28	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak	External event (airplane crash, etc)	F1	E2
W058-INTEG30	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	Seismic event	F1	E2
W058-PRES01	Release of radioactive slurry to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	Water hammer plus mitigative features failure	F3	E2
W058-PRES03	Release of radioactive supernate to the soil surface from overflow in the SY-A or SY-B valve pit due to piping system leak (pool)	Water hammer plus mitigative features failure	F3	E2
XS-01-FLOW01	Release of radioactive aerosols from 244-TX DCRT due to ignition of flammable gas atmosphere	Pressure drop in transfer line releases flammable gas into DCRT atmosphere and ignition source causes deflagration	F2	E2
XS-01-FLOW05	Release of radioactive contaminated liquid from transfer piping to 244-TX-DCRT via the raw water system due to reverse flow of liquid waste (pool)	Mis-valving causes mixing of waste into raw water system that causes leak in the flush pit cover block	F2	E2
XS-01-FLOW06	Release of liquid radioactive waste from saltwell pumping transfer piping in DCRT pump pit to surface due to overflow (pool)	Open jumper in single shell tank pump pit leads to overflowing of pump pit	F3	E2
XS-01-FLOW07	Release of liquid radioactive waste to the soil from transfer piping from SST to DCRT due to leakage (plume)	Pipe failure from various causes	F3	E2
XS-01-PRES01	Release of liquid radioactive waste from damaged transfer piping to 244-TX DCRT due to over pressure (pool)	Use of wrong size pump and closed valve causes over pressure and subsequent pipe failure	F2	E2
XS-01-TEMP01	Release of steam-aerosol from transfer piping in pump pit due to steam hammer and resulting pipe damage	Extended recirculation and consequential heating of saltwell liquid with sudden opening of valve when cover block is open	F3	E2

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
XS-02-FLOW02	Release of aerosols and particulate from DCRT ventilation filter due to transfer of steam from PFP steam jet into DCRT headspace	Human error (failure to shut off steam jet at completion of transfer) which causes DCRT ventilation filter failure	F3	E1
XS-02-FLOW03	Release of toxic gases (oxides of nitrogen) from DCRT due to chemical reaction	Chemical reaction between sodium nitrite (DCRT) and nitric acid (PFP transfer) due to failure to adjust waste pH prior to transfer	F2	E1
XS-02-FLOW04	Release of liquid radioactive waste to soil from transfer pipe (non-pool) subsurface plume	Failure to adjust waste pH prior to transfer causes leak	F2	E2
XS-02-FLOW05	Release of liquid radioactive waste to the soil from PFP transfer piping due to pipe break	Pipe break from various causes	F3	E2
XS-03-LEVE01 XS-21-LEVE (244-S DCRT)	Release of combustion products from 244-TX DCRT due to flammable gas burn in tank atmosphere	Evaporation of DCRT contents causing decreased ability of waste to retain flammable gases and spark source	F2	E2
XS-03-LEVE02 XS-21-LEVE (244-S DCRT)	Release of fission product gases and aerosols from 244-TX DCRT due to criticality	Evaporation of DCRT contents with increased solids settling on DCRT bottom creates critical mass	F3	E2
XS-03-PRES01 XS-21-PRES (244-S DCRT)	Release of liquid aerosols from 244-TX-DCRT due to flammable gas burn in tank atmosphere	Loss of ventilation flow with accumulation of flammable gas and spark source	F2	E2
XS-03-PRES02 XS-21-PRES (244-S-DCRT)	Release of toxic vapors from 244-TX DCRT due to decreased ability to keep vapors in solution (fan on)	Heating of DCRT or chemical adjustment	F3	E1
XS-03-PRES05	Release of toxic vapors from DCRT due to increased concentrations in DCRT atmosphere	Transfer of steam from PFP causing evolution of toxic gases due to heating tank	F2	E2
XS-03-TEMP01	Release of radioactive aerosols from 244-TX DCRT headspace due to positive pressure	Chemical reaction in DCRT causes positive pressure	F2	E1
XS-03-TEMP02	Release of toxic vapor from DCRT due to chemical reaction	Chemical reaction in DCRT toxic vapor	F2	E1
XS-03-TEMP02 XS-21-TEMP (244-S-DCRT)	Release of fission product gases and aerosols from 244-TX DCRT due to criticality	Transfer of material into tank that violates criticality specification	F3	E2
XS-03-TEMP03 XS-21-TEMP (244-S-DCRT)	Release of liquid aerosols from 244-TX-DCRT due to flammable gas burn-fire/explosion in tank atmosphere	Buildup of gases, loss of ventilation, and spark source	F2	E2
XS-03-TEMP04 XS-21-TEMP (244-S-DCRT)	Release of liquid radioactive waste from 244 TX DCRT due to overflow	Freezing temperatures causing raw water line break-leak with leakage to tank causes overflow	F3	E2
XS-05-FLOW01	Release of aerosols and filter media from DCRT ventilation system due to HEPA filter damage	Replacement of exhaust fan with larger capacity fan causes HEPA filter damage	F2	E1

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
XS-05-TEMP01	Release to atmosphere of materials from DCRT ventilation filters and tank due to filter degradation	Fire in ventilation system due to failure of ventilation heater controls	F3	E2
XS-05-TEMP02	Release to atmosphere of materials from DCRT ventilation filters and tank due to filter degradation	Fire in ventilation system due to flammable gas buildup and ignition	F3	E2
XS-06-FLOW01	Release of fission product gases and aerosols from 244-TX DCRT due to criticality	Transfer of inadequately recirculated waste from tank due to failure to appropriately balance flow between recirculation and transfer line causing buildup of solids creating critical mass	F3	E2
XS-06-FLOW04	Release of liquid radioactive waste from transfer piping from an SST to a DCRT due to spray leak (SPUTTER) of saltwell liquor from DCRT pump pit	Pipe failure	F2	E3
XS-06-FLOW05	Release of waste from transfer pipe out of 244-TX-DCRT to the soil due to flow path to soil	Concurrent failure of transfer piping and encasement	F2	E2
XS-07-FLOW01	Release of radioactive waste to soil from transfer piping out of 244-TX DCRT due to leak in primary pipe and encasement	Excavation accident fails primary pipe and encasement	F3	E2
XS-07-FLOW02	Release of radioactive waste to soil from transfer piping out of 244-TX DCRT due to leak in primary pipe and encasement	Corrosion of inner and outer pipe	F3	E2
XS-07-FLOW03	Release of radioactive waste to soil from transfer pipe out of 244-TX DCRT due to leak in primary pipe and encasement	High structural loading from traffic or cranes cause failure of primary pipe and encasement	F3	E2
XS-07-FLOW04	Release of radioactive waste to soil from transfer piping of 244-TX-DCRT due to leak in primary pipe and encasement	Seismic event fails primary pipe and encasement	F2	E2
XS-07-FLOW05	Release of radioactive waste to soil from transfer pipe out of 244-TX DCRT due to leak in primary pipe and encasement	Undermining due to leak of nearby pipes cause failure of primary pipe and encasement	F3	E2
XS-07-FLOW06	Release of radioactive waste to soil from transfer pipe out of 244-TX-DCRT due to leak in primary pipe and encasement	Water hammer causes failure of primary pipe and encasement	F3	E2
XS-11-LEVE01	Release of radioactive waste from diversion box to surface due to overflow of transfer from 244-TX	Plugged drain and misrouting causes overflow	F3	E2
XS-11-LEVE02	Release of radioactive waste from diversion box to surface due to overflow of transfer from 244-TX	Plugged drain and open jumper causes overflow	F3	E2
XS-11-LEVE03	Release of radioactive waste from diversion box to surface due to overflow	Plugged drain and piping leak causes overflow	F3	E2
XS-12-FLOW02	Release of aerosols from Diversion Box 241-U-152 due to flammable gas deflagration	Chemical reaction of catch tank material with backflow of vapors via diversion box drain line	F1	E1

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
XS-12-FLOW03	Release of aerosols from Diversion Box 241-U-152 due to hydrogen deflagration	Radiolysis of catch tank material with backflow of vapors via diversion box drain line and ignition source	F1	E1
XS-12-FLOW05	Release of radioactive waste from diversion box to surface due to overflow of transfer from 244-TX	Backflow from catch tank causes overflow from diversion box	F3	E2
XS-13-PRES01	Release of radioactive aerosols from 241-U-301B catch tank due to chemical reaction	Draining of incompatible chemicals to catch tank	F3	E2
XS-13-PRES03	Release of toxic vapors due to chemical reaction from 241-U-301B	Draining of incompatible chemicals to catch tank	F2	E1
XS-13-PRES04	Release of fission product gases and aerosols from catch tank 241-U-301B due to criticality	Transfer of excess fissile material to catch tank creates critical mass	F1	E2
XS-20-FLOW01	Release of radioactive aerosols from 244-TX DCRT due to chemical reaction	Transfer of incompatible waste to 244-TX DCRT due to improper valve lineup	F3	E2
XS-20-FLOW03	Release of radioactive aerosols from 244-TX DCRT due to positive pressure caused by chemical reaction	Chemical reaction of 244-S material with contents of 244-TX caused by misrouting	F2	E2
XS-20-FLOW04	Release of toxic vapors from 244-TX DCRT due to chemical reaction with incompatible material in 244-S DCRT	Mixing contents of 244-TX and 244-S due to misrouting causes chemical reaction	F2	E2
XS-20-FLOW05	Release of fission product gases and aerosols from 244-S DCRT (not designated solids receiver) due to criticality	Transfer of waste from 244-TX DCRT due to improper valve lineup creates critical mass	F1	E2
XS-20-FLOW08	Release of radioactive waste from 244-TX DCRT to surface due to overflow	Transfer of excess waste to 244-TX DCRT due to improper valve lineup causes overflow	F3	E2
XS-20-FLOW09	Release of radioactive waste from 244S DCRT to surface due to overflow	Transfer of waste from 244-TX DCRT due to improper valve lineup causes overflow	F3	E2
XS-26-PRES XS-26-TEMP	Release of toxic vapors from Tank 241-SY-102 due to chemical reaction	Mistransfer of incompatible waste causes chemical reaction	F3	E2
XS-26-PRES XS-26-TEMP 102-AW-TEMP (FOR TK-102-AW)	Release of fission product gases and aerosols from Tank 241-SY-102 due to criticality	Transfer of critical mass of fissile material and achievement of critical geometry	F1	E2
XS-26-PRES01	Release of radioactive aerosols from Tank 241-SY-102 due to chemical reaction	Mis-transfer of incompatible waste causes chemical reaction	F3	E2
XS-26-TEMP01	Release of radioactive aerosols from Tank 241-AW-102 due to tank bump	High heat waste plus loss of cooling contributes to tank bump	F2	E2
XS-35-FLOW02	Release of radioactive waste to surface from 242-S Evaporator sump due to backflow to and overflow	Human error of leaving open flow path after emptying the sump and backflow and subsequent overflow	F3	E2

Table D3.4-2. Hazardous Conditions With Potential Significant Onsite Consequences (S2).[1] (26 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
XS-37-FLOW01	Release of radioactive liquid waste from catch tank to surface due to overfilling (pool)	Leak of transfer piping with drainage to catch tank causes overflow	F3	E2
XS-37-FLOW02	Release of radioactive liquid waste to soil from transfer piping due to leak of liquid waste from concrete encasement (subsurface plume)	Leak of transfer piping with encasement leak or blocked drain to catch tank (liquid oozes out concrete encasement)	F3	E2
XS-41A-FLOW01	Release of radioactive waste from vent station nozzle pit to surface due to overflow	Catastrophic failure of vent piping causes overflow of nozzle pit	F3	E2
XS-41A-FLOW02	Release of radioactive waste to surface from vent station nozzle pit due to overflow	Vent valve left open or leaking during transfer causes overflow	F3	E2
XS-41B-LEVE01	Release of radioactive aerosols from vent station catch tank due to flammable gas fire/explosion in nozzle pit	Failure to empty catch tank with buildup of flammable gas in nozzle pit plus ignition source	F2	E2
XS-41B-LEVE03	Release of radioactive waste to surface from vent station nozzle pit due to overflow	Failure to empty catch tank, causing overflow of tank and pit due to transfer failure	F3	E2
XS-41C-LEVE01	Release of radioactive aerosols from vent station catch tank due to flammable gas fire/explosion in catch tank pit	Leak of catch tank with buildup of flammable gas in catch tank pit plus ignition source	F2	E2
XS-48-FLOW	Release of liquid waste to soil from transfer piping between B-Plant and 241-ER-152 diversion box due to leak (plume)	Piping failure from various causes	F3	E2
XS-52-FLOW01	Release of radioactive waste to surface from transfer piping to Tank 244-CR-003 due to leak (pool)	Failure of pipe from various causes	F2	E2
XS-52-FLOW02	Release of radioactive waste from Tank 244-CR-003 to surface due to overflow (pool)	Mis-valving or valve failure during cross-site transfer causes overflow	F3	E2

[1]This table was generated from a relational database of hazards information. Changes from the previous revision of this table have been independently reviewed, but are not highlighted in Redline.

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (S1).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
102AW-02-LEVE	Release of radioactive aerosols from Tank 241-AW-102 annulus due to the presence of radioactive liquid waste in Tank 241-AW-102 annulus	Primary tank leakage from various causes	F3	E1
102AW-02-LEVE02	Release of liquid radioactive waste from Tank 241-AW-102 due to leak of primary and secondary tank	Structural failure of primary tank when annulus leaks	F1	E3
102AW-02-LEVE02A	Release of radioactive aerosols from Tank 241-AW-102 annulus ventilation system due to the presence of radioactive liquid waste in the annulus	Mis-routing of transfer to annulus instead of primary tank	F3	E1
102AW-02-LEVE06	Release of radioactive liquid to soil column from Tank 241-AW-102 annulus due to leakage	Primary tank leakage from various causes combined with annulus leakage	F1	E3
102AW-02-PRES.01 XS-26-PRES.01	Personnel injured by projectile debris from catastrophic fan failure	Loss of fan due to high pressure causing fan to walk into another object and become airborne	NA	NA
102AW-03-PRES01 102AW-03-LEVE	Release of radioactive aerosols from Tank 241-AW-102 annulus due to the presence of radioactive liquid waste in Tank 241-AW-102 annulus	Leak of primary tank to annulus combined with annulus ventilation fan failure	F2	E1
102AW-03-PRES02 102AW-03-LEVE	Release of radioactive aerosols from Tank 241-AW-102 annulus due to the presence of radioactive liquid waste in Tank 241-AW-102 annulus	Leak of primary tank to annulus combined with loss of power to annulus ventilation	F2	E1
102AW-04-LEVE01	Release of radioactive aerosols from Tank 241-AW-102 central pump pit due to accumulation of radioactive liquids in the central pump pit	Leak of primary piping	F3	E1
102AW-04-LEVE02	Release of radioactive aerosols from Tank 241-AW-102 central pump pit due to accumulation of radioactive liquids in the central pump pit	Misrouting through an open jumper plus clogged drain	F3	E1
102AW-04-LEVE03	Release of radioactive aerosols from Tank 241-AW-102 central pump pit due to accumulation of radioactive liquids in the central pump pit	Dissolution of residual contamination in central pump pit caused by erroneous use of raw water	F3	E1
102AW-04-LEVE04	Release of radioactive aerosols from Tank 241-AW-102 central pump pit due to accumulation of radioactive liquids in the central pump pit	Dissolution of residual contamination in central pump pit caused by pit cleaning plus clogged drain	F3	E1
102AW-04-PRES.01	Personnel exposure higher than expected	Removal of cover block and pressure release due to loss of fan.	NA	NA
102AW-04-PRES01	Release of radioactive particulate from Tank 241-AW-102 central pump pit due to pressurization	Loss of primary tank ventilation causes pressurization of pump pit.	F3	E1
102AW-04-PRES02	Release of radioactive particulate from Tank 241-AW-102 central pump pit due to its being open to atmosphere	Removal of cover block	F3	E1
102AW-04-STRU.01	Personnel injured by falling equipment	Equipment drop during crane work	NA	NA

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (SI).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
102AW-04-STRU.02	Release of radioactive particulate from Tank 241-AW-102 central pump pit due to confinement inadequacies	Structural degradation with time	F2	E1
102AW-04-STRU01B	Release of radioactive particulate from Tank 241-AW-102 central pump pit due pump pit structural failure	Seismic-induced failure of central pump pit	F1	E1
102AW-08-COMP01	Release of radioactive aerosols from tank vapor space due to production of aerosols from sludge and migration	Chemical reactions causing agitation	F2	E1
102AW-08-COMP06	Release of toxic gases from Tank 241-AW-102 tank vapor space due to production and migration of toxic gases from sludge	Chemical reactions in waste causes production of toxic gases	F3	E1
102AW-09-COMP03	Release of toxic vapors from a separable organic layer in Tank 241-AW-102 due to fuel spill into tank	External event (fuel spill)	F3	E1
102AW-09-COMP04	Release of toxic vapors from a separable organic layer in Tank 241-AW-102	Core sampling (NPH) releases trapped vapors	F3	E1
102AW-09-COMP05	Release of toxic vapors from a separable organic layer in Tank 241-AW-102 due to error in transfer	Generator erroneous transfer of insoluble organic material	F3	E1
102AW-09-TEMP02	Release of aerosols from annulus due to leak of liquid waste into the annulus	Tank leak due to thermal stress caused by transfer of hot solution to an almost empty tank	F1	E1
102AW-13-FLOW.01	Personnel exposure due to radiation doses from contaminated pipes	Multiple valving errors and failure of backflow prevention causing reverse flow from valve pit to flush pit	NA	NA
102S-02.d3	Release of radioactive aerosols to atmosphere from Tank 241-S-102 pit due to burning fuel on top of pit caused by ignition of gas from ruptured gas tank.	Vehicle drives into pit cover puncturing gas tank + Ignition	F3	E1
102S-04.e2	Release of radioactive aerosols contained in tank vapor space to atmosphere due to generation of excessive heat	Chemical reaction in waste Addition of incompatible waste/chemical (misroute)	F2	E1
102S-06.a	Release of radioactive aerosols from Tank 241-S-102 vapor space to atmosphere due to ventilation system failure	Filter plugged	F3	E1
106C-01K	Release of radioactive and/or hazardous material from Tank 241-C-106 tank due to high temperature	Water evaporation	F3	E1
106C-01S	Release of radioactive and/or hazardous material from Tank 241-C-106 caused by low level in waste tank due to high temperature	Water evaporation	F3	E1
106C-01Sa	Release of radioactive and/or hazardous material from Tank 241-C-106, due to low tank level because of tank leak	Waste tank leak	F3	E3

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (SI).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
106C-01T	Release of radioactive and/or hazardous material from Tank 241-C-106 due to low level in waste tank	Failure to add water to tank	F3	E1
106C-01W	Release of radioactive and/or hazardous material from Tank 241-C-106, due to high level in waste tank	Level change due to barometric changes	F1	E1
106C-06A	Release of radioactive and/or hazardous material from Tank 241-C-106 pump pit, due to pump pit being opened to atmosphere	Cover blocks removed	F3	E1
106C-06F	Release (minor) of radioactive and/or hazardous material from Tank 241-C-106 pump pit, due to pump pit high level	Plugged pit drain while adding water	F3	E1
106C-06G	Release (minor) of radioactive and/or hazardous material from Tank 241-C-106 pump pit due to pump pit high level	Plugged pit drain with rain or snow melt intrusion	F3	E1
106C-06H	Release (minor) of radioactive and/or hazardous material from Tank 241-C-106 pump pit due to pump pit high level	Plugged pit drain during pit cleaning, cover blocks are off	F3	E1
106C-06K	Release of radioactive and/or hazardous material from Tank 241-C-106 pump pit due to decreased pump pit structural integrity caused by drop	Equipment drop during crane work	F3	E1
106C-10F	Release of radioactive and/or hazardous material from Tank 241-C-106, potential spread of contamination due to reverse air flow if intake HEPAs damaged	Loss of tank active ventilation	F3	E1
106C-10H	Release of radioactive and/or hazardous material from Tank 241-C-106 due to HEPA filter damage	Low ambient air temperature results in ice on filter and filter damage	F1	E1
106C-10K	Release of radioactive and/or hazardous material from Tank 241-C-106, spread of contamination, due to ventilation air intake open to atmosphere	HEPA filter breach	F3	E1
106C-10L	Release of radioactive and/or hazardous material from Tank 241-C-106, spread of contamination, due to ventilation air intake open to atmosphere	Air intake ductwork damaged	F3	E1
106C-11A	Release of radioactive and/or hazardous material from Tank 241-C-106, due to HEPA filter damage	HEPA filters plugged	F3	E1
106C-11G	Release of tank atmosphere through exhauster drain from Tank 241-C-106 due to leak or failure to add water routinely	Loss of exhauster seal pot water due to leak or failure to add water routinely	F3	E1
106C-11H	Release of radioactive and/or hazardous material from Tank 241-C-106 due to condensate backing up into filters, de-entrainer or heater	Exhauster seal pot water freezing due to loss of heat trace	F3	E1
106C-11I	Release of radioactive and/or hazardous material from Tank 241-C-106 due to moisture carryover into HEPAs causing loss of efficiency	Exhauster heater failure	F3	E1

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (S1).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
106C-11N	Release of radioactive and/or hazardous material from Tank 241-C-106, through HEPA filter path, due to filter degradation over time	HEPA filter degradation	F3	E1
106C-12A	Release of radioactive and/or hazardous material from Tank 241-C-106 due to tank falling below level limit, caused by excessive tank evaporation from high temperature	Pit drain plug, water addition fails	F3	E1
106C-12B	Release of radioactive and/or hazardous material from Tank 241-C-106 due to low tank level	Water addition tank truck breakdown	F3	E1
106C-12C	Release of radioactive and/or hazardous material from Tank 241-C-106 due to low tank level because of increased evaporation	Water addition tank truck leak	F3	E1
106C-12D	Release of radioactive and/or hazardous material from Tank 241-C-106 due to excessive tank evaporation from high temperature which causes tank to fall below level limit	Tank level instrumentation fails, does not prompt water addition	F3	E1
107AN-01-LEVE03	Release of caustic material from truck tank due to leak	Failure to secure truck	F3	E2
107AN-01-TEMP.01	Thermal hazard to personnel	Caustic in tank heated too hot at source	NA	NA
107AN-02-FLOW03	Release of concentrated caustic solution to surface from transfer piping due to leak	Caustic solution transfer line leak	F2	E2
107AN-02-TEMP01	Release of caustic material from transfer piping due to low temperature during transfer	Low temperature from truck	F2	E1
107AN-03-FLOW	Release of concentrated caustic solution to surface from transfer piping due to backflow of caustic	Low temperature causes backflow	F3	E1
114SX-04.a.1a	Radioactive aerosols released from Tank 241-SX-114 head space, via tank ventilation (requires failure of outlet filter), to the atmosphere due to exhauster failure	Exhauster failure Mechanical Low temperature (thermocouple in exhaust duct not insulated picks up radiated temperature from ductwork.)	F3	E0
114SX-04.a.1b	Radioactive aerosols released from Tank 241-SX-114 head space, via tank ventilation (requires failure of outlet filter), to the atmosphere due to exhauster failure	Filter plugged	F3	E0
114SX-04.a.4	Release of radioactive aerosols from Tank 241-SX-114 headspace to atmosphere due to inlet HEPA filter failure coupled with exhauster failure	Filter failure	F3	E1
114SX-04.b.1.a.1	Release of radioactive aerosols from Tank 241-SX-114 headspace to atmosphere due to inlet HEPA filter failure coupled with exhaust butterfly valve closure	Human error: Closure of Tank 241-SX-114 exhaust butterfly valve isolating tank from exhaust plenum	F3	E1

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (S1).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
114SX-04.b.1.b.1a	Release radioactive aerosols released from Tank 241-SX-114 head space to the atmosphere due to ventilation system ducting failure (with failed inlet filter)	Ducting failure from bad welds	F3	E1
114SX-04.b.1.c.1	Release of radioactive aerosols from Tank 241-SX-114 head space to atmosphere due to exhauster failure and multiple filter failure	Exhauster failure Fan failure Filter rupture (low differential pressure shutdown) Resulting in tank degradation	F3	E1
114SX-04.b.1.d.1	Release of radioactive aerosols from Tank 241-SX-114 head space to atmosphere due to exhauster filter plugging (requires failure of inlet filter)	Exhaust filter plugging plus inlet filter failure	F3	E1
114SX-04.b.5	Release of radioactive aerosols from Tank 241-SX-114 head space to atmosphere due to failure of exhauster HEPA filters	No ventilation flow High ambient temperature conditions Leading to filter failure	F3	E1
114SX-06.b	Personnel exposed to ionizing radiation due to lack of shielding	Inadvertent removal of tank overburden (gravel)	NA	NA
204AR-01A	Release and spread of airborne radiological contamination from the rail car due to over pressurization	Over pressure in the rail car due to chemical reaction, rupture disk fails	F3	E1
204AR-01B	Release of airborne contamination and toxic chemical exposure to worker from the rail car due to high ambient temperature	Over pressure in the rail car due to high ambient temperature, rupture disk fails	F3	E1
204AR-01C	Release of airborne contamination and toxic chemical exposure to worker from the rail car due to chemical reaction causing over pressurization	High temperature in the rail car due to chemical reaction of the rail car contents, rupture disk fails	F3	E1
204AR-01D	Release and spread of airborne contamination and toxic chemical exposure to worker from the rail car due to leaking rail car caused by high ambient temperature and over pressurization of car tank	High ambient temperature causing pressurization of rail car and possible leakage, failed rupture disk	F3	E1
204AR-01E	Release of airborne contamination and toxic chemical exposure to worker from the rail car due to damaged rupture disk	Chemical reaction or internal fire resulting in an over pressure condition on rail car	F2	E1
204AR-01F	Release of airborne contamination and toxic chemical exposure to worker from the rail car due to an over pressurization which results from a diesel fuel fire under the car	Fire from diesel fuel of the locomotive that results in an over pressure condition on the rail car, rupture disk fails	F1	E1
204AR-01G	Release of airborne and liquid contamination from overflowing catch tank due to siphoning of rail car contents	Vacuum condition on rail car results in siphoning of rail car contents to the catch tank	F2	E1

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (S1).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
204AR-01J	Release of airborne contamination from overflowing catch tank due to overfilling through priming line	Priming line inadvertently fills up rail car and overflows rail car through its vent line to the catch tank	F3	E1
204AR-01K	Release of airborne contamination from unloader room due to overflowing catch tank	During sluicing operations, fill up rail car and overflow through its vent line to the catch tank	F3	E1
204AR-02C	Release of airborne and toxic chemical exposure to worker from the rail car due to over pressurization on trailer	Chemical reaction in trailer resulting in an over pressure condition, rupture disk fails	F2	E1
204AR-02D	Release of airborne and toxic chemical exposure to worker from the rail car due to diesel fuel fire causing over pressurization on the trailer	Diesel fuel fire from the truck causing an over pressure condition in the tank trailer, rupture disk fails	F2	E1
204AR-02E	Release of radioactive material and toxic chemicals from trailer due to damage caused by trailer jack failure	Leak from tank trailer due to trailer jack failure	F3	E1
204AR-02F	Release of airborne contamination from unloader room due to overflowing catch tank	Priming line inadvertently fills up trailer and overflows trailer through vent line to the catch tank	F3	E1
204AR-03A	Release of contamination and airborne release around the catch tank area and chemical exposure in mechanical equipment room from catch tank or Sodium Nitrate Tank due to failed tank	Sodium Nitrite Tank #2 either fails or has a drain valve open and empties its contents to the floor drains in the mechanical equipment room	F3	E1
204AR-03B	Release of airborne contamination around the catch tank area and chemical exposure in mechanical equipment room from the Sodium Nitrite Tank #2 due to overfilling and spilling to catch tank.	Sodium Nitrite Tank #2 overfilled and contents spilled into floor drains	F3	E1
204AR-03C	Release of airborne contamination in unloader room and chemical exposure to worker from overfilled catch tank due to tank failure.	Sodium Nitrite Tank #2 tank failure (leak at bottom) filling the catch tank with potential for airborne	F2	E1
204AR-04A	Release of airborne and waterborne contamination from high level in the catch tank due to Sodium Hydroxide Tank #3 failure	Sodium Hydroxide Tank #3 failure or drain valve open which empties contents into the floor drains	F3	E1
204AR-04B	Release of airborne contamination around the catch tank area and chemical exposure in mechanical equipment room from the Sodium Hydroxide Tank #3 and catch tanks due to overfilling of the Sodium Hydroxide Tank	Sodium Hydroxide Tank #3 overfilled and contents spilled into the floor drains	F3	E1
204AR-04C	Release of chemicals to the mechanical equipment room environment from the Sodium Nitrite Tank due to adding chemicals too quickly	Adding caustic chemicals too quickly to the tank - human error	F3	E1
204AR-04D	Release of sodium hydroxide particulates from the Sodium Hydroxide Tank due to thermal stress to piping and eventual valve leakage of Sodium Hydroxide Tank piping	Adding too much sodium hydroxide resulting in high temperatures	F3	E1

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (SI).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
204AR-04E	Release of sodium hydroxide particulates from the Sodium Hydroxide Tank due to damage to the chemical addition pump diaphragm	Adding steam heat to the coils resulting in high temperatures	F3	E1
204AR-04F	Release of airborne and waterborne contamination from high level in the catch tank due to Sodium Hydroxide Tank failure	Sodium Hydroxide Tank #3 failure (leak at bottom) filling the catch tank with potential for airborne	F2	E1
204AR-05A	Release of toxic chemicals to mechanical equipment room from chemical addition piping due to large leak in chemical addition piping	Large leak in the chemical addition piping during the transfer process	F2	E1
204AR-05B	Release of toxic chemicals and worker exposure from chemical addition piping due to over pressure of piping and subsequent damage	Over pressure while running chemical addition pump due to dead heading the pump	F3	E1
204AR-05C	Release of Tank 241-AY-102 liquid radioactive waste to the mechanical equipment room from Tank 241-AY-102 due to pumping and reversing flow from Tank 241-AY-102 to the 204-AR facility	Reverse flow of transfer piping fluid through the chemical addition piping in the mechanical equipment room	F2	E1
204AR-06A	Release of liquid radioactive waste to the unloader room or caustic chemicals to the mechanical equipment room from the priming water piping or transfer piping due to over pressurization of piping	Raw water supply pressure higher than normal	F3	E1
204AR-06B	Release of liquid radioactive waste to the unloader room or caustic chemicals to the mechanical equipment room from the priming water piping or transfer piping due to over pressurization of piping	Water hammer in priming piping from raw water supply	F3	E1
204AR-06C	Release of airborne contamination from unloader room due to overflowing catch tank	High flow through the priming line and transfer piping due to misalignment which fills up the rail car or trailer and overflows it to the catch tank	F3	E1
204AR-07B	Release of contaminated water to encasement outside of 204-AR building and floor drains inside building from the transfer piping due to over pressure and leakage from raw water flush	Over pressure of raw water through transfer piping during post transfer flush	F3	E1
204AR-07C	Release of airborne and spread of contamination from the transfer piping due to leak from improper valve lineup	Leaking transfer piping due to transfer pump being dead headed (e.g., a valve in the transfer line is closed)	F2	E1
204AR-09E	Release of airborne contamination and increased radiation levels from catch tank due to blocked catch tank ventilation and over pressure of catch tank	A heat source is in the catch tank and the overflow and vent of the catch tank are blocked off or obstructed, resulting in a catch tank over pressure	F2	E1
204AR-09F	Release of airborne contamination and increased radiation levels from catch tank due to blocked catch tank ventilation and over pressure of catch tank	Ventilation to the catch tank is blocked off with heaters on, resulting in a catch tank high pressure	F3	E1

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (S1).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
204AR-09H	Release of airborne and waterborne contamination in the unloader room from transfer piping and sump pit due to floating the catch tank and damaging piping	Rupture of raw water line piping above sump pit, causing sump pit to fill before catch tank	F2	E1
204AR-11A	Release of airborne radioactivity from unloader room due to loss of confinement caused by power failure	Loss of confinement due to power failure and total loss of ventilation fan	F3	E1
204AR-11B	Release of airborne radioactivity from unloader room due to loss of confinement caused by low ventilation flow	Loss of confinement due to low ventilation flow	F3	E1
204AR-11C	Release of airborne contamination from the unloader room due to failure of ventilation fan	Failure of EF-1 fan resulting in loss of confinement	F3	E1
204AR-11D	Release of airborne contamination from the unloader room due to blocked ventilation flow	No ventilation flow because of damper closed	F3	E1
204AR-11E	Release of airborne contamination from the unloader room due to plugged ventilation flow	No ventilation flow because of plugged HEPA filter	F3	E1
213 W-01	Release of radioactive and/or hazardous materials in 213-W work room due to error in repackaging or instrument repair	Handling error (forklift, spills, etc)	F3	E1
213 W-02	Release of radioactive and/or hazardous materials in 213-W work room due to error in repackaging or instrument repair	Failure of tools	F3	E1
213 W-03	Release of radioactive and/or toxic materials from 213-W due to fire in ventilation system	Electrical fault in ventilation or monitoring system	F2	E1
213 W-04	Release of radioactive and/or hazardous materials in 213-W work room due to fire	Human error (handling, smoking, hot tools)	F2	E1
213 W-05	Release of radioactive and/or hazardous materials in 213-W work room due to fire	Electrical or mechanical fault in tools, heating system, or hydraulics	F2	E1
213 W-06	Release of radioactive and/or toxic materials from 213-W due to fire in ventilation system	Lightning	F2	E1
213 W-07	Release of radioactive and/or toxic materials from 213-W due to structural failure of building	Seismic event	F1	E1
213 W-08	Release of radioactive and/or toxic materials from 213-W due to structural failure of building	High winds or tornado	F2	E1
213 W-09	Release of radioactive and/or toxic materials from 213-W due to structural failure of building	Loss of control of vehicle in vicinity of building	F3	E1
244AR-01.a.03	Radioactive aerosols released from tank headspace exit building through the inlet side of the canyon ventilation system due to mechanical failure	Failure of vessel venting with open vents to cell atmosphere and jetting operations occurring plus failure of exhaust fans	F3	E1

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (S1).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
244AR-01.b.01	Radioactive aerosols released from tank headspace and exit building through the inlet side of the canyon ventilation system due to mechanical failure	Fan Failure with jetting occurring	F3	E1
244AR-01.b.02	Radioactive aerosols released from tank headspace and exit building through the inlet side of the canyon ventilation system due to mechanical failure	HEPA filter plugged with jetting occurring	F3	E1
244AR-01.b.03	Radioactive aerosols released from tank headspace and exit building through the inlet side of the canyon ventilation system due to human error	Damper closed with jetting occurring	F3	E1
244AR-01.c.01	Release of radioactive aerosols from vessel headspace into canyon atmosphere due to vessel ventilation failure	Plugged vessel ventilation system filters	F3	E0
244AR-01.c.02	Release of radioactive aerosols from vessel headspace into canyon atmosphere due to ventilation system failure	Vessel ventilation system fan shutdown or failure	F3	E0
244AR-01.c.03	Release of radioactive aerosols from vessel headspace into canyon atmosphere due to human error	Valve closed in exhaust flow path	F3	E0
244AR-01.c.07	Release of radioactive aerosols from vessel headspace into canyon atmosphere due to human error	All inlets to tank sealed with pumping of tank occurring	F2	E0
244AR-01.c.08	Release of radioactive aerosols from vessel headspace into canyon atmosphere due tank rupture	Plugged tank vents with gas evolution in tank contents	F3	E0
244AR-01.c.10	Release of radioactive aerosols from vessel headspace into canyon atmosphere due to plugged ventilation system	Air purge operating with ventilation system plugged	F3	E0
244AR-01.c.11	Release of radioactive aerosols from vessel headspace into canyon atmosphere due to ventilation system filter plugging	Air heaters off (steam supplied)	F3	E0
244AR-01.c.13	Release of radioactive aerosols from vessel headspace into canyon atmosphere due to ventilation system filter plugging	Air heater off with significant heat generating waste in tanks	F2	E0
244AR-02.a.08	Release of radioactive liquid into cells due to jumper leak causing release of aerosols through cracks	Jumper leak (general)	F3	E0
244AR-02.a.09	Release of radioactive liquid to soil from leaking sump filled by leaking jumper	Jumper leak (general)	F3	E2
244AR-02.a.10	Release of radioactive liquid into cells due to jumper leak	Jumper (B Plant to AY Tank Farm through cell) leak	F3	E0
244AR-02.a.11	Release of radioactive liquid to soil from leaking sump filled by leaking jumper	Jumper (B Plant to AY Tank Farm through cell) leak	F3	E2

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (SI).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
244AR-02.a.12	Release of radioactive liquid into cells due to tank leak	Tank leak	F3	E0
244AR-03.a.03	Release of radioactive aerosols into cell due to collapse of tank	Complete sealing of all risers with vessel ventilation system piping blocked and pumping of tank occurring	F1	E1
244AR-03.a.06	Release of radioactive aerosols from tanks headspace due to steam pressure control failure for jetting system	Jetting operation with failure of jetting steam pressure regulation	F3	E1
244AR-03.a.07	Release of radioactive aerosols from tanks headspace due to air purge pressure control failure	Air purge with blocked ventilation and risers and failure of air pressure control	F2	E1
244AR-03.a.13	Release of radioactive aerosol being jetted from tank or sump due to overflow into sump	Jetting activities moving material from sump or another tank	F3	E0
244AR-03.a.14	Release of radioactive liquid being jetted from tank or sump due to overflow of tank	Inter-facility tank transfers	F3	E0
244AR-03.a.18	Release of radioactive aerosols from tank due to seismic event	Seismic event	F2	E0
244AR-04.a.01	Release of radioactive aerosols in sump due to disturbance of radioactive material by falling crane	Seismic event	F2	E0
244AR-05.a.01	Weak roof structure permits person to fall through roof	Aging (roof)	NA	NA
244AR-06.a.02	High activity radioactive material exposes person to ionizing radiation	Tank ventilation heater coil failure	NA	NA
244AR-07.a.01	Radioactive contamination contained in cells moved out of cell area into canyon area due to steam pressure control failure	Failure of PRV during jetting activities coupled with failure of ventilation systems	F2	E1
244AR-07.a.02	Radioactive contamination back flow into steam system due to steam supply failure	Steam supply failure	F3	E1
244AR-07.a.03	Radioactive contamination back flow into steam system due to compressed air failure	Steam supply failure and air blow failure	F3	E1
244AR-07.a.04	Exposure to low concentrations of radioactive material	Excess water used in steam jet flush	F3	NA
244AR-PH01	Water hammer during setup for jetting	Condensate in the lines coming into contact with steam	NA	NA
244AR-PH02	Asphyxiation due to entry into confined space	Lack of oxygen due to corrosion, decomposition or fire/explosion	NA	NA
244AR-PH03	Contamination of personnel with radioactive material	Radioactive contamination in canyon or sample gallery being disturbed by personnel entry	NA	NA
244AR-PH04	Person falls from elevated surface	Roof weakness (more than 2 stories high)	NA	NA
244AR-PH05	Person falls from elevated surface	Crane maintenance activities	NA	NA

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (S1).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
244AR-PH06	Person falls from elevated surface	Walking over weak filter vault roof	NA	NA
244AR-PH07	Person falls from elevated surface	Ladder climbing	NA	NA
244AR-PH08	Person comes in contact with rotating equipment	Maintenance work on rotating equipment	NA	NA
244AR-PH09	Person comes in contact with rotating equipment	Process operations activities	NA	NA
244AR-PH10	Person injured by failure of equipment during over speed event	Equipment malfunction	NA	NA
244AR-PH11	Personnel injury from contact with energized circuits or faulted equipment	Insulation failure	NA	NA
244AR-PH12	Personnel injury from contact with energized circuits or faulted equipment	Maintenance activities	NA	NA
244AR-PH13	Personnel injury from contact with energized circuits or faulted equipment	Mechanical damage to insulation	NA	NA
244AR-PH14	Personnel injury due to electrical fire	Insulation failure	NA	NA
244AR-PH15	Personnel injury due to electrical fire	Overload conditions, breaker failure, sparking in flammable atmosphere	NA	NA
244AR-PH16	Personnel exposure to insulation or construction materials containing asbestos	Disturbance from: fire, maintenance, wind, aging, water intrusion	NA	NA
244AR-PH17	Personnel exposed to toxic or corrosive materials	Maintenance and operations activities combined with leakage such as pipe failure, pump failure or valve packing leaks	NA	NA
244AR-PH18	Personnel injured by high pressure gas bottles becoming projectiles	Malfunction of bottle regulator	NA	NA
244AR-PH19	Personnel injured by high pressure gas bottles becoming projectiles	Improper storage and transport	NA	NA
2727W-01	Release of hazardous materials from 2727-W due to sodium reactions with limited water	Water enters through roof vents when tanks not sealed	F2	E1
90D-01	Release of radioactive and toxic aerosols/vapors from 90 Day Storage Pad due to container breach	Container breach from internal chemical, thermal or radiolysis reactions; corrosion, freeze-thaw cycles	F3	E1
90D-02	Release of radioactive and toxic aerosols/vapors from 90 Day Storage Pad due to container breach	Container breach from external impact from handling error, forklift, handling equipment airborne missile from wind, seismic	F3	E1
90D-03	Release of radioactive and toxic aerosols/vapors from 90 Day Storage Pad due to container breach	Container breach from airborne missile from wind, or from a seismic event	F3	E1

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (S1).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
90D-04	Release of radioactive and toxic aerosols/vapors from 90 Day Storage Pad due to fire or explosion	Waste ignition from spontaneous combustion, incompatible wastes, heat from sun, waste handling or other human activities	F3	E1
90D-05	Release of radioactive and toxic aerosols/vapors from 90 Day Storage Pad due to fire or explosion	External events cause waste ignition (range fires, lightning, seismic event, airplane crash)	F1	E1
90D-06	Release of radioactive and toxic aerosols/vapors from Intermediate Holding Area due to container breach	Container breach from internal chemical, thermal or radiolysis reactions; corrosion, freeze-thaw cycles	F3	E1
90D-07	Release of radioactive and toxic aerosols/vapors from Intermediate Holding Area due to container breach	Container breach from external impact from handling error, forklift, handling equipment airborne missile from wind, seismic	F3	E1
90D-08	Release of radioactive and toxic aerosols/vapors from Intermediate Holding Area due to container breach	Container breach from airborne missile from wind, or from a seismic event	F3	E1
90D-09	Release of radioactive and toxic aerosols/vapors from Intermediate Holding area due to fire/explosion	Waste ignition from spontaneous combustion, incompatible wastes, heat from sun, waste handling or other human activities	F2	E1
90D-10	Release of radioactive and toxic aerosols/vapors from Intermediate Holding Area due to fire/explosion	Natural Phenomena cause waste ignition (range fires, lightning, seismic event)	F1	E1
90D-11	Release of radioactive and toxic aerosols/vapors from waste transport vehicle due to loss of waste confinement	Failure to secure waste, vehicle accident, improper packaging, waste reactions	F3	E1
BND-01	Industrial hazards (lifting, bending, tool accidents; creates tripping hazard)	Failure to follow safe work practices, equipment failures	NA	NA
BND-01-I	Injury of worker from (lifting, bending, tool accidents; creates tripping hazard) due to bonding activities	Failure to follow safe work practices, equipment failures	NA	E1
BND-02-I	Injury of worker from ignition of combustibles due to preparation for bonding	Drilling holes for bonding attachments causes sparks which is a hazard	F2	E1
CCF-02	Radioactive and hazardous release from tanks due to short term loss of ventilation	Loss of offsite power	F3	E1
CCF-03	Degraded ventilation performance at 702-A due to condensed water vapors on HEPAs	Sustained loss of water supply (month)	F3	E0
CCF-04	Degraded ventilation performance at 702-A due to condensed water vapors on HEPAs	Sustained loss of steam supply	F3	E0
CCF-14	Personnel illness or asphyxiation due to air supply faults	SCBA air supply of poor quality	NA	NA

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (S1).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
CCF-15	Degraded operations, increased down time, possible personnel injury due to supply of inferior parts	Faulty parts or equipment supplied (e.g. o-rings, seals, electronics, HEPAs, pressure regulators, etc)	NA	NA
CCF-16	Subsurface releases of radioactive or hazardous material due to leaks in multiple tanks	Tanks, tank penetrations and tank components deteriorate due to corrosion	F3	E3
CDP-01	Release of radioactive contamination to soil surface from crib or ditch due to animal intrusion	Animal intrusion into crib or ditch	F3	E1
CDP-03	Release of radioactive contamination to soil surface from inactive pond due flooding in crib or ditch	Flooding	F3	E1
CDP-05	Release of radioactive contamination to atmosphere from inactive pond due to high wind/tornado disturbing radioactive contamination in crib or ditch	High winds/tornados	F2	E1
CDP-06	Release of radioactive contamination to atmosphere from inactive pond due to high wind/tornado disturbing inactive pond	High winds/tornadoes	F3	E0
CDP-08	Release of airborne radioactive contamination from contaminated vegetation due to fire in weed growth on top of cribs or ditches	Range fire	F3	E1
CDP-09	Driver error during drive-by causes injury to personnel	Driver error	NA	NA
COB-02	Release of radioactive and/or hazardous material from COB due to spray leak	Flange, gasket or valve, spray leak with COB lid in place	F3	E2
COB-03	Release of radioactive and/or hazardous material from COB due to spray leak	Piping leak into COB due to chemical reaction degrading pipe, lid in place	F3	E2
COB-05a	Release of radioactive and/or hazardous material from COB due to existing contamination inside COB and lid removed	Inspection of COB	F3	E1
COB-05b	Release of radioactive and/or hazardous material from COB due to existing contamination inside COB and lid off during high wind	High wind with COB cover off	F3	E1
COB-05c	Release of radioactive and/or hazardous material from COB due to flooding	Flooding of COB due to rain/snow melt	F3	E1
COB-05d	Release of radioactive and/or hazardous material release from COB due to vehicle accident	Vehicle accident involving COB	F3	E1
COB-05e	Release of radioactive and/or hazardous material from COB due to seismic event	Seismic event	F3	E1
COB-05f	Release of radioactive and/or hazardous material from COB due to existing contamination inside COB and COB lid off	Human error leaving COB lid off	F3	E1

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (S1).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
COB-06a	Release of radioactive and/or hazardous material from COB due to COB caisson pressurized	Weather heatup with HEPA filter plugged	F3	E1
COB-06b	Release of radioactive and/or hazardous material from COB due to COB caisson pressurized	Leak into COB with HEPA filter plugged	F3	E1
COB-07	Release of radioactive and/or hazardous material from COB due to reverse flow through COB from adjacent transfer line	COB setup is such that a transfer through the adjacent transfer line backflows through the COB drain line into the primary transfer line that the COB is attached to	F2	E1
CP-GRT-01	Personnel exposure to contaminated pipe string due to removal of pipe during grouting	Contaminated soil in pipe	F3	E0
CP-MSP-02	Release of radioactive or toxic material to soil (plume) remaining subsurface from transfer line due to puncture of line during transfer	Human error caused puncture to transfer line during push operations	F3	E3
CP-MSP-04	Release of radioactive or toxic material to soil (plume) remaining subsurface from waste tank due to puncture of tank	Human error - Undetected deflection of drill string pipe causes breach of tank	F1	E3
CP-MSP-09	Release of isotope source to the soil surface due to load drop	Human Error caused load drop	F3	E0
CP-MSP-10	Release of isotope source to the soil surface due to load drop	Mechanical failure caused load drop	F2	E0
CP-MSP-11	Release of radioactive material to the soil surface due to crushed sensor package	Human Error: Heavy load inadvertently set on top of sensor package	F3	E1
CP-RMV-01	Release of radioactive or toxic material to soil (plume) remaining subsurface from inactive transfer line damaged during push operations	Human error caused puncture to inactive transfer line during push operations	F3	E2
CP-RMV-02	Personnel exposure to high level waste contamination on surface of pipe string due contact with leaking waste	Human error caused puncture to inactive transfer line during push operations	F3	E0
CP-RMV-04	Personnel exposure to radiation through push pipe due to puncture of tank dome	Human error results in removal of sample canister containment	F3	E1
CP-SET-01	Release of radioactive or toxic material from above ground structure due to load movement	Mechanical failure of equipment causes load to swing into above ground structure	F3	E1
CP-SET-02	Release of radioactive or toxic material from above ground structure due to load movement	Human error causes load to swing into above ground structure	F3	E1
CP-SET-03	Release of radioactive or toxic material from above ground structure due to load movement	High wind causes load to swing into above ground structure	F1	E1
CP-SET-09	Release of isotope source from the MSP to the soil surface due to load drop	Human error causes load drop	F3	E1
CP-SET-10	Release of isotope source from the MSP to the soil surface due to load drop	Mechanical failure causes load drop	F2	E1

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (S1).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
CP-SET-11	Release of radioactive material from the MSP to the soil surface due to crushing of the sensor package	Human error: Heavy load is inadvertently set on top of the sensor package	F3	E1
CP-SSP-02	Release of radioactive or toxic material to soil (plume) remaining subsurface from transfer line due to puncture of line during transfer	Human error caused puncture to transfer line during push operations	F3	E3
CP-SSP-04	Release of radioactive or toxic material to soil (plume) remaining subsurface from waste tank due to puncture of tank	Human error - Undetected deflection of drill string pipe causes breach of tank	F1	E3
CP-SSP-06	Personnel exposure to contaminated soil sample while removing sampling canister from pipe sleeve	Human error	F3	E0
CP-SSP-07	Personnel exposure to contaminated soil sample while removing sampling canister from pipe sleeve	Mechanical failure	F2	E0
CP-SSP-08	Personnel exposure to contaminated soil sample while removing sampling canister from pipe sleeve	High wind	F2	E0
CP-SSP-09	Personnel exposure to contaminated pipe string caused by failure of sampling canister soil catcher to close properly	Mechanical failure	F3	E0
CP-SSP-10	Personnel exposure to puff release of contaminated dust (particulates) caused by air movement as the sample canister is withdrawn from pipe sleeve	Contaminated inner tube	F3	E1
CP-SSP-11	Release of contamination to environment due to dropping of the sample canister during transfer of sample from pipe to the shipping cask	Human error - workers drop sample canister or fail to handle properly	F3	E1
CP-SSP-12	Release of contamination to environment due to dropping of the sample canister during transfer of sample from pipe to the shipping cask	Mechanical failure of the sample canister	F3	E1
CP-SSP-13	Release of contamination to environment due to dropping of the sample canister during transfer of sample from outer push pipe to the shipping cask	High wind	F3	E1
CP-SSP-14	Release of contamination to environment due to dropping of the repackaged soil sample container	Human error - workers drop sample canister or fail to handle properly	F3	E1
CP-SSP-15	Release of contamination to environment due to dropping of the repackaged soil sample container	High wind	F2	E1
CP-SSP-19	Release of radioactive material to the soil surface due to rupture of the probe capsule	Human error: Results in package being ruptured when vehicle runs over the probe	F2	E1
CRN-01	Release of radioactive and/or toxic materials from riser due to breach by crane movement	Human errors or failure to follow safe work practices	F3	E1

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (S1).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
CRN-01-I	Release of radioactive and/or toxic materials from riser breach due to crane movement	Human errors or failure to follow safe work practices	F3	E1
CRN-02	Release of radioactive and/or toxic materials from riser due to breach by crane movement	Mechanical failures of crane (brakes, throttle)	F3	E1
CRN-02-I	Release of radioactive and/or toxic materials from riser breach due to crane movement	Mechanical failures of crane (brakes, throttle)	F2	E1
CRN-05-I	Release of radioactive and/or toxic materials from surface contamination and fuel tank on crane or support vehicle due to fuel tank fire (see In-Facility Equipment Installation for facility fires)	Human error in positioning crane load	F3	E1
CRN-06-I	Release of radioactive and/or toxic materials from surface contamination and fuel tank on crane or support vehicle due to fuel tank fire (see In-Facility Equipment Installation for facility fires)	Mechanical failure in positioning crane load causes crane fuel tank rupture and fire	F3	E1
CRN-07-I	Release of radioactive and/or toxic materials from surface contamination and fuel tank on crane or support vehicle due to fuel tank fire (see In-Facility Equipment Installation for facility fires)	Crane hits electrical lines/supplies	F2	E1
CRN-08-I	Release of radioactive and/or toxic materials from surface contamination and fuel tank on crane or support vehicle due to fuel tank fire (see In-Facility Equipment Installation for facility fires)	Lightning	F1	E1
CRN-14	Boom failure leads to worker injury or exposure	Human error: improper load assembly, rigging, crane overloaded	NA	NA
CRN-14-I	Injury of worker from boom failure due to human error	Human error: improper load assembly, rigging, crane overloaded	NA	E1
CRN-15	Boom failure leads to worker injury or exposure	Mechanical failure: corrosion, faulty materials	NA	NA
CRN-15-I	Injury of worker from boom failure due to mechanical failure	Mechanical failure: corrosion, faulty materials	NA	E1
CRN-16	Boom failure leads to worker injury or exposure	High wind or seismic event	NA	NA
CRN-16-I	Injury of worker from boom failure due to high wind or seismic	High wind or seismic event	NA	E1
CRN-17	Release of radioactive or toxic material from tanks due to power failure from crane hitting power lines/supplies	Human error: improper load assembly, rigging, crane positioning	F3	E1
CRN-17-I	Injury of worker from electricity due to crane hitting powerlines/supplies	Human error: improper load assembly, rigging, crane positioning	NA	E1

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (SI).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
CRN-24	Carbon monoxide from crane accumulates in pits or temporary confinement (greenhouse, etc)	Oxygen deficient atmosphere and failure to provide adequate ventilation, Failure to sniff or improper sniffing	NA	NA
CRN-24-I	Injury of worker from carbon monoxide accumulation in pits or temporary confinement (greenhouse, etc) due to crane motor exhaust	Failure to provide adequate ventilation,!Failure to sniff or improper sniffing	NA	E1
CRN-25	Loss of lateral load control, swinging load into personnel or equipment	Human error: improper load assembly, rigging, positioning error	NA	NA
CRN-25-IA	Injury of worker from swinging load into personnel due to loss of lateral load control	Human error: improper load assembly, rigging, positioning error	NA	E1
CRN-26	Loss of lateral load control, swinging load into personnel or equipment	Mechanical failure: corrosion, faulty materials, hydraulics, outriggers in soft soil	NA	NA
CRN-26-IA	Injury of worker from swinging load into personnel due to loss of lateral load control	Mechanical failure: corrosion, faulty materials, hydraulics, outriggers in soft soil	NA	E1
CRN-27	Loss of lateral load control, swinging load into personnel or equipment	High wind or seismic event	NA	NA
CRN-27-IA	Injury of worker from swinging load into personnel due to loss of lateral load control	High wind or seismic event	NA	E1
CVR-01	Release (greater than expected) of radioactive or hazardous material from pit due to lifting cover blocks	Failure to monitor or improper monitoring	F3	E1
CVR-01-I	Release of greater than expected amount of radioactive or hazardous material from pit upon lifting coverblocks due to monitoring failure	Failure to monitor or improper monitoring	F3	E1
CVR-02	Release (greater than expected) of radioactive or hazardous material from pit due to lifting cover blocks	Mechanical failure of equipment in pit (corrosion, leaks, etc)	F3	E1
CVR-02-I	Release of greater than expected amount of radioactive or hazardous material from pit upon lifting coverblocks due to mechanical failures	Mechanical failure of equipment in pit (corrosion, leaks, etc)	F3	E1
CVR-03	Release (greater than expected) of radioactive or hazardous material from pit due to lifting cover blocks	Wind or dust devil	F3	E1
CVR-03-I	Release of greater than expected amount of radioactive or hazardous material from pit upon lifting coverblocks due to windy conditions	Wind or dust devil	F3	E1
CVR-04	Release (greater than expected) of radioactive or hazardous material from pit due to earthquake lifting cover blocks	Seismic event	F1	E1
CVR-04-I	Release of greater than expected amount of radioactive or hazardous material from pit upon lifting coverblocks due to seismic event	Seismic event	F2	E1

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (SI).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
CVR-05-I	Release of radioactive or hazardous material from pit due to combustion or explosion of materials in pit	Failure to sniff or improper sniffing	F1	E1
CVR-06	Person falls in pit sustaining injury or exposed to surface radiation in pit	Failure to erect fence or failure to erect securely	NA	NA
CVR-06-I	Injury of worker from falling into pit due to missing or improperly installed fence possibly resulting in personnel exposure	Failure to erect fence or failure to erect securely	NA	E1
CVR-07	Person falls in pit sustaining injury or exposed to surface radiation in pit	Person leans over fence too far	NA	NA
CVR-07-I	Injury of worker from falling into pit due to human error possibly resulting in personnel exposure	Person leans over fence too far	NA	E1
CVR-08	Person falls in pit sustaining injury or exposed to surface radiation in pit	Fence failure	NA	NA
CVR-08-I	Injury of worker from falling into pit due to fence failure possibly resulting in personnel exposure	Fence failure	NA	E1
CVR-09	Person falls in pit sustaining injury or exposed to radiation	Seismic event or high wind/tornado	NA	NA
CVR-09-I	Injury of worker from falling into pit due to seismic event or high winds possibly resulting in personnel exposure	Seismic event or high wind/tornado	NA	E1
CVR-10	Person(s) asphyxiated	Oxygen deficient atmosphere and failure to sniff or improper sniffing	NA	NA
CVR-10-I	Injury of worker from asphyxiation due to pit atmosphere	Failure to sniff or improper sniffing	NA	E1
CVR-11	Person(s) asphyxiated	Oxygen deficient atmosphere and fresh air supply faults	NA	NA
CVR-11-I	Injury of worker from asphyxiation due to fresh air supply faults	Fresh air supply faults	NA	E1
CVR-12-I	Release of radioactive or hazardous material from pit upon lifting coverblocks due to incorrect spraying of fixative	Spraying of fixative (soil cement) causes spray of material out of pit	F3	E1
CVR-13-I	Release of radioactive or hazardous material from pit upon lifting coverblocks due to open nozzles or risers in pit	Open nozzles or risers in pit with radioactive or hazardous material inside	F3	E1
CVR-14-I	Injury of worker from biological hazards (spiders, snakes, etc.) due to open nozzles or risers in pit	Open nozzles or risers in pit with biological hazards (spiders, snakes, etc.) inside	F3	E1
DCN-01	Decontamination personnel are contaminated or exposed	Failure of PPE	NA	NA
DCN-01-I	Injury of worker from contamination or exposure of decontamination personnel due to failed PPE	Failure of PPE	NA	E1

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (S1).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
DCN-02	Release of radioactive or toxic material outside immediate area from equipment removed from tank due to decontamination of equipment	Miss direction of cleaning spray (human error)	F3	E1
DCN-02-IA	Release of radioactive or toxic material outside immediate area from equipment being decontaminated due to spray misdirection	Misdirection of cleaning spray (mechanical failure of spray ring)	F2	E1
DCN-02-IB	Release of radioactive or toxic material outside immediate area from equipment being decontaminated due to spray misdirection	Misdirection of cleaning spray (mechanical failure of spray ring)	F2	E1
DCN-03	Decon personnel are contaminated, aerosol release outside immediate area	Seismic event	F1	E1
DCN-03-I	Decontamination personnel are contaminated, release of aerosol outside immediate area from equipment being decontaminated due to seismic event	Seismic event	F2	E1
DCN-04	Decon personnel are contaminated, aerosol release outside immediate area	Wind/tornado	F2	E1
DCN-04-I	Decontamination personnel are contaminated, release of aerosol outside immediate area from equipment being decontaminated due to wind	Wind/tornado	F2	E2
DCN-05-I	Injury of worker from contact with tools due to human error during decontamination activities	Human error	NA	E1
DCN-06	Personnel exposure higher than expected	More contamination than expected	NA	NA
DCN-06-I	Injury of worker from higher than expected exposure due to unknown contamination	More contamination than expected	NA	E1
DCN-07-I	Injury of worker from exposure to asphyxiant due to PPE failure	PPE failure or absence in confined space	NA	E1
EE-02	Release of radioactive contaminants from Tank Farms due to external fires	Range fire	F3	E1
EE-03	Release of radioactive and hazardous materials from tanks due to loss of active ventilation	Dam collapse	F2	E1
EE-06	Release of radioactive and hazardous materials from tank farm due to external fires	On-site rail accident involving flammable materials	F2	E1
EE-09	Surface flooding at tank farm	Water line breaks and causes flooding at tank farm	F3	E0
EE-10	Release of radioactive and hazardous materials from tanks due to loss of tank integrity	Water line breaks, saturates subsurface, and hydrostatic head causes tank to float	F0	E3
EE-12	Washout of soils surrounding a transfer pipe	Water main to evaporator or steam plant breaks	NA	E0
EE-14	Worker injury due to electrocution	Excavation into power source	NA	NA

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (SI).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
EE-15	Washout of soils resulting in sink hole due to excavation error	Excavation into water line	NA	NA
GRN-01	Industrial hazards (lifting, bending, trips and falls, tool operations)	Human errors	NA	NA
GRN-01-I	Injury of worker from (lifting, bending, tool accidents; creates tripping hazard) due to temporary confinement activities	Human errors	NA	E1
GRN-02	Industrial hazards (lifting, bending, trips and falls, tool operations)	Mechanical failure of equipment, tools	NA	NA
GRN-02-I	Injury of worker from (lifting, bending, trips and falls, tool operations) due to mechanical failures	Mechanical failure of equipment, tools	NA	E1
GRN-03-I	Injury of worker from asphyxiants in greenhouse due to collection of asphyxiants before removal	Human error	NA	E1
I-222S-1-CMP-A	Release of 222-S lab waste from transfer line due to leak from rapid corrosion caused by transfer of pH 1 solution	Human error - failure to add sodium hydroxide	F3	E1
I-222S-2-FLW-A	Release (steam) of aerosols and particulates to the atmosphere due to reverse flowing steam into Tank 219-S-102 which saturates the HEPAs	Block valve inadvertently closed at tank farms and transfer via this line	F3	E1
I-242A-2-CMP-A	Release (potential for leak) to tank annulus (secondary confinement) caused by damage to feed tank due to overfilling of tank	Valve failure or inadvertently opened valve	F3	E1
I-242A-4-FLW-A	Release of diluted high level waste to the ground through risers after unmitigated over filling of Tank 241-AW-102 and annulus with condensate	Tube rupture of raw water in condenser	F3	E1
I-242A-6-FLW-A	Release of diluted high level waste to the ground through risers after unmitigated over filling of Tank 241-AW-102 and annulus with raw water	Rupture of raw water line in condenser/pump room	F3	E1
I-242A-6-FLW-C	Release of contaminated aerosols to the 242-A Evaporator building through the drain lines, potential worker hazard	Higher vacuum at evaporator than at tank farms	F3	E0
I-242A-7-CMP-A	Release of aerosols through the risers due to potential to get glycol into instrument air and pressure monitoring system, potential for pressure gages to fail and inability for operators to detect tank pressurization	Compressor head leaks 241-AW Tank Farm air supplied from 242-A, a tank pressurization event for a release	F1	E1
I-242A-7-PRS-A	Personnel hazard from ruptured compressed air line	Failure of compressor unloading switch due mechanical failure or incorrect setting during maintenance	F2	E0
I-242S-1-PRS-A	Release of airborne contaminates through cracks due to over pressurization of 242-S building and contamination of control room where tank farm controls are located	Exhaust fan failure	F3	E1

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (S1).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
I-242S-1-TMP-A	Release of contaminated water to the ground outside of the 242-S Evaporator due to unmitigated leak in the pump room from the fire protection system's frozen and ruptured line	Low ambient temperature freezes and breaks pipe	F3	E1
I-242S-2-FLW-B	Release of contaminated water to condenser room increasing contamination in the condenser room due to overfilling Tank 241-C-100	Human error - incorrect valve line up	F2	E0
I-242S-4-FLW-B	Release of high level waste to the 242-S condenser room due to reverse flow from Tank 241-SY-102 caused by improper valve line up	Human error - incorrect valve line up	F2	E0
I-242S-4-LEK-B	Release of contaminated water to the atmosphere due to spray leak at the condenser room, caused by corrosion in the pipe	Corrosion in pipe line	F3	E0
I-242S-4-LEK-C	Release of contaminated water to the atmosphere due to spray leak at the rupture of the line from excavation	Inadvertent excavation of line causes spray leak	F2	E0
I-242S-5-CMP-A	Release of aerosols through the risers from various tanks due to loss pressure monitoring system caused by glycol in the instrument air and results in failure of pressure gages and inability of operators to detect tank pressurization	Compressor head leaks, tank pressurization event to get a release	F2	E1
I-242S-5-CMP-B	Release of aerosols through the risers from various tanks due to loss of instrument air to pressure monitoring system caused by glycol damage desiccant which plugs the filter, if pressure gages fail, inability for operator to detect tank pressurization	Compressor head leaks, tank pressurization event to get a release	F2	E1
I-242S-5-CMP-C	Release of aerosols through the risers from various tanks due to desiccant plugging filter resulting in loss of instrument air to pressure monitoring system causing pressure gages to fail and inability for operators to detect tank pressurization	Clogged filter cutting off air supply, tank pressurization event to get a release	F2	E1
I-242S-5-CMP-D	Release of aerosols through the risers from various tanks due to release of desiccant into instrument air which damages the pressures gages and causes the inability of operators to detect tank pressurization	Blow out Filter damaging instrument air, tank pressurization event to get a release	F2	E1
I-242S-5-FLW-A	Release of aerosols through the risers from various tanks due to loss of instrument air to pressure monitoring system which causes the pressure gages to fail and the inability for operators to detect tank pressurization	Compressor fails, tank pressurization event to get a release	F2	E1
I-242S-5-FLW-B	Release of aerosols through the risers from various tanks due to loss of instrument air to pressure monitoring system which causes pressure gages to fail and the inability for operators to detect tank pressurization	Block valve inadvertently closed, tank pressurization event to get a release	F2	E1

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (SI).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
I-242S-5-FLW-C	Release of aerosols through the risers from various tanks due to loss of instrument air to pressure monitoring system which causes pressure gages to fail and the inability for operators to detect tank pressurization	Filter plugged, tank pressurization event to get a release	F2	E1
I-242S-5-PRS-A	Personnel hazard due to rupture of compressed air line	Human error - failure of compressor unloading switch due to incorrect setting during maintenance	F2	E0
I-242T-3-FLW-A	Release of high level waste to the ground surface by overflowing the "new" diversion box caused by opened or leaking valve	Block valve inadvertently opened or leaking	F3	E1
I-242T-4-FLW-A	Release of high level waste to the ground surface from overflowing the "new" diversion box due to failure of 242-T building and rupture of tanks in 242-T	Catastrophic failure of the building due to aging effects	F3	E1
I-BPLANT-1-TMP-A	Release of aerosols from pressurizing receiver tank due to transfer of hot material from Tank 24-1 to receiver tank	Human error - sending steam to Tank 24-1, inadvertently transferring to tank farms	F2	E1
I-BPLANT-2-FLW-C	Release (ground surface) of low level waste from overflow of receiver tank to pits due to transfer of excessive low level waste from B Plant	Human error - filling Tank 24-1 while transferring to tank farms, receiver tank at maximum administrative level	F1	E1
I-PFP-1-LVL-A	Release (underground) of TRU mixed waste at DCRT pit due to potential to send steam vapor to 244-TX-DCRT, potential for thermal expansion to damage transfer pipe and leak to encasement pipe which drains to DCRT pit	Human error - failing to stop transfer to 244-TX when Tank D-5 is empty	F3	E1
I-PFP-2-TMP-A	Release of TRU mixed waste at DCRT pit due to potential to send steam vapor to 244-TX-DCRT steam jet gassing it out, potential for thermal expansion to damage transfer pipe	Failure of steam reducer causes spray leak	F2	E1
I-PFP-3-FLW-C	Release of TRU mixed waste from 244-TX overfilling due to transfer error	Transferring from Tank D-7 or Tank D-8 to Tank D-5 while transferring from Tank D-5 to 244-TX	F3	E1
I-PUREX-1-TMP-A	Release from Tank 241-AW-105 through cracks in the cover block due to pressurizing tank from addition of hot waste to the tank	Human error - adding caustic (sodium hydroxide) to waste or transferring to U-3 via a steam jet and transferring from U-3 to Tank 241-AW-105 before the waste cools	F3	E1
I-PUREX-2-PRS-B	Release of aerosols through cracks in the cover block due to pressurizing the receiver tank from an extended air purge of the transfer line	Extended air purge after transfer (mechanical failure)	F3	E1
I-PUREX-2-PRS-C	Personnel exposure due to vacuum pulling radioactive material back to operating gallery, worker hazard at PUREX (dose concern)	Failure to air purge line after transfer (mechanical failure)	F2	E0

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (SI).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
I-PUREX-3-TMP-A	Release of aerosols from Tank 241-AW-105 through cracks in the cover block due to pressurizing tank from addition of hot waste	Human error - adding caustic (sodium hydroxide) to waste or transferring to U-3 via a steam jet and transferring from U-3 to Tank 241-AW-105 before the waste cools	F3	E1
I-PUREX-4-PRS-B	Release of aerosols through cracks in the cover block due to pressurizing the receiver tank from an extended air purge of the transfer line	Extended air purge after transfer (mechanical failure)	F3	E1
I-PUREX-4-PRS-C	Personnel exposure due to vacuum to pulling radioactive material back to operating gallery, worker hazard at Purex (dose concern)	Failure to air purge line after transfer (mechanical failure)	F2	E0
I-PUREX-5-FLW-A	Release of aerosols through cracks in cover block due to pressurizing receiver tank caused by transferring waste with steam which heats the waste	Multiple deactivation locks removed and valves opened or multiple valves leaking	F3	E1
I-PUREX-5-FLW-B	Release of aerosols from receiver tank due to fire caused by transfer of organic from PUREX	Organic material present in Tank R-8	F2	E1
I-PUREX-6-FLW-B	Release (ground surface) of liquid waste in Catch Tank 302-A diluted with flush water due to overfilling the tank and the pump pit and/or the diversion box due to improper valve line up of flush water	Multiple flush water block valves inadvertently opened or leaking	F2	E1
I-PUREX-6-FLW-C	Release of high level tank waste due to overfilling Tank 302-A into the diversion box and into an open nozzle which directs the flow to other tanks in the tank farm	Multiple flush water block valves inadvertently opened or leaking	F2	E1
I-TPLANT-1-TMP-A	Release of aerosols from pressurizing receiver tank due to transfer of hot material from Tank 15-1 to receiver tank	Human error - sending steam to Tank 15-1 and inadvertently transferring to tank farms	F2	E1
I-TPLANT-2-FLW-B	Release of low level waste from overflow of receiver tank to pits due to transfer of excessive low level waste from T Plant	Human error - filling Tank 15-1 while transferring to tank farms and receiver tank at maximum administrative level	F1	E1
I-UPLANT-1-RAN-A	Release of contaminated rain water to the ground surface from overfilling catch tank and diversion box due to severe rain	Severe Rain	F2	E1
ITK-01	Radioactive and/or hazardous material release from point of in-tank access (non-fire, non-explosion) due to intrusive activity	Chemical/thermal reaction of materials in equipment/waste	F2	E1
ITK-01-I	Release of radioactive and/or hazardous material from point of in-facility access due to chemical/thermal reaction (non-fire, non-explosion)	Chemical/thermal reaction of materials in equipment/waste	F3	E1
ITK-02	Radioactive and/or hazardous material release from point of in-tank access (non-fire, non-explosion) due to intrusive activity	Pressurized equipment fails in tank and increases tank pressure	F2	E1

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (S1).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
ITK-02-I	Release of radioactive and/or hazardous material from point of in-facility access due to equipment pressurization release event (non-fire, non-explosion)	Pressurized equipment fails in facility and increases facility pressure	F1	E1
ITK-03	Release of radioactive and/or hazardous material from point of in-tank access (non-fire, non-explosion) due to intrusive activity	Contaminated equipment removed or reused	F3	E1
ITK-03-I	Release of radioactive and/or hazardous material from point of in-facility access due to equipment removal (non-fire, non-explosion)	Contaminated equipment removed or reused	F3	E1
ITK-04	Release of radioactive and/or hazardous material from point of in-tank access (non-fire, non-explosion) due to earthquake or high wind with open access	Seismic event or high wind when access open	F3	E1
ITK-04-I	Release of radioactive and/or hazardous material from point of in-facility access due to seismic event or high wind (non-fire, non-explosion)	Seismic event or high wind when access open	F2	E1
ITK-07	Radioactive and/or hazardous material release from tank below grade (non-fire, non-explosion) due to intrusive activity	Dropped equipment in tank from human error or equipment failures (also see crane operations) Penetration of tank with linear-force, high pressure, or rotational equipment from human error or equipment failure	F3	E3
ITK-07-IA	Release of radioactive and/or hazardous material from facility below grade due to breach of facility confinement (non-fire, non-explosion)	Dropped equipment in facility from human error or equipment failures (also see crane operations) Penetration of facility confinement with linear-force, high pressure, or rotational equipment from human error or equipment failure	F2	E1
ITK-07-IB	Release of radioactive and/or hazardous material from facility at surface due to breach of facility confinement (non-fire, non-explosion)	Dropped equipment in facility from human error or equipment failures (also see crane operations) Penetration of facility confinement with linear-force, high pressure, or rotational equipment from human error or equipment failure	F2	E2
ITK-FR-01	Release of radioactive or hazardous material from flex receiver due to flushing with insufficient drainage	Riser not drained correctly or drain clogged causing plugging of riser	F3	E1
ITK-FR-02	Release of radioactive or hazardous material from flex receiver due to equipment jam in riser and non-procedural efforts to dislodge	Equipment becomes lodged in riser upon retrieval and non-procedural efforts to remove provide release path for tank material and/or flush water	F3	E1
ITK-FR-05	Release of radioactive or hazardous material from flex receiver due to structural failure	Human error tears flex receiver bag	F3	E1

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (S1).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
ITK-FR-06	Release of radioactive or hazardous material from flex receiver due to structural failure	Equipment failure/misalignment tears flex receiver bag (crane operation, hydraulic jack stand)	F3	E1
ITK-FR-07	Release of radioactive or hazardous material from flex receiver due to structural failure	Structural degradation	F3	E1
ITK-FR-09	Release of radioactive or hazardous material from flex receiver due to mechanical equipment failure	Failure of automatic cinch or inappropriate tightening of cables, condition goes unnoticed and receiver is sheared	F2	E1
ITK-FR-10	Release of radioactive or hazardous material from flex receiver due to mechanical equipment failure	Failure of cinching cables causing loss of containment after receiver is sheared	F2	E1
ITK-FR-11	Release or radioactive or hazardous material from flex receiver due to loss of hydraulics	Hydraulic power is lost while bag is being sealed resulting in failure of seal and leak path from bag	F1	E1
ITK-FR-12	Release or radioactive or hazardous material from flex receiver due to loss of hydraulics	Mechanical failure or inadequate operating pressure of hydraulics while bag is being sealed resulting in failure of seal and leak path from bag	F1	E1
ITK-FR-14	Release of radioactive or hazardous material from flex receiver due to leak from flanges	Non-acceptable torque on bolts connecting bellows - torque too low not enough pressure for adequate seal, to high destroys seal material	F3	E1
ITK-FR-15	Release of radioactive or hazardous material from flex receiver due to errors in installation	Incorrect installation of receiver provides release path (misalignment of bellows)	F3	E1
ITK-FR-16	Release of radioactive or hazardous material from flex receiver due to containment failure during transfer	Failure of cinched end/receiver material and secondary containment bag during transfer of equipment to trailer	F2	E1
ITK-FR-17	Release of radioactive or hazardous material from flex receiver due to leak from bag	Flaw in bag construction provides leak path for material	F2	E1
ITK-FR-18	Release of radioactive or hazardous material from flex receiver due to damage from operation of hydraulic jacks	Hydraulic jacks on assembly stand are operated while assembly is bolted to flange damaging flex receiver or riser creating release path	F3	E1
ITK-FR-20	Release of radioactive or hazardous material from flex receiver due to wrong bag being used	Containment bag is too short to hold equipment being withdrawn from tank, condition goes unnoticed until containment is lost	F3	E1
ITK-FR-21	Release of radioactive or hazardous material from flex receiver due to operation in extreme weather	Operation in cold weather compromises strength of flex receiver, equipment breaks providing release path	F3	E1

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (SI).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
ITK-FR-23	Release of radioactive or hazardous material from flex receiver due to equipment failure	Plexiglass window on receiver breaks causing release path	F3	E1
ITK-FR-24	Release of radioactive aerosols from flex receiver due to cutter misoperation damaging metal housing	Cutter cuts through containment (metal housing), venturi effect spread aerolized waste outside of containment (cutter not turned off in time, water pressure/flow too high, or cutting spread increased because of abrasive characteristics)	F2	E0
ITK-FR-25	Release of radioactive or hazardous vapors due to pump or water supply failure	Loss of cutting water due to pump or water supply failure provides open pathway from tank through silica hopper	F2	E0
ITK-FR-26	Release of radioactive or hazardous material from flex receiver due to leak from bag	Equipment mispositioned in receiver bag creating inappropriate seal and leak	F3	E1
ITK-FR-27	Release of radioactive or hazardous material from flex receiver due to containment breach during transfer	Unable to lock lifting ring onto skid, equipment falls off skid ripping bag and creating a release path	F2	E1
ITK-FR-28	Release of radioactive or hazardous material from flex receiver due to containment breach during transfer	Receiver trailer falls over with bagged equipment attached ripping bag and creating release path	F3	E1
LDUA 1-10	Worker exposure due to leak of waste into LDUA components	Line plug	F3	E0
LDUA 1-11	Worker exposure due to leak of waste into LDUA components	Line break	F3	E0
LDUA 1-34	Worker exposure due to operation error or mechanical failure	Operator error or mechanical failure	F3	E0
LDUA 2-13	Worker exposure due to leak of waste into LDUA components	Line plug	F3	E0
LDUA 2-14	Worker exposure due to leak of waste into LDUA components	Line break	F3	E0
LDUA 2-50	Worker injury due to equipment damage	Human error, software bug	F3	E0
LDUA 2-53	Worker exposure due to contamination in LDUA	LDUA contamination - due to in-tank activities	F3	E0
LDUA 2-54	Worker injury due to industrial accidents	Industrial accidents	F3	E0
LDUA 3-1	Release of radioactive aerosols from the TRIC due to filter plug and pressurization	TRIC filter inlet plugs (dust, ice, etc.)	F3	E1
LDUA 3-15	Release of radioactive aerosols from the TRIC due to filter plug and pressurization	HEPA filter plugs with frozen condensation	F3	E1
LDUA 3-19	Worker injury due to general industrial hazards	General industrial hazards (e.g. during end effector change out)	F3	E0

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (S1).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
LDUA 3-2	Release of contamination from LDUA due to loss of containment	Door not sealed, loss of glove	F3	E1
LDUA 3-20	Worker injury due to electric shock	Electric shock hazards during hook-up and maintenance	F3	E0
LDUA 3-21	Release of contamination to ground from LDUA due to impact from pressurized water/decontamination system	500-psi water (from decontamination system) causes impact hazards	F3	E1
LDUA 3-22	Release of contamination from riser and TRIC due to loss of confinement	Riser valve open while end effectors being placed in TRIC	F3	E1
LDUA 3-23	Release or radioactive aerosols from riser due to spark igniting flammable gas	Plug gauge (carbon steel) becomes stuck in riser during riser characterization	F3	E1
LDUA 3-24	Release of contamination from TRIC due to load drop	TRIC dropped from crane	F3	E1
LDUA 3-25	Release of contamination from LDUA due to incorrect installation	VPM adapter, HEPA, Gloves, Door, incorrectly installed/sealed (leaks)	F3	E1
LDUA 3-28	Release of contamination from riser due to high winds	High winds stress riser	F3	E1
LDUA 3-4	Worker exposure due to purge system overpressure - increased contamination in TRIC	Purge system overpressure (VPM auxiliary hookup)	F3	E0
LDUA 3-5	Worker exposure due to loss of decontamination water flow	Loss of decontamination water flow	F3	E0
LDUA 3-7	Worker exposure due to plug in decontamination line resulting in poor decontamination	Decontamination water line plugs due to solids	F3	E0
LDUA 4-10	Worker exposure due to ignition of flammable gas inside VPM	Loss of supply air from VPM outer tube.	F3	E0
LDUA 4-11	Worker injury due to blow out of housing panel	Supply pressure on with the VPM housing gate closed	F3	E0
LDUA 4-27	Release of contamination due to thermal degradation of VPM housing	Thermal expansion/contraction of atmosphere in housing while in storage	F3	E1
LDUA 4-30	Release of contamination due to corrosion of VPM	Poor decontamination, caustic waste contacts arm, causes corrosion of VPM	F3	E1
LDUA 4-39	Worker exposure due to loss of computer controls/ requires manual retrieval of mast	Loss of computer	F3	E0
LDUA 4-40	Worker exposure due to insufficient decontamination	Mast tubes not sufficiently decontaminated prior to removal	F3	E0
LDUA 4-43	Worker injury due to industrial hazards	Industrial hazards during maintenance	F3	E0
LDUA 4-8	Worker exposure due to leak of waste into LDUA components	Line plug	F3	E0
LDUA 4-9	Worker exposure due to leak of waste into LDUA components	Line break	F3	E0

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (S1).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
LDUA 5-17	Worker injury due to inadvertent motion of valve	Operator error, improperly positioned valves	F3	E0
LDUA 5-21	Worker injury due to shock load damaging equipment	Shock load causes damage	F3	E0
LDUA 5-23	Release of hazardous material to environment from truck battery due to inadvertent spill/potential ignition	Truck battery acid spill, deflagration	F3	E1
LDUA 5-29	Release of contamination from LDUA or riser due to spark igniting flammable gas	Truck backs into tank farm equipment (e.g., riser, pump pit)	F3	E1
LDUA 5-30	Release of contamination from LDUA or riser due to damage from vehicles	Truck moves after setup	F3	E1
LDUA 5-31	Release of contamination due to transport vehicle accident.	Vehicle accident during transport	F3	E1
LDUA 5-32	Worker injury due to vehicle engine fire	Vehicle engine fire	F3	E0
LDUA 5-33	Release of contamination from LDUA or riser due to damage from vehicles	Failure to deploy outriggers or premature retraction of outriggers	F3	E1
LDUA 5-35	Worker exposure due to misalignment of mast arm during insertion creating external contamination	Misaligning during insertion	F3	E0
LDUA 5-36	Release of contamination from LDUA or riser due to damage from improper operation	Attempting to lower VPM to horizontal while arm is in riser	F3	E1
LDUA 5-39	Release of contamination from LDUA or riser due to equipment failure causing riser damage	Brakes not operating as designed	F3	E1
LDUA 5-41	Release of contamination from TRIC and tank riser due to damage during seismic event	Seismic event	F3	E1
LDUA 5-42	Release of contamination from LDUA or riser due to damage from vehicle operation resulting in fire	Other truck impact	F3	E1
LDUA 5-44	Release of contamination from LDUA or riser due to damage from vehicle operation	Heavy rain or ponded surface water or flood	F3	E1
LDUA 6-28	Worker injury due to communication failure	Communication failure between control locations and TRIC during maintenance	F3	E0
LDUA 6-29	Worker injury due to lifting	Lifting injuries in moving heavy cable	F3	E0
LDUA 6-30	Worker injury due to electric shock	Electrical malfunction	F3	E0
LDUA 6-5	Worker injury due to fire	Fire	F3	E0
LDUA 6-7	Worker injury due to electric shock	Impact, severing of cable by heavy equipment	F3	E0
LDUA 7-12	Worker injury due to accident when parking trailer	Collision with obstacles during parking of trailer	F3	E0
LDUA 7-13	Worker injury due to electric shock	Improper grounding - bonding	F3	E0

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (SI).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
LDUA 7-14	Worker injury due to electric shock	Electrical shock hazards during hook-up	F3	E0
LDUA 7-16	Worker injury due to electric shock	Dust in electronic distribution disconnects and junction box	F3	E0
LDUA 7-3	Worker injury due to slipping hazard	Slipping hazards	F3	E0
LDUA 7-4	Worker injury due to fire	Fire in trailer	F3	E0
LDUA 7-6	Worker injury due to trailer falling over	Wind	F3	E0
LDUA 7-7	Worker injury due to trailer falling over	Seismic event	F3	E0
LDUA/EREE 1-10	Worker exposure due to leak of waste into EREE	Line break	F3	E0
LDUA/EREE 1-29	Worker exposure due to operator error/mechanical failure	Operator error or mechanical failure	F3	E0
LDUA/EREE 1-30	Worker exposure due to operator error/mechanical failure	Operator error or mechanical failure	F3	E0
LDUA/EREE 1-8	Worker exposure due to leak of waste into EREE	Compressor fails	F2	E0
LDUA/EREE 1-9	Worker exposure due to leak of waste into EREE	Line plug	F3	E0
NP-01	Radioactive and hazardous material release from tanks and ventilation system due to loss of electric power	Lightning strikes power distribution system	F3	E1
NP-06	Radioactive and hazardous material releases from tanks, nearby ground surfaces, and ventilation systems due to above ground disturbances	High wind	F3	E1
NP-09	Radioactive and hazardous material releases from tanks due to seismic event	Seismic event results in tank leaks or below grade tank ruptures	F1	E3
NP-10	Radioactive and hazardous material releases from tanks due to loss of power to ventilation systems	Ash fall from volcanic activity	F2	E1
NP-12	Radioactive and hazardous material releases from tanks due to ventilation system failures	Dust storms/dust devils	F3	E1
NP-14	Radioactive and hazardous material releases from tanks due to loss of power to ventilation systems	Severe hail	F3	E1
OGT-FLOW1-01	Personnel exposure to radioactive or hazardous material in the primary pipe due to pump failure	Pump failure, material settles in line (crystallization) and plugs line prohibiting transfer/waste is sitting in line and creates increased exposure to personnel	F3	E0

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (SI).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
OGT-FLOW2-01A	Release of radioactive or hazardous material from the primary pipe due to leak caused by incorrect pump installed	Incorrect pump installed creates excessive flow and isolation valve closed on secondary pipe, erosion of EPDM and pressurization of secondary pipe causing leaks from flanges gasket within concrete shield	F2	E2
OGT-FLOW2-03A	Release of radioactive or hazardous material from the primary pipe due to leak caused by incorrect pump installed	Installation of incorrect pump, failure of inner pipe and isolation valves closed on secondary pipe drains causing leak from failed welds on flange within the concrete shield	F1	E2
OGT-INTEG3-01	Release of radioactive or hazardous material from overflow of pit due to leak caused by loss of primary pipe integrity from aging	Primary pipe failure due to radiation/chemical age related damage, leak of primary pipe, flow to pit from secondary pipe drains when pipe drains are in open position with pipe drains open and insufficient drainage from pit	F1	E1
OGT-OPS1-01	Release of radioactive or hazardous material from the primary pipe due to line crushing from equipment drop	Drop shield blocks on transfer line during disassembly after pumping complete, potential to break primary and secondary line	F3	E1
OGT-SPEC1-01	Personnel exposure to radioactive or hazardous material in the primary pipe due to loss of electrical supply	Loss of flow leading to line plug and the need to remove/replace, unclog line	F3	E0
OGT-TEMP1-01	Personnel exposure to radioactive or hazardous material from the primary pipe due leak caused by low ambient temperature	Plugging of pipe due to crystallization or due to freezing for very low temperature	F1	E0
RAD-01	Exposure to radioactive and/or toxic materials from pits or risers due to radiation monitoring failure	Failure to monitor	NA	NA
RAD-01-I	Injury of worker from exposure to radioactive materials due to failure to monitor radiation	Failure to monitor	NA	E1
RAD-02	Exposure to radioactive and/or toxic materials from pits or risers due to radiation monitoring failure	Failure of monitoring instrument	NA	NA
RAD-02-I	Injury of worker from exposure to radioactive materials due to radiation monitoring failure	Failure of monitoring instrument	NA	E1
RAD-03	Exposure to radioactive and/or toxic materials from pits or risers due to radiation monitoring failure	Improper calibration of monitoring instrument	NA	NA
RAD-03-I	Injury of worker from exposure to radioactive materials due to radiation monitoring failure	Improper calibration of monitoring instrument	NA	E1
RSR-01	Release of radioactive and/or toxic material upon opening of riser due to human error	Human error - improper contamination control, failure to monitor (rad or sniff), improper monitoring	F3	E1

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (S1).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
RSR-01-I	Release of radioactive and/or toxic material from the vapor space due to opening of riser	Human error - improper contamination control, failure to monitor (rad or sniff), improper monitoring	F3	E1
RSR-02	Asbestos hazard from gasket materials during access to riser	Failure to follow asbestos procedures	NA	NA
RSR-02-I	Injury of worker from exposure to asbestos from gasket materials during access to riser due to failure to follow procedures	Failure to follow asbestos procedures	NA	E1
RSR-03	Asbestos hazard from gasket materials during access to riser	Failure of mask or fresh air (if appropriate)	NA	NA
RSR-03-I	Injury of worker from exposure to asbestos from gasket materials during access to riser due to failure of PPE or fresh air supply	Failure of mask or fresh air (if appropriate)	NA	E1
RSR-04	Direct radiation exposure from open riser due to human error	Failure to follow procedures, failure to monitor or improper monitoring	NA	NA
RSR-04-I	Injury of worker from exposure to direct radiation exposure from open riser due to failure to follow procedures	Failure to follow procedures, failure to monitor or improper monitoring	NA	E1
RSR-05-IA	Facility confinement breach from dropped equipment (tools, mirrors) into facility	Failure to attach lanyard or other position limiting device Failure of lanyard or device	F2	E1
RSR-05-IB	Facility confinement breach from dropped equipment (tools, mirrors) into facility	Failure to attach lanyard or other position limiting device Failure of lanyard or device	F2	E2
RSR-08-I	Injury of worker from falling into facility due to large access opening and human error	Human error	NA	E1
SFF-01	Release of radioactive and/or toxic materials during sniff sampling due to human error or instrument failure	Improper sniffing technique or instrument failure, failure to perform radiation monitoring, improper monitoring, or instrument failure	F3	E1
SFF-01-I	Injury of worker from exposure to toxic materials due to sniff sampling failure	Improper sniffing technique or instrument failure	NA	E1
VEH-04	Personnel receive radiation exposure from casks during transport due to human error	Personnel drive the vehicles or work near the cask transport vehicle	NA	NA
VEH-04-I	Injury of worker from radiation exposure from casks during transport due to inappropriate ALARA practices	Driver receives unexpected exposure or personnel work near the cask transport vehicle	NA	E1
VEH-05	Vehicle impact with electrical power pole	Loss of control of vehicle or lack of attention to driving	NA	NA
VEH-05-I	Injury of worker from impact with electrical power pole due to vehicle accident	Loss of control of vehicle or lack of attention to driving	NA	E1

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (SI).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
VEH-06	Personnel are pinched or crushed between vehicle and solid structure	Vehicle moves exerting pressure on personnel between vehicle and solid structure	NA	NA
VEH-06-I	Injury of worker from being pinched or crushed between vehicle and solid structure due to inattention to situation	Vehicle exerts pressure on personnel located between the vehicle and solid structure	NA	E1
VSU-01	Release of residual contamination and/or hazardous material from VSU due to VSU lid being left off	VSU lid is left off due to human error, wind blows	F3	E1
VSU-02	Release of residual contamination and/or hazardous material from VSU due to VSU lid being left off	VSU lid is left off due to human error, rain/snow melt seeps out bottom of VSU	F3	E1
VSU-03	Release of residual contamination and/or hazardous material from VSU due to VSU wall degradation	VSU wall degradation over time	F3	E1
VSU-04	Release of residual contamination and/or hazardous material from VSU due to internal VSU pressurization	Covered VSU pressurizes due to ambient temperature heat-up	F3	E1
VSU-05	Tripping hazard	Exposure above ground level	NA	NA
VSU-06	Falling hazard	VSU without a lid and not capped	NA	NA
XS-01-FLOW04	Release of liquid radioactive waste due to overflow from 244-TX DCRT to annulus	Human error (leaving water on after extended flush) causes overflow to annulus	F2	E1
XS-01-PRES02	Release of liquid radioactive waste from transfer pipe due to damaged saltwell pump	Leak from pump or seal from various causes	F3	E2
XS-01-TEMP02	Release of steam-aerosol from transfer piping in pump pit due to steam hammer and resulting pipe damage	Extended recirculation and consequential heating of saltwell liquid with sudden opening of valve when cover block is in place	F3	E1
XS-02-FLOW01	Release of headspace aerosols from 244-TX DCRT into PFP due to jumper misalignment	Jumper misalignment allowing PFP steam jet or ventilation system to pull vapors DCRT	F2	E1
XS-02-FLOW06	Release of liquid radioactive waste from DCRT due to overflowing of PFP sending tank (in facility)	Reverse flow caused by jumper misalignment	F3	E1
XS-03-LEVE	Release of radioactive liquids from DCRT "annulus" (vault) due to DCRT leak	Corrosion or structural failure of DCRT or associated piping	F3	E2
XS-03-PRES01	Release of toxic vapors from DCRT due to increased concentrations in DCRT atmosphere	Tank isolated from forced ventilation with gas evolution	F3	E1
XS-03-PRES01A	Release of radioactive aerosols from DCRT headspace due to positive pressure	Loss of ventilation flow due to failure of ventilation fans causes positive pressure in tank	F3	E1
XS-03-PRES02	Release of radioactive aerosols from DCRT headspace due to positive pressure	Dampers inadvertently closed causing positive pressure in tank	F3	E1

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (S1).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
XS-03-PRES03	Release of radioactive aerosols from DCRT headspace due to positive pressure in DCRT	Ductwork damage due to external event causes positive pressure in DCRT	F3	E1
XS-03-PRES04	Release of radioactive aerosols from DCRT headspace due to positive pressure	Loss of power causes positive pressure in tank	F3	E1
XS-03-TEMP04	Release of radioactive aerosols from 244-TX DCRT due to fire	Burning of flammable gas in DCRT	F1	E1
XS-03-TEMP05	Release of radioactive aerosols from DCRT headspace due to positive pressure	Excessive agitation-pumping causes positive pressure and generates aerosols	F3	E1
XS-03-TEMP06	Release of toxic vapors from DCRT headspace due to positive pressure in DCRT	Excessive agitation-pumping causes positive pressure	F3	E1
XS-03-TEMP07	Release of radioactive aerosols from DCRT headspace due to positive pressure	Loss of ventilation flow due to HEPA filter blockage in cold weather causes positive pressure in tank	F3	E1
XS-03-TEMP08	Release of radioactive aerosols from DCRT headspace due to positive pressure	Loss of ventilation flow plus high heat waste causes positive pressure in tank	F3	E1
XS-06-FLOW06	Release of radioactive aerosols from DCRT annulus due to a spill of radioactive liquid	Overfilling DCRT due to a misrouting causes spill into DCRT annulus	F3	E1
XS-12-FLOW01	Release of toxic gas from diversion box due to accumulation of toxic vapors from catch tank	Chemical reaction of catch tank material with backflow of vapors via diversion box drain line	F3	E1
XS-12-FLOW04	Release of toxic gas from diversion box due to accumulation of toxic vapors from catch tank	Radiolysis of catch tank material with backflow of vapors via diversion box drain line	F3	E1
XS-12-FLOW06	Release of radioactive waste to the soil from diversion box drain due to a spill of radioactive liquid into 241-U-152 diversion box	Leak of diversion box drain line upstream of catch tank	F3	E2
XS-20-FLOW02	Release of radioactive aerosols from T-Plant tank due to chemical reaction	Transfer of incompatible waste to T-Plant due to improper valve lineup	F2	E2
XS-20-FLOW06	Release of radioactive aerosols from T-Plant tank due to positive pressure	Chemical reaction of 244-S material with contents of T-Plant tank due to misrouting causes positive pressure in tank	F2	E2
XS-20-FLOW07	Release of toxic vapors from T-Plant due to chemical reaction with incompatible material in 244-S DCRT	Mixing contents of 244-S with contents of T-Plant tank due to misrouting causes chemical reaction	F2	E2
XS-26-PRES01A 102AW-02-PRES	Release of radioactive aerosols from Tank 241-SY-102 due to positive pressure	Blockage of exhaust path causes pressure in tank	F3	E1
XS-26-PRES02A 102AW-02-PRES	Release of radioactive aerosols from Tank 241-SY-102 due to positive pressure	Failure of ventilation fans causes pressure in tank	F3	E1

Table D3.4-3. Hazardous Conditions With Potential Significant Worker Consequences (SI).[1] (34 sheets)

ID	Hazardous Condition	Cause	Freq NC	Env Cons
XS-26-PRES03	Release of radioactive aerosols from Tank 241-SY-102 due to positive pressure	Use of hot water to decontaminate equipment in tank atmosphere - generate aerosols and pressurizes the tank	F3	E1
XS-26-PRES03 102AW-02-PRES	Release of radioactive aerosols from Tank 241-SY-102 due to positive pressure	Loss of power to ventilation system causes positive pressure in tank	F3	E1
XS-26-TEMP 102AW-08-TEMP	Release of radioactive aerosols from Tank 241-SY-102 annulus due to leak of tank contents to annulus	Exceeding design temperature of tank due to high heat waste and loss of primary ventilation system	F1	E1
XS-26-TEMP02	Release of radioactive aerosols from Tank 241-SY-102 annulus due to leak of tank contents to annulus	Exceeding design temperature of tank due to failure of annulus ventilation	F1	E1
XS-41B-LEVE02	Release of toxic gas from vent station access pit via valve operator seals due to liquid accumulation in vent station nozzle pit	Overflow of vent station catch tank into nozzle pit causes tank gas accumulation	F3	E1
XS-41B-LEVE04	Release of radioactive liquid from vent station access pit via valve operator seals due to liquid accumulation in vent station nozzle pit	Overflow of vent station catch tank into nozzle pit	F3	E1
XS-41C-LEVE02	Release of radioactive aerosols from catch tank pit due to presence of liquid from collapse of catch tank	Intrusion plus plugged drain creating external load on catch tank	F1	E1
XS-41C-LEVE03	Release of toxic gas from vent station catch tank pit due to presence of liquid waste in pit	Backflow from cross-site piping encasement leak causes tank gas accumulation	F3	E1

[1]This table was generated from a relational database of hazards information. Changes from the previous revision of this table have been independently reviewed, but are not highlighted in Redline.

Table D3.4-4. Hazardous Conditions With Potential Occupational Safety Consequence (OCC).[1] (5 sheets)

ID	Hazardous Condition	Cause
102AW-02-PRES.01 XS-26-PRES.01	Personnel injured by projectile debris from catastrophic fan failure	Loss of fan due to high pressure causing fan to walk into another object and become airborne
102AW-04-STRU.01	Personnel injured by falling equipment	Equipment drop during crane work
107AN-01-TEMP.01	Thermal hazard to personnel	Caustic in tank heated too hot at source
244AR-05.a.01	Weak roof structure permits person to fall through roof	Aging (roof)
244AR-PH01	Water hammer during setup for jetting	Condensate in the lines coming into contact with steam
244AR-PH02	Asphyxiation due to entry into confined space	Lack of oxygen due to corrosion, decomposition or fire/explosion
244AR-PH04	Person falls from elevated surface	Roof weakness (more than 2 stories high)
244AR-PH05	Person falls from elevated surface	Crane maintenance activities
244AR-PH06	Person falls from elevated surface	Walking over weak filter vault roof
244AR-PH07	Person falls from elevated surface	Ladder climbing
244AR-PH08	Person comes in contact with rotating equipment	Maintenance work on rotating equipment
244AR-PH09	Person comes in contact with rotating equipment	Process operations activities
244AR-PH10	Person injured by failure of equipment during over speed event	Equipment malfunction
244AR-PH11	Personnel injury from contact with energized circuits or faulted equipment	Insulation failure
244AR-PH12	Personnel injury from contact with energized circuits or faulted equipment	Maintenance activities
244AR-PH13	Personnel injury from contact with energized circuits or faulted equipment	Mechanical damage to insulation
244AR-PH14	Personnel injury due to electrical fire	Insulation failure
244AR-PH15	Personnel injury due to electrical fire	Overload conditions, breaker failure, sparking in flammable atmosphere
244AR-PH16	Personnel exposure to insulation or construction materials containing asbestos	Disturbance from: fire, maintenance, wind, aging, water intrusion
244AR-PH17	Personnel exposed to toxic or corrosive materials	Maintenance and operations activities combined with leakage such as pipe failure, pump failure or valve packing leaks
244AR-PH18	Personnel injured by high pressure gas bottles becoming projectiles	Malfunction of bottle regulator
244AR-PH19	Personnel injured by high pressure gas bottles becoming projectiles	Improper storage and transport
BND-01	Industrial hazards (lifting, bending, tool accidents; creates tripping hazard)	Failure to follow safe work practices, equipment failures
BND-01-I	Injury of worker from (lifting, bending, tool accidents; creates tripping hazard) due to bonding activities	Failure to follow safe work practices, equipment failures

Table D3.4-4. Hazardous Conditions With Potential Occupational Safety Consequence (OCC).[1] (5 sheets)

ID	Hazardous Condition	Cause
BND-02-I	Injury of worker from ignition of combustibles due to preparation for bonding	Drilling holes for bonding attachments causes sparks which is a hazard
CCF-14	Personnel illness or asphyxiation due to air supply faults	SCBA air supply of poor quality
CCF-15	Degraded operations, increased down time, possible personnel injury due to supply of inferior parts	Faulty parts or equipment supplied (e.g. o-rings, seals, electronics, HEPAs, pressure regulators, etc)
CDP-09	Driver error during drive-by causes injury to personnel	Driver error
CRN-14-I	Injury of worker from boom failure due to human error	Human error: improper load assembly, rigging, crane overloaded
CRN-15-I	Injury of worker from boom failure due to mechanical failure	Mechanical failure: corrosion, faulty materials
CRN-16-I	Injury of worker from boom failure due to high wind or seismic	High wind or seismic event
CRN-17-I	Injury of worker from electricity due to crane hitting powerlines/supplies	Human error: improper load assembly, rigging, crane positioning
CRN-24	Carbon monoxide from crane accumulates in pits or temporary confinement (greenhouse, etc)	Oxygen deficient atmosphere and failure to provide adequate ventilation, Failure to sniff or improper sniffing
CRN-24-I	Injury of worker from carbon monoxide accumulation in pits or temporary confinement (greenhouse, etc) due to crane motor exhaust	Failure to provide adequate ventilation,!Failure to sniff or improper sniffing
CRN-25	Loss of lateral load control, swinging load into personnel or equipment	Human error: improper load assembly, rigging, positioning error
CRN-25-IA	Injury of worker from swinging load into personnel due to loss of lateral load control	Human error: improper load assembly, rigging, positioning error
CRN-26	Loss of lateral load control, swinging load into personnel or equipment	Mechanical failure: corrosion, faulty materials, hydraulics, outriggers in soft soil
CRN-26-IA	Injury of worker from swinging load into personnel due to loss of lateral load control	Mechanical failure: corrosion, faulty materials, hydraulics, outriggers in soft soil
CRN-27	Loss of lateral load control, swinging load into personnel or equipment	High wind or seismic event
CVR-10	Person(s) asphyxiated	Oxygen deficient atmosphere and failure to sniff or improper sniffing
CVR-10-I	Injury of worker from asphyxiation due to pit atmosphere	Failure to sniff or improper sniffing
CVR-11	Person(s) asphyxiated	Oxygen deficient atmosphere and fresh air supply faults
CVR-11-I	Injury of worker from asphyxiation due to fresh air supply faults	Fresh air supply faults
CVR-14-I	Injury of worker from biological hazards (spiders, snakes, etc.) due to open nozzles or risers in pit	Open nozzles or risers in pit with biological hazards (spiders, snakes, etc.) inside
DCN-05	Personnel injury by contact with tools	Human error

Table D3.4-4. Hazardous Conditions With Potential Occupational Safety Consequence (OCC).[1] (5 sheets)

ID	Hazardous Condition	Cause
DCN-05-I	Injury of worker from contact with tools due to human error during decontamination activities	Human error
DCN-07	Personnel exposed to asphyxiant	Oxygen deficient atmosphere and PPE failure or absence in confined space
DCN-07-I	Injury of worker from exposure to asphyxiant due to PPE failure	PPE failure or absence in confined space
EE-12	Washout of soils surrounding a transfer pipe	Water main to evaporator or steam plant breaks
EE-13	Steam jet impinges on equipment supporting multiple tanks	Steam line break
EE-14	Worker injury due to electrocution	Excavation into power source
EE-15	Washout of soils resulting in sink hole due to excavation error	Excavation into water line
GRN-01	Industrial hazards (lifting, bending, trips and falls, tool operations)	Human errors
GRN-01-I	Injury of worker from (lifting, bending, tool accidents; creates tripping hazard) due to temporary confinement activities	Human errors
GRN-02	Industrial hazards (lifting, bending, trips and falls, tool operations)	Mechanical failure of equipment, tools
GRN-02-I	Injury of worker from (lifting, bending, trips and falls, tool operations) due to mechanical failures	Mechanical failure of equipment, tools
GRN-03-I	Injury of worker from asphyxiants in greenhouse due to collection of asphyxiants before removal	Human error
I-242A-2-CMP-A	Release (potential for leak) to tank annulus (secondary confinement) caused by damage to feed tank due to overfilling of tank	Valve failure or inadvertently opened valve
I-242A-7-PRS-A	Personnel hazard from ruptured compressed air line	Failure of compressor unloading switch due mechanical failure or incorrect setting during maintenance
I-242S-5-PRS-A	Personnel hazard due to rupture of compressed air line	Human error - failure of compressor unloading switch due to incorrect setting during maintenance
LDUA 2-50	Worker injury due to equipment damage	Human error, software bug
LDUA 2-54	Worker injury due to industrial accidents	Industrial accidents
LDUA 3-19	Worker injury due to general industrial hazards	General industrial hazards (e.g. during end effector change out)
LDUA 3-20	Worker injury due to electric shock	Electric shock hazards during hook-up and maintenance
LDUA 4-11	Worker injury due to blow out of housing panel	Supply pressure on with the VPM housing gate closed
LDUA 4-43	Worker injury due to industrial hazards	Industrial hazards during maintenance
LDUA 5-17	Worker injury due to inadvertent motion of valve	Operator error, improperly positioned valves
LDUA 5-21	Worker injury due to shock load damaging equipment	Shock load causes damage
LDUA 5-32	Worker injury due to vehicle engine fire	Vehicle engine fire

Table D3.4-4. Hazardous Conditions With Potential Occupational Safety Consequence (OCC).[1] (5 sheets)

ID	Hazardous Condition	Cause
LDUA 6-28	Worker injury due to communication failure	Communication failure between control locations and TRIC during maintenance
LDUA 6-29	Worker injury due to lifting	Lifting injuries in moving heavy cable
LDUA 6-30	Worker injury due to electric shock	Electrical malfunction
LDUA 6-5	Worker injury due to fire	Fire
LDUA 6-7	Worker injury due to electric shock	Impact, severing of cable by heavy equipment
LDUA 7-12	Worker injury due to accident when parking trailer	Collision with obstacles during parking of trailer
LDUA 7-13	Worker injury due to electric shock	Improper grounding - bonding
LDUA 7-14	Worker injury due to electric shock	Electrical shock hazards during hook-up
LDUA 7-16	Worker injury due to electric shock	Dust in electronic distribution disconnects and junction box
LDUA 7-3	Worker injury due to slipping hazard	Slipping hazards
LDUA 7-4	Worker injury due to fire	Fire in trailer
LDUA 7-6	Worker injury due to trailer falling over	Wind
LDUA 7-7	Worker injury due to trailer falling over	Seismic event
RAD-02-1	Injury of worker from exposure to radioactive materials due to radiation monitoring failure	Failure of monitoring instrument
RAD-03-1	Injury of worker from exposure to radioactive materials due to radiation monitoring failure	Improper calibration of monitoring instrument
RSR-02	Asbestos hazard from gasket materials during access to riser	Failure to follow asbestos procedures
RSR-03	Asbestos hazard from gasket materials during access to riser	Failure of mask or fresh air (if appropriate)
RSR-08-1	Injury of worker from falling into facility due to large access opening and human error	Human error
SFF-01-1	Injury of worker from exposure to toxic materials due to sniff sampling failure	Improper sniffing technique or instrument failure
VEH-05	Vehicle impact with electrical power pole	Loss of control of vehicle or lack of attention to driving
VEH-05-1	Injury of worker from impact with electrical power pole due to vehicle accident	Loss of control of vehicle or lack of attention to driving
VEH-06	Personnel are pinched or crushed between vehicle and solid structure	Vehicle moves exerting pressure on personnel between vehicle and solid structure
VEH-06-1	Injury of worker from being pinched or crushed between vehicle and solid structure due to inattention to situation	Vehicle exerts pressure on personnel located between the vehicle and solid structure
VSU-05	Tripping hazard	Exposure above ground level

Table D3.4-4. Hazardous Conditions With Potential Occupational Safety Consequence (OCC).[1] (5 sheets)

ID	Hazardous Condition	Cause
VSU-06	Falling hazard	VSU without a lid and not capped

[1]This table was generated from a relational database of hazards information. Changes from the previous revision of this table have been independently reviewed, but are not highlighted in Redline.

This page intentionally left blank.

Table D3.4-5. Hazardous Conditions With Potential Radiation Exposure Consequences (RP).[1] (4 sheets)

ID	Hazardous Condition	Cause
102AW-04-PRES.01	Personnel exposure higher than expected	Removal of cover block and pressure release due to loss of fan.
102AW-13-FLOW.01	Personnel exposure due to radiation doses from contaminated pipes	Multiple valving errors and failure of backflow prevention causing reverse flow from valve pit to flush pit
114SX-06.b	Personnel exposed to ionizing radiation due to lack of shielding	Inadvertent removal of tank overburden (gravel)
244AR-06.a.02	High activity radioactive material exposes person to ionizing radiation	Tank ventilation heater coil failure
244AR-07.a.04	Exposure to low concentrations of radioactive material	Excess water used in steam jet flush
244AR-PH03	Contamination of personnel with radioactive material	Radioactive contamination in canyon or sample gallery being disturbed by personnel entry
CP-GRT-01	Personnel exposure to contaminated pipe string due to removal of pipe during grouting	Contaminated soil in pipe
CP-MSP-09	Release of isotope source to the soil surface due to load drop	Human Error caused load drop
CP-MSP-11	Release of radioactive material to the soil surface due to crushed sensor package	Human Error: Heavy load inadvertently set on top of sensor package
CP-RMV-02	Personnel exposure to high level waste contamination on surface of pipe string due contact with leaking waste	Human error caused puncture to inactive transfer line during push operations
CP-RMV-04	Personnel exposure to radiation through push pipe due to puncture of tank dome	Human error results in removal of sample canister containment
CP-SET-09	Release of isotope source from the MSP to the soil surface due to load drop	Human error causes load drop
CP-SET-11	Release of radioactive material from the MSP to the soil surface due to crushing of the sensor package	Human error: Heavy load is inadvertently set on top of the sensor package
CP-SSP-06	Personnel exposure to contaminated soil sample while removing sampling canister from pipe sleeve	Human error
CP-SSP-07	Personnel exposure to contaminated soil sample while removing sampling canister from pipe sleeve	Mechanical failure
CP-SSP-08	Personnel exposure to contaminated soil sample while removing sampling canister from pipe sleeve	High wind
CP-SSP-09	Personnel exposure to contaminated pipe string caused by failure of sampling canister soil catcher to close properly	Mechanical failure
CP-SSP-10	Personnel exposure to puff release of contaminated dust (particulates) caused by air movement as the sample canister is withdrawn from pipe sleeve	Contaminated inner tube
CP-SSP-11	Release of contamination to environment due to dropping of the sample canister during transfer of sample from pipe to the shipping cask	Human error - workers drop sample canister or fail to handle properly

Table D3.4-5. Hazardous Conditions With Potential Radiation Exposure Consequences (RP).[1] (4 sheets)

ID	Hazardous Condition	Cause
CP-SSP-12	Release of contamination to environment due to dropping of the sample canister during transfer of sample from pipe to the shipping cask	Mechanical failure of the sample canister
CP-SSP-13	Release of contamination to environment due to dropping of the sample canister during transfer of sample from outer push pipe to the shipping cask	High wind
CP-SSP-14	Release of contamination to environment due to dropping of the repackaged soil sample container	Human error - workers drop sample canister or fail to handle properly
CP-SSP-15	Release of contamination to environment due to dropping of the repackaged soil sample container	High wind
CRN-14	Boom failure leads to worker injury or exposure	Human error: improper load assembly, rigging, crane overloaded
CRN-15	Boom failure leads to worker injury or exposure	Mechanical failure: corrosion, faulty materials
CRN-16	Boom failure leads to worker injury or exposure	High wind or seismic event
CVR-06	Person falls in pit sustaining injury or exposed to surface radiation in pit	Failure to erect fence or failure to erect securely
CVR-07	Person falls in pit sustaining injury or exposed to surface radiation in pit	Person leans over fence too far
CVR-08	Person falls in pit sustaining injury or exposed to surface radiation in pit	Fence failure
CVR-09	Person falls in pit sustaining injury or exposed to radiation	Seismic event or high wind/tornado
DCN-01	Decontamination personnel are contaminated or exposed	Failure of PPE
DCN-01-I	Injury of worker from contamination or exposure of decontamination personnel due to failed PPE	Failure of PPE
DCN-06	Personnel exposure higher than expected	More contamination than expected
DCN-06-I	Injury of worker from higher than expected exposure due to unknown contamination	More contamination than expected
I-PUREX-2-PRS-C	Personnel exposure due to vacuum pulling radioactive material back to operating gallery, worker hazard at PUREX (dose concern)	Failure to air purge line after transfer (mechanical failure)
I-PUREX-4-PRS-C	Personnel exposure due to vacuum to pulling radioactive material back to operating gallery, worker hazard at Purex (dose concern)	Failure to air purge line after transfer (mechanical failure)
LDUA 1-10	Worker exposure due to leak of waste into LDUA components	Line plug
LDUA 1-11	Worker exposure due to leak of waste into LDUA components	Line break
LDUA 1-34	Worker exposure due to operation error or mechanical failure	Operator error or mechanical failure
LDUA 2-13	Worker exposure due to leak of waste into LDUA components	Line plug
LDUA 2-14	Worker exposure due to leak of waste into LDUA components	Line break

Table D3.4-5. Hazardous Conditions With Potential Radiation Exposure Consequences (RP).[1] (4 sheets)

ID	Hazardous Condition	Cause
LDUA 2-53	Worker exposure due to contamination in LDUA	LDUA contamination - due to in-tank activities
LDUA 3-4	Worker exposure due to purge system overpressure - increased contamination in TRIC	Purge system overpressure (VPM auxiliary hookup)
LDUA 3-5	Worker exposure due to loss of decontamination water flow	Loss of decontamination water flow
LDUA 3-7	Worker exposure due to plug in decontamination line resulting in poor decontamination	Decontamination water line plugs due to solids
LDUA 4-10	Worker exposure due to ignition of flammable gas inside VPM	Loss of supply air from VPM outer tube.
LDUA 4-39	Worker exposure due to loss of computer controls/ requires manual retrieval of mast	Loss of computer
LDUA 4-40	Worker exposure due to insufficient decontamination	Mast tubes not sufficiently decontaminated prior to removal
LDUA 4-8	Worker exposure due to leak of waste into LDUA components	Line plug
LDUA 4-9	Worker exposure due to leak of waste into LDUA components	Line break
LDUA 5-35	Worker exposure due to misalignment of mast arm during insertion creating external contamination	Misaligning during insertion
LDUA/EREE 1-10	Worker exposure due to leak of waste into EREE	Line break
LDUA/EREE 1-29	Worker exposure due to operator error/mechanical failure	Operator error or mechanical failure
LDUA/EREE 1-30	Worker exposure due to operator error/mechanical failure	Operator error or mechanical failure
LDUA/EREE 1-8	Worker exposure due to leak of waste into EREE	Compressor fails
LDUA/EREE 1-9	Worker exposure due to leak of waste into EREE	Line plug
OGT-FLOW1-01	Personnel exposure to radioactive or hazardous material in the primary pipe due to pump failure	Pump failure, material settles in line (crystallization) and plugs line prohibiting transfer/waste is sitting in line and creates increased exposure to personnel
OGT-SPEC1-01	Personnel exposure to radioactive or hazardous material in the primary pipe due to loss of electrical supply	Loss of flow leading to line plug and the need to remove/replace, unclog line
OGT-TEMP1-01	Personnel exposure to radioactive or hazardous material from the primary pipe due leak caused by low ambient temperature	Plugging of pipe due to crystallization or due to freezing for very low temperature
RAD-01	Exposure to radioactive and/or toxic materials from pits or risers due to radiation monitoring failure	Failure to monitor
RAD-01-I	Injury of worker from exposure to radioactive materials due to failure to monitor radiation	Failure to monitor
RAD-02	Exposure to radioactive and/or toxic materials from pits or risers due to radiation monitoring failure	Failure of monitoring instrument
RAD-03	Exposure to radioactive and/or toxic materials from pits or risers due to radiation monitoring failure	Improper calibration of monitoring instrument

Table D3.4-5. Hazardous Conditions With Potential Radiation Exposure Consequences (RP).[1] (4 sheets)

ID	Hazardous Condition	Cause
RSR-02-I	Injury of worker from exposure to asbestos from gasket materials during access to riser due to failure to follow procedures	Failure to follow asbestos procedures
RSR-03-I	Injury of worker from exposure to asbestos from gasket materials during access to riser due to failure of PPE or fresh air supply	Failure of mask or fresh air (if appropriate)
RSR-04	Direct radiation exposure from open riser due to human error	Failure to follow procedures, failure to monitor or improper monitoring
RSR-04-I	Injury of worker from exposure to direct radiation exposure from open riser due to failure to follow procedures	Failure to follow procedures, failure to monitor or improper monitoring
VEH-04	Personnel receive radiation exposure from casks during transport due to human error	Personnel drive the vehicles or work near the cask transport vehicle
VEH-04-I	Injury of worker from radiation exposure from casks during transport due to inappropriate ALARA practices	Driver receives unexpected exposure or personnel work near the cask transport vehicle

[1]This table was generated from a relational database of hazards information. Changes from the previous revision of this table have been independently reviewed, but are not highlighted in Redline.

This document was too large to scan as a single document; therefore, it has been divided into smaller sections.

Section 6 of 10

Document Information			
Document #	SD-WM-BIO-001	**Revision**	1
Title	TWRS BASIS FOR INTERIM OPERATION

APPENDIX E
FLAMMABLE GAS/SLURRY GROWTH UNREVIEWED SAFETY QUESTION: JUSTIFICATION FOR CONTINUED OPERATION FOR THE TANK FARMS AT THE HANFORD SITE

This page intentionally left blank.

EXECUTIVE SUMMARY

The flammable gas hazards present in the Tank Waste Remediation System (TWRS) facilities have been declared a redefined Unreviewed Safety Question (USQ) as described in Wagoner 1996, *Contract Number DE-AC06-96RL13200; the U.S. Department of Energy (DOE), Richland Operations Office (RL) Definition and Declaration of Flammable Gas Unreviewed Safety Question Issues.* This expands and replaces a previously declared USQ. The redefined flammable gas USQ is based on USQ Determination TF-96-0433, *Consolidation of Flammable Gas/Slurry Growth Unreviewed Safety Question Issues.* This Justification for Continued Operation (JCO) (1) clarifies the flammable gas hazards involved with the USQ, (2) provides a logic for a control strategy including a basis for control grading, (3) specifies ventilation to address the flammable gas hazards, and (4) specifies the applicability of the requirements to the TWRS facilities covered in the scope of this JCO. In this manner, the JCO provides the basis for the flammable gas related controls that are included in the TWRS Basis for Interim Operation (BIO) Technical Safety Requirements (TSRs).

The scope of the JCO covers engineered structures, containers, or receivers managed and operated by the contractor at TWRS that may store Hanford high-level waste in a condition and for a period of time that may result in generation, accumulation, and/or release of flammable gas. These structures include single-shell tanks (SSTs); double-shell tanks (DSTs); aging waste facilities (AWF); double-contained receiver tanks (DCRTs); TWRS managed inactive miscellaneous underground storage tanks (IMUSTs); catch tanks,

including 204-AR-TK-1, and waste transfer systems. The scope of the JCO also includes the 244-AR Facility, 242-S and 242-T Evaporators, 244-CR facility, and the pits associated with the 242-A Evaporator feed tank (241-AW-102). The Tank 241-SY-101 flammable gas hazard controls are included in Level I requirements of LA-UR-92-3196, *A Safety Assessment for Proposed Pump Mixing Operations to Mitigate Episodic Gas Releases in Tank 241-SY-101: Hanford Site, Richland, Washington.*

Since the original identification of the USQ in 1990, the understanding of the hazards associated with flammable gas in tanks has expanded considerably. The USQ has been expanded to include the following hazards:

- Generation of potentially flammable concentrations of hydrogen, ammonia, and methane or other gases
- Steady state release of flammable gas from the waste
- Accumulation of flammable gas in ex-tank intrusive areas such as sealed pits, risers, and connected ventilation spaces
- Accumulation of flammable gas in the headspace
- Retention of flammable gas in the waste, allowing spontaneous and induced releases
- Deflagration in the waste

- Plume burns

- Accumulation of flammable gas in waste-intruding equipment such as drill strings and failed liquid observation wells.

This JCO identifies the control strategy required to ensure safe storage and operations with the following exceptions:

(1) Rotary mode core sampling (RMCS), has an approved Authorization Basis (WHC-SD-WM-SAD-035, *A Safety Assessment of Rotary Mode Core Sampling in Flammable Gas Single-Shell Tanks: Hanford Site, Richland, Washington*), for RMCS activities (excluding flammable gas hazards);

(2) Controls for safe storage and operations in Tank 241-SY-101 exist within the current Authorization Basis, including Level I controls from LA-UR-92-3196, and are not superseded by this document; and,

(3) Adding and removing tanks from the Flammable Gas Watch List is not within the scope of this JCO.

Instead of identifying other normal or anticipated operations that should be included or excluded, the JCO states the controls that must be applied (from a flammable gas perspective only) to perform work in and around the facilities affected by the USQ. The acceptability of performing activities in and around the TWRS facilities affected by this USQ must be evaluated for each activity to ensure that all other Authorization Basis requirements are met.

The process to ensure that tank farm activities are performed consistent with the control strategy and requirements specified in the JCO is documented in Appendix EB.

The JCO control strategy is twofold. First, to manage risk associated with steady state accumulation of flammable gas in the headspace, sealed pits, risers, and other ex-tank intrusive areas, the JCO requires adequate passive or active ventilation, where practical, to minimize the possibility for gas concentrations to exceed 25% of the Lower Flammability Limit (LFL). The use of 25% of the LFL as the maximum allowed gas concentration provides margin to the concentration where a deflagration is actually possible (100% of the LFL). Second, to manage risk associated with retention of flammable gas within waste, the JCO requires equipment and work controls to prevent spark sources in the tanks when and where flammable conditions may exist.

The JCO also groups tanks that may be subject to large versus small gas release events (GREs). Large GREs may cause the headspace concentration of flammable gas in tanks to exceed 25% of the LFL (global impact). Small releases may elevate the concentration of flammable gas beyond 25% of the LFL in a localized area of the tank only (local impact).

To assign graded control sets, each TWRS-managed tank has been placed into one of three Facility Groups depending on which types of gas release events are associated with the tank. Tanks that have demonstrated a propensity for large spontaneous and induced GREs are in Facility Group 1. Tanks that may be susceptible to large induced GREs but only small spontaneous GREs are in Facility Group 2. All remaining large underground waste storage

tanks are assigned to Facility Group 3, where it is judged that spontaneous releases do not occur, but small induced releases may be possible in some tanks. Facilities where a GRE is judged to not be a concern are included as non-GRE facilities. The hazards and associated control sets for each group are highlighted and summarized in matrices.

The tank grouping is based, in part, on a published methodology that estimated the quantities of releasable gas in each tank (WHC-SD-WM-TI-724, *Methodology for Flammable Gas Evaluations*). Although this methodology cannot provide precise quantitative results, it indicates the presence of retained flammable gas. The technical uncertainties associated with this methodology are discussed in WHC-SD-WM-ER-594, *Evaluation of Recommendation for Addition of Tanks to the Flammable Gas Watch List*. Despite the technical uncertainty, this methodology, coupled with physical observations and sample results, provides a basis for the tank grouping described in this JCO.

This document concludes that compliance with the JCO control strategy provides prudent risk management for storage and operations with respect to the flammable gas hazard. The JCO has been incorporated into the TWRS Authorization Basis and controls identified in the JCO have been implemented as Technical Safety Requirements (TSRs). (See HNF-SD-WM-TSR-006, *Tank Waste Remediation System Technical Safety Requirements*.)

DEFINITION OF TERMS

Gas Release Events. Gas release events are flammable gas releases that occur at a relatively high rate. The released gas must include gas that has been generated and retained in waste because gas release rates far exceed the gas generation rates. Gas release events are distinctive although in some tanks releases may be a part of a larger series of events (that is, episodic). Gas release events generally have a sudden onset, a sharp increase in gas release rate above steady state rates, and a short duration compared to the ventilation dilution time constants. Gas release events may occur spontaneously, be caused by outside natural phenomena such as seismic events, or be induced by operation or activity-related disturbances of the waste. The release rate can be so high that dilution by mixing with headspace air and dilution with ventilation cannot prevent flammable conditions from occurring, at least for some duration of time, in some portion of the headspace.

Steady State Releases. A steady state release is an ongoing release of generated flammable gases where the rate of release changes negligibly over time. The release rates are relatively slow (compared to gas release events) because the generation rates are relatively low. Steady state releases cause concern only where the released gases are allowed to accumulate to flammable concentrations in tank system headspace. Such an accumulation takes a relatively long time (hours to months) and can be managed by dilution using ventilation. Because radioactive tank wastes generate flammable gases on an ongoing basis, these releases and their potential accumulation are a chronic hazard for all waste-containing vessels.

Waste Intruding Equipment. Waste intruding equipment includes open-ended or breached objects that are inserted below the waste surface and create an unvented vapor space where flammable gases retained in the waste may accumulate.

The vapor space inside equipment inserted below the waste surface and properly sealed (e.g., thermocouple trees or liquid observation wells [LOWs]) is not considered to be waste intruding equipment.

FLAMMABLE GAS/SLURRY GROWTH UNREVIEWED SAFETY QUESTION: JUSTIFICATION FOR CONTINUED OPERATION FOR THE TANK FARMS AT THE HANFORD SITE

E1.0 PURPOSE

This Justification for Continued Operation (JCO) specifies the safety requirements and provides the basis and control strategy for the flammable gas hazards identified in the flammable gas/slurry growth Unreviewed Safety Question (USQ). These safety requirements provide a basis to perform operations and activities for facilities where this USQ applies.

This page intentionally left blank.

E2.0 SCOPE

The scope of this JCO covers allowed conditions, operations, and activities in 176 high-level waste tanks and associated waste transfer systems; double-contained receiver tanks (DCRTs); catch tanks, including 204-AR-TK-1, the 242-T and 242-S Evaporators; the 244-AR Vault; the 244-CR vault; and inactive miscellaneous underground storage tanks (IMUSTs) relative to flammable gas hazards. The Tank 241-SY-101 flammable gas hazard controls are included in Level I requirements of LA-UR-92-3196. This JCO also applies to the pits associated with the 242-A Evaporator feed tank (241-AW-102) which are within the scope of WHC-SD-WM-SAR-023, *242-A Evaporator/Crystallizer Final Safety Analysis Report (FSAR)*. This JCO specifies:

(1) Flammable Gas Facility Group assignments

(2) Ventilation requirements related to flammable gas hazards

(3) Ignition source control requirements

(4) Flammable gas monitoring requirements

(5) Requirement grading and applicability to the TWRS facilities covered by this JCO.

This page intentionally left blank.

E3.0 DEFINITION OF THE FLAMMABLE GAS UNREVIEWED SAFETY QUESTION

Nuclear waste stored at the Hanford Site generates flammable gases (primarily hydrogen) in most tanks. Hydrogen is generated by radiolysis of water, thermolytic decomposition of organics, and corrosion. Radiolysis also generates ammonia in nitrate- and nitrite-bearing waste, and thermolytic decomposition generates methane. Gas is released continually (that is, steady state) to the tank headspace or is retained by the waste matrix. The retained gas can be released as a spontaneous or induced gas release event that can significantly increase the flammable gas concentration in the tank headspace. The flammable gas hazard and the control strategy are summarized below.

E3.1 ORIGINAL UNREVIEWED SAFETY QUESTION DECLARATION

The flammable gas issue was declared a USQ in May 1990 (Lawrence 1990, *Unreviewed Safety Question-Waste Storage Tank*). The original statement (Dougherty 1990, *Activity Plans for DST/SST*) said, "Recent Westinghouse reviews of the tank headspace flammability identified that the gas under the crust is potentially flammable because nitrous oxide and hydrogen can create flammable mixtures. This is considered an Unreviewed Safety Question." The phenomenon of gases being generated and entrapped in waste slurry and beneath the crust was called "slurry growth." The U.S. Department of Energy, Richland Operations Office (RL) sent notification (Lawrence 1990) to U.S. Department of Energy-Headquarters, which stated, "RL has determined that the matter of hydrogen and nitrous oxide evolution within the material in certain waste tanks and subsequent hypothetical ignition is an Unreviewed Safety Question."

E3.2 REFINEMENTS TO THE UNREVIEWED SAFETY QUESTION DEFINITION

Since 1990, new information has been obtained from tank samples, monitoring data, laboratory experiments, and theoretical modeling and analysis. This information has led to increased understanding of the flammable gas and "slurry growth" phenomena and to refinements in the definition of the flammable gas USQ.

E3.2.1 Flammable Gas Composition

Radioactive waste generates hydrogen through the radiolysis of water, thermolytic decomposition of organic components, and corrosion of a tank's carbon steel walls. Radiolysis and thermolytic decomposition also generate ammonia. Non-flammable gases such as nitrogen, which act as diluents, are also produced. Additional flammable gases, such as methane and an oxidizer, nitrous oxide, are generated by chemical reactions between various degradation products of organic chemicals originally present in the tanks. Volatile or semivolatile organic chemicals in some tanks also produce organic vapors.

E3.2.1.1 Hydrogen. Hydrogen gas has been identified as a major component of flammable gas in tanks. A primary source of hydrogen gas is the thermolysis of organic components which is a function of total organic carbon, the liquid volume of waste, and waste temperature. Radiolytic decomposition of water is

another primary source of hydrogen gas, and it is proportional to the radionuclide content or decay heat load of the tank. Corrosion of waste tank walls also produces hydrogen gas, but it is an insignificant portion of the overall generation rate.

Although hydrogen is a major component of gas samples, and hydrogen generation mechanisms are known, uncertainties still exist in the parameters of the equation used to estimate generation rates. Conservative calculations have been performed to estimate tank vapor space flammable gas concentrations based upon calculated tank gas generation rates or release of a significant fraction of the estimated retained gas in the tank. The resulting equilibrium hydrogen concentrations range from very low (less than 0.1% of the lower flammability limit [LFL]) to values above 25% of the LFL. The measured hydrogen concentrations in tanks sampled to date, including all single-shell tanks (SSTs) that have been calculated to exceed 25% of the LFL, have been lower than the calculated values and well below 25% of the LFL.

E3.2.1.2 Ammonia. In October 1993, an Occurrence Report (RL-WHC-TANKFARM-1993-0090, *Waste Tank 241-SY-101 Safety Analysis Calculation Error for Ammonia Release Mechanism Results in an Unreviewed Safety Question*) was issued because of the measurement of ammonia gas in the headspace of Tank 241-SY-101 during release event "I" and because of increased ammonia background level in the tank following mixer pump operation. The presence of ammonia gas was judged to increase the fuel content of the gases released, however, it did not reduce the ignition energy. This JCO includes the available data, hazard conditions, and controls to address ammonia as an additional flammability hazard.

E3.2.1.3 Methane. In December 1993, an Occurrence Report (RL-WHC-TANKFARM-1993-0105, *Methane Gas in SY-101 Discovered to Add 10% Energy to the Burn Analysis Results Included in the Current Safety Assessment*) was issued because of the measurement of methane gas (1,000 parts per million [ppm]) in the headspace of Tank 241-SY-101 during Window I activities that occurred in June 1993. The presence of methane was judged to increase the fuel content of released gases; however, it did not reduce the ignition energy. This JCO includes the available data, hazard conditions, and controls to address methane as an additional flammability hazard.

E3.2.1.4 Other Gases. Other flammable gases and oxidizers have been identified in waste tanks. Nonmethane organic compounds from past chemical processing operations have been found at very low concentrations (less than 0.1% of the LFL) in the headspaces of most tanks. By using a conservative concentration for methane in the LFL calculations, the contribution of nonmethane organic is assumed to have negligible impact; therefore, no additional hazards or controls for organic vapors are identified in this JCO.

Nitrous oxide is not a flammable gas, but is an oxidizer. Its presence in trapped waste gases can cause the trapped gas mixture to be flammable without needing to mix with air. When gases are released from the waste and diluted with the air in the tank vapor space, the effect of nitrous oxide on the LFL is significantly reduced.

Nitrogen is also a significant component of waste gas. It is not a flammable gas or oxidizer. Its presence will dilute flammable gases in the waste gas mixture, but is not accounted for in calculations of waste gas LFL. This is discussed further in Appendix EA.

E3.2.1.5 Hydrogen Concentration in Slurry Gas at 25% of the LFL. Slurry gas is composed of a number of fuel gases and an oxidizer, nitrous oxide. A major component is hydrogen, and hydrogen concentration is often the only gas measurement available for tank conditions. These measurements are obtained with a Standard Hydrogen Monitoring System (SHMS). Some evaluation and assumptions are needed to establish the correlation between the measured hydrogen concentration and the percent of the LFL for the mixture in the tank where the measurement was taken. In addition to variations in slurry gas composition, many measurements are taken in the tank headspace where the slurry gas has been mixed with headspace air, and oxygen is the predominant oxidizer. An evaluation to establish the hydrogen concentration measurement that represents 25% of the LFL for monitoring SHMS alarm set points and work control action limits is described in WHC-SD-WM-ES-346, *Flammable Gas Tank Safety Program: Technical Basis for Gas Sampling and Monitoring.* This evaluation concludes that a hydrogen measurement of 6,250 parts per million by volume (ppmv) is a conservative value to use for this purpose. Appendix EA evaluates additional data and assumptions to determine a reasonable hydrogen concentration that represents 25% of the LFL when evaluating sample data to better understand the actual condition relative to the LFL. This evaluation concludes that 7,500 ppmv is a reasonable yet conservative value to use for this purpose. However, this JCO continues to use 6,250 ppmv to define the conservative SHMS hydrogen monitoring limit that represents 25% of the LFL when SHMS is used for work activity flammable gas monitoring.

E3.2.2 Vapor Space Accumulation of Flammable Gas Because of Steady State Releases

Flammable gases are generated by all radioactive wastes, and although a fraction of the gas may be retained in tanks containing waste solids, a portion of the generated gas is continuously released at a very low rate. These steady state releases are different from the acute, episodic releases of retained gas. Steady state releases are managed by diluting and removing the gases from the tank headspace through active or passive ventilation to prevent a steady accumulation of gas reaching flammable concentrations. Concentrations have been maintained very low with the existing ventilation configurations. In addition, maintaining low concentrations in headspaces reduces the severity of gas release events by providing relatively clean air in which to dilute the released gases.

For tanks having small waste volumes, low-decay heat loads, small concentrations of organic chemicals, and relatively large headspaces, steady state gas releases can be maintained at low concentrations with passive ventilation. Passive ventilation consists of atmospheric breathing combined with (1) a convective flow through tank openings and tank-to-tank connections caused by the buoyancy effects from gas temperature differences,
(2) a bernoulli flow caused by wind blowing past the tank exhausts, or
(3) instrument purge flows.

A number of SX and C Farm SSTs and all double-shell tanks (DSTs) are actively ventilated with exhausters and breather filters. Although the ventilation for each tank is established by procedure, and the flow rate can be estimated by design parameters or measured with portable instruments, actual tank ventilation flow rates are not monitored because of the lack of installed instrumentation.

Although the calculation of the theoretical steady-state gas concentration is simple and straightforward, the actual concentration is difficult to estimate precisely (Given a steady state gas generation rate (G) and a ventilation rate (V), the steady state gas concentration is defined as G/V.). However, because of uncertainties in calculating the hydrogen generation rates and the lack of accurate ventilation data, it is not possible to accurately calculate the steady state flammable gas concentrations (WHC-SD-WM-ER-594).

The ventilation effects may be reduced in the high points of sealed risers and sealed pits thereby enabling flammable gas to accumulate in concentrations that are higher than in the unobstructed headspace. Buoyancy effects may cause flammable gases to migrate upwards into risers or pits that are isolated from tank ventilation.

Formal vapor samples have been taken from approximately 55% of the SSTs as of January 1, 1997. An additional 31% of the SSTs have combustible gas meter (CGM) readings taken specifically for the TWRS Characterization Program (Appendix EA). The DSTs have been sampled during work activities, but the measurements have not been recorded in the gas sample results database. The actual steady state gas concentrations measured to date are consistently below 25% of the LFL. These measurements have demonstrated that measured values are significantly lower than calculated values for passively ventilated tanks (WHC-SD-WM-ER-526, *Evaluation of Hanford Tanks for Trapped Gas*). The results of the vapor space sampling are published annually in HNF-SD-WM-TI-797, *Results of Vapor Space Monitoring of Flammable Gas Watch List Tanks.*

For the purposes of this JCO, it is concluded that the current ventilation configurations in SSTs, DSTs, and AWF tanks adequately address steady state accumulation of flammable gases. Therefore, ventilation requirements have been upgraded to reflect their importance in managing flammable gases more clearly.

E3.2.3 Gas Accumulation Within the Waste

Some generated gas is retained in the waste. Because retained gases can include fuel (for example, hydrogen, ammonia, methane) and an oxidizer (for example, nitrous oxide), the gases can be in flammable concentrations. Retained gas presents a flammability hazard in the following ways.

- It is theorized that the retained gas could burn below the waste surface if ignited; and the amount of gas, bubble type, size, and distribution could enable flame propagation.

- Gases can be released from the waste and burn in tank domes, connected vapor spaces such as pits, ventilation systems, and outside of tank openings such as ventilation inlet paths or open risers if still above 100% of the LFL.

- The retained gases can be released and ignited inside equipment inserted into the waste, such as core sample drill strings.

E3.2.3.1 Deflagrations Below the Waste Surface. Lawrence (1990) acknowledged that a flammable mixture of gases may exist in the waste thereby creating the possibility of a combustion event below the waste surface. The likelihood and consequences of such an event are not analyzed in the Tank Farm Authorization Basis (except for Tank 241-SY-101). The hazard of igniting flammable gases that may be retained below the waste surface is covered by the flammable gas USQ and the controls in this JCO address this hazard.

E3.2.3.2 Gas Accumulation in Equipment That Penetrates the Waste. On September 28, 1995, an Occurrence Report (RL-WHC-TANKFARM-95-0078, *Vapor Sampling of Core Sampling Drill String Exceed Lower Explosive Limit*) was issued because flammable gas inside the drill string used for push mode core sampling (PMCS) Tank 241-S-107 was in excess of the LFL. Another incident occurred one month later in Tank 241-BY-110. In both incidents, the cause was attributed to encountering gas pockets in the waste which in turn caused flammable gases to enter and accumulate in the drill string in concentrations that were in excess of the LFL. Flammable gas is known to have accumulated in drill strings in several other tanks. Accumulation of flammable gases in waste intruding equipment is considered part of the flammable gas USQ. The controls in this JCO address this hazard.

Tank 241-BY-110 was not listed as a flammable gas USQ tank at the time of the occurrence. The USQ evaluation for these incidents concluded that although a tank may not contain sufficient trapped gas to warrant flammable gas controls because the potential is low for high headspace flammable gas concentrations, it still could be a concern for waste intruding equipment. There may be gas pockets encountered under the waste surface which have a high concentration of flammable gas. A somewhat similar situation occurred in the LOW in Tank 241-SX-104. The LOW accumulated flammable gases that were in excess of the LFL (102% of the LFL as read with a CGM). This event is described in an Occurrence Report (RL-WHC-TANKFARM-1994-0073, *High Flammable Gas and Ammonia Levels Discovered in SX-104 Liquid Observation Well (LOW) During Riser Liner Installation Activities*). The high gas concentrations were attributed to a breach in the LOW below the waste interstitial liquid level. This enabled gases to enter and accumulate in the LOW which is sealed at the top, thus preventing ventilation flow. The headspace in Tank 241-SX-104 was sampled. It was 0% of the LFL and had no indicated ammonia.

This JCO specifies controls to be used with waste intruding equipment in all waste tanks where gas accumulation is a concern. These controls are judged to be adequate to manage risk from potential flammable gas accumulation in waste intruding equipment.

E3.2.3.3. Gas Release Events. Many wastes have the ability to retain a substantial fraction of generated gases in the waste matrix. Periodically, the waste may spontaneously release large volumes of the trapped gas which can

raise the gas concentrations in the headspace to flammable levels in a very short time. Many activities also may trigger an induced release of retained gas. These spontaneous or induced gas release events (GREs) contrast sharply with the continuous steady state releases described earlier.

For the purpose of applying controls, each DST, SST, DCRT, AWF tank, IMUST, and catch tank has been placed in one of four Facility Groups depending on whether the waste is postulated to present a hazard from large or small GREs and whether the GREs may be spontaneous or occur only during waste disturbing (induced) operations or no GREs are postulated. Ignition source controls and monitoring requirements are applied at times when and in locations where flammable conditions resulting from GREs can be present, as appropriate to this grouping scheme. Five tanks within the scope of this JCO (excluding Tank 241-SY-101) that have had significant GREs are conservatively postulated to have the potential for large spontaneous and large induced GREs. These tanks have been assigned to Facility Group 1. If a tank is postulated to have the potential for a large induced GRE but only a small spontaneous GRE, it is assigned to Facility Group 2. The remaining SSTs, which show no propensity for spontaneous GREs but may produce a small induced GRE, are assigned to Facility Group 3. Facilities with little or no waste solids capable of retaining gases are categorized as non-GRE. All Facility Groups assume that the subject tanks undergo steady state gas generation at all times.

The grouping of facilities reflects a conservative approach even in light of uncertainties in the underlying methodology. It also enables a graded application of controls based on perceived hazards and frees less hazardous tanks from unnecessarily restrictive or burdensome controls. This method also enables a degree of simplicity in applying control sets to specific tanks.

Measured Gas Releases. Information about spontaneous GREs has been gathered by the SHMSs that continuously sample tank headspace hydrogen concentrations. The systems are installed on six DSTs and 22 SSTs. Tables E3-1, E3-2, and E3-3 summarize data from the DSTs, 18 of the 22 SSTs, and headspace concentration predictions from the GRE evaluation (WHC-SD-WM-ER-526).

Table E3-1. Summary of Gas Release Measurements for SHMS Instrumented Double-Shell Tanks. (1 sheet)

Tank	Maximum measured H_2 concentration	When maximum was measured[1]	Observed release periodicity	Predicted concentration following acute release[2]
241-AN-103	3,000 ppm (10% LFL[3])	08/22/95	Once since 10/94	334% LFL (SLR[4]) 301% LFL (BPE[5])
241-AN-104	5,000 ppm (17% LFL)	10/08/95	Every 3-5 months	505% LFL (SLR) 246% LFL (BPE)
241-AN-105	17,000 ppm (57% LFL)	08/21/95	Sporadic. 15 months between last two events	743% LFL (SLR) 411% LFL (BPE)
241-AW-101	8,800 ppm (29% LFL)	10/94	About every 2 months	231% LFL (SLR) 233% LFL (BPE)
241-SY-101	53,000 ppm (177% LFL) 51,200 ppm (174% LFL)	12/04/91 09/03/92	Every 3-4 months (none since mixer pump installation)	825% LFL (SLR) 572% LFL (BPE)
241-SY-103	2,900 ppm (10% LFL)	05/95	About every 2 months	79% LFL (SLR) 57% LFL (BPE)

[4] BPE - Tank headspace concentration (as percent of LFL) using the BPE methodology WHC-SD-WM-ER-526.
[5] nc - There was insufficient correlation between barometric pressure changes and waste level changes to use the methodology.
[6] LPF - Low pressure weather front.

DSTs. Data are documented for six of the 28 DSTs with SHMS. Tables E3-1 and E3-2 show Tank 241-SY-101 has had headspace concentrations that exceeded the LFL. Tanks 241-AN-105 and 241-AW-101 have had hydrogen concentration measurements that exceeded 25% of the LFL for slurry gas in air. The hydrogen concentrations for all other instrumented tanks are less than 25% of the LFL. The measured concentrations are significantly less than the concentrations predicted by the GRE evaluation (WHC-SD-WM-ER-526). The data for Table E3-1 are from Wilkins (*Tank 241-AN-103 Data Review Update; Tank 241-AW-101 Data Review Update; Tank 241-AN-104 Data Review Update; Tank 241-AN-105 Data Review Update*). The data for Table E3-2 are from Wilkins (1995), *Recent Gas Release Events in 241-SY-103*. SHMS data is obtained on an ongoing basis and evaluated. The results are reported in HNF-SD-WM-TI-797 on an annual basis.

SSTs. Studies into the growth of bubbles in settled solids have demonstrated that the presence of a supernatant liquid layer enables large, buoyancy-induced rollovers that trigger large, spontaneous GREs (PNL-10120, *Mechanisms of Gas Bubble Retention*; PNL-10740, *Gas Bubble Retention and Its Effect on Waste Properties: Retention Mechanisms, Viscosity, and Tensile and Shear Strengths*; PNL-10893; *The Effect of Dilution on the Gas Retention Behavior of Tank 241-SY-103*). Because SSTs usually do not contain a supernatant layer (or at most a very small one), large buoyancy-induced rollovers are not possible.

The available SHMS data for SSTs, which are summarized in WHC-SD-WM-ER-576, *Compilation of Hydrogen Data for 22 Single Shell Flammable Gas Watch List Tanks*, is consistent with this hypothesis. The data indicate small gas releases that appear to coincide with low-pressure barometric fronts, but no other phenomena. In addition to SHMS data, vapor grab sample data was obtained during the calibration and baselining effort of SHMS start up. Table E3-3 summarizes the release events for tanks where SHMS data is available. As indicated in Table E3-3, however, the highest measured concentrations are well below 25% of the LFL, even when instrument errors and calibration drift are accounted for in the SHMS Whittaker cells.

E3.2.3.4 Spontaneous Gas Release Events. Five DSTs within the scope of the JCO (Tanks 241-AN-103, 241-AN-104, 241-AN-105, 241-AW-101, and 241-SY-103) have been observed releasing large gas quantities at times when no operations or activities disturbed the waste. In addition, Tank 241-SY-101 exhibited spontaneous GREs before the operation of the mixer pump in this tank. Because Tank 241-SY-101 has an approved safety analysis, it is not within the scope of this JCO. The large "spontaneous" gas releases in these tanks are believed to be caused by instabilities that result from density differences between the gas retaining waste and the overlying supernatant liquid. As waste entrains more gases, it becomes more buoyant. When the density differences are large enough to overcome the forces that keep the gas retaining wastes in place, a waste rollover occurs and gas is released.

All DSTs with significant sludge to retain gas are considered to have the potential for spontaneous releases. They all have significant amounts of supernatant liquid and may be able to create instabilities that result from density differences between the gas-retaining waste and the supernatant liquid.

However, DSTs (other than the above-mentioned five and excluding Tank 241-SY-101) have not shown evidence of large spontaneous GREs based on historical monitoring of waste surface level rises and falls, tank vacuum levels, and waste temperature profiles. These DSTs are postulated to be prone to small spontaneous GREs.

As previously noted, SSTs are not likely to exhibit a large, spontaneous GRE, but some have exhibited small spontaneous releases. Other postulated release mechanisms for large releases have been reviewed by a team assembled by RL to evaluate the technical basis used by the Westinghouse Hanford Company in analyzing the hazards associated with flammable gas storage and release. The findings are documented in WHC-SD-WM-ER-594. The general view of the team is that the only mechanism likely to produce a rapid spontaneous release of a large fraction of a tank's retained gas is the buoyancy-induced rollover. Based on the physical conditions and phenomena affecting rollovers, it was considered improbable for such a release to occur in SSTs. Based on this understanding, this JCO does not postulate large spontaneous GREs as a significant hazard in SSTs. However, certain SSTs have exhibited small spontaneous GREs.

E3.2.3.5 Induced Releases (Waste Disturbing Operations and Activities). Retained gas may be released during many waste disturbing operations or activities. It is hypothesized that these operations or activities may release gas directly from the waste in the local volume where waste is disturbed or indirectly by triggering a release from a larger volume, such as by triggering a rollover.

E3.2.3.6 Experience During Waste-Disturbing Activities. Forty-nine waste sampling activities and 38 LOW installation activities were evaluated to determine whether these activities caused a gas release (Schofield 1996a, *Evidence of Release Events During Waste Intrusive Activities in Flammable Gas Watch List (FGWL) and Proposed FGWL Tanks*). Based on the temperature data from 87 activities, the evaluations concluded that no gas releases were evident; however, waste level data could not rule out the possibility of two gas releases in the mid-1980s. Surface level data showed the waste level reading dropped several inches about the same time that one LOW installation and one sampling event occurred during the 87 activities. It is not possible to reconstruct whether the level reading drop was caused by an FIC or manual tape adjustment or a plummet flush or how close to the waste intrusion event the level reading change occurred, although one level reading change may have occurred a day or two before the intrusion.

Of 27 recent waste core sampling events where gas monitoring was available, small gas releases were indicated by CGM readings from the tank headspace during three events. The gas release volume was estimated for two of the events. Based upon CGM readings and conservatively assuming the entire tank headspace was at the indicated CGM value, less than 0.68 m^3 (24 ft^3) of hydrogen was released during the sampling event in Tank 241-S-102, and less than 1.33 m^3 (47 ft^3) of hydrogen was released in the Tank 241-U-109 sampling event (Schofield 1996b, *Volume of Gas Released for a Given Rise % Rise in the LFL in S-102 and U-109*). Readings from SHMS cabinets on the same tanks showed negligible hydrogen increases at the same time the CGMs showed the increases.

This provides evidence that the gas releases were small and did not fill the tank headspace to the CGM concentration. Therefore, the volume of hydrogen released in each event was likely to be less than the 0.71 to 1.42 m^3 (25 to 50 ft^3) range.

Although the fraction of retained gas released for each operation or activity has not been quantified, it is postulated for this JCO that waste disturbing operations can be graded into local and global waste disturbing operations. Local waste disturbing operations can cause a small GRE in any tank, and a global waste disturbing operation can cause a large GRE in tanks that may retain a large amount of gas.

E3.2.3.7 Large Versus Small Gas Release Events. Actively ventilated tanks, which are DSTs, AWFs, and some SSTs, normally operate with the headspace at a slight vacuum. However, large gas releases can pressurize the headspace above atmospheric pressure. For this reason, the flow of headspace gases into pits, out open risers to the atmosphere, and through the ventilation system to other connected tanks must be postulated.

Tank 241-SY-101 experienced several gas release events prior to mitigation pump operation that were large enough to create flammable conditions in a large portion of the headspace and to pressurize the headspace. Table E3-2 summarizes two events where the pressure increased from -498 Pa (gauge) [-2 in. WG] to approximately 1,449 Pa (gauge) [+6 in. WG]. Gas concentrations were measured in the ventilation system about 4.9 m (15 ft) from Tank 241-SY-101 upstream of connections to other tanks. During GREs, the concentrations in the ventilation system are lower than in the headspace as demonstrated by the December 4, 1991, event. This GRE resulted in concentrations in the headspace of 53,000 ppm while vent duct concentrations remained below the LFL (maximum measured concentration was 26,000 ppm). The event also caused pressurization in the headspace that increased the ventilation flow rate from 0.23 m^3/s (500 cfm) to 1 m^3/s (2,125 cfm).

The headspace of passively ventilated tanks is normally at atmospheric pressure; therefore, large gas release events could cause a positive pressure and outflow of gases into pits, breather filters, and open risers. Large releases that can cause a significant portion of the headspace to exceed the LFL are postulated to cause flammable conditions outside the headspace in passively ventilated tanks.

Tanks estimated to retain relatively small amounts of gas are judged less likely to present a risk of creating flammable conditions outside the tank. Small releases would probably be mixed and diluted by headspace air before exiting. For this JCO, tanks with estimated retained gas amounts too small to cause the headspace concentration to exceed 25% of the LFL (if 25% of the gas is released per WHC-SD-WM-ER-526) are considered too unlikely to create flammable conditions in vapor spaces located outside the headspace to warrant ignition source controls in these areas.

Small GREs pose some risk of creating localized flammable regions within the headspace (for example, plumes) until mixing occurs with headspace air. However, they are unlikely to cause flammable conditions outside the tank headspace.

E3.2.3.8 Estimated Gas Release Potential. WHC-SD-WM-ER-526 has documented 177 tanks that have been evaluated for gas retention and release potential. The first step was to estimate the quantity of retained flammable gases in the tank waste using the quick screen. If the quick screen method predicted headspace concentrations of less than 25% of the LFL, no further evaluation was done. If it predicted headspace concentrations of greater than 25% of the LFL, one of two additional methods was used to estimate retained and releasable gas: using waste surface rise to calculate that amount of retained gas or using the waste level variation with corresponding barometric pressure changes to indicate retained gas. This screening process identified tanks where the released gas was calculated to cause hydrogen concentrations to exceed 25% of the LFL in a well mixed tank headspace. Tables E3-1 and E3-3 show that the predicted concentrations following a gas release event WHC-SD-WM-ER-526 are much higher than the measured concentrations for GREs monitored to date.

E3.3 FACILITY GROUP (FG) ASSIGNMENT

The TWRS-managed facilities affected by this JCO have been divided into four Facility Groups to enable control grading and minimize operational complexity. Control grading recognizes that flammable gas hazards vary widely and that technical uncertainties prohibit precise determinations about the hazard potentials of each facility. Facility Group assignments for ancillary facilities are described in Section E5.0 of this appendix.

E3.3.1 Facility Group 1

Facility Group 1 is made up of the facilities of greatest concern with respect to the flammable gas hazard. Specifically, the five tanks (241-AN-103, 241-AN-104, 241-AN-105, 241-AW-101, and 241-SY-103) within the scope of this JCO that have undergone observed, significant GREs are conservatively postulated to have the potential for large spontaneous and induced GREs. The level of rigor for these tanks is the maximum possible to manage the risk while continuing to perform essential waste storage functions and meet planned TWRS mission objectives.

E3.3.2 Facility Group 2

Facility Group 2 is made up of tanks that are postulated to have the potential for a large induced GRE but only a small spontaneous GRE. For the purposes of this JCO, SSTs that fail the GRE evaluation are considered to have the potential for large induced releases. SSTs that fail the GRE evaluation are those that are estimated to retain sufficient gas amounts to cause the headspace concentration to exceed 25% of the LFL if 25% of the gas is released. However, SSTs are not postulated to undergo large spontaneous releases.

Facility Group 2 reflects the uncertainty in fully understanding tank flammable gas hazards and characterizing tank specific contents and behaviors. It contains all DSTs and AWFs that are not in Facility Group 1 and all SSTs that are documented to "fail" the GRE evaluation.

The DSTs and AWFs are within their design life and are integral to the safe waste storage and disposal mission. They will receive new waste from other Hanford Site facilities and will undergo liquid reductions, waste consolidation, multiple transfers, and mixing. Procedures are in place to minimize the likelihood that these operations would create conditions resulting in large spontaneous gas release behavior. However, it is recognized that some operations may result in increased gas generation and retention. Therefore, it is appropriate to categorize these facilities in Facility Group 2 or higher. In the unlikely event that significant GRE behavior develops in these facilities, they will be moved to Facility Group 1.

Several ancillary facilities have been assigned to Facility Group 2 because they contain significant sludge and significant supernate, which are postulated to present the potential for gas retention and release, either spontaneously or as a result of waste disturbing operations.

E3.3.3 Facility Group 3

Facility Group 3 includes all remaining SSTs. The controls for Facility Group 3 reflect the widely accepted judgment that many SSTs, particularly those that have been stabilized, pose a significantly lower risk from flammable gas hazards than those in Facility Group 1 or Facility Group 2.

Three tanks (241-SX-104, 241-AX-101, and 241-AX-103) currently on the Flammable Gas Watch List are placed into Facility Group 3. The inclusion of these SSTs into Facility Group 3 is based on the results of the GRE evaluation (WHC-SD-WM-ER-526). The Watch List status for tanks is based on different evaluation methodologies that were used in the past.

E3.3.4 Facility Group non-GRE

Facility Group non-GRE consists of the facilities for which no GRE hazard is postulated. Flammable gas hazards are limited to steady state generation, release, and accumulation caused by low ventilation conditions. Waste containing facilities with little or no waste solids are in this group because gas retention and potential release are not postulated unless waste solids are present to retain the gas. Because these facilities contain little or no waste solids and gas accumulation is not postulated, waste intrusive and waste intruding locations and associated ignition source controls are not applicable. Facilities placed in the group include: catch tanks; DCRTs; 244-AR TKs 001, 003, and 004; 242-T TK-B1 and the evaporator vessel; and IMUSTs 231-W-151-001, 231-W-151-002, 241-S-302B, 241-TY-302B. No SSTs, DSTs, or AWF tanks are included in this group.

This page intentionally left blank.

E4.0 TANK CONTROL STRATEGY

To effectively manage the risk associated with steady state accumulation, this JCO requires passive or active ventilation for tanks to ensure that steady state flammable gas concentrations are well below the LFL. For certain facilities where adequate ventilation has not been verified by a means such as gas sampling, installed equipment is required to meet ignition source controls or be deenergized. To manage the risks associated with retained gases and GREs, specific ignition source controls and continuing monitoring requirements are applied on a graded basis to Facility Groups 1, 2, and 3 tanks depending on the work performed.

Table E4-1 summarizes the application of the control strategies to address each flammable gas hazard discussed in Section E3.2.2, "Vapor Space Accumulation of Flammable Gas Because of Steady State Releases" and E3.2.3, "Gas Accumulations within the Waste" of this appendix. Each strategy is discussed in the following section.

E4.1 TANK REGIONS

This JCO stipulates specific equipment and work controls for any TWRS-managed tank, container, or receiver that could present a waste-related flammable gas hazard and lead to a fire or explosion. These controls shall apply to all Facility Group tanks unless the equipment or work meets the definition of nonintrusive, as follows. For unique situations that are not clearly addressed by the following definitions and configurations, the applicable controls will be addressed by the TWRS Plant Review Committee (PRC) or their designee.

E4.1.1 Nonintrusive

Nonintrusive includes all equipment located in parts of the tank or ventilation system isolated from the tank head space by a seal barrier (i.e., compressive mechanical barriers, adhesive barrier, ventilation system seal loops, drain line seal loops, welded enclosures). The opening diameter is defined as the diameter of the smallest opening into the waste intruding equipment vapor space. For an actively ventilated system (when the ventilation system is operating), the inside of the ventilation system duct downstream of the first mixing point with flow from another tank is a nonintrusive region.

Table E4-1. Summary of Flammable Gas Controls Strategy.

Flammable Gas Hazard	Control Strategy
Steady state accumulation in headspaces	1. Dilution by ventilation and 2. Gas monitoring (characterization sampling and work activity entry gas monitoring) 3. If adequate ventilation cannot be verified, apply ignition source controls (Set 2) or deenergize
Accumulation in sealed risers and sealed pits	1. Ignition source controls (Set 2) at all times and 2. Work activity entry gas monitoring
Ignition of flammable gas retained within the waste	1. Ignition source controls (Set 1) at all times
Large spontaneous GREs	1. Ignition source controls (Set 2) in ex-tank and dome intrusive locations at all times 2. Continuous gas monitoring during manned work activity
Small spontaneous GREs	1. Ignition source controls (Set 2) for dome-intrusive locations at all times and 2. Continuous gas monitoring during manned work activity
Large induced GREs	1. Ignition source controls (Set 2) in ex-tank and dome intrusive locations during waste disturbing operations and activities and 2. Continuous gas monitoring during manned waste disturbing activities
Small induced GREs	1. Ignition source controls (Set 2) for dome intrusive locations during waste disturbing operations and activities and 2. Continuous gas monitoring during manned waste disturbing activities
Accumulation in waste intruding equipment	1. Purge or flush before energizing equipment and during use of equipment or 2. Ignition source controls (Set 1) at all times

There are no JCO related flammable gas controls for nonintrusive equipment or work, conversely, equipment and work meeting the definition of intrusive (ex-tank intrusive, dome intrusive, or waste intrusive) shall be subject to the control strategy specified in this JCO. These intrusive tank regions are defined in Sections E4.1.2, "Ex-Tank Intrusive" through E4.1.4, "Waste Intrusive" and shown in Figures E4-1, E4-2, and E4-3 for passively ventilated tanks, actively ventilated tanks, and actively ventilated tanks where the ventilation system is not operating, respectively. The control strategy is based, in part, on the region in which equipment and activities are located.

E4.1.2 Ex-Tank Intrusive

Ex-tank intrusive includes the following:

- All vapor spaces that have a direct connection to the tank headspace, but do not meet the definition of dome or waste intrusive.
- Pits, such as pump pits and transfer pits, that are not isolated from the tank dome by a seal barrier.
- The environment outside of tank openings that are directly connected to the headspace out to a distance of 18 opening diameters; 4.57 m (15 ft); or the boundary of temporary containment devices, whichever is shorter. This portion of the ex-tank region is only a concern from a flammable gas standpoint, when a large GRE is postulated (i.e., Facility Group 1 at all times, Facility Group 2 during global waste disturbing operations). Flammable gas is not postulated to accumulate in these open air regions due to steady state gas releases.
- Inside ventilation system duct work, downstream of the first mixing point with flow from another tank, when the ventilation system is not operating. (When the ventilation system is operating, the inside of ventilation system ductwork downstream of the first mixing point with flow from another tank is not an intrusive region because of mixing and dilution provided by flow from other tanks.)
- Activities in direct contact with the outside of the boundary between the ex-tank region and nonintrusive regions, such as welding or grinding, that could result in an ignition source inside the boundary. Equipment in these areas shall have ignition source control requirements.
- The ex-tank intrusive region also includes the environment outside a tank opening, which is directly connected to the dome space, out to the shortest of the following distances:

- 18 opening diameters[1]
- 4.57 m (15 ft)
- The boundary of temporary containment devices.

E4.1.3 Dome Intrusive

Dome intrusive includes any location within the tank between the top of a riser and the surface of the waste. It also includes ventilation ducting up to the first mixing point with flow from another tank. Because the filter housing and connecting ducting extends the riser, the dome intrusive region extends to the open-air inlet/outlet of breather filters or active ventilation system inlet filters or bags/sleeving around an open riser. However, if shut down, the ventilation system downstream of the first mixing point is considered an ex-tank intrusive region. A sealed pit which is open to the tank dome region (a dome intrusive region) is considered dome intrusive region.

The dome intrusive region definition also applies to work and activities, such as welding or grinding, that are in direct contact with the outside of the boundary and that could result in an ignition source inside the boundary (e.g., welding on the outside of risers or breather filters).

During the operation of salt well pumps, salt well pits are considered part of the dome intrusive region. This designation and the accompanying control requirements are made according to WHC-SD-WM-ER-571, *Evaluation of Hydrogen Release During Saltwell Pumping for Tanks T107, S110 and S108* which concluded that released gases could be channeled to the pit by the salt well, thereby creating localized flammable conditions in the pit while the rest of the dome intrusive region is well below the LFL.

Ignition source controls are applied to equipment installed in the region at the top of sealed risers and pits. Higher concentrations may result in this region because of buoyancy effects and the reduced ventilation provided to these potentially stagnant areas. Based on anecdotal evidence from entry monitoring and the expected effects of diffusion, accumulation of gas concentrations above the LFL in this region is judged to be unlikely. Ignition source controls that are consistent with this judgement are applied. Once the riser or pit is opened and entry monitoring confirmed and gas concentrations are less than 25% of the LFL, normal GRE controls are applicable.

[1]The opening diameter is defined as the hydraulic diameter of the most restrictive portion of the flow path.

Figure E4-1. Ex-Tank, Dome, and Waste Intrusive Regions in Passively Ventilated Tanks.

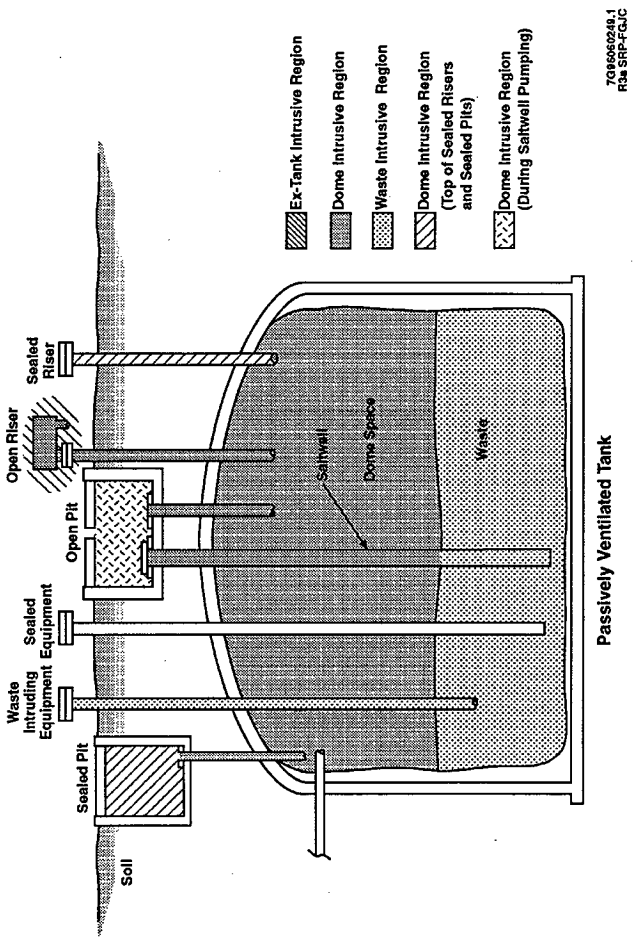

Figure E4-2. Ex-Tank, Dome, and Waste Intrusive Region in Actively Ventilated Tank (Ventilation On).

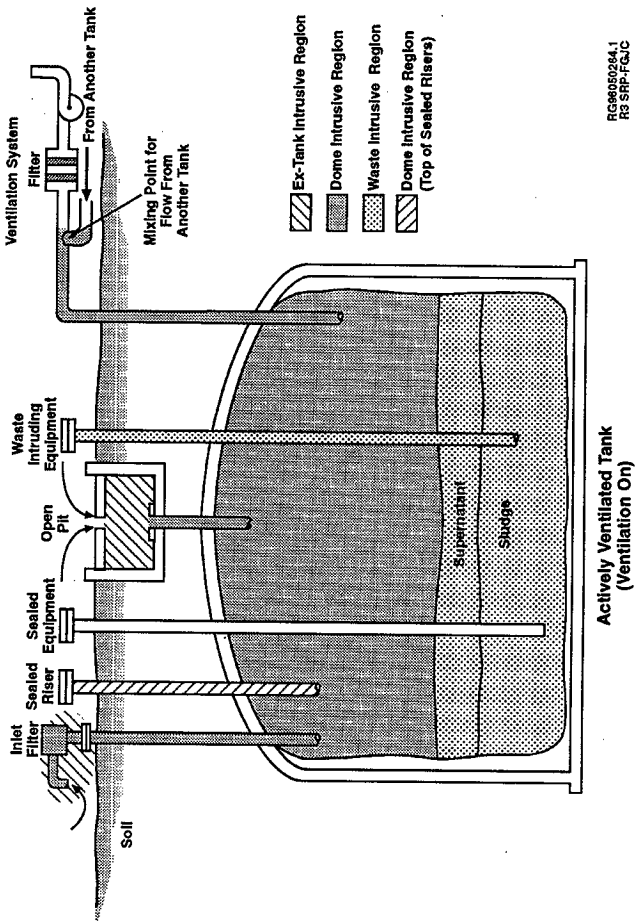

Figure E4-3. Ex-Tank, Dome, and Waste Intrusive Regions in Actively Ventilated Tanks (Ventilation Off).

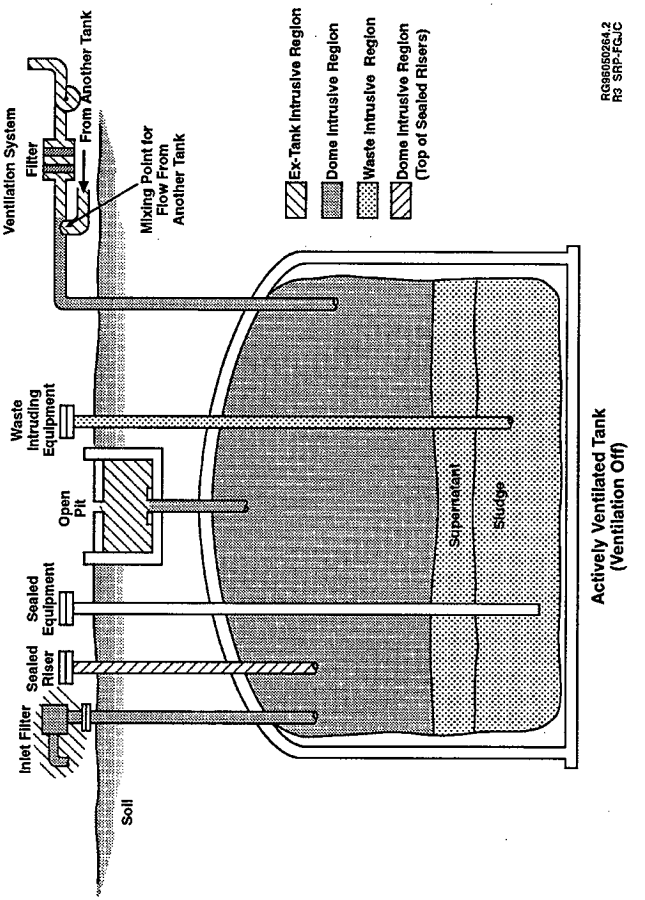

E4.1.4 Waste Intrusive

Waste intrusive refers to the region below the waste surface. It also includes vapor space inside the waste intruding equipment, where flammable gas retained in the waste may accumulate. This region is defined so that gas retained within the waste is considered as a possible flammable environment. Significant gas retention is not postulated unless waste solids such as sludge or salt cake are present. Equipment that comes in contact with gas bubbles retained within the waste is therefore considered to be in a waste intrusive location.

Waste intruding equipment includes open-ended and breached objects that are inserted below the waste surface that may create an unvented vapor space where flammable gases retained in the waste may accumulate. Waste intruding equipment includes core sample drill pipes, pump suction legs, and weight factor dip tubes.

Equipment, such as thermocouple trees and LOWs, inserted below the waste surface and properly sealed is not considered waste intruding equipment. For LOWs, where the potential for accumulation for flammable gas only exists if the LOW is breached, swabbing for contamination will be performed at each entry and before potential ignition sources (LOW gamma or neutron scanning equipment) are inserted into the LOW. If swabbing indicates that the LOW is breached, waste intruding gas monitoring and entry requirements shall be followed. Equipment insertion and operation shall not proceed if flammable gases are above 25% of the LFL. Equipment used in a breached LOW shall meet ignition source control (Set 1) requirements.

E4.1.5 Waste Disturbing Operations and Activities

Waste disturbing operations or activities include all work that may result in significant motion under the waste surface. Waste disturbing operations and activities include global waste disturbing and local waste disturbing operations defined as follows:

- **Global Waste Disturbing.** Operations and activities that cause a large global disturbance of the waste. These activities include, but are not limited to: waste transfers into or out of a tank; the removal, installation, or operation of mixer pumps; and large water additions.

- **Local Waste Disturbing.** Operations and activities that disturb only a small, local portion of the waste. Operations and activities that disturb only a small, local portion of the waste, such as removal of air lances or thermocouple trees, are quite different than operations that can cause a large global disturbance such as the operation of a mixer pump.

Examples of global and local waste disturbing operations and activities are shown in Table E4-2.

Waste disturbances may also occur because of seismic events. No special controls are imposed by this JCO that relate to flammable gas deflagrations which may be caused by a seismic event.

E4.2 VENTILATION CONTROLS FOR SST, DST, AND AWF TANKS

In-situ measurements have demonstrated that steady-state flammable gas concentrations are consistently below calculated values and 25% of the LFL in passively and actively ventilated tanks WHC-SD-WM-ER-526. Because current ventilation methods maintain steady state gas concentrations below 25% of the LFL, controls similar to existing ventilation controls should be maintained to manage the risk associated with gas added to the headspace by steady state and small induced or spontaneous releases. These controls require almost constant operation of DST and AWF exhausters. For passively ventilated tanks, breather filters are verified to be operable at least every 12 months and breather filter isolation valves are verified to be open weekly.

These historical operating practices have been used to form the basis for upgrading the operating requirements to controls that reflect the importance of ventilation performance in controlling flammable gas concentrations caused by steady state releases. Loss of normal ventilation can result in the build up of flammable gas concentrations to greater than the LFL for a number of tanks. The loss of normal ventilation condition has been assessed in HNF-SD-WM-CN-116, *Calculation Note: Hydrogen Generation Rates at Steady-State Flammable Gas Concentrations for Single Shell Tanks*, and HNF-SD-WM-CN-177, *Calculation Note: Calculation of Hydrogen Release Rate at Steady State for Double Shell Tanks*, for SSTs and DSTs respectively. These assessments form the basis for TSR surveillance frequencies and action times for the ventilation controls for this hazard. Section E5.0 describes ventilation of ancillary facilities.

E4.3 IGNITION SOURCE CONTROLS

Ignition source controls are applied to equipment installed or used during work activities in tank intrusive locations on a graded basis according to Facility Groups 1, 2, and 3. Additionally, controls shall be applied to all equipment used in waste intrusive locations at all times.

The location classifications in and around facilities are in accordance with National Fire Protection Association (NFPA) guidelines. They are documented in HNF-SD-WM-HC-017, *Electrical Classification Study for the Flammable Gas Watch List Tanks*, and will be updated according to available data, if necessary.

The ignition source controls in this JCO are applied when and where flammable gases are postulated to be present. The controls are applied to a Facility Group or to an activity/operation type. Field implementation, however, accounts for the specific details of the facility and activity/operation under consideration. Implementation of JCO controls ensures that the ignition controls are met across facility configurations and the planned operations and activities. TSRs implement JCO controls. The ignition source controls described in the JCO are the baseline in meeting the intent of industry standards.

A process is followed to specify the allowed safe conditions and control requirements to address the flammable gas hazards as described in this JCO. A sample process is described in Appendix EB. Ignition source control

requirements and work activity compliance with the requirements is documented by this process. In cases where direct compliance with the ignition source controls cannot be accomplished, the equipment and activity can be evaluated to determine if equivalent safety can be established. A Flammable Gas Equipment Advisory Board (FGEAB) has been formed to determine when specific work level control implementation provides equivalent safety to the baseline controls in this JCO. The development of equivalencies shall involve analysis, evaluation, or testing and will include appropriate documentation, review, and approval. The FGEAB, consisting of TWRS Engineering, representatives from the Hanford Electrical Codes Board, and the contractor NFPA Interpretive Authority, will review the design based on equivalent safety, and approve the equipment and its installation.

E4.3.1 Ignition Source Control Set 1

All equipment installed or used during work activities is evaluated and Set 1 is used for that portion of the equipment that can make contact with the gases retained in the waste (in waste intrusive locations) or undiluted gases which may be present in the vapor space of waste intruding equipment. The basis is that flammable conditions may be present in these locations; therefore the highest level of control consistent with NFPA 70 Class I, Division 1 is appropriate. The application of this control set is as indicated in Table E4-3.

1. Mechanical tooling, equipment, and materials (including lubricants, adhesives, gaskets, corrosion inhibitors, epoxies) shall be constructed of spark-resistant material, or shall be rendered incapable of sparking with sufficient energy to combust hydrogen, or shall have been analyzed and evaluated to be incapable of sparking with sufficient energy to combust hydrogen under the applied conditions (Johnson 1990, *Selection of Spark Resistant Tool Material for use in 101-SY*). Material compatibility shall be evaluated for thermite reaction potential (Ermold 1996, *Actions to Response to Spark Reported During Work on Tank 241-U-109*).

2. Electrostatic ignition sources shall be controlled by providing bonding or grounding according to NFPA 77, Recommended Practice on Static Electricity .

3. Exposed polymer materials shall be rendered incapable of electrostatic charge or discharge potential with sufficient energy to combust hydrogen by design or through acceptable workaround practices or by evaluation of the applied conditions (NFPA 77).

4. The surface temperatures of heat-generating devices (this includes potential compression heating mechanisms and open flames) shall not exceed 416 °C (780.8 °F). The surface temperature is limited to a maximum of 160 °C (320 °F) if the device can contact the waste and cause ignition by triggering exothermic (organic-nitrate) reactions in the waste. Internal temperatures of heat generating devices may exceed these temperatures (NFPA 70, National Electricity Code,

Articles 500-Hazardous (Classified) Locations and 501-Class 1 Locations) if the heat source is isolated (pressurized) from the gas environment, or if the design of the device enclosure meets the requirements for explosion-proof housings.

5. Electrical equipment shall be designed to meet NFPA 70, Class 1, Division 1, Group B criteria (NFPA 70) or provide equivalent safety. At a minimum, this shall be interpreted to mean that no single point failure of energized equipment can result in an arc, spark, or gas burn propagation to the environment external to the source enclosure (NFPA 70). In the case of waste-submerged equipment containing potential ignition sources, demonstration by design that the equipment is nonsparking under normal operation and is designed to be isolated from the waste environment is an acceptable alternative.

6. Shutdown of purged and pressurized electrical equipment and purged and pressurized heat-generating equipment, upon loss of protective gas pressure or flow, shall be automatic by design as defined by NFPA 496, Standard for Purged and Pressurized Enclosures for Electrical Equipment, Type X pressurization.

7. Interlocked start-up of purged and pressurized electrical or purged and pressurized heat-generating equipment shall only be allowed when the system senses preset safety limits. An example would be adequate protective gas pressure established as defined by NFPA 496 (NFPA 77). If pressurized enclosures are used to isolate energized components, a minimum of 4 enclosure volumes shall be purged through the enclosure for energized components, and/or 10 volumes shall be purged for enclosed motors before controlled start-up of the system components (NFPA 70 and 496).

E4.3.2 Ignition Source Control Set 2

Set 2 is applied to vapor space locations (ex-tank intrusive and dome intrusive) when a GRE is postulated to create flammable conditions. Set 2 is similar to Set 1 except that requirements (5), (6), and (7) are modified to allow the use of more readily available equipment. The basis is that the flammable conditions are unlikely. Therefore, the use of equipment that meets the intent of NFPA 70 Class I, Division 2 or equivalent is adequate. The application of this control set is as indicated in Table E4-3.

1. Mechanical tooling, equipment, and materials (including lubricants, adhesives, gaskets, corrosion inhibitors, epoxies) shall be constructed of spark-resistant material, or shall be rendered incapable of sparking with sufficient energy to combust hydrogen, or shall have been analyzed and evaluated to be incapable of sparking with sufficient energy to combust hydrogen under the applied conditions (Johnson 1990). Material compatibility shall be evaluated for thermite reaction potential (Ermold 1996).

2. Electrostatic ignition sources shall be controlled by providing bonding or grounding according to NFPA 77.

3. Exposed polymer materials shall be rendered incapable of electrostatic charge or discharge potential with sufficient energy to combust hydrogen by design or through acceptable workaround practices or by evaluation of the applied conditions (NFPA 77).

4. The surface temperatures of heat-generating devices (this includes potential compression heating mechanisms and open flames) shall not exceed 416 °C (780.8 °F). The surface temperature is limited to a maximum of 160 °C (320 °F) if the device can contact the waste and cause ignition by triggering exothermic (organic-nitrate) reactions in the waste. Internal temperatures of heat generating devices may exceed these temperatures (NFPA 70) if the heat source is isolated (pressurized) from the gas environment, or if the design of the device enclosure meets the requirements for explosion-proof housings.

5. Electrical equipment shall be designed to meet NFPA 70, Class I, Division 2, Group B criteria (NFPA 70) or provide equivalent safety. As a minimum, this shall be interpreted to mean the equipment is nonsparking under normal operation or, if normally sparking, the sparking component(s) shall be continuously isolated (purged and pressurized) from the potentially flammable gas environment, or the design of the device enclosure shall be of sufficient strength (explosion-proof) to prevent propagation of a gas burn to the environment external to the enclosure.

6. Automatic shutdown or alarming with manual shutdown will be required upon loss of protective gas pressure or flow as defined by NFPA 496 Type Z pressurization.

7. Automatic or manual start-up of purged and pressurized electrical or purged and pressurized heat-generating equipment shall only be allowed on system sensing of preset safety limits, such as adequate protective gas pressure established as defined by NFPA 496. If pressurized enclosures are used to isolate energized components, a minimum of 4 enclosure volumes shall be purged through the enclosure for energized components, or 10 volumes shall be purged for enclosed motors before controlled start-up of the system components (NFPA 70, NFPA 496). When combustible gas detection shutdown systems are employed, start-up of equipment shall only be allowed once measured acceptable flammable gas levels are indicated.

Table E4-3. Flammable Gas Ignition Source Control Set Application Requirements.

Tanks	During Non-Waste Disturbing Activities		During Local Waste Disturbing Activities		During Global Waste Disturbing Activities		Waste Intrusive or Inside Waste Intruding Equipment

Notes:

1 - Ignition Source Control Set #1 applies at all times

2 - Ignition Source Control Set #2 applies at all times

2A - Ignition Source Control Set #2 applies only for the duration of the waste disturbance

2B - Ignition Source Control Set #2 applies to activity related equipment and materials until work activity entry monitoring requirements (Table E4-5) are met. Ignition source controls are not required by 2B (ignition source controls during entry monitoring) in the ex-tank intrusive region defined as the environment outside of tank openings that are directly connected to the headspace out to a distance of 18 opening diameters; 4.92 m (15 ft); or the boundary of temporary containment devices, whichever is shorter.

2C - Ignition Source Control Set 2 applies to installed equipment, Ignition Source Control Set #2 applies to activity related equipment and materials until work activity entry monitoring requirements (Table E4-5) are met.

Non-GRE These are Facility Group Non-GRE because there is little or no waste solids, gas accumulation is not postulated for these facilities and therefore, waste intrusive and waste intruding locations and associated ignition source controls are not applicable.

E4.3.3 Exceptions to Ignition Source Control Requirements

Table E4-43 covers equipment and materials that do not meet the ignition source control requirements and do not have safety equivalency with ignition source controls (Set 1 or Set 2) established by the TWRS FGEAB. Most of these items are used throughout tank farm field activities. A few items are specific to certain activities, such as grab sampling and PMCS. Therefore, the exceptions in Table E4-4 are required to perform tank farm operations.

A number of items in Table E4-4 are considered to be "de minimus" exceptions because they are judged to pose a negligible risk as ignition sources. These de minimus items are judged to represent uncontrolled, but negligible spark sources. Most are associated with manned work. In these cases, the work location monitoring requirements, as called for in this JCO, are in force. Several items, however, involve the materials that make up installed equipment. These items are therefore present in the tanks even when monitoring is not required.

Additional items in Table E4-4 are equipment, materials, and activities that do not meet the JCO ignition source control requirements and do not have safety equivalency established by the TWRS FGEAB. These items do not meet the definition of "de minimus." Flammable gas risk management, therefore, depends on flammable gas monitoring (standard monitoring as required in JCO section E4.4 or augmented monitoring as indicted in Table E4-4), ventilation, and/or work practices (for example, slow insertion of non-spark-resistant thermocouple trees). These practices provide confidence that a spark source would not be present when a flammable gas environment exists. This second category contains items that are evaluated to have an associated small, incremental increase in risk, but the benefits associated with their use justify their continued application in the field. It is judged that the risk posed by these items is acceptable for ongoing operations. This decision is based on a qualitative assessment of the importance of the waste management and safety-related activities and operations that must use these items. Appendix EC describes the justification for each exception listed in Table E4-4.

Table E4-4. Exceptions to Ignition Source Control Requirements. (3 sheets)

Item #	Authorized Activities
1	Personal Protective Equipment (i.e., raingear, airline respirator hoses, rubber/plastic and canvas gloves, respirator masks, rubber/plastic boots, masking tape, Tyvek coveralls) are authorized for use in ex-tank locations, but may be used in a minimally dome intrusive location (e.g., at the plane of a riser).
2	Wearing of plastic badges, badge holders, and dosimeters.
3	Installation of, removal of, working on, or extended presence of nonconductive lead blankets in ex-tank (global waste disturbing) regions. Lead blankets shall not be used in a vapor trapping configuration
4	Installation, removal, or extended presence of nonconductive adhesive tape (e.g., green tape, white tape) in ex-tank regions, dome intrusive regions, and in waste intruding equipment.
5	Use of Portable Alpha Monitor (PAM) in ex-tank regions, dome intrusive regions, and in waste intruding equipment.
6	Use of nonconductive poly bottles in ex-tank and dome intrusive regions.
7	Use of zip cords in ex-tank regions, dome intrusive regions, and in waste intruding equipment (e.g., inside failed LOWs).
8	Use of nonconductive plastic ropes in ex-tank regions.
9	Use of nonconductive plastic tubing in ex-tank regions and dome intrusive regions (e.g., aerosol testing). Nonconductive plastic tubing shall not be used below the plane of a riser.
10	Installation and removal of Garlock gaskets in ex-tank regions.
11	Use of nonconductive plastic garden type sprayer (approximately 5 gallons, hand pump pressurizer and brass spray wand) in ex-tank regions.
12	Use of grab sample cap, sampling and sludge weight retrieval device and coated steel cable in ex-tank and dome intrusive regions.
13	Installation and removal of polyvinyl chloride (PVC) riser liners in dome intrusive regions.
14	Presence of PVC liners for manual tapes, FICs, flushing, ignition source control (IC) 1 compliant equipment, and authorized activities in dome intrusive regions.
15	Presence of manual tapes in ex-tank and dome intrusive regions.
16	Installation and removal of manual tapes in ex-tank and dome intrusive regions.

Table E4-4. Exceptions to Ignition Source Control Requirements. (3 sheets)

Item #	Authorized Activities
17	Installation of, removal of, working with, or extended presence of the pipe wiper (Frisbee) during PMCS with Truck 1, 2, and 3, in ex-tank and dome intrusive regions.
18	Installation of, removal of, or extended presence of plastic cam-lock caps during PMCS with Trucks 1, 2, or 3 in ex-tank and dome intrusive regions.
19	The presence of extension cords in ex-tank regions. Power strips (and outlet strips) are not allowed in these regions. Energized lines shall not be connected or disconnected in an ex-tank region.
20	Installation, removal, and use of low and high pressure spray whirlie and operation of valve handles in ex-tank and dome intrusive regions.
21	Electrical bonding is not required for removal or installation of fittings on openings less than or equal to 2.54 cm (1 in.) inside diameter during intrusive location entry.
22	Use of Type 4 vapor sampling head in ex-tank and dome intrusive regions. Conductive plastic sleeving shall be used during Type 4 vapor sampling.
23	Use of electric impact wrench in ex-tank regions.
24	Use of Type 4 vapor cart in ex-tank and dome intrusive regions.
25	Open pit work related equipment (e.g. Pike Poles, T-Bars, Sockets, Chokers, Shackles, and Bull Hooks) in ex-tank regions. Installation and removal of process blanks, vapor seals, jumpers, and leak detectors in ex-tank regions. Continuous monitoring in the tank dome and the pit is required during use of this exception.
26	Installation and removal of valve handles in ex-tank regions. This activity is performed in closed pits when no global waste disturbing activities are in progress.

Table E4-4. Exceptions to Ignition Source Control Requirements. (3 sheets)

Item #	Authorized Activities
27	Installation, removal, presence of, or movement of cover blocks, riser flanges, shield plugs, tank installed waste and non waste intrusive equipment items (e.g. T/C trees, steel LOWs, pumps, manual tapes, FICs, ENRAFs, radar gauges, heated vapor probes, MITs, corrosion probes, velocity-density temperature trees (VDTTs), water lances, void fraction meter, core sampling drill string, salt well screens, dip tubes, cameras/lights, viscometer, auger, sampler) each as used in ex-tank or dome intrusive or waste intrusive regions. Work packages and procedures will include practical measures to reduce the likelihood of a mechanical spark when equipment movement performed as part of an operation or activity can create mechanical sparks. Such measures may include: limiting insertion speeds, water bathing of equipment, prevention of contact with other non-spark resistent materials by use of collars or bumpers, use of critical lift procedures where appropriate. This exception does not cover the operation of large mixer pumps that might cause significant motion of installed equipment. Any other ignition source hazards (other than mechanical spark source potential) must comply with this JCO's requirements for ignition source controls.
28	Use of pressure switches, limit switches, and leak detector for the salt well pumping system for Tank 241-T-104. Continuous monitoring of the pump pit is required during pumping with automatic shutoff at 10% of LFL.
29	Use of pressure switches, limit switches and leak detectors for the salt well pumping system for Tank 241-BY-109 after it is re-categorized to a Facility Group 3 tank. Continuous monitoring of the pump pit required during pumping with automatic shutoff at 10% of the LFL.
30	Presence of intact fiberglass and Tefzel LOWs in Facility Group 2 or 3 tanks or presence of failed fiberglass LOWs as waste-intruding equipment. (Work in a known failed LOW shall meet IC Set 1 controls).
31	Use of Continuous Air Samplers (CASs) in ex-tank regions in Facility Group 1 tanks or Facility Group 2 tanks during global waste disturbing operations. CASs shall be shutdown if 10% of the LFL is exceeded in the ex-tank area. Motor shall be placed outside the ex-tank region. Continuous monitoring in the tank dome and the pit is required during use of this exception.

E4.4 GAS MONITORING REQUIREMENTS

Flammable gas monitoring is used as part of the flammable gas hazard management strategy for the following reasons:

- To prevent the introduction of an uncontrolled or errant spark source into a location when and where flammable gas concentrations are above a level of concern for fire, deflagration, or detonation. This includes entry monitoring for all manned work to be performed in intrusive locations for the facilities within the scope of this JCO. It includes monitoring of intrusive locations in non-GRE facilities before using equipment that does not meet ignition source controls in situations where ventilation has not been verified to be adequate to address steady state accumulation hazards, such as when operating pumps in catch tanks (Section E5.8). This function also is used if required ventilation is not operable so that equipment that does not meet ignition source controls can be shut down before concentrations of concern develop.

- To prevent the continued use of equipment and materials that may present uncontrolled spark sources or errant spark sources if flammable gas concentrations of concern develop during manned work activities. This includes manned activities in facilities when and where the effects of GREs must be considered. Continuous monitoring is required to satisfy this function.

- To halt global waste disturbing operations (e.g., salt well pumping) in passively ventilated tanks if pit or dome space concentrations exceed 25% of the LFL. Because equipment in use during such operations meets ignition source controls, monitoring is not used as the primary safety approach to preventing an accident. Therefore, periodic monitoring is adequate for this function.

These functions and requirements are discussed in the following paragraphs. The application of the monitoring requirements are identified in Table E4-5.

E4.4.1 Entry Monitoring (and Associated Ignition Source Controls)

Flammable gas concentrations in intrusive work locations must be verified to be below the flammable gas work control limits before beginning manned work. This requirement shall be applied to all manned work activities in waste containing vessels when the manned work activity is near an opening in the vessel containment. Meeting this requirement will ensure that flammable conditions in the work space are not present as a result of steady state accumulation and/or recent GREs.

For manned activities on tanks, the entry monitoring requirements are:

1. Monitor at breather filter or vent duct prior to start of activity.

2. For work in pits, monitor in pit prior to the start of pit work.

3. Monitor inside riser (passive or active ventilation) or allow for a one minute pause with riser opened (active ventilation only) prior to start of dome intrusive activities.

4. For dome intrusive work, follow 1 and 3 above, plus monitor below bottom of riser (passive or active ventilation) or in vent duct upstream of first mixing point (active ventilation only) prior to start of activity.

5. For manned activities inside of waste intruding equipment, monitor in the vapor space prior to start of activity.

For manned activities in non-tank waste transfer system regions, monitor in the vapor space where the activity is to be performed.

Manned work shall not begin or proceed if flammable gas concentrations are greater than 25% of the LFL except for gas sampling and necessary actions to reduce gas concentrations, deenergize ignition sources, etc. Installed qualified equipment (equipment that is qualified in accordance with the appropriate ignition source controls) may continue to operate (not be deenergized) if flammable gas concentrations are greater than 25% of the LFL.

Until gas concentrations of less than 25% of the LFL are verified, the equipment used to perform this verification shall meet the requirements of ignition source controls (Set 2).

E4.4.2 Manned Activities (Continuous Monitoring)

Because of the possibility of flammable conditions developing during work as a result of a GRE depending on the flammable gas Facility Group and activity type, work space (ex-tank intrusive or dome intrusive) monitoring is continued. This means using a continuous monitor, such as a SHMS, or portable CGMs that monitor continuously and is set to alarm before flammable gas concentration exceeds 25% LFL. Ignition source controls are also imposed in these locations to prevent ignition in the unlikely event that flammable conditions develop. The potential for an errant (uncontrolled) spark is judged to be higher during manned work activities even though all equipment must meet ignition source controls for manned activities and unmanned operations. The chance of an errant spark is judged to be higher during manned activities because equipment is being manipulated, and the chance for human error is present. Therefore, a distinction is made between manned and unmanned activities. Manned activities require continuous monitoring and work stoppage if the concentrations exceed 25% of LFL; unmanned operations generally do not require monitoring. Monitoring thus provides an additional safety measure to the ignition source controls during these activities. Therefore, all manned work activities must immediately halt if flammable gas concentrations exceed 25% of the LFL, with exceptions such as gas sampling and necessary actions to reduce gas concentrations, and deenergizing ignition sources.

E4.4.3 Unmanned Operations

Unmanned operations, such as waste transfers and operation of air lift circulators or mixer pumps in actively ventilated tanks, do not require continued monitoring because installed equipment must meet ignition source control requirements, and errant spark sources (that might result during manned activities) are minimal. Released gases will be diluted and swept from the tank by the ventilation flow. Adequate protection is provided by requiring installed equipment to meet ignition source controls.

During unmanned global waste disturbing operations in passively ventilated tanks, flammable gas concentrations from GREs may persist for a long time because of low ventilation flows. Because continued operation in this condition is judged to be imprudent if the flammable gas concentration is greater than 25% of the LFL, periodic monitoring is required. For long duration operations such as salt well pumping, periodic monitoring can be defined as follows:

- Monitor dome space and salt well pit once an hour for 5 hours following initiation of pumping
- Monitor dome space and salt well pit once a day for the next 3 days (or once each 24 nominal hours run time)
- Monitor weekly or once each 168 hours nominal run time). Revise sampling period:
  - If less than 15% of LFL, sample every 7 days, not to exceed 10 days
  - If greater than 15% to $\leq$ 25% LFL, sample daily
  - If greater than 25% LFL, stop waste disturbing operation.

E4.4.4 Monitoring Following a Loss of Ventilation

Monitoring is used to cause the shutdown of uncontrolled spark sources if flammable gas concentrations of concern develop because of a loss of required ventilation. Ventilation in many TWRS facilities is provided to prevent the accumulation of flammable gas caused by steady-state releases and to dilute released gases before they reach ventilation system equipment that does not meet ignition source control requirements (such as pressure switches and continuous air monitors in DST ventilation systems). If this ventilation is lost, flammable gas concentrations may increase, but in a steady manner. Following a loss of ventilation, periodic monitoring is required to trend the flammable gas concentrations and actions are taken to eliminate the uncontrolled spark sources if levels of concern are reached.

Table E4-5. Flammable Gas Monitoring Requirements.

Tanks	During Manned* Non-Waste Disturbing Activities		During Manned* Local Waste Disturbing Activities		During Manned* Global Waste Disturbing Activities		During Unmanned Non Waste Disturbing Activities	During Unmanned Local and Global Waste Disturbing Activities	Inside Waste Intruding Equipment
	Ex-Tank & Dome Intrusive (Riser or Duct only)	Dome Intrusive in Dome Space	Ex-Tank Intrusive	Dome Intrusive	Ex-Tank Intrusive	Dome Intrusive			
Facility Group 1	A2 or C, A3 for pit work	C	A2 or C	C	A2 or C	C		No applicable activities	E
Facility Group 2	A1	C		C	A2 or C	C		D	E
Facility Group 3	A1	B		C		C		D	E
244-AR TK-002	A1	B		C		C			E
244-CR Tks-001, -002, -003	A1	B		C		C			E
Non Tank Waste Transfer System	A1								
DCRT	A1	B							
244-AR TKs-001, -003, -004	A1	B							
244-CR TK-011	A1	B							
Catch Tanks and Catch Tank Pits	A1	B	G		G		G	G	
242-S	A1	B							
242-T	A1	B	F		F		F	F	
W-151-001, W-151-002, S-302B, TY-302B	A1	B	F		F		F	F	

A1 - 1. Monitor at breather filter (passive ventilation) or vent duct (active ventilation), when present, prior to start of activity.
2. Monitor inside riser (passive or active ventilation) or one minute pause with riser opened (active ventilation only) prior to start of dome intrusive activities. For open pit work, monitor inside pit prior to start of activity. This entry monitoring does not require the monitoring of the ex-tank region defined as the environment outside of tank openings that are directly connected to the headspace out to a distance of 18 opening diameters; 4.92 m (15 ft); or the boundary of temporary containment devices, whichever is shorter.

A2 - Continuous monitoring in ex-tank area during activity (See TSR Control AC 5.11.a.3).

A3 - Continuous monitoring of pit and dome space prior to and during work with tools listed as exceptions for pit work in Table E4-4, for pits connected to a Facility Group 1 DST vapor space.

B - A1 above, plus monitor below bottom of riser (passive or active ventilation) or in vent duct upstream of first mixing point (active ventilation only) prior to start of activity.

C - B above, plus continuous monitoring in dome intrusive regions where work is being performed such as below bottom of riser (passive or active ventilation), inside of breather filters, inlet filters or temporary glove bags, or in vent duct upstream of first mixing point (active ventilation only) during activity.

D - 1. No monitoring requirements for DSTs.
2. Monitor per requirements in TSR Control AC 5.11.b.2 for salt well pumping.

E - Monitor inside waste intruding equipment vapor space prior to entry. Monitoring outside of waste intruding equipment (e.g., open drill string) is not required.

F - Monitor prior to energizing or using equipment that does not meet IC 2 controls.

G - Monitor tank and pit prior to energizing or using installed equipment that does not meet IC 2 controls, or within 7 days prior to making transfer.

* Manned refers to personnel performing work related to activity only.

This page intentionally left blank.

E5.0 APPLICATION OF CONTROLS TO FACILITY GROUPS

The flammable gas Facility Group assignments are shown in Table E5-1 and described below. Flammable gas ignition source controls and monitoring requirements are graded based on the Facility Group assignment.

E5.1 FACILITY GROUP 1

Five tanks (241-AN-103, 241-AN-104, 241-AN-105, 241-AW-101, and 241-SY-103) that have undergone observed, significant GREs are conservatively postulated to have the potential for large spontaneous and induced GREs that could create flammable conditions in the ex-tank region. For this reason, stringent controls are applied to these Facility Group 1 tanks.

Ventilation controls shall be maintained to mitigate steady state gas accumulation.

Because of the possibility of a large spontaneous GRE in Facility Group 1 tanks, ignition source controls (Set 2) (Section E4.3.2, "Ignition Source Control Set 2") shall be applied to the ex-tank and dome intrusive regions at all times. Additionally, continuous flammable gas monitoring (Section E4.4, "Gas Monitoring Requirements") shall be in place for ex-tank and dome regions during ex-tank intrusive and dome intrusive manned work activities. These controls are aimed at managing the risk of ignition in the event of a large spontaneous or induced GRE that could cause flammable gas conditions and pressurization of the dome region and result in an outflow of flammable gases to ex-tank regions.

Ignition source controls (Set 1) (Section E4.3.1, "Ignition Source Control Set 1") shall be applied to all waste intrusive or waste intruding equipment.

The work practice of reviewing Facility Group 1 tank data before manned work is being pursued as a Defense-in-Depth measure (McClusky 1996, *Flammable Gas Waste Tank Data Review*). The data review is performed to determine, as closely as possible, whether gas retention and release behavior has changed in an unexpected manner or whether the data support the existence of a "potential near-term" gas release event. This review is performed before dome intrusive, waste intrusive, and waste disturbing activities in these tanks. The JCO provides controls that are appropriate assuming a GRE can occur during the activity. The predictions about tank GRE behavior are sufficiently uncertain that this review process does not lend itself to be included as an Authorization Basis control and, therefore, will be implemented outside of the JCO.

E5.2 FACILITY GROUP 2

Facility Group 2 tanks differ from those in Facility Group 1 in that they are postulated not to be subject to large spontaneous GREs. The only large GREs postulated for Facility Group 2 tanks are those triggered by global waste disturbing operations. Because gas outflow to the ex-tank region is only postulated during global waste disturbing operations and activities, ignition source controls can be limited.

During non-waste disturbing and local waste disturbing operations, ignition source controls (Set 2) (Section E4.3.2) shall apply to the dome intrusive region only because of the decreased likelihood of gas release that can result in flammable concentrations outside the dome region. Similarly, continuous monitoring (Section E4.4) is required in the dome intrusive region only during manned work activities. These are judged to be sufficient to mitigate hazards posed by small spontaneous and induced GREs.

Global waste disturbing operations are postulated to be capable of triggering a large induced GRE that could result in flammable concentrations in ex-tank regions. For the duration of the global waste disturbing operation, ignition controls (Set 2) shall be extended to the ex-tank region. Continuous monitoring is also required for these ex-tank regions during manned activities. After completing a global waste disturbing activity and verifying that flammable conditions do not exist, these ex-tank controls can be removed for the ex-tank locations.

Ignition source controls (Set 1) (Section E4.3.1) shall be applied to all waste intrusive or waste intruding equipment.

Finally, ventilation controls (Section E4.2, "Ventilation Controls for SST, DST, and AWF Tanks") shall be maintained in Facility Group 2 tanks to mitigate steady state gas accumulation.

E5.3 FACILITY GROUP 3

Because Facility Group 3 tanks are postulated to be subject only to small induced GREs, its control set is the least restrictive. No event is postulated to cause a GRE that could cause flammability conditions to exist beyond the dome region. The control set is limited to the dome and waste regions.

During non-waste disturbing operations, ignition source controls (Set 2) shall apply to the initial entry. After flammable gas concentrations are verified as less than 25% of the LFL, the ignition source controls may be removed. Continuous gas monitoring is not required for non-waste disturbing activities if the initial sample is below 25% of the LFL.

Any local or global waste disturbing operation is postulated to induce a small GRE in the dome. For this reason, ignition source controls (Set 2) shall be applied to the dome intrusive region for the duration of the waste

disturbing activities. In addition, continuous monitoring is required in the dome intrusive region during manned, waste disturbing activities. After completing the waste disturbing activity and verifying that flammable conditions do not exist, these controls can be removed.

Ignition source controls (Set 1) (Section E4.3.1) shall be applied to all waste intrusive or intruding equipment.

Ventilation controls (Section E4.2) shall be maintained in Facility Group 3 tanks to mitigate steady state gas accumulation. Finally, ignition source controls (Set 2) are applied to sealed risers and sealed pits, at all times that they are sealed.

E5.4 NONTANK WASTE TRANSFER SYSTEM COMPONENTS

Miscellaneous transfer system components (e.g., transfer lines, valve pits, diversion boxes, process pits, transfer line clean out boxes) that are not directly connected to the waste tank headspaces are judged to pose a low flammable gas deflagration risk. The potential for flammable gases in these transfer system components is limited to the gas accumulation from chronic generation and release from contained waste and corrosion. Risk is reduced by flushing transfer lines after use. Historical evidence exists that the risk posed by this hazard is low. In addition, gas concentrations are monitored during entry to all vapor spaces, such as process pits, that might be connected to transfer lines. Gas monitoring verifies the risk is low. Flushing practices are required to be continued to maintain a low risk of flammable gas generation and accumulation. It is judged that additional controls are not warranted at this time.

E5.5 DOUBLE-CONTAINED RECEIVER TANKS

DCRTs are used primarily as lag storage facilities for supernatant and interstitial liquids for SSTs that are being pumped to complete the interim stabilization process. Tank 241-TX-244 also receives waste transfer from the Plutonium Finishing Plant (PFP).

The DCRTs consist of a steel tank located in an underground concrete vault. Mechanical exhausters provide the ventilation flow through the vault and suction to the tank. The inlet flow from the vault to the tanks is provided through leak paths at instrument connections with the tank (except for 244-U, which has a filtered inlet path). Because DCRTs contain waste heels and remnants of contaminated flush water, continued dip tube air flow is provided in these tanks. Gas generation rates from the heels and for waste temporarily stored in the DCRT during typical transfer operations are generally low enough that ventilation flow rates of a few cubic feet per hour are judged adequate for continued operations.

Ventilation flow is provided by instrument air injected into the tank at an estimated 0.08 m^3/hr (3 ft^3/hr) as part of the waste level dip tube operation.

Table E5-1. Flammable Gas Facility Group Assignments.

Notes:

[1]Tank 241-SX-109 passes the GRE evaluation documented in WHC-SD-WM-ER-526. As such it would be placed in Facility Group 3. However, it is included in Facility Group 2 because a number of tanks in the SX farm are Facility Group 2 tanks and, because of the unique ventilation configuration of the SX Farm, these tanks vent through the headspace of Tank 241-SX-109.

[2]Three tanks (241-SX-104, 241-AX-101, and 241-AX-103), which are currently on the Flammable Gas Watch List, are placed into Facility Group 3. The inclusion of SSTs into this group is based on the results of the GRE evaluation in WHC-SD-WM-ER-526. The watch list status for tanks is based on different evaluation methodologies used in the past.

Ventilation rates will be established and verified adequate to maintain DCRT gas concentrations below 25% of the LFL before placing new waste types (that is, waste types that may generate flammable gases at a higher rate than those handled currently) in the receiver tanks. The methodology for assessing the adequacy of the ventilation provided to the DCRTs during waste transfers is described in HNF-SD-WM-CN-118, *Calculation of Flammable Gas Mixtures in Double-Contained Receiver Tanks*.

Because of the limited storage time and small amounts of solids stored in DCRT waste, DCRTs are judged not to have significant GRE potential and are not subject to waste intrusive, waste intruding, or GRE controls.

Table E5-2 lists the DCRTs and the JCO control requirements.

E5.6 244-AR VAULT LAG STORAGE TANKS

The 244-AR-Vault facility is an inactive canyon building that was used for waste transfers and lag storage enroute from the Plutonium Uranium Extraction (PUREX) Facility to B Plant and waste enroute from B Plant and the Waste Encapsulation Storage Facility to the tank farms. The facility was also used during waste sluicing/transfer operations from the A and AX Farms. The 244-AR vault has four storage tanks (TK-001, TK-002, TK-003, and TK-004).

Table E5-3 shows the best estimate of tank contents, gas sample results, required ventilation controls, and the Facility Grouping. TK-002 contains 87,000 L (23,000 gal) of radioactive waste, including 2,300 L (600 gal) of neutralized current acid waste sludge left from the sluicing/waste transfer operations in AX Farm. The remaining three tanks in this facility are believed to contain very dilute liquids from flushing operations. These liquids have been collected from facility sumps and, therefore, are primarily water which has little potential for gas generation.

When the facility was active, a vessel vent system (K4) controlled hydrogen buildup and provided confinement for the storage tanks. Because this system has been inactive for several years, ventilation flow is provided by dip tube air flow to all four tanks. TK-002 had the only nonzero flammable gas concentration measured, indicating a hydrogen concentration of 2,200 ppm or the equivalent of 5.5% of the LFL (0.222 %vol hydrogen). For this tank, 4.0 %vol hydrogen can be used for total flammable gas concentrations because the measured concentrations of methane and ammonia are less than 0.001 %vol. This concentration has resulted from operation of dip tube air purge of 0.08 m^3/hr. Based on these sampling results, continued operation of dip tube air is judged to be adequate to control flammable gases in TK-002 until the waste can be removed while TK-001, TK-003, and TK-004 are judged to be safe without dip tube air purging. The flammable gas-related ventilation controls for TK-002 maintain ventilation purge through two dip tubes.

TK-002 may contain a 2,300-L (600-gal) heel of sludge from Tank 241-AX-104 that may cause gas retention; therefore, waste intrusive and waste intruding regions apply. Because of the sludge heel, this tank is treated with Facility Group 3 controls to ensure that flammable gas controls mitigate the hazards posed by potential release of gas retained within the sludge during sludge disturbing operations.

Table E5-2. Double-Contained Receiver Tank Flammable Gas Control Information.

DCRT	Use	Ventilation Requirements	Facility Group	Installed Equipment Ignition Source Controls
244-A	Cross-site, B-plant and some evaporator feed transfers. Drainage from transfer lines.	Dip tube operating to vent gases generated by waste heel. Assess dip tube flow requirements before placing new waste types in tank.	Non-GRE	None[2]
244-BX	Lag storage of 241-B, 241-BX, and 241-BY Tank Farm salt well liquids. Currently contains a significant sludge heel.	Dip tube operating to vent gases generated by waste heel. Assess before placing new waste types in tank.	Non-GRE	None[2]
244-S	Lag storage of 241-S and 241-SX Tank Farm salt well liquids and miscellaneous plant wastes. Drainage from cross-site transfer line.	Dip tube operating to vent gases generated by waste heel. Assess dip tube flow before placing new waste types in tank.	Non-GRE	None[2]
244-TX	Lag storage of 241-T Tank Farm salt well liquids. Lag storage for PFP waste transfers.	Dip tube operating to vent gases generated by waste heel. Assess dip tube flow requirements prior to placing new waste types in tank.	Non-GRE	None[2]
244-U	Lag storage of 241-U Tank Farm salt well liquids. Drainage from 241-SY Tank Farm transfer lines.	Tank/vault ventilation provided during lag storage of wastes.	Non-GRE	None[2]

Notes:

[1] DCRTs have been judged to pose little risk from GREs and therefore no GRE related controls are required.

[2] Flammable gas hazards are limited to steady state accumulation which is controlled by required ventilation; therefore, ignition source controls are not applied to installed equipment.

Table E5-3. 244-AR Storage Tank Flammable Gas Control Information.

Tank 244-AR	Contents	Gas Sample Results[1]	Ventilation Control Requirements	Facility Group	Installed Equipment Ignition Source Controls
TK-001	9100 L (2,400 gal) of mostly water from flushing and sump collection.	0% of LFL	None	Non-GRE	None
TK-002	2300 L (600 gal) of Tank 241-AX-104 sludge and 84,800 L (22,400 gal) of mainly water from flushing and sump collections.	5.4% of LFL	Continued dip tube air flow	Group 3	IC Set 2 during waste disturbing operations
TK-003	7600 L (2,000 gal) of mainly water from flushing operations and sump collections.	0% of LFL	none	Non-GRE	None
TK-004	380 L (100 gal) of mainly water from flushing of Tank 241-AX-104 sludge to TK-002.	0% of LFL	none	Non-GRE	None

Notes:

E5.7 INACTIVE MISCELLANEOUS UNDERGROUND STORAGE TANKS

The TWRS is responsible for managing 36 IMUSTs (WHC-SD-WM-PD-046, *Tank Waste Remediation System Inactive, Miscellaneous Underground Storage Tanks Program Plan*) that were physically isolated for at least 10 years. Knowledge about the contents of these tanks ranges from adequate to unknown, but they are all suspected to contain radioactive waste. Because many IMUSTs contain waste similar in composition to SST waste, it is postulated that flammable gas behavior (gas generation, retention, and release) is analogous to that in SSTs, but on a much smaller scale because of the small amount of waste present.

Because of the inactive and sealed condition of the IMUSTs, even slow gas generation rates can create potentially hazardous flammable gas accumulation over a long period. The gas generation rates, seal quality, and possible passive ventilation rates provided to the IMUSTs is unknown. For these reasons, this JCO imposes flammable gas ignition source and work activity monitoring controls required by the Facility Group control set assigned in Table E5-4.

The IMUSTs were evaluated for flammable gas generation and accumulation rate (WHC-EP-0861, *Status Report for IMUSTs at Hanford Site 200 Areas*) to obtain estimates of gas generation based on the radiolysis of water given the best available information regarding ^{137}Cs and ^{90}Sr inventories and the assumption of a completely sealed tank. Based on this estimate, the IMUSTs were assigned a flammable gas relative hazard ranking as defined in Table E5-4. These rankings are for information purposes and are not used to establish JCO flammable gas control requirements. Actual gas samples taken from three IMUSTs (241-C-301C, 241-TY-302A, 241-TY-302B) have indicated flammable gas concentrations of less than 1% of the LFL.

The Facility Group control sets were assigned based on the amount of waste solids and overlying supernatant known or suspected to be contained in the tank. The IMUSTs with significant solids but little supernatant (either less than 378.5 L [100 gal] or less than 1% of the tank capacity) were assigned to Facility Group 3. Conversely, IMUSTs with significant solids and a large supernatant layer were assigned to Facility Group 2. If the waste solid and liquid volumes of an IMUST were unknown, the tank was assigned to Facility Group 2 as a prudent measure until better knowledge of the waste contents is obtained. A group 2 assignment is judged to be conservative because the IMUSTs generally have been interim stabilized by removing as much liquid as technically and economically practical. Because a significant supernatant is unlikely to exist in these tanks, a spontaneous GRE is judged to be very unlikely. Finally, those IMUSTs containing mostly liquids with only a small amount of solids (less than 378.5 L [100 gal]) are judged not to warrant GRE controls.

The IMUSTs generally do not have energized equipment, so the potential for ignition sources is judged to be very low. Liquid levels are monitored in four tanks: Tanks 241-A-302B and 241-TX-302B are monitored for liquid level using a manual tape and Tanks 240-S-302 and 241-S-302A are monitored with FIC level detectors in the intrusion mode. These level measurement systems meet ignition source controls (Set 2) requirements.

Notes:

[1]The criteria for determining the priority rank of high, moderate, or low with regard to hydrogen generation and buildup as a potential safety issue are as follows.
High: Hydrogen accumulation reaches more than 1 %vol of the tank headspace (25 percent of the LFL) in 10 years or less.
Moderate: Hydrogen accumulation reaches more than 1 %vol of the tank headspace in 10 to 25 years.
Low: A tank is empty or hydrogen accumulation reaches more than 1 %vol percent of the headspace in more than 25 years.
If there are no data to calculate hydrogen generation, and there is less than a 50 percent void space ratio, the tank is ranked moderate.
If there are no data to calculate hydrogen generation, and there is greater than or equal to a 50 percent void space ratio, the tank is ranked low.

[2]HLW indicates waste contents could be any or a mixture of a number of typical High Level Wastes (HLW) similar to those found in the SSTs. More details are contained in WHC-EP-0861, 1995, Status Report for Inactive Miscellaneous Underground Storage Tanks at Hanford Site 200 Areas, Rev. 0, Westinghouse Hanford Company, Richland, Washington.

[4]Goheen (1995b, Gas Sample Analysis from Tank 302-B)

E5.8 CATCH TANKS

Catch tanks are underground storage tanks used to collect drainage of waste from diversion boxes, valve pits, and other waste transfer system equipment. Although newer catch tanks are contained within concrete vaults that provide secondary containment, older catch tanks are buried directly in the ground. Generally, catch tanks are located below pits that contain pumps and leak detection equipment.

The ventilation provided to each catch tank is unknown and may vary due to differing designs. Ventilation may be provided by tie-ins to tank ventilation systems, passive ventilation through breather filters, and/or passive ventilation through cracks in tank connections and pit cover blocks. Exact ventilation performance in each catch tank is difficult to quantify because of a lack of instrumentation. Furthermore, these tanks use manual tape, FIC, or ENRAF level measuring devices rather than dip tubes so purge air is not provided to the catch tanks. Therefore, this JCO must assume that adequate ventilation has not been verified.

Because of the small amounts of waste solids stored in the catch tanks, waste intrusive and waste intruding regions do not apply. Small induced GREs are not postulated for these tanks. The flammable gas hazard is thus limited to steady state release and accumulation. Because a steady state hazard exists if waste heels or contaminated flushwater remnants are present, unless adequate ventilation is verified, including gas sampling, the control strategy for catch tanks in this JCO is to verify that equipment in the vapor spaces connected to the catch tanks meets the requirements of ignition source controls (Set 2) (Section E4.3.2). Additionally, catch tanks shall be verified to be less than 25% of the LFL during work activities using standard work entry controls. Ignition source controls for manned work activities are applied only during work entry until flammable gas concentrations are verified to be less than 25% of the LFL.

Tank 241-A-350 differs from other DCRTs or catch tanks. It is used as a catch tank as it receives drainage from the 241-A Tank Farm in the event of a waste transfer leak.

Tank 241-A-350 is also used for lag storage during the transfer of evaporator condensate from 207-A to Tank 241-AW-102. This condensate is very dilute in radionuclides and is not a significant gas generation source; therefore, active ventilation, such as a required dip tube air supply, is judged to not be required for this lag storage operation.

Tank 241-A-350 is treated as a catch tank in terms of JCO flammable gas controls.

Table E5-5 lists the catch tanks addressed in this JCO and the flammable gas control requirements.

E5.9 242-S AND 242-T EVAPORATORS

E5.9.1 242-S Evaporator

The 242-S Evaporator facility was placed in a shutdown/standby condition in 1985, as documented in WHC-SD-WM-SSP-002, *242-S Facility Shutdown/Standby Plan*. The facility was flushed and radioactive liquids were removed. The aqueous makeup tanks, feed and slurry lines, acid addition lines, Tank 241-C-100 and evaporator vessel CA1 were flushed with water, along with having the lines blanked.

A facility walkdown was done in accordance with the WHC-SD-WM-FHA-022, *Fire Hazards Analysis for the 242-S Evaporator*. No reservoirs were found containing solely flammable or combustible liquids in excess of 3.7 L (1 gal) in the process areas.

Because this facility is inactive, additional flammable gas controls beyond those required for normal industrial hazards are not needed.

E5.9.2 242-T Evaporator

Operations in the process areas of 242-T Evaporator were discontinued in November of 1980. SD-HS-SAR-009, *242-T Evaporator Facility Shutdown/Standby to Condition V Safety Analysis Report*, was issued to maintain the facility process areas in a safe shutdown mode until decommissioning work could be initiated.

Facility records indicate that drain and transfer lines from the facility have been cut and capped, isolating the facility from SSTs, DSTs, and DCRTs, but the records do not describe flushing or waste removal from the process tanks. Hydrogen can arise from the corrosion of iron as well as the radiolytic degradation of water and organics such as tributyl phosphate. However, hydrogen generation in aqueous solutions low in fission products, such as PFP waste is expected to be slow. Because PFP waste was the last waste handled in the process tanks and the evaporator tanks are passively ventilated, flammable gas concentrations are expected to be low.

Because of uncertainties about the amount of remaining residual waste, it is prudent for this JCO to impose flammable gas ignition source and work activity monitoring controls for the blend tank (TK-B1) and the evaporator vessel in 242-T. Until gas sampling is performed to verify that flammable gases are not accumulating, equipment installed in these tanks must meet ignition control (Set 2) requirements or be deenergized. Entry monitoring must be performed before performing work activities. These controls are justified based on the type of waste and the manner in which it was processed through these tanks.

Table E5-5. Catch Tank Flammable Gas Control Information. (2 sheets)

Catch Tank	Use	Manual Work Activity Controls	Ventilation and Installed Equipment Requirements
241-S-304	Drainage from Diversion Box DB-241-S-151, precipitation and run-off	IC Set 2 until entry monitoring is completed	Verify adequate ventilation or meet IC Set 2

241-A-417	Drainage from 241-AY/AZ ventilation condensate system and possibly steam condensate from 241-AX-501 valve pit and 241-AZ-154	IC Set 2 until entry monitoring is completed	Verify adequate ventilation or meet IC Set 2
241-AX-152	Drainage from 241-AX-152 diverter station, DB-241-AX-155, AY-501 and 702-A seal pot	IC Set 2 until entry monitoring is completed	Verify adequate ventilation or meet IC Set 2
241-AZ-151	Drainage from DB-241-AZ-152, AZ ventilation seal loops, leak detection pits, 801-AZ Instrument Building, precipitation and run-off	IC Set 2 until entry monitoring is completed	Verify adequate ventilation or meet IC Set 2

Table E5-5. Catch Tank Flammable Gas Control Information. (2 sheets)

Catch Tank	Use	Manual Work Activity Controls	Ventilation and Installed Equipment Requirements
241-AZ-154	Condensate from Tank 241-AZ-101, 102 steam coils, precipitation and run-off	IC Set 2 until entry monitoring is completed	Verify adequate ventilation or meet IC Set 2
241-ER-311	Drainage from DB-241-ER-151 and DB-241-ER-152	IC Set 2 until entry monitoring is completed	Verify adequate ventilation or meet IC Set 2
241-EW-151	Vent station for cross-site transfers	IC Set 2 until entry monitoring is completed	Verify adequate ventilation or meet IC Set 2
204-AR-TK-1	204-AR Waste Unloading Facility catch tank	IC Set 2 until entry monitoring is completed	Verify adequate ventilation or meet IC Set 2
241-A-350	Received drainage from 241-A Tank Farm. Lag storage of condensate transfers from 207-A Retention Basin to Tank 241-AW-102	IC Set 2 until entry monitoring is completed	Verify adequate ventilation or meet IC Set 2 when waste is present. No requirements during transfer/lag storage of condensate.

E5.10 244-CR VAULT LAG STORAGE TANKS

The 244-CR-Vault facility is an inactive facility that functioned as a lag storage and transfer station for various waste streams including liquid discharge from Hot Semiworks and fission product "crudes" being transported between PUREX and B Plant. Until 1973, 244-CR Vault served as an interface facility providing lag storage and transfer service for PUREX acidified sludge (PAS) in transit from the 244-AR Vault to B Plant. The facility has also been used for routing waste transfers from 241-C Tank system to the DST system. The 244-CR Vault is a reinforced structure that houses two 40,000 gallon tanks (TK-CR-001 and TK-CR-011) and two 15,000 gallon tanks (TK-CR-002 and TK-CR-003).

Table E5-6 presents a summarization of the best estimate of the tank contents, volumes, required ventilation controls, and applicable Facility Grouping. TK-CR-001 was last used during the uranium recovery program in the 1950's. It contains a residual heel, less than 7,600 L (2,000 gal). TK-CR-002 contains less than 5,700 L (1,500 gal) of radioactive waste, consisting primarily of PAS transferred from Tank 244-AR-001 to B Plant for strontium recovery. TK-CR-003 was last used in 1995 during the SST stabilization campaign for Tank 241-C-102, Tank 241-C-107, and Tank 241-C-110. Those waste streams have since been removed from TK-CR-003. The current waste volume in TK-CR-003 is approximately 15,000 L (4,000 gal). This remaining heel in TK-CR-003 consists of PAS and Hot Semiworks waste. In the 1970's, TK-CR-011 was used as the sump receiver for 244-CR-Vault and for Hot Semiworks. Small rainwater accumulations were jetted from the other three 244-CR-Vault sumps and from Tank 69 at Hot Semiworks. As of 1986, TK-CR-011 contained approximately 133,000 L (35,000 gal) of liquid. The bulk of this inventory is approximately 21,000 gal of Tank 241-CX-70 supernatant liquid transferred to TK-CR-011 in 1979; and the remaining inventory is rainwater from Hot Semiworks and 244-CR-Vault sump drainage.

The 244-CR-Vault ventilation consists of a gravity or ambient air supply with air directed and controlled through the vault by operation of the 291-CR ventilation, air filtration, and exhaust system. The 244-CR Vault is divided into an upper and lower section. The upper section is considered the pump pit and riser pit areas, and the lower vault section houses the primary tanks which are separated from the vault by annular spaces. The upper and lower vault sections are connected by exhaust ports allowing air flow between the two sections. Air is removed from the lower vault section at the floor level and routed into a filter plenum. The air is then treated by a double bank of HEPA filters prior to being exhausted to the atmosphere through the stack. However, there is no separate vessel ventilation system for the tanks themselves. Exhaust air from the tanks enters the lower and upper vault sections via floor drains and exhaust ports; and is then swept away by the vault ventilation system air flow.

There are no ventilation flow instruments for the tanks themselves. In addition, no gas monitoring has been performed for these tanks to determine if the ventilation provided to these tanks by the vault ventilation system is adequate to maintain the flammable gas concentrations within acceptable levels

(i.e., less than 25% of the LFL). Until adequate ventilation is verified, and controls for maintaining it operable are implemented, equipment located in the headspace of these tanks must meet ignition source controls (Set 2) or be deenergized.

Gas sampling of Tanks TK-CR-001, 002 and 011 is impractical in the near term as riser access has been eliminated as part of the intrusion prevention effort (i.e., the risers have been foamed over). Tank modifications are planned for the future to re-establish access as part of the facility clean out process. Because TK-CR-003 is desired to be maintained in an active status (for the possible use of providing lag storage of pumped liquids during the salt well pumping of Tank 241-C-103), and gas sampling is more practical (tank access is available via the manual tape access riser) the adequacy of the ventilation provided to TK-CR-003 will be verified by obtaining gas samples of the TK-CR-003 vapor space. Air purging will be provided in this facility if sample results indicate concentrations $\geq$ 25% LFL. With adequate ventilation being provided, ignition source controls can be removed (during non-waste disturbing operations). LCO 3.2.4 requires the operability of the ventilation to Tank TK-CR-003 (HNF-SD-WM-TSR-006). In addition, AC 5.11.2.d requires that the ventilation flow be verified to be adequate for new waste types prior to placing new waste types in this tank (HNF-SD-WM-TSR-006).

Due to the remaining sludge heels in Tanks TK-CR-001, -002 and -003, these tanks are categorized as Facility Group 3. This conservative categorization ensures that the potential hazard of releasing gases that may be retained by the waste solids is adequately considered during waste disturbing operations (e.g., sludge heel removal). The supernate contained in TK-CR-011 is judged to have no significant gas retention potential and therefore this tank is categorized as non-GRE and is not subject to waste intrusive, waste intruding, or GRE controls as identified in this JCO.

Table E5-6. 244-CR Vault Storage Tank Flammable Gas Control Information.

244-CR Vault	Contents	Ventilation Control Requirements	Facility Group	Installed Equipment Ignition Source Controls
TK-CR-001	Less than 7,600 L (2,000 gal) of waste from Uranium Recovery Program (mostly waste solids)	None[1]	Facility Group 3	IC set 2 or deenergize
TK-CR-002	Less than 5,700 L (1,500 gal) of radioactive waste consisting primarily of PAS (mostly waste solids)	None[1]	Facility Group 3	IC Set 2 or deenergize
TK-CR-003	15,000 L (4,000 gal) of PAS and Hot Semiworks discharge (mostly waste solids)	Verify vault ventilation system is adequate via gas sampling or purging if necessary. Assess ventilation flow requirements prior to placing new waste in tank	Facility Group 3	None during non-waste disturbing operations IC Set 2 during waste disturbing operations
TK-CR-011	133,000 L (35,000 gal) of supernate and rainwater from Tank 241-CX-70, Hot Semiworks, and 244-CR Vault sumps	None[1]	Non-GRE	IC Set 2 or deenergize

[1] Although ventilation may be provided to this tank by the vault ventilation system, verification of its adequacy is not practical at this time. Until adequacy can be established by gas sampling, no ventilation requirements can be implemented. Until adequate ventilation is verified and a requirement (e.g., TSR) implemented, installed equipment must meet IC Set 2 or be deenergized.

This page intentionally left blank.

E6.0 JUSTIFICATION FOR CONTINUED OPERATIONS AND RESIDUAL RISK FROM CONDITIONS, OPERATIONS, AND ACTIVITIES IN FACILITIES INVOLVING THE FLAMMABLE GAS USQ

E6.1 EFFECTIVENESS OF CONTROLS FOR MANAGING THE RISK POSED BY FLAMMABLE GASES

The control strategy for flammable gas includes ventilation, ignition sources, and monitoring. Ventilation controls limit the risk of flammable gas accumulation by removing continuously evolved gases (steady state) and diluting gas release events. Monitoring flammable gas levels validates ventilation effectiveness and provides a basis for managing the risks posed by tank intrusive activities. If flammable gas concentration exceeds the LFL, control of ignition sources introduced into intrusive environments limits the risk of igniting flammable gas mixtures.

E6.1.1 Effectiveness of Ventilation

E6.1.1.1 Control of Flammable Gases Released in a Steady State Manner. For purposes of this JCO, all available tank headspace data are judged to imply that current ventilation procedures are generally effective in managing the risk of steady state flammable gas accumulation in waste storage tanks. Measurements for 77% of the SSTs, which were taken as part of vapor space characterization and flammable gas monitoring, indicate that concentrations are well below flammable levels. For this reason, this JCO continues current practices related to tank ventilation. The longer term effort to upgrade the Authorization Basis with respect to management of flammable gas hazards will benefit from additional vapor space sampling and quantitative bases for ventilation performance requirements.

The DCRT ventilation provided by the vault ventilation system is not verified as adequate. Therefore, DCRTs are required to be purged with instrument air. The adequacy of instrument air purge will be verified before placing new waste types in DCRTs. 244-CR TK 003, which does not have instrument air purge, must be sampled to verify that the vault ventilation system is adequate.

Instrument air purge of Tank 244-AR TK-002 is required and has been verified as adequate. Tanks TK-001, TK-003, and TK-004 have been sampled for flammable gas concentration and do not require air purges.

E6.1.1.2 Gas Release Events. The ventilation rate through the tank has little effect on the peak concentration after a GRE. Because the headspaces are generally quite large in SSTs and DSTs (850 to 2,830 m^3 [30,000 to 100,000 ft^3]) compared to active ventilation rates (typically 0.85 to 5.7 m^3/min [30 to 200 ft^3/min]), the ventilation effects on the concentrations in the tank headspace after a GRE are not dramatic. For releases that can cause concentrations that significantly exceed the LFL in a well mixed headspace, the time at risk could easily exceed several hours, even with high ventilation rates (WHC-SD-WM-SAD-034, *A Safety Assessment for Salt Well Pump Operations in Tank 241-A-101: Hanford Site, Richland, Washington*).

Ventilation controls cannot guarantee concentrations will be maintained below the LFL during GREs although concentrations above the LFL have not been measured except during a few GREs in Tank 241-SY-101. Ventilation system modifications and controls (tank vacuum levels, flow rates, mixing effects) directly aimed at reducing risk from GREs are not included as part of this JCO. Refinements to ventilation controls are being developed as part of the Final Safety Analysis Report/Technical Safety Requirement effort.

For GRE events, deflagration and combustion are prevented by controlling ignition sources through equipment design and by properly monitoring headspace concentrations during work activities. The controls described in this JCO provide these defensive measures.

E6.1.2 Effectiveness of Ignition Source Controls

If flammable gas concentrations accumulate above the LFL, the primary defense against the flammable gas hazard is the control of ignition sources. Although such controls cannot eliminate all possible ignition sources, the selected controls meet the intent of industry standards and allow continued tank farm operations and prudent use of TWRS resources.

Ignition source controls, as presented in Section E4.3, include the following: modifications to installed electrical equipment, control of electrostatic sparks, use of spark-resistant materials for tools and equipment, use of nonsparking or intrinsically safe or purged equipment.

E6.1.2.1 Installed Electrical Equipment. Most electrical equipment installed in tanks and in connected headspaces existed before the flammable gas USQ determinations. Although the majority of equipment is considered adequate, some electrical equipment must be replaced or modified to manage the risk from flammable gases and allow important waste management functions to continue.

E6.1.2.2 Control of Electrostatic Sparks. Electrically conductive objects are bonded in accordance with NFPA 77 during intrusive work. Exceptions are listed in Section E4.3, "Ignition Source Controls"; justifications are described in Appendix E. In most situations where verbatim compliance is not practical, work activity monitoring provides confidence that an electrostatic spark situation will not exist if flammable conditions exist.

The differences of potential between risers or other earth grounds may vary, typically by a fraction of a volt and at relatively high impedances. *Intrinsically Safe Apparatus for Use in Hazardous Locations* (UL 1988) provides information about ignition curves for hydrogen that show that, in the most conservative applications, nothing less than 12 volts could generate enough energy on faulting to ignite hydrogen. Therefore, riser ground loops are considered intrinsically safe.

E6.1.2.3 Spark Resistant Materials. Spark resistant materials are used in tools and some equipment in an intrusive manner to reduce the likelihood of mechanical "impact sparks" and "thermite reactions." The use of such materials is not practical in all applications, such as existing thermocouple trees, auger guide tubes, and core drill strings. The use of nonspark resistant materials is justified if they are nonsparking during normal use or

if measures are taken to reduce the likelihood of creating mechanical sparks when and where flammable conditions might exist. Mechanical spark control measures can include the following: restraints to prevent dropping equipment, slow insertion and removal rates through risers, riser sleeves made of spark resistant materials, and wetting down of risers during equipment insertion and removal. Such measures are included in work packages and procedures if they are relied upon to establish ignition source control equivalencies or to utilize ignition source control exception (Table E4-3, Item 27).

E6.1.3 Effectiveness of Monitoring Controls

Flammable gas monitoring is the third aspect of the flammable gas control strategy. Before and during intrusive work, the headspace is monitored for flammable gases in the environment where flammable gas might exist and the work, or possible ignition sources, are located. Under all circumstances, manned work shall immediately halt if flammable gas concentrations exceed 25% of the LFL.

Monitoring may be conducted using continuous monitoring with alarmed CGM, SHMS, or installed combustible gas monitors. Although a requirement for two redundant continuous monitors was considered, this was not judged to be warranted at present because the JCO provides ignition source controls as the primary defense against deflagrations. Monitoring is used as an additional control feature when manned work activities are in progress and errant ignition sources are more likely. It is not considered prudent to continue manned work if 25% of the LFL has been exceeded even though equipment ignition source control requirements are met. Installed, qualified equipment may be allowed to operate (not be deenergized) if concentrations are above 25% of the LFL.

Periodic monitoring during unmanned, global waste disturbing operations, such as salt well pumping, in passively ventilated SSTs is prudent. According to JCO logic, safety is maintained independent of this monitoring by using equipment that is acceptable in a flammable environment. Acceptable equipment meets ignition source control Set 2. Ongoing, but periodic, monitoring as specified in the JCO will be required as a prudent additional measure in passively ventilated tanks during global waste-disturbing operations. Continuous monitoring for this function is judged to not be warranted.

E6.2 UNCERTAINTIES AND RESIDUAL RISK

E6.2.1 Tank Flammable Gas Categorization and Grading of Controls

The sorting of TWRS-managed tanks into four Facility Groups enables consistent application of control sets for similarly situated tanks and provides a practical degree of consistency in controls. This method also permits the relaxation of controls to the maximum extent possible given the existing uncertainties in tank conditions and tank flammable gas hazards phenomena.

Although the methodology used to estimate gas release volumes has weaknesses, it is the only methodology currently available and will continue to be used cautiously until a better methodology is developed. Errors associated with underlying assumptions and calculations tend to be conservative and do not negatively impact safety. The use of the methodology in this JCO is limited to distinguishing Facility Group 2 and Facility Group 3 SSTs.

The risks associated with relaxing the controls for DCRTs, IMUSTs, catch tanks, and other facilities that contain only small amounts of waste solids are judged to be low. Because these ancillary tanks contain very little waste solids, they are not postulated to retain flammable gases in the waste matrix. Should a particular tank in this group subsequently be shown to contain a substantial quantity of waste solids, Facility Group 3 controls are applied to that particular tank.

E6.2.2 Risk From Natural Phenomena

The risks of a flammable gas deflagration resulting from natural phenomena, such as lightning and seismic events, are being investigated as part of the TWRS Final Safety Analysis Report upgrade effort.

E6.2.2.1 Lightning. The lightning hazard was addressed recently in WHC-SD-WM-ES-387, *Probability, Consequences and Mitigation for Lightning Strikes to Hanford Site High-Level Waste Tanks.* This analysis determined that demonstrating quantitatively that an unacceptable lightning-caused combustion (organic-nitrate, organic solvent, flammable gas) event is not credible is impossible at this time. The lightning strike probability evaluation indicates the possibility of a strike in the tank farms during the rest of the waste storage mission. The qualitative factors that are known, however, support the conclusion that the likelihood of igniting the waste is low. However, because of the uncertainty associated with this analysis, it has been concluded that providing additional mitigation for the tank farms is appropriate. Installation of lightning arresters on existing poles in the tank farms and improving grounding of tank risers that have high riser-to-ground resistance measurements are planned. These measures are expected to reduce risk from lightning ignition of flammable gases and are an acceptable basis for continued operation.

E6.2.2.2 Seismic Events. The risk of seismic events is uncertain. A concern is for a common cause scenario where the seismic event induces a GRE while causing a spark within the headspace. Currently, no near-term controls for such a scenario have been identified. The benefits of possible mitigation actions for such a scenario need to be evaluated and weighed against the penalties. The penalties include possible loss of tank monitoring, waste management capability such as interim stabilization and transfer capability, before implementation.

APPENDIX EA

FLAMMABLE GAS SAMPLE RESULTS AND SLURRY GAS LOWER FLAMMABILITY LIMIT

EA1.0 FLAMMABLE GAS CONTROL LIMIT BASIS

This appendix provides the basis for establishing the flammable gas control limit at 25% of the lower flammability limit (LFL). It also derives a conservative hydrogen concentration value to use as 25% of the LFL when hydrogen is the only flammable gas being monitored for and other flammable gases may be present. A discussion is included regarding flammable gas monitoring to ensure compliance with the limit.

The National Fire Protection Association (NFPA) recommends (NFPA 69, *Explosion Prevention Systems*) that processes be controlled so that flammable gas concentrations are less than 25% of the LFL, when relying on vapor space flammability levels to preclude the possibility of an ignition. For this reason, a control of less than 25% of the LFL has been established for performing manned activities in and around the facilities identified in this Justification for Continued Operation (JCO).

Because of the uncontrollable nature of gas release events (GREs), it is not possible to ensure that 25% of the LFL is never exceeded. Procedures and controls are in place to minimize the potential for a tank to exceed 25% of the LFL and to cease work in areas common with the tank vapor space, if the flammable gas concentration exceeds this level.

EA2.0 FLAMMABLE GAS COMPOSITIONS AND ASSUMPTIONS REGARDING THE LOWER FLAMMABILITY LIMIT

The flammable gas limit is stated as a percent of the LFL rather than a specific gas concentration. The primary flammable gas generated in the Hanford Site waste tanks is hydrogen which has an LFL of 4.0 volume percent (vol%) (40,000 parts per million by volume [ppmv]) in air. Other flammable gases are frequently present. The gases of potential concern for determination of LFL are ammonia, methane, and carbon monoxide.

EA2.1 AVAILABLE GAS COMPOSITION AND CONCENTRATION DATA

Table EA-1 summarizes the readily available flammable gas, organic vapor and other vapor results from specific combustible gas meter (CGM) readings and samples taken to support the safety program, and from formal vapor samples (Type 2, 3 or 4) taken from single-shell tank (SST) headspaces. The result from one inactive miscellaneous underground storage tank (IMUST) (241-C-301C) is also included.

The specific safety program samples were taken in the tank headspace a nominal 20 feet down from the riser top or a minimum of 3 feet below where the riser enters the tank. These samples were obtained to meet safety program

requirements. They included CGM readings, and drager tube ammonia measurements and total organic carbon (TOC) measurements. Although the CGM readings were essentially the same as routine measurements taken by industrial hygiene technologists (IHTs), they were obtained in specific, controlled work packages. Routine vapor monitoring results taken as part of daily maintenance or operations tasks are not reported in Table EA-1. Of the 46 samples taken, 41 (89%) read 0% of the LFL. Of the 5 samples that showed positive values, all were small, ranging from 1 to 7% of the LFL, and averaged 2.6%. CGM readings are high by approximately 100% per the manufacturer when calibrated on pentane and used for hydrogen monitoring. Applying the manufacturers 0.5 correction factor, the average for the positive reading samples was about 1.3% of the LFL for hydrogen in air. Onsite testing indicates that in concentrations below 1200 parts per million (ppm) hydrogen (3.0% of the LFL for hydrogen in air) the meters are unreliable or read zero. At 1200 ppm they read about the actual % LFL, without the correction factor applied. Above 1200 ppm the units read somewhat high even with the correction factor applied. The CGMs were also shown to indicate conservatively high when used in hydrogen-ammonia and nitrous oxide mixtures. See Section EA4.0 for discussion on CGM accuracy.

Type 2, 3, and 4 vapor samples were taken from the tank headspace using approved procedures. The percent LFL was calculated using Le Chatelier's rule for flammable gases and exclude organic hydrocarbons other than methane. The highest hydrogen, ammonia, and methane values were used, where a range is given. Where below detection limit "<" values are reported, the "<" value was used in the calculations. Carbon monoxide was not included in Table EA-1 because the values were insignificant.

Of the 81 samples reported in Table EA-1, 59 (73%) reported a < value for hydrogen or, when the reported values for hydrogen, ammonia, and methane were used to calculate a percent of the LFL, the result was $\leq$0.5% of the LFL. For the 22 samples that did not have a < value reported for hydrogen and resulted in a calculated concentration greater than 0.5% of the LFL, the values ranged from 0.54 to 2.51% and averaged 1.48% of the LFL.

The % LFL values shown in Table EA-1 are based upon the highest concentration of the flammable gases present in the respective samples. The highest calculated % LFL shown is for 241-A-101. A flammable gas mixture of 786 ppm hydrogen, 800 ppm ammonia and 12 ppm methane (49.19% hydrogen, 50.01% ammonia, 0.80% methane) has a calculated LFL of 63,759 ppm, or 6.4 vol%. With 1,598 ppm of flammable gases present, the percent LFL is (1,598 ÷ 63,759) x 100 = 2.51%. If only hydrogen was being monitored for, the hydrogen at 100% of the LFL for the flammable gas mixture would be 0.4919 x 63,759 = 31,363 ppm, or 3.1% hydrogen. An alarm at 25% of the LFL would be extremely conservative when set at 0.25 x 31363 = 7840 ppm hydrogen. For higher volume gas releases that would result in 60,000+ ppm flammable gases in the vapor space, the hydrogen:ammonia would be much larger than the 0.492:0.501 ratio assumed. This is due to ammonia being a soluble gas that would be in equilibrium with ammonia in solution. In order to get to 30,000 ppm ammonia in the vapor space, the waste concentration would have to have a very high ammonia content, i.e., ammonia would have to be present in the waste as a major chemical constituent, not as a degradation product. The last significant volumes of ammonia bearing wastes sent to tank farms were

declad wastes from Plutonium-Uranium Extraction Facility (PUREX) in the mid-1980s which went to a few selected double-shell tanks (DSTs) in AW and AP farms. Any SSTs which received ammonia wastes from PUREX in the late 1960s or early 1970s would have had the majority of the ammonia evaporated by now.

Nitrous oxide was not considered in the LFL calculations for Table EA-1. Although it is present at about 28% of the hydrogen concentration in Tank 241-A-101, its effect on the calculated vapor phase LFL is negligible. The vapor phase for Tank 241-A-101 has an oxygen concentration approximately 1,000 times the nitrous oxide level.

The total nonmethane organic hydrocarbon (TNMHC) percent LFL was calculated separately from the "normal" LFL and assumed that 45,000 mg/m^3 is equivalent to 100% LFL. The TNMHC values referred to in this appendix includes organic vapors in equilibrium with small quantities of organics in the tank liquids. A concentration of 46,000 mg/m^3 is the LFL for the kerosene hydrocarbons used as an organic diluent in PUREX and some B Plant processing operations (Bates, 1996, *Transmittal of Letter Report "Preliminary Retained Gas Sampler Results for Tank 241-AW-101"*). Further, a value of 45,000 mg/m^3 is normally used as the LFL for the range of organic vapors occasionally found in the Hanford Site waste tanks. Only four tanks showed greater than 0.49% LFL for organic vapors and mists. The four values ranged from 0.49% to 3.80%. Only two tanks (241-C-103 and 241-BY-108) have shown nonmethane organics above 1% of the LFL in the tank headspace (Table EA-1). These organics are mostly kerosene-type hydrocarbons. They are associated with past chemical processing operations that have entered the waste tanks in minor quantities along with aqueous waste streams. Methane is included in the LFL calculations in Table EA-1, but not in the few organic % LFLs. Gaseous nonmethane hydrocarbons such as ethane and propane were not included in the organic vapor LFL calculations, but were included as methane with the LFL calculations supporting Figure EA-1.

Gaseous hydrocarbons such as methane, and to a lesser extent ethane and propane, occasionally are present in low concentrations in waste gases (Table EA-4). They are believed to be formed from degradation of organic chemicals present in the waste in some tanks. By using a conservative concentration for methane (about 0.5 vol% in the undiluted waste gas) in the LFL calculations for Figure EA-1, the contribution of other organics to the LFL can be assumed to have negligible impact on the LFL.

The CGM reading and Type 3 sample for one IMUST were taken from approximately the middle of the tank headspace. No detectable flammable gas was found.

Table EA-1 summarizes the analytical results available for 81 formal vapor samples as of January 1, 1997, and the results of the 46 special tank safety program CGM reading and samples. Fourteen tanks had both types of samples taken. Thus, readily available headspace sample results for 114 SSTs (77% of the total) indicate that 70 to 90% of the sampled tanks show negligible or nondetectable flammable gas levels when no waste intrusive work is being done, and the remaining nominal 10 to 30% of the tanks average about 1.2 to 1.5% of the LFL. The highest CGM reading (7%) equates to approximately 3.5% of the LFL. The highest vapor sample was calculated to correlate to

2.51% of the LFL. One IMUST tank sampled showed no flammable gas present. The highest organic concentration, 3.8% of the LFL, was found in Tank 241-C-103. This waste tank is known to have a significant floating organic layer on top of the waste.

The flammable gases of concern in the waste tanks require an oxidizer to burn. The primary oxidizer in the tank headspace is oxygen, which is present in air at about 20.95 vol%. Nitrous oxide is present in the waste slurry gas, at an estimated nitrous oxide:hydrogen ratio of 0.85 for Tank 241-SY-101 (LA-UR-92-3196, *A Safety Assessment for Proposed Pump Mixing Operations to Mitigate Episodic Gas Releases in Tank 241-SY-101: Hanford Site, Richland, Washington*). Eight core sampling drill strings and one failed liquid observation well (LOW) have shown high LFL readings. Samples obtained from these locations (Table EA-4) indicated nitrous oxide:hydrogen ratio of 0 to 0.86, with an average of 0.40. Analytical results are available (Bates, 1996) from 5 tanks which have had retained gas samples (RGS) taken to date. These show a range of nitrous oxide:hydrogen ratio of 0.06 to 0.40 with an average of 0.17. Nitrous oxide in high concentrations can affect the calculated LFL for the undiluted waste gas as it acts as an oxidizer in addition to any oxygen present. When waste gas is diluted by air in the tank vapor space the nitrous oxide is overshadowed by the oxygen in the air and will thus have little effect on the calculated LFL for the tank vapor space (Section EA2.4).

EA2.2 TECHNICAL BASES FOR LFL

The potential reactions between flammable gases and oxidizers in the waste tanks are in WHC-SD-WM-SARR-002 and -004, (WHC-SD-WM-SARR-002, *Safety Basis for Activities in Double-Shell Tanks with Flammable Gas Concerns* and WHC-SD-WM-SARR-004, *Safety Basis for Activities in Single-Shell Tanks with Flammable Gas Concerns*) and repeated in Table EA-2.

The internal energy of the combustion reaction is defined as the enthalpy of the combustion reaction minus any pressure-volume work done by the process. Mathematically this is:

$$U_{RP} = h_{RP} - RT(n_P - n_R)$$

where h_{RP} is the enthalpy of combustion
R is the ideal gas constant
T is the temperature of the vapor space after mixing (34 °C assumed)
n_P is the number of moles of products
n_R is the number of moles of reactants.

As shown in Table EA-2, the reaction of hydrogen with oxygen generates the least heat per mole of the reactions given. Because of the predominance of hydrogen and ammonia as flammable gases, the major contributor to the total energy released in an ignition event in a tank headspace would be hydrogen or ammonia combining with oxygen.

Waste Slurry Gas Composition. To calculate an LFL for a waste gas mixture, it is necessary to know the waste gas concentration. The waste gas composition has been evaluated extensively for Tank 241-SY-101 and to a lesser extent for other tanks by analyzing the diluted off gas and backing out the contribution from nitrogen and oxygen in air.

Table EA-3 summarizes the values used in LA-UR-92-3196, WHC-SD-WM-SARR-002 and WHC-SD-WM-SARR-004, and WHC-SD-WM-ES-346, *Flammable Gas Tank Safety Program: Technical Basis for Gas Sampling and Monitoring*, as conservative gas mixtures in calculations of tank LFLs. These compositions were based upon DST releases, for which sample results were available, because only negligible significant observed releases from SSTs have occurred since the flammable gas Unreviewed Safety Question (USQ) was declared.

In the fall of 1995, monitoring for flammable gases was initiated inside core sampling drill strings. Since then, eight gas samples have been taken from inside drill strings which have exhibited high LFL readings. The sample results are given in Table EA-4. The samples represent an opportunity to obtain waste gas samples prior to dilution in the tank headspace. Some of the samples have been diluted by nitrogen or argon purge gas, or air in the drill string. Ammonia results from these samples are low, however, due to absorption during the informal grab sampling process, but the ratios of nitrous oxide, carbon monoxide, carbon dioxide, methane, or other C_nH_{2n+2} to hydrogen are useful data. Where the effect of air can be accounted for, the ratio of nitrogen to hydrogen is also given. In mid-1995 a grab sample was retrieved from a failed LOW. Results from this sample are also included in Table EA-4.

In 1996, the first RGSs were taken from Tank 241-AW-101. These samplers were designed to trap waste gases and liquid/solid waste taken during core sampling operations. The samples will allow analysis of concentrated waste gases and provide other information on waste gas makeup. Bates (1996) describes the sampling and analytical process and summarizes the results from the samples obtained to date. These results are given in Table EA-5. The gases in the RGS samples are extracted in the laboratory by repeatedly evacuating the sample and trapping the off gas. Because ammonia is a soluble gas, the ammonia in the gas phase in a waste gas pocket is in equilibrium with ammonia in solution in the waste around it. Thus, more ammonia is drawn out of solution to return the gas phase to equilibrium when an RGS sample is evacuated. Therefore, RGS sample results for ammonia in the gas phase will be biased high if all the recovered ammonia is reported. The ammonia values given in Table EA-5 are calculated quantities based upon the Henry's law constant. The derivation of this value and the calculations performed to estimate the lower bound on the ammonia vapor concentration in the waste gas is described in detail in Bates (1996).

EA2.4 DERIVATION OF 25% OF THE LFL ALARM LIMIT WHEN MONITORING FOR HYDROGEN ONLY

The LFL used in this JCO is the lowest concentration of a flammable gas mixture that will support combustion in the presence of a given oxidizer. The LFL will vary with the oxidizer. Table EA-6 summarizes values from the referenced sources of the LFLs for the flammable gases of concern in air and in nitrous oxide.

Using Le Chatelier's rule, the LFL of an ideal gas mixture can be calculated by

$$LFL_{mix} = \frac{1}{\frac{f_{fg1}}{LFL_{fg1}} + \frac{f_{fg2}}{LFL_{fg2}} + \frac{f_{fg3}}{LFL_{fg3}} + \ldots \frac{f_{fgn}}{LFL_{fgn}}}$$

where f_{fg1} = mole fraction of flammable gas #1
LFL_{fg1} = LFL of flammable gas #1

The LFL_{mix} and the mole fractions of flammable gas 1, 2, etc. are based on the flammable gases present only, i.e., all nonflammable constituents are excluded.

Assumptions, evaluations, and results of previous estimates for hydrogen concentrations that represent the LFL or 25% of the LFL are summarized for consideration in establishing the values used in this JCO.

EA.2.4.1 Tank 241-SY-101

LA-UR-92-3196, Appendix B. This reference estimated the LFL for Tank 241-SY-101 waste gases based on Le Chatelier's rule and using the concentrations given in column 2a of Table EA-3 (after revising to a flammable gas constituent only basis) with the LFL in air values in column 2 of Table EA-6.

The LFL value of the mixture calculates to 5.3 vol% in the tank vapor space based on the flammable gas constituents only, or 11.1 vol% if all waste gas constituents are included. This means that 11.1% of the tank dome space would have to be filled with all the gases in Table EA-3, in the ratios given, with the remaining 88.9% being air, for the tank dome space to be at 100% of the LFL. Monitoring for all the waste slurry gases in the tank dome space is impractical, so the hydrogen concentration at 100% of the LFL is calculated and used as a basis for monitoring. The hydrogen concentration at a waste gas concentration of 11.1 vol% in the tank vapor space calculates to 3.5 vol%. LA-UR-92-3196 gives 3.5% hydrogen in the tank vapor space as a conservative value that would indicate the presence of waste gas at 100% of the LFL in the tank vapor space, with 25% of the LFL being 8,750 ppm. LA-UR-92-3196 recommends using 8,750 ppm as 25% of the LFL, but with an administrative control of 7,500 ppm hydrogen as a monitoring limit to account for instrument uncertainties.

LA-UR-92-3196 discusses the effect of nitrous oxide on the LFL for 241-SY-101. Using the "conservative" composition for 241-SY-101 waste gas, the dome space would contain about 12.7% waste gas when the concentration of

hydrogen reached 4% in the tank dome. With a hydrogen concentration of 4%, the concentrations of ammonia and nitrous oxide would be about 1.9% and 3.4%, respectively. Bureau of Mines data referenced in LA-UR-92-3196 showed that at up to 2% ammonia in a stoichiometric mix of hydrogen and nitrous oxide diluted with air, Le Chatelier's law was appropriate for determining the LFL.

EA.2.4.2 All Tanks

WHC-SD-WM-SARR-002 and -004 Appendices B, and WHC-SD-WM-ES-346. These references used Le Chatelier's rule to arrive at a ppm hydrogen limit that could be used for the vapor space of all tanks. The method included the effect of nitrous oxide on the LFL and looked at varying the hydrogen level in the waste gas. These documents recommended using 6,250 ppm hydrogen as the alarm point for hydrogen monitoring systems to indicate when 25% of the LFL may have been reached in a tank vapor space.

The 6,250 ppm limit is very conservative because the following assumptions were used:

- A LFL of 3.5% was used for hydrogen in air
- A LFL of 8% was used for ammonia in air
- A plot was presented of the waste gas LFL versus the hydrogen concentration in the waste slurry gas excluding noncombustibles. Interpretation of the plot assumed an extremely conservative hydrogen concentration in the waste slurry gas.

EA.2.4.3 Current Data

The sample data from Table EA-1 was used to calculate the % LFL for each tank with formal sample analyses. The tank % LFLs are repeated in Table EA-8 from Table EA-1. The LFL of the flammable gas mixture and the equivalent hydrogen concentration at 25% of the LFL were calculated for the flammable gas mixture in the tank vapor space for all 81 samples. This information is presented in Table EA-8. Also included in Table EA-8 are calculations based upon the sample data from Table EA-4 for the Tank 241-BY-110 drill string and the Tank 241-SX-104 failed LOW.

Where a range was given in Table EA-1, the highest gas concentrations were used. Where a < value is stated, the < value was used as the concentration. The calculated tank vapor space flammable gas LFLs ranged from 4.27% to 10.78% by volume. Hydrogen concentration equivalent to 25% of the LFL ranged from 1,270 ppmv to 9,720 ppmv. The average LFL for all samples (excluding the Tanks 241-BY-110 and 241-SX-104 waste gas samples) was 6.36% and the average hydrogen concentration at 25% of the LFL was 6,150 ppm. The average LFL including only samples with detectable concentrations calculating above 0.5% of the LFL (again, excluding Tanks 241-BY-110 and 241-SX-104 waste gas results) was 5.32% and the average hydrogen concentration at 25% of the LFL was 7,700 ppm. The average of the LFL for the Tanks 241-BY-110 and 241-SX-104 waste gases was 4.29%, and the average hydrogen concentration at 25% of the LFL was 9,310 ppm.

These results are skewed due to the low flammable gas concentrations present, and by using < values instead of zero in the LFL calculations. The results should not be extrapolated to higher flammable gas concentrations, and should not be used as valid hydrogen concentrations at 25% of the LFL. Hydrogen, ammonia, and methane are generated by radiolysis within the waste.

Ammonia is a soluble gas and largely remains in solution. Being in solution in the waste, ammonia will be present in the tank vapor space in equilibrium with dissolved ammonia. For this reason ammonia is present in detectable concentrations in most tank vapor spaces. Hydrogen and methane, being insoluble, can be trapped in pockets instead of being released. This explains the low or non detectable levels of these gases in many tanks. Basing calculated LFLs or hydrogen concentrations at 25% of the LFL on low level tank vapor results is misleading. At low levels of flammable gases in a tank, ammonia will predominate and skew the sample results to give a high tank LFL and a low hydrogen concentration at a calculated 25% of the LFL. Flammable gas levels approaching 25% of the LFL would only occur following a release of significant hydrogen or methane from the waste, which will mean a much lower ratio of ammonia to these gases than is present during steady state releases. Should a GRE occur, significant hydrogen and methane could be released, but the ammonia should be no more than what would be in equilibrium with ammonia in the liquid waste at the tank bottom.

This effect can be seen in the data in Table EA-8. Including all tank vapor space data the calculated hydrogen concentration at 25% of the LFL was 6,150 ppm. This rises to 7,460 ppm when only vapor spaces above 0.5% of the LFL are considered, to 7,700 ppm when only vapor spaces above 2% of the LFL are included, and reaches 9,310 ppm for the waste gas samples at 650% and 64% of the LFL. Based upon this data, 7,500 ppm is a reasonable value for the hydrogen concentration at 25% of the LFL.

EA.2.4.4 Calculated Limit

Limit As Applied To This JCO. LA-UR-92-3196, WHC-SD-WM-SARR-002, WHC-SD-WM-SARR-004, and WHC-SD-WM-ES-346 calculated hydrogen concentrations that give 25% of the LFL for a conservative waste gas composition, but may have some limitations. The method in LA-UR-92-3196 is for Tank 241-SY-101 only. The other references vary the hydrogen content of the waste slurry gas to provide a range of LFLs. They use conservative values for the LFLs for hydrogen and ammonia in air, and a conservative assumption is used in interpretation of the results.

The LFL calculations were redone for this document using the following assumptions:

- The ratios of ammonia:methane:carbon monoxide were kept constant and equal to those in column 2b of Table EA-3.
- The values for LFL in air were assumed equal to those in column 7 of Table EA-6 CRC Handbook of Chemistry and Physics and for LFL in nitrous oxide were assumed equal to those in column 6.

- The LFL values used in subsequent calculations were based on a gas of 92.6% air/7.4% nitrous oxide, as was done for WHC-SD-WM-SARR-002 and -004. This is conservative as the ratios of oxygen to nitrous oxide present in the tank vapor space will be far greater than this, and result in the oxygen swamping the nitrous oxide. A linear interpolation was made between the values for LFL in air and in nitrous oxide for hydrogen, ammonia, and methane. The value for LFL in air was used for carbon monoxide. These resulted in using conservative LFL values of 3.84 for hydrogen, 14.5 for ammonia, 4.69 for methane, and 12.5 for carbon monoxide in the air/nitrous oxide mix.

- The LFL was calculated for a waste slurry gas consisting of the four flammable constituents, with the hydrogen concentration varying, but the other three constituents kept in the same ratio to each other, and making up the remainder of the flammable gas mixture. The percent hydrogen that would occur in the tank vapor space at 100% of the LFL for the waste slurry gas in the tank vapor space was then plotted as a function of the percent hydrogen in the waste slurry flammable gases, (i.e., excluding all noncombustible constituents).

This plot is provided as Figure EA-1 for this JCO. The conservative hydrogen concentration in the 241-SY-101 waste slurry gas (and as used in References 3 and 4), from Table EA-3 column 2a, is 31.41% hydrogen, which is 66.3% of the flammable gases. From Figure EA-1, this equates to a vapor space hydrogen concentration of about 3.4% hydrogen, which is essentially the same as the 3.5% recommended in LA-UR-92-3196.

Estimates of the actual hydrogen concentration in the tank waste gases range from 30 to 70% per WHC-SD-WM-SARR-002 and -004, but this range includes the presence of noncombustibles for significant releases. Including just the combustibles, the hydrogen concentration is expected to be 60% or higher. The "best estimate" gas compositions from LA-UR-92-3196, WHC-SD-WM-SARR-002 and -004, and WHC-SD-WM-ES-346 are given in Table EA-7.

According to this table, the percent hydrogen based on the flammable gases in the waste slurry gas only is 61 to 71%. As shown in Table EA-1, the ratio of hydrogen to ammonia found in tank vapor spaces from chronic releases shows hydrogen could range from less than 10% to greater than 90% of the flammable gases in a tank at very small (<3% of the LFL) concentrations. Experience with monitoring from larger DST releases (the basis for Tables EA-3 and EA-7), and as shown by the waste gas drill string sample results shown in Table EA-4 and RGS sample results in Table EA-5, indicate the majority of flammable gas in GREs or concentrated waste gas samples is hydrogen.

Using Figure EA-1, and assuming 60% of the flammable gas in a waste slurry gas is hydrogen, the hydrogen concentration at 100% of the LFL in a tank vapor space conservatively calculates to 3.22%. Setting a hydrogen concentration that equals 25% of the LFL based on this reasoning calculates to approximately 8,000 ppmv.

EA3.0 SUMMARY

A value of 6,250 ppmv hydrogen shall be assumed as 25% of the LFL for work in tank farms, when hydrogen is the only flammable gas monitored for. This is based on the following:

- LA-UR-92-3196 calculated a value of 8,750 ppm hydrogen as 25% of the LFL for Tank 241-SY-101 waste slurry gas in the tank dome space
- WHC-SD-WM-SARR-002 AND -004 and WHC-SD-WM-ES-346 recommended that a value of 6,250 ppm hydrogen be used as 25% of the LFL for SSTs or DSTs. Overly conservative assumptions were used to derive this number. WHC-SD-WM-SARR-002 and -004 states a value of 7,375 ppm hydrogen should be used as 25% of the LFL if a value of 15% is used for the LFL of ammonia in air.
- Per Table EA-8, the calculated hydrogen concentration at 25% of the LFL could be anywhere from 1,300 ppm to 9,700 ppm for gas mixtures present in very low concentrations. The calculated hydrogen concentration at 25% LFL rises with increasing flammable gas levels and averaged 7,700 ppm for the 7 tanks above 2% of the LFL.
- In this document, a value of about 8,000 ppm hydrogen is calculated as being $\leq$25%of the LFL for tank waste slurry gas in the tank dome space for any tank.
- Based upon the evaluation provided in this appendix, a 7,500 ppm value for hydrogen at 25% of the LFL is reasonable for use in evaluating gas measurements to understand the actual hazard present. However, the conclusion and supporting analysis for the value to use in setting monitoring alarm setpoints and action limits is described in WHC-SD-WM-ES-346. Until this document is revised and reviewed, 6,250 ppm hydrogen will be used for monitoring alarm and action setpoints.

EA4.0 FLAMMABLE GAS MONITORING METHODS

Several methods are used to monitor for various flammable gases or vapors in the tank farms. These include CGMs, organic vapor monitors (OVMs), Drager tubes, Standard Hydrogen Monitoring Systems (SHMS), gas chromatographs, and taking Type 2, 3, and 4 vapor samples. Because this section covers monitoring for hydrogen or flammable gases to demonstrate compliance with the 25% of the LFL control limit, the discussion will address only CGMs, SHMS, and Belhaven monitors.

EA4.1 COMBUSTIBLE GAS METERS

The CGM predominantly used in the tank farms is the Industrial Scientific Corporation model LTX 310. This unit is calibrated on pentane before and after each shift it is used, in accordance with Industrial Hygiene procedures. The manufacturer provides a table of conversion factors to be applied when the model LTX 310 is used for monitoring for gases other than pentane. Following

the manufacturer's information, the CGM reading should be multiplied by a correction factor of 0.5 when monitoring for hydrogen. Thus, a reading of 20% of the LFL on the LTX 310 means that the actual hydrogen concentration is 10% of the LFL, assuming hydrogen is the only flammable gas present. For conservatism, and to avoid confusion in the field, the LTX 310 reading is not multiplied by the correction factor, so a 20% of the LFL reading is treated as 20% of the LFL, not 10%.

According to the manufacturer, the conversion factors to be applied when monitoring for other gases are accurate to about +/-25%. A 25% of the LFL indication on the LTX 310 means that the actual hydrogen concentration is in the nominal range of 9.4% to 15.6% of the LFL. Therefore, without applying the correction factor, the indicated CGM reading is 60 to 167% higher than the actual percent of the LFL for hydrogen, assuming hydrogen is the only flammable gas present. Tank farm procedures require a reading to be treated at the indicated value, so when performing work a 25% of the LFL indication on a CGM is assumed to mean 25% of the LFL for a flammable gas mixture is present.

WHC-SD-WM-TRP-256, *Test Evaluation of Industrial Hygiene Hand Held Combustible Gas Monitor* evaluated the response of the CGMs to hydrogen in air. The data showed that below 3% of the LFL for hydrogen in air (about 1,200 ppm hydrogen), the units were unable to accurately measure the LFL as the concentrations were too low. Around 1,200 ppm the units were fairly accurate without applying the 0.5 correction factor. As the percent hydrogen rose above 1,200 ppm the indicated LFL, even after applying the 0.5 correction factor, was 5 to 40% above the actual. The CGM response was also checked in the presence of nitrous oxide and ammonia. The presence of ammonia and/or nitrous oxide also resulted in the indicated LFL reading being higher than actual after applying the correction factor.

The LTX 310 CGM, as employed in the tank farms, is not applicable for characterization of tank vapor spaces, but can be safely and conservatively used for LFL monitoring to an indicated 25% of the LFL, and is expected to read high for any gas mixture present. Therefore, a 25% of the LFL monitoring limit is acceptable when using these instruments. When 25% of the LFL is indicated, response shall be as required by the flammable gas specification limit of this JCO.

EA4.2 STANDARD HYDROGEN MONITORING SYSTEMS

These monitors are installed on many of the tanks currently on the Flammable Gas Watch List. They operate using a Whittaker cell to detect hydrogen only. These monitors currently have a 6,250 ppm hydrogen set point.

EA4.3 CONTINUOUS INSTALLED COMBUSTIBLE GAS METERS

These meters are currently used to monitor the salt well pit vapor space of several tanks being salt well pumped. These units are calibrated on methane approximately monthly. According to the manufacturer the correlation is 1:1 (no correction factor) when monitoring hydrogen. Based on a test gas mixture of hydrogen, ammonia, and methane in air, the unit read slightly

higher for hydrogen than the level present in the test gas. When measuring a gas with an LFL of 2.5% for hydrogen in air, a value of 3.2% was indicated. Below 5% of the LFL the units appear to read high. The units work best on a concentration of 5 to 30% of the LFL. Based on experience, the installed CGMs can be used to adequately monitor for compliance with the 25% LFL limit using the recommended monitoring limit.

EA4.4 OTHER HYDROGEN/FLAMMABLE GAS MONITORS

Some tanks have gas chromatographs installed to analyze the vapor space. Other hydrogen monitors may be selected for use in the future. Any such monitor may be used for monitoring for compliance with the flammable gas specification limit as long as it is shown to read conservatively at less than 25% of the LFL for a conservative waste gas mixture.

1 Remaining gas concentrations not readily available for S-107 drill string grab sample.
2 A drager tube sample of the drill string taken about the time of the gas sample indicated about 1000 ppm ammonia (0.1 %).
3 OVM reading of the drill string taken about the time of the gas sample indicated an organic level of 234 ppm (0.02 %).
4 Nitrogen and oxygen ratios not meaningful as majority of nitrogen believed from drill string purge gas, and oxygen present believed from air inleakage.
5 Argon present due to argon used to purge drill string of flammable gases.
6 Nitrogen in waste gas derived by calculating nitrogen contamination from air at 3.7279[oxygen], and subtracting this from total nitrogen.
7 Ammonia values may be low due to gas absorbing on walls of sampling equipment, or for S-107, AN-104 and AN-103 due to absorption in the LiBr solution in the drill string.
8 Nitrogen and oxygen ratios not meaningful as majority of nitrogen/oxygen believed from air inleakage.

Table EA-5. Summary of RGS Sample Results.

APPENDIX EB

SAMPLE FLAMMABLE GAS CONTROLS SPECIFICATION PROCESS

This Appendix shows a sample process that can be used to specify the allowed safe conditions and control requirements to address the flammable gas hazards as described in TF-96-0433 (USQ Tracking No.), *Consolidation of Flammable Gas/Slurry Growth Unreviewed Safety Question Issues*. The process is used by the Project Hanford Management Contractor (PHMC) to establish whether proposed activities are within the allowed conditions and requirements of the flammable gas Justification for Continued Operation (JCO) for the flammable gas hazard. This process description is not an Authorization Basis document. The process uses existing Tank Waste Remediation System (TWRS) procedures and work practices, as well as certain new work practices created as part of the flammable gas JCO. This attachment must be used in concert with the TWRS USQ procedure as found in HNF-IP-0842, *TWRS Administration*, Volume IV, Section 5.4. This process is **not** a substitute for the USQ process. The process flow is summarized in Figure EB-1 and described in the following paragraphs.

Signature to release work signifies that the process described in this appendix has been completed and that required controls are implemented.

EB1.0 APPLICABILITY

The JCO and, therefore, this process applies to work packages and operating procedures that cover activities involving any of the following locations or characteristics: ex-tank intrusive, dome space intrusive, waste intrusive, local waste disturbing, or global waste disturbing.

NOTE: If the activity or operation involves only non-intrusive locations, is not waste disturbing, and applicable ventilation requirements are met, the activity or operation does not involve the flammable gas USQ and no applicable ignition source control (IC) or monitoring JCO requirements are related to the flammable gas hazard.

EB2.0 WORK AUTHORIZATION PROCESS OVERVIEW

Comparison with Flammable Gas JCO Conditions for Safe Operation

The information in the work package or operating procedure is used to answer the following questions to establish the appropriate and required JCO controls.

[a] Is this activity or operation expressly prohibited by the JCO?

Yes ____
No ____

If YES, the Authorization Basis must be amended and specific approval by the U.S. Department of Energy, Richland Operations Office (RL) must be sought.

[b] Which JCO facility groups are affected by this activity or operation?

Facility Group 1 ____
Facility Group 2 ____
Facility Group 3 ____
Non-GRE (gas release event) ____

[c] Which regions of the affected facilities are involved in this activity or operation? NOTE: Activities and equipment may involve more than one region.

Nonintrusive ____
Ex-tank Intrusive ____
Dome Space Intrusive ____
Waste Intrusive ____
Inside Waste Intruding Equipment ____

[d] What is the nature of the activity or operation in the affected facilities?

Non-Waste Disturbing ____
Local Waste Disturbing ____
Global Waste Disturbing ____
For non-GRE facilities, this does not apply ____

NOTE: If the activity or operation involves only Nonintrusive locations and is not waste disturbing, the activity or operation does not involve the flammable gas USQ and no JCO requirements apply.

[e] Determine the ventilation requirements for the affected facilities, as specified in the JCO. (Check the applicable requirements.)

Double-Shell Tank (DST) and Aging Waste Facility (AWF) Tank Ventilation ____
Single-Shell Tank (SST) Active Ventilation ____
SST Passive Ventilation ____
Double-contained receiver tank (DCRT) Ventilation ____
244-AR, TK-002 Ventilation ____
No ventilation is required ____

Can the work activity or procedure be performed without violating the applicable requirements?

Yes ____
No ____

If NO, is there a RL-approved Authorization Basis for this activity or operation that provides alternative ventilation requirements and addresses the flammable gas hazards as described USQ TF-96-0433, Rev. 1?

Specify: _____

If YES, does this approved basis clearly apply to the affected facilities?

Yes ____
No ____ ([h] below)

[f] In light of the answers to [b], [c], and [d], which ignition source requirements apply? Go to the Ignition Source Control Evaluation Worksheet before proceeding, to determine specific requirements and compliance.) Document the requirements on an IC Evaluation Worksheet.

Are the equipment and materials (1) in compliance with the ICs, or (2) do they provide equivalent safety per the Flammable Gas Equipment Advisory Board (FGEAB) or (3) or are they exempted as listed in Table E4-4?

Yes ____
No ____

If NO, is there a RL approved Authorization Basis for this activity or operation that provides alternative ignition source requirements and addresses the flammable gas hazards as described USQ TF-96-0433, Rev. 1?:

Specify: _____

If YES, does this approved basis clearly apply to the affected facilities?

Yes ____
No ____ ([h] below)

[g] In light of the answers to [b], [c], and [d], check the applicable requirements.

Entry monitoring only ____

Continuous monitoring during manned activities ____

Continuing periodic monitoring during unmanned global waste disturbing activities in passively ventilated SSTs ____

For non-GRE facilities: monitoring before energizing equipment that does not meet ICs, when ventilation has not been verified to be adequate and operable (e.g., catch tanks) ____

Monitoring as a compensatory measure to ICs. Specify applicable monitoring requirements: _____

No monitoring is required ____

Are the monitoring requirements for the affected facilities, as specified in the JCO, contained in the operating procedure or the work package?

Yes ____
No ____

If No, is there a RL-approved Authorization Basis for this activity or operation that provides alternative monitoring requirements and addresses the flammable gas hazards as described USQ TF-96-0433, Rev. 1?:

Specify: _____

Does this approved basis clearly apply to the affected facilities?

Yes ____
No ____ ([h] below)

[h] Are all of the requirements indicated in items [e], [f], or [g] satisfied?

Yes ____ The activity or operation is within the JCO and TSRs from the perspective of the flammable gas hazard only.

No ____ The activity or operation is not permitted per the approved JCO and an amendment to the TWRS Authorization Basis is required before the activity or operation may proceed as proposed.

APPENDIX EC

EXCEPTIONS TO IGNITION SOURCE CONTROLS

This page intentionally left blank.

LIST OF TERMS

ALARA	As Low As Reasonably Achievable
CAS	Continuous Air Sampler
CGM	Combustible gas meter
FG	Facility Group
FGEAB	Flammable Gas Equipment Advisory Board
FIC	Food Instrument Corporation (level gauge)
GRE	gas release event
GWD	global waste disturbing activities
ICS	Ignition Control Set
IMUST	inactive miscellaneous underground storage tank
ISVS	in-situ vapor system
JCO	Justification for Continued Operation
LFL	Lower Flammability Limit
LOW	liquid observation wells
LWD	local waste disturbing activities
MITs	Multiple instrument trees
NFPA	National Fire Protection Association
NWD	non-waste disturbing activities
OVM	organic vapor monitor
PAM	portable alpha monitor
PMCS	push mode core sampling
PVC	polyvinyl chloride
RCT	radiological control technician
RH	relative humidity
RMCS	rotary mode core sampling
SHMS	Standard Hydrogen Monitoring System
TCR	Tank Characterization Report
VDTT	velocity-density temperature tree

This page intentionally left blank.

ITEM CLASSIFICATION: DE MINIMUS

ITEM NUMBER: 1 (page 1 of 4)

EQUIPMENT: Rubber/plastic gloves, canvas gloves. Tyvek clothing, plastic clothing

CATEGORY: Static Spark Potential

USE:

Used for protecting personnel from contamination.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #3 (ICS 1 #3) (ignition control set)	FG 1 ex-tank FG 2 ex-tank global waste disturbing activities (GWD) FG 1,2 dome intrusive FG 3 dome intrusive (local waste disturbing activities [LWD], GWD)

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

Surgeon's gloves, or other "rubber" gloves, are worn in radiation areas for personnel protection. Canvas gloves are coated with a vinyl covering when new, most of which eventually gets removed in the laundry. Gloves are worn in ex-tank regions, but occasionally might be placed minimally inside a dome intrusive area or waste intruding equipment. Tyvek clothing or plastic clothing is worn during operations with the potential for high personnel contamination. Tyvek clothing complies with the Flammable Gas Justification for Continued Operation (JCO) when grounded. This is not done at this time. Plastic clothing does not comply with the Flammable Gas JCO. Use of either of those articles of protective clothing is a significant issue with respect to personnel contamination control. These are judged to have a negligible potential for creating sparks. Finger ring use (for radiological monitoring) meets equivalence with the Flammable Gas JCO, and so finger rings are not included in the above items.

RISK ACCEPTANCE:

This is an item where worker safety must be balanced with negligible ignition source risk. Gloves are used in ex-tank locations, but may be used in a minimally dome or waste intrusive location (e.g., at the entry of a riser or liquid observation well [LOW]). Tyvek and plastic clothing is only worn in an ex-tank region. The risk of personnel contamination due to not using these gloves or clothing is unacceptable. The resulting delay to all sampling work, and most other tank intrusive work, the ability to obtain characterization data from waste tanks that is used both for helping to close safety issues and for design of privatization waste handling facilities must be balanced with the small risk of a flammable gas ignition event due to a spark from the gloves or clothing. The risk associated with continuing to use the gloves or clothing is managed by performing flammable gas monitoring, with safe shutdown controls, prior to and/or during use. This will include monitoring per method [A] as appropriate for the activity. See definition of monitoring methods at the end of this section.

The person performing the initial monitoring per [A] will be wearing rubber gloves, probably canvas gloves, and possible Tyvek or plastic clothing. It is an acceptable risk to have him perform the monitoring while wearing these items.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Would stop all ex-tank and dome intrusive work

Facility Group 2 Tanks-Would stop all dome intrusive and some ex-tank work.

Facility Group 3 or other Tanks-Would stop all waste disturbing dome intrusive work.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring controls [A] for rubber gloves, canvas gloves, and Tyvek or plastic clothing in:

1) FG 1 ex-tank regions
2) FG 1,2 tanks during dome intrusive activities.
3) FG 2 ex-tank region (GWD).
4) FG 3 tanks for dome intrusive regions (LWD, or GWD).

ITEM CLASSIFICATION: DE MINIMUS

ITEM NUMBER: 1 (page 2 of 4)

EQUIPMENT: Air respirators, air fed hoods, and breathing air hoses

CATEGORY: Static Spark Potential

USE:

Used for providing adequate breathing air.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #3	FG 1 ex-tank FG 2 ex-tank (GWD)

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

Air respirators are made from rubber and plastic. Breathing air hoses are made from rubber. These are judged to have a negligible potential for creating sparks.

RISK ACCEPTANCE:

This is an item where worker safety must be balanced with negligible ignition source risk. The risk of internal contamination or inhalation of potentially toxic vapors due to not using respirators or breathing air when needed is unacceptable. The resulting delay to sampling work, and most other tank intrusive work, the ability to obtain characterization data from waste tanks that is used both for helping to close safety issues and for design of privatization waste handling facilities must be balanced with the small risk of a flammable gas ignition event due to a spark from the respirators or hoses. The risk associated with continuing their use is managed by performing flammable gas monitoring, with safe shutdown controls, prior to and/or during use. This will include monitoring per method [A] for the activity. See definition of monitoring methods at the end of this section.

The person performing the initial monitoring per [A] may be wearing a respirator or an air hose. It is an acceptable risk to have him perform the monitoring while wearing these items.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Would stop all ex-tank, and by default, most dome intrusive work and waste intruding equipment work.

Facility Group 2 Tanks-Would stop all ex-tank, and by default, most dome intrusive work and waste intruding equipment work during GWD.

Facility Group 3 or other Tanks-No Impact.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring control [A] for respirators and breathing air hoses in:

1) FG 1 ex-tank regions
2) FG 2 ex-tank regions (GWD)

ITEM CLASSIFICATION: DE MINIMUS

ITEM NUMBER: 1 (page 3 of 4)

EQUIPMENT: Rubber/plastic footwear

CATEGORY: Static Spark Potential

USE:

Used for protecting feet from contamination.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #3	FG 1 ex-tank FG 2 ex-tank (GWD)

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

Rubber boots are worn in radiation areas for personnel protection. Rubber boots are judged to have a negligible potential for creating sparks.

RISK ACCEPTANCE:

This is an item where worker safety must be balanced with negligible ignition source risk. The risk of personnel contamination and loss of contamination control due to not using boots is unacceptable. The resulting delay to sampling work, and most other tank intrusive work, the ability to obtain characterization data from waste tanks that is used both for helping to close safety issues and for design of privatization waste handling facilities must be balanced with the small risk of a flammable gas ignition event due to a spark from the boots. The risk associated with continuing to use the boots is managed by performing flammable gas monitoring, with safe shutdown controls, prior to and/or during use. This will include monitoring per method [A] for the activity. See definition of monitoring methods at the end of this section.

The person performing the initial monitoring per [A] will be wearing rubber boots. It is an acceptable risk to have him perform the monitoring while wearing the boots.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Would stop all ex-tank, and by default, most dome intrusive work and waste intruding equipment work.

Facility Group 2 Tanks-Would stop all ex-tank, and by default, most dome intrusive work and waste intruding equipment work during GWD.

Facility Group 3 or other Tanks-No Impact.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring control [A] for rubber boots in:

1) FG 1 ex-tank regions
2) FG 2 ex-tank regions (GWD)

ITEM CLASSIFICATION: DE MINIMUS

ITEM NUMBER: 1 (page 4 of 4)

EQUIPMENT: Installation, removal or use of masking tape

CATEGORY: Static Spark Potential

USE:

Used for taping up protective clothing.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #3	FG 1 ex-tank FG 2 ex-tank (GWD)

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

Masking tape is used for taping personal protective clothing, therefore, is present in ex-tank regions. The primary spark potential is when applying or removing the tape. Applying or removing masking tape could form small static sparks under certain conditions. Taping is not normally done in an ex-tank area, but may be necessary in certain circumstances. Masking tape is judged to have a negligible potential for creating sparks.

RISK ACCEPTANCE:

This is an item where worker safety must be balanced with negligible ignition source risk. The risk of contamination due to not using masking tape is unacceptable. The resulting delay to sampling work, and most other tank intrusive work, the ability to obtain characterization data from waste tanks that is used both for helping to close safety issues and for design of privatization waste handling facilities must be balanced with the small risk of a flammable gas ignition event due to a spark from the tape. The risk associated with continuing the tape use is managed by performing flammable gas monitoring, with safe shutdown controls, prior to and/or during use. This will include monitoring per method [A] for the activity. See definition of monitoring methods at the end of this section.

The person performing the initial monitoring per [A] will be wearing masking tape. It is an acceptable risk to have him perform the monitoring while wearing the tape.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Would stop all ex-tank, and by default, most dome intrusive work and waste intruding equipment work.

Facility Group 2 Tanks-Would stop all ex-tank, and by default, most dome intrusive work and waste intruding equipment work during GWD.

Facility Group 3 or other Tanks-No Impact.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring control [A] for masking tape in:

1) FG 1 ex-tank regions
2) FG 2 ex-tank regions (GWD)

ITEM CLASSIFICATION: DE MINIMUS

ITEM NUMBER: 2

EQUIPMENT: Wearing of plastic badges, badge holders, and dosimeters.

CATEGORY: Static Spark Potential

USE:

Used for security and dosimetry.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #3	FG 1 ex-tank FG 2 ex-tank (GWD)

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

Badges and dosimeters are small, plastic items which all personnel are required to carry for security and exposure monitoring. Risk of a static spark in the above listed ex-tank regions from these items should be small, especially if they are inside another pair of protective clothing. Badges, badge holders, and dosimeters are judged to have a negligible potential for causing flammable gas ignition under the applied conditions.

RISK ACCEPTANCE:

This is an item where worker safety must be balanced with negligible ignition source risk. The risk of overexposure due to not using dosimetry, and the violation of security requirements is unacceptable. The resulting delay to sampling work, and most other tank intrusive work, the ability to obtain characterization data from waste tanks that is used both for helping to close safety issues and for design of privatization waste handling facilities must be balanced with the small risk of a flammable gas ignition event due to a spark from the items. The risk associated with continuing their use is managed by performing flammable gas monitoring, with safe shutdown controls, prior to and/or during use. This will include monitoring per method [A] for the activity. See definition of monitoring methods at the end of this section.

The person performing the initial monitoring per [A] will be wearing a badge, badge holder, and dosimetry. It is an acceptable risk to have him perform the monitoring while wearing these items.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Would stop all ex-tank, and by default, most dome intrusive work and waste intruding equipment work.

Facility Group 2 Tanks-Would stop all ex-tank, and by default, most dome intrusive work and waste intruding equipment work during GWD.

Facility Group 3 or other Tanks-No Impact.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring control [A] for badges, badge holders and dosimeters in:

1) FG 1 ex-tank work
2) FG 2 ex-tank regions (GWD)

ITEM CLASSIFICATION: DE MINIMUS

ITEM NUMBER: 3

EQUIPMENT: Installation of, removal of, working on, or extended presence of nonconductive lead blankets

CATEGORY: Static Spark Potential

USE:

Used for portable shielding.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #3	FG 1 ex-tank FG 2 ex-tank (GWD)

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

The lead blankets currently in use are constructed of a nonconductive polymer jacket surrounding a lead wool blanket. The blankets are used for shielding in the work area. This equipment may be in or outside of an ex-tank exclusion zone. There is no ignition source issue with the lead; the verbatim compliance issue is due to the plastic coating. Lead blankets are judged to have a negligible potential for creating sparks.

RISK ACCEPTANCE:

This is an item where worker safety must be balanced with negligible ignition source risk. Lead blankets are not arranged in a manner which could trap flammable gases. These blankets are normally installed and removed when ex-tank regions are not present (i.e., before a riser is opened or after it is closed). During limited instances it may be necessary to move these blankets in one of the above listed ex-tank areas. Removal is normally done after a riser is sealed. The risk of not using lead blankets would lead to higher personnel exposure if the items cannot be relocated. Failure to approve use of the lead blankets will result in considerable costs. This would restrict some work in the above listed ex-tank regions until suitable replacements, if available, were obtained. The resulting delay to sampling work and most other tank intrusive work, and the ability to obtain characterization data from waste tanks that is used both for helping to close safety issues and for design of privatization waste handling facilities must be balanced with the small risk of a flammable gas ignition event due to a spark from the blankets. The risk associated with continuing their use is managed by performing flammable gas monitoring, with safe shutdown controls, prior to and/or during use. This will include monitoring per method [A] for the activity. See definition of monitoring methods at the end of this section. This monitoring is in full compliance with the monitoring requirements referenced by U.S. Department of Energy, Richland Operations Office (RL) letter 96-WSD-283 (Wagoner 1996).

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Would stop some of ex-tank, and by default some dome intrusive work and waste intruding equipment work.

Facility Group 2 Tanks-Would stop some ex-tank, and by default most dome intrusive work and waste intruding equipment work during GWD.

Facility Group 3 or other Tanks-No Impact.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring control [A] for lead blankets in:

1) FG 1 ex-tank regions
2) FG 2 ex-tank regions (GWD)

ITEM CLASSIFICATION: DE MINIMUS

ITEM NUMBER: 4

EQUIPMENT: Installation, removal, or extended presence of nonconductive adhesive tape

CATEGORY: Static Spark Potential

USE:

Used for taping plastics and other miscellaneous items.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #3, ICS 1 #3	FG 1 ex-tank FG 2 ex-tank (GWD) FG 1,2 dome intrusive FG 3 dome intrusive (LWD, GWD) FG 1,2,3 waste intruding equipment

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

Nonconductive adhesive tape is used routinely in ex-tank regions. Because of the nature of its use portions of tape will occasionally be exposed to tank vapors during sleeving, bagout or other activities, and as a result it is also included as a dome intrusive and waste intruding equipment item.

RISK ACCEPTANCE:

The minimal risk is primarily associated with tape application and removal, thus the time at risk is small. Tape is used in ex-tank locations, but may be used in a minimally dome or waste intrusive location. It is used primarily for taping down plastics for contamination control. Depending upon the location, the work to be done, and the contamination level, tape may on occasion be placed around the edge of or just inside a dome intrusive region or item of waste intruding equipment. Tape is also used when "horsetailing" out contaminated equipment from a tank. The contaminated item is brought up into a plastic sleeve, the plastic twisted around under the object, and tape wrapped around the twist. The taped area is then cut through and the waste item removed. Should the taped joint come apart, the edge of the tape could be exposed to the tank vapors. Tape is also used to seal sleeves around items such as cameras which are lowered into tank vapor spaces. In such cases the tape is in the tank dome for anywhere from a few minutes to a few days. Not using tape would lead to ceasing most activities in the above areas. The resulting delay to sampling work, and most other tank intrusive work, the ability to obtain characterization data from waste tanks that is used both for helping to close safety issues and for design of privatization waste handling facilities must be balanced with the small risk of a flammable gas ignition event due to a spark from the tape. The risk associated with continuing its use is managed by performing flammable gas monitoring, with safe shutdown controls, prior to and/or during use. This will include monitoring per method [A] or [B] applicable for the activity. See definition of monitoring methods at the end of this section.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Would stop all sampling related activities, and most other tank intrusive work.

Facility Group 2 Tanks-Would stop all sampling related activities, and most other tank intrusive work.

Facility Group 3 or other Tanks-Would stop all core sampling, and other tank activities with waste intruding equipment.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring control [A] or [B] as appropriate for use of green tape in:

1) FG 1 ex-tank regions
2) FG 2 tanks for ex-tank regions (GWD)
3) FG 1,2 dome intrusive regions
4) FG 3 tanks for dome intrusive regions (LWD, GWD)
5) FG 1,2,3 tank waste intruding equipment

ITEM CLASSIFICATION: DE MINIMUS

ITEM NUMBER: 5

EQUIPMENT: Portable Alpha Monitor (PAM)

CATEGORY: Electrical Spark Potential

USE:

Used for monitoring for alpha contamination

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #5 ICS 1 #5	FG 1 ex-tank FG 2 ex-tank (GWD) FG 1,2 dome intrusive FG 3 dome intrusive (LWD, GWD) FG 1,2,3 waste intruding equipment

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

The portable alpha monitor (PAM) is battery powered. The unit is judged not in verbatim compliance with the Flammable Gas JCO. Per ICS #2: "As a minimum the equipment is non-sparking under normal operation...". While the PAM normally meets this requirement, the probe source is easily damaged and a postulated spark could occur if internal electronics were shorted out. The PAM is usually used for determining alpha contamination on smears rather than near a riser or in a waste intruding equipment item. However, sometimes it is necessary to use the PAM to determine contamination levels (fixed or smearable) on the equipment. PAMs are judged to have a negligible potential for causing flammable gas ignition.

RISK ACCEPTANCE:

This is an item where worker safety must be balanced with negligible ignition source risk. The PAM is used in ex-tank locations, but may be used in a minimally dome or waste intrusive location (e.g., at the entry of a riser or LOW). The PAM is needed for monitoring for alpha contamination. The potential problems arising from an alpha contamination spread are more severe than from a beta gamma spread. Monitoring for alpha contamination is required by the RWPs for most waste intruding or dome intrusive activities on tanks which have shown a potential for alpha contamination problems. The requirement for using alpha monitors comes in part from two letters: Caldwell, C.L., 1997, Justification for Dual Survey Exemption in 200 East Tank Farms (Interoffice Memo 771EO-97-006 to W. E. Ross, March 12), Lockheed Martin Hanford Corporation, Richland, Washington; and Dossett, S.D., 1997, Justification for Dual Survey Exemption in 200 West Tank Farms (Interoffice Memo 77B50-97-008 to J. Burton, March 17), Lockheed Martin Hanford Corporation, Richland, Washington. Per discussion with a vendor, there are no known battery powered, intrinsically safe, alternatives available for the PAMs. Furthermore, switching to a different monitor could not be made without significant delays due to required testing. PAMs are inspected frequently and checked prior to use, which minimizes the possibility of using a monitor with a failed window. The risk associated with continuing to use the PAM is managed by performing flammable gas monitoring, with safe shutdown controls, prior to and/or during use of the PAM. This will include monitoring per method [A] or [B] as appropriate for the activity. See definition of monitoring methods at the end of this section.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Restricts radiological control technician (RCT) flexibility to monitor riser area for alpha contamination and results in lowering of radiological control and contamination problems. Failure to accept the risk of continuing to use the PAM will shut down or restrict most waste intrusive work.

Facility Group 2 Tanks-Same as above.

Facility Group 3 or other Tanks-Same as above(LWD, GWD).

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring controls [A] or [B] for use of PAMs in:

1) Ex-tank regions in FG 1 tanks.
2) Dome intrusive regions in FG 1,2 tanks.
3) Waste intruding equipment in FG 1,2,3 tanks.
4) Dome intrusive regions (LWD, GWD) for FG 3 tanks
5) Ex-tank regions in FG 2 tanks (GWD)

ITEM CLASSIFICATION: DE MINIMUS

ITEM NUMBER: 6

EQUIPMENT: Nonconductive poly bottle

CATEGORY: Static Spark Potential

USE:

Used for contamination control

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #3, ICS 1 #3	FG 1 ex-tank FG 1,2 dome intrusive FG 2 ex-tank (GWD)

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

Nonconductive poly bottles are used in ex-tank regions, but may be used in a minimally intrusive region for washing off some equipment items by pouring the solution inside the bottle over the item and down a riser. Glass bottles could be used as a substitute, but poly bottles have been used because they are safer (non-breakable). Poly bottles are judged to have a negligible potential for creating sparks.

RISK ACCEPTANCE:

These bottles are normally used in ex-tank locations, but may be used in a minimally dome intrusive region when pouring the liquid down a riser. The amount of liquid used is small, nominally $\leq$ 1 liter. The velocity of the poured liquid is limited to gravity flow and the wetting action of the liquid on the bottle will minimize static buildup. The potential safety concern associated with breakage of a glass bottle is a greater concern than the small risk of a flammable gas ignition event due to a spark from the plastic bottle. The risk associated with continuing use of the poly bottle is managed by performing flammable gas monitoring, with safe shutdown controls, prior to and/or during use. This will include monitoring per method [A]. See definition of monitoring methods at the end of this section.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Small impact. Would switch to glass or other container meeting Flammable Gas JCO requirements. Will be a slight increase in the personnel risk for cuts in radiation zones.

Facility Group 2 Tanks-Small impact. Would switch to glass or other container meeting Flammable Gas JCO requirements. Will be a slight increase in the personnel risk for cuts in radiation zones.

Facility Group 3 or other Tanks-No impact, except when using around/in waste intruding equipment. Would switch to glass or other container meeting Flammable Gas JCO requirements. Will be a slight increase in the personnel risk for cuts in radiation zones.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring control [A] for use of nonconductive poly bottles in:

1) FG 1 ex-tank regions
2) FG 1,2 dome intrusive regions
3) FG 2 ex-tank regions(GWD)

ITEM CLASSIFICATION: DE MINIMUS

ITEM NUMBER: 7

EQUIPMENT: Zip cords

CATEGORY: Static Spark Potential

USE:

Used for taking waste level measurements.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #3, ICS 1 #3	FG 1 ex-tank FG 1,2 dome intrusive FG 1,2,3 waste intrusive

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

A zip cord is an insulated wire that is inserted into a riser and lowered down to the waste surface. Waste intruding equipment is included in this evaluation because on rare occasions it may be necessary to use a zip cord in a failed LOW or drill string. The electrical spark produced by the zip cord's contact with the waste or the metal riser is similar to that for manual tapes, which has been analyzed in WHC-SD-WM-ES-176, and is limited by the portable ohm meter used to take the reading. The current level and voltage values are orders of magnitude below the ignition curve in UL 913. Bonding of zip cords is impractical since this would interfere with their operation. Coating of the zip cords with a static reducing compound would provide little reduction in the static discharge risk, and could increase the potential for contamination or waste disposal problems. Zip cords are judged to have a negligible potential for creating sparks.

RISK ACCEPTANCE:

See risk acceptance starting on next page.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Would shut down most sampling activities until an alternate was available, or run the risk of errors in sampling and resulting questions with Tank Characterization Reports (TCRs).

Facility Group 2 Tanks-Would shut down most sampling activities until an alternate was available, or run the risk of errors in sampling and resulting questions with TCRs.

Facility Group 3 or other Tanks-No impact, except when needed for waste intruding equipment.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring controls [A] or [B] as applicable for use of nonconductive coated zip cords in:

1) FG 1 ex-tank regions
1) FG 1,2 dome intrusive regions
2) Waste intruding equipment (such as failed LOWs) in FG 1,2,3 tanks

Risk Acceptance for Zip Cords.

The distance between a specific riser and the waste surface is required for many waste intrusive jobs such as leak detection, sampling, level gauge installations/repairs or tank equipment installations. Zip cords have been shown to be an inexpensive and easy means of detecting the waste level in tanks. Alternate non tank intrusive measurement systems have been evaluated and determined to be cost prohibitive and substantially more complex.

The relative humidity (RH) has been measured at >50% in 95% of the non-exhausted tanks sampled. The remaining 5% of the non exhausted tanks all measured between 40 to 50% RH. The SX Farm exhausted tanks measured between 20 to 40% RH, except one tank which was 65% RH. Tank 241-C-105 measured between 40 to 60% RH, and 241-C-106 measured between 50 to 100% RH. Therefore, for non-exhausted tanks, plastic coated zip cords in dome intrusive regions are expected to be in compliance with the Flammable Gas JCO about 95% of the time. For exhausted tanks, 241-C-105 and 241-C-106 are approximately 50% RH. Most double shell tanks would be expected to be the same due to the liquid or moist solid surfaces. For waste intruding equipment, waste gases will be at 100% RH because the gases come from waste pockets surrounded by liquid waste. In such pockets the water vapor in the gas would be at equilibrium with the water in the liquid. The gas in waste intruding equipment may be partially mixed with tank vapors depending upon the work being done but, as most tank vapors have a high RH, the RH of the mixed vapors in waste intruding equipment is expected to be >50%.

Most sampling would have to be shut down without the use of zip cords. The resulting delay to sampling work, and some other tank intrusive work, the ability to double check questionable ENRAF, manual tape or Food Instrument Corporation (FIC) readings, and the ability to obtain characterization data from waste tanks that is used both for helping to close safety issues and for design of privatization waste handling facilities must be balanced with the small risk of a flammable gas ignition event due to a spark from the zip cord. The risk associated with continuing use of the zip cords is managed by performing flammable gas monitoring, with safe shutdown controls, prior to and/or during use. This will include monitoring per method [A] or [B] as applicable. See definition of monitoring methods at the end of this section.

ITEM CLASSIFICATION: DE MINIMUS

ITEM NUMBER: 8

EQUIPMENT: Nonconductive plastic ropes

CATEGORY: Static Spark Potential

USE:

Used for tieing tools used around open risers or miscellaneous purposes.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #3, ICS 1 #3	FG 1 ex-tank FG 2 ex-tank (GWD)

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

Nonconductive plastic rope is used as lanyards for tools around open risers and other miscellaneous needs. Plastic rope is judged to have a negligible potential for causing flammable gas ignition under the applied conditions.

RISK ACCEPTANCE:

Nonconductive plastic rope is used for a variety of applications in addition to restraining tools. If nonconductive plastic rope cannot be used, manila rope can be used as an alternative. However, manila rope is not as strong and can weaken with time when exposed to the elements. Contaminated plastic rope can be wiped down easier. Plastic rope has proven to be more effective and less expensive for general use in tank farms and is used in ex-tank regions. Normal use of nonconductive plastic ropes does not involve activities that would build up a significant static charge.

The use of plastic rope is advantageous for operations. The inability to use this rope is a significant concern due to increased personnel and clothing contamination potential than the minimal risk of a flammable gas ignition event due to a spark from the plastic rope. The risk associated with continuing use of the rope is managed by performing flammable gas monitoring, with safe shutdown controls, prior to and/or during use. This will include monitoring per method [A]. See definition of monitoring methods at the end of this section.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Minor impact, would switch to manila or similar rope, would increase potential for personnel contamination.

Facility Group 2 Tanks-Minor impact, would switch to manila or similar rope, would increase potential for personnel contamination.

Facility Group 3 or other Tanks-No impact, except when using around/in waste intruding equipment, would switch to manila or similar rope, would increase potential for personnel contamination.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring control [A] for use of nonconductive plastic rope in:

1) FG 1 ex-tank regions
2) FG 2 ex-tank regions (GWD)

ITEM CLASSIFICATION: DE MINIMUS

ITEM NUMBER: 9

EQUIPMENT: Nonconductive plastic tubing

CATEGORY: Static Spark Potential

USE:

Used for purge lines or miscellaneous purposes.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #3, ICS 1 #3	FG 1 ex-tank FG 1,2 dome intrusive FG 2 ex-tank (GWD)

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

Nonconductive plastic tubing is used for miscellaneous needs, including temporary gas purge lines, vent and balance testing and aerosol testing of filters, temporary drain lines and temporary instrument lines during calibration or operation. Nonconductive plastic tubing is judged to have a negligible potential for causing flammable gas ignition under the applied conditions. Nonconductive plastic tubing shall not be used below the plane of a riser.

RISK ACCEPTANCE:

Nonconductive plastic tubing is used as described above in ex-tank areas. The nonconductive plastic tubing is also considered to be used in dome intrusive activities because it is connected to fittings which are in communication with the dome vapor space. During use, it is normally immobile. Static charge due to friction is minimized during insertion or removal. If nonconductive plastic tubing cannot be used, the only alternatives are rigid tubing or the wire wrapped tubing used during CGM sampling. Rigid tubing use is undesirable due to the extra cost and time for installation and waste disposal. Wire wrapped tubing is more expensive than nonconductive plastic tubing and is primarily available in a few specific lengths. The costs associated with these alternatives are a greater concern than the small risk of a flammable gas ignition event due to a spark from the plastic tubing. The risk associated with continuing to use this tubing is managed by performing flammable gas monitoring, with safe shutdown controls, prior to and/or during use. This will include monitoring per method [A] as applicable for the activity at the time the tubing is used. See definition of monitoring methods at the end of this section.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Moderate impact due to occasional work delays. Would switch to alternate higher cost (in both time and money) tubing now available.

Facility Group 2 Tanks-Moderate impact due to occasional work delays. Would switch to alternate higher cost (in both time and money) tubing now available.

Facility Group 3 or other Tanks-No impact.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring control [A] as appropriate for nonconductive plastic tubing in:

1) FG 1 ex-tank regions
2) FG 1,2 dome intrusive regions
3) FG 2 ex-tank regions (GWD)

ITEM CLASSIFICATION: DE MINIMUS

ITEM NUMBER: 10

EQUIPMENT: Installation and removal of Garlock gaskets

CATEGORY: Static Spark Potential

USE:

Used for sealing riser flanges to risers.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #3	FG 1 ex-tank

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

Garlock gaskets are used for sealing riser flanges to risers. Garlock gaskets are a replacement for asbestos gaskets, which are no longer used for reasons related to worker safety and asbestos abatement. Ex-tank use for gaskets in Facility Group 1 tanks is included to avoid confusion because the gaskets are handled in an ex-tank area prior to installation. Garlock gasket installation and removal is judged to have a negligible potential for causing flammable gas ignition under the applied conditions.

RISK ACCEPTANCE:

Garlock gaskets are a replacement for asbestos gaskets, which are no longer used for reasons related to worker safety and asbestos abatement. They have been installed on hundreds of risers in recent years. The barrier provided by the gaskets is needed to seal the risers. Using other materials is undesirable from an environmental standpoint. The gaskets are sandwiched between two steel flanges during use, with only a small portion of the gasket (less than 1/8 inch) open to the vapor space. There is no process which would be expected to build up a static charge on the gaskets. The installed orientation of the gasket and flanges is such that a static charge would not be retained. Therefore, the risk associated with Garlock gaskets is strictly confined to installation and removal. Since installation and removal tasks are of a short duration, the actual time at risk is small.

The problems with using alternative gaskets are a more significant concern than the low risk of a flammable gas ignition event due to a spark from a gasket. The risk associated with continuing use of the gaskets is managed by performing flammable gas monitoring, with safe shutdown controls, prior to and/or during installation. This will include monitoring per method [A]. See definition of monitoring methods at the end of this section.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-There is no reasonably available gasket material which has equivalent performance for worker safety and contamination control.

Facility Group 2 Tanks-No Impact.

Facility Group 3 or other Tanks-No Impact.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring control [A] for installation and removal of Garlock gaskets in tanks without flammable gas monitoring or response actions in:

1) FG 1 ex-tank regions

ITEM CLASSIFICATION: DE MINIMUS

ITEM NUMBER: 11

EQUIPMENT: Nonconductive plastic garden type sprayer

CATEGORY: Static Spark Potential

USE:

Used for contamination control.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #3	FG 1 ex-tank FG 2 ex-tank (GWD)

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

The garden sprayer is a commercial unit containing less than 5 gallons of liquid. It is hand pumped and is used in Tank Farms for localized wetting and contamination control. The non-sparking brass end may enter dome intrusive regions, but the container and wand are located outside, or in ex-tank regions only. The garden type sprayer is judged to have a negligible potential for causing flammable gas ignition under the applied conditions.

RISK ACCEPTANCE:

The sprayer has proven to be an inexpensive, easy to use, flexible tool for use in tank farms. Static buildup on the sprayer tip from the water spray is believed to be minimal. The nozzle velocity is limited by the air pressure that can be generated by hand pumping. The sprayer is used for less than a minute at a time. The risk associated with continued use of the sprayer is managed by performing flammable gas monitoring, with safe shutdown controls, prior to and/or during use. This will include monitoring per method [A]. See definition of monitoring methods at the end of this section.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Minor impact, would switch to stainless steel sprayer.

Facility Group 2 Tanks-Negligible impact.

Facility Group 3 or other Tanks-No impact.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring control [A] for use of nonconductive plastic sprayer in:

1) FG 1 ex-tank regions
2) FG 2 ex-tank regions (GWD)

ITEM CLASSIFICATION: DE MINIMUS

ITEM NUMBER: 12

EQUIPMENT: Use of grab sample cap, sampling and sludge weight retrieval device, and coated steel cable.

CATEGORY: Static Spark Potential

USE:

Used for obtaining grab samples and sludge weight retrieval.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #3	FG 1 ex-tank FG 1,2 dome intrusive FG 3 dome intrusive (LWD, GWD)

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

The grab sample bottle is glass and is held in a stainless steel holder assembly. The grab sampler meets the Flammable Gas JCO and is not included in this exception request. The sample bottle cap is a small plastic item. The cable holding the stainless steel holder assembly is steel covered with a plastic coating to allow decontamination. The grab sample and sludge weight retrieval device includes a piece of PVC pipe with a PVC cap on the top and open on the bottom. This PVC enclosure has a metallic crank used to withdraw the stainless steel holder assembly up from the tank using the plastic coated steel cable. The PVC enclosure sits over the sampling riser. The retrieval device is usually outside the glove bag and therefore not in an ex-tank region. However, depending upon the riser arrangement it may be necessary to place part of the retrieval device inside the glove bag, which would then make it in an ex-tank or dome intrusive region. These grab sampling and sludge weight removal items are judged to have a minimal potential for causing flammable gas ignition under the applied conditions.

RISK ACCEPTANCE:

See risk acceptance writeup starting on next page.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Would halt grab sampling or sludge weight removal until alternate items were available, or would have to accept significant personnel exposure and contamination.

Facility Group 2 Tanks-Would halt grab sampling or sludge weight removal until alternate items were available, or would have to accept significant personnel exposure and contamination.

Facility Group 3 or other Tanks-Would halt grab sampling or sludge weight removal until alternate items were available, or would have to accept significant personnel exposure and contamination.

REQUESTED APPROVAL FROM DOE:

Continued use of the listed equipment when performing flammable gas monitoring control [A] for above items:

1) FG 1 ex-tank regions
2) FG 1,2 tanks dome intrusive regions
3) FG 3 tanks for dome intrusive regions (LWD, GWD).

Risk Acceptance for Grab Sample Items.

The cap is a negligible source of static discharge. The RH has been measured at >50% in 95% of the non-exhausted tanks sampled. The remaining 5% of the non-exhausted tanks all measured between 40 to 50% RH. The SX Farm exhausted tanks measured between 20 to 40% RH, except one tank which was 65% RH.

Tank 241-C-105 measured between 40 to 60% RH, and Tank 241-C-106 measured between 50 to 100% RH. Therefore, for non-exhausted tanks, use of the cable and enclosure in dome intrusive regions is expected to be in compliance with the Flammable Gas JCO about 95% of the time. Exhausted Tanks 241-C-105 and 241-C-106 are approximately 50% RH. Most double-shell tanks would be expected to be the same due to the liquid or moist solid surfaces.

Not using the coated cable would lead to a significant increase in personnel exposure and contamination. The static buildup resulting from the cable rubbing against the inside of the PVC riser adapter is judged to have minimal risk for causing flammable gas ignition under the applied conditions. Not only is the humidity above 50% much of the time, the cable is inserted/retrieved slowly and the whole insertion or removal step only takes a few minutes. Not using the retrieval device would result in more personnel exposure. The impact of halting waste transfers and characterization from halting grab sampling must be balanced against the low risk of a flammable gas ignition event due to a spark from these items. The risk associated with continued use of the items is managed by performing flammable gas monitoring, with safe shutdown controls, prior to and/or during use. This will include monitoring per method [A]. See definition of monitoring methods at the end of this section.

ITEM CLASSIFICATION: DE MINIMUS

ITEM NUMBER: 13, 14

EQUIPMENT: Installation, removal, and presence of PVC liners for manual tapes and FICs

CATEGORY: Static Spark Potential

USE:

Used for keeping metal tapes from grounding out against the insides of risers.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #3	FG 1,2, dome intrusive FG 3 dome intrusive (LWD, GWD)

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

The PVC liners are present on most single-shell and double-shell tanks with manual tapes or FICs, to prevent the metal tapes from making contact with the riser wall. Removal and replacement of these liners is done occasionally. Approximately four times in the past, a manual tape or FIC has been removed to permit sampling when another riser was not available. To date, this has been done to allow push mode core sampling (PMCS), which would result in a steel pipe being inserted into the riser. Grab sampling has been done at least once in the last three years through a liner.

RISK ACCEPTANCE:

The RH has been measured at >50% in 95% of the non-exhausted tanks sampled. The remaining 5% of the non-exhausted tanks all measured between 40 to 50% RH. The SX Farm exhausted tanks measured between 20 to 40% RH, except one tank which was 65% RH. Tank 241-C-105 measured between 40 to 60% RH, and Tank 241-C-106 measured between 50 to 100% RH. Therefore, for non-exhausted tanks, use of the cable and enclosure in dome intrusive regions is expected to be in compliance with the Flammable Gas JCO about 95% of the time. Exhausted Tanks 241-C-105 and 241-C-106 are approximately 50% RH. Most double-shell tanks would be expected to be the same due to the liquid or moist solid surfaces.

The PVC liners are already installed in the tanks. The cost in labor, time, waste disposal, and personnel exposure to remove them is a more significant concern than the small risk of a flammable gas ignition event due to a spark from a liner. The risk associated with continued use of the liners is managed by performing flammable gas monitoring, with safe shutdown controls, prior to and/or during installation. This will include monitoring per method [A]. See definition of monitoring methods at the end of this section.

Core sampling is seldom performed through a riser liner, and rarely for grab sampling. During grab sampling, the plastic coated steel cable would be raised and lowered while in occasional contact with the riser liner. This does not pose a significant static buildup hazard. Flammable gas monitoring is done while taking the sample and the discussion above on the tank humidity levels applies.

No monitoring for flammable gas is done for the routine presence of the PVC liners in a tank vapor space. It is an acceptable risk to have the liners installed in the tanks without monitoring for flammable gases during their presence.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Almost all the tanks would be out of compliance, and the risk of removing the liners is far greater from cost and As Low As Reasonably Achievable (ALARA) standpoints, than the risk involved with leaving them in place.

Facility Group 2 Tanks-Same as for FG 1 tanks.

Facility Group 3 or other Tanks-Same as for FG 1 tanks.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring control [A] for installation or removal of PVC riser liners, and their extended presence in tanks without flammable gas monitoring in:

1) FG 1,2,3 dome intrusive regions

ITEM CLASSIFICATION: DE MINIMUS

ITEM NUMBER: 15, 16

EQUIPMENT: Manual Tapes

CATEGORY: Static Spark Potential

USE:

Used for measuring waste level surfaces.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #2	FG 1,2 dome intrusive FG 3 dome intrusive (LWD, GWD)

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

The electrical spark produced by the manual tape contact with the waste has been evaluated in WHC-SD-WM-ES-176, and is limited by the portable ohm meter used to take the reading. The current and voltage values are orders of magnitude below the ignition curve in UL 913. The manual tapes are not bonded to the tank, which could be interpreted as being required by the ICS 2 control #2 in the Flammable Gas JCO. These tapes will not function if bonded to the tank. Manual tapes are judged to have a negligible potential for causing flammable gas ignition under the applied conditions.

RISK ACCEPTANCE:

The metal tapes used for the manual tape level gauges represent a small potential static discharge source. If the manual tape acquired a static charge, it would dissipate over time. If a portable ohm meter is connected to the manual tape when it held a charge, it would be dissipated through the meter circuitry to ground. Any spark at the time of connection would be outside the controlled area. The loss of manual tapes for determining waste levels to detect leaks to the environment is greater than the small risk of a flammable gas ignition event due to a spark from a tape. The risk associated with continuing use of the tapes is managed by performing flammable gas monitoring, with safe shutdown controls, prior to and/or during installation and removal. This includes monitoring per method [A]. See definition of monitoring methods at the end of this section.

Monitoring is not an appropriate control for the presence of the manual tapes in a tank vapor space as no response actions are available. Per the above discussion, it is an acceptable risk to have the manual tapes installed in the tanks without monitoring for flammable gases during their presence.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-All tanks would be out of compliance and the risk of removing the tapes is far greater from cost, ALARA, and lack of level monitoring standpoints, than the risk involved with leaving them in place.

Facility Group 2 Tanks-Almost all tanks would be out of compliance and the risk of removing the tapes is far greater from cost, ALARA, and lack of level monitoring standpoints than the risk involved with leaving them in place.

Facility Group 3 or other Tanks-Same as for FG 2 tanks.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring control [A] for installation or removal of manual tapes in:

1) FG 1,2 dome intrusive regions

Continued extended presence of manual tapes without flammable gas monitoring in:

2) FG 1,2,3 dome intrusive regions

ITEM CLASSIFICATION: DE MINIMUS

ITEM NUMBER: 17

EQUIPMENT: Core Sampling Equipment-Installation, use, removal, or extended presence of Pipe Wiper (Frisbee), Rainer Rubber #R2325 (Truck 1), H-2-821457 (Trucks 2 and 3)

CATEGORY: Static Spark Potential

USE:

Used for sealing around drill string during core sampling.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #3	FG 1,2 dome intrusive FG 3 dome intrusive (LWD)

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

The frisbee is a rubber disc approximately nine inches in diameter and is located at the top of a riser during core sampling. It is used to provide a seal around the drill string between the tank vapor space and the area outside the tank. About a two inch annular area of the frisbee is exposed to the tank vapor space. Frisbees have a negligible potential for causing a flammable gas ignition under the applied conditions. The FGEAB reviewed the use of the frisbee and determined that the frisbee met equivalence with the Flammable Gas JCO because of the lubricant used to wet it down prior to insertion of the drill string. The frisbee is still included in this exception because it cannot be guaranteed that the lubricant will remain present should the drill string be in place for an extended period of time with no sampling activity ongoing.

RISK ACCEPTANCE:

WHC-SD-WM-SAD-035 Rev 0-b for rotary mode core sampling (RMCS) in flammable gas single-shell tanks concluded the use of the frisbee was acceptable for RMCS in flammable gas tanks. The conclusion from this document cannot be directly applied to PMCS. However, the continued risk of using the frisbee is low. Not using the current frisbee would cease all PMCS and retained gas sampling.

The frisbee design cannot be readily changed. The frisbee was tested at the Bureau of Mines and must stay the same configuration for RMCS unless a new design is tested. The resulting delay to sampling work and the ability to obtain characterization data from waste tanks that is used for both helping to close safety issues and for design of privatization waste handling facilities must be balanced with the small risk of a flammable gas ignition event due to a spark from the frisbee. The risk associated with continuing its use is managed by performing flammable gas monitoring, with safe shutdown controls, prior to and/or during use. This will include monitoring per method [A] as applicable for the core sampling step being performed. See definition of monitoring methods at the end of this section.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Would stop all PMCS and retained gas sampling.

Facility Group 2 Tanks-Would stop all PMCS and retained gas sampling.

Facility Group 3 or other Tanks-Would stop all PMCS and retained gas sampling.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring control [A] as appropriate for use of the core sampling frisbee in:

1) FG 1,2 dome intrusive regions
2) FG 3 tanks dome intrusive regions (LWD)

ITEM CLASSIFICATION: DE MINIMUS

ITEM NUMBER: 18

EQUIPMENT: Core Sampling Equipment-Installation, removal, and use of plastic cam-lock caps.

CATEGORY: Static Spark Potential

USE:

Used for capping the quill rod when disconnected from the drill string

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #3	FG 1,2 dome intrusive

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

Cam-lock caps are placed on the bottom of the quill rod when it is disconnected from the drill string for contamination control. The cam-lock caps in use are constructed of nonconductive polymer material. The quill rod is not connected to the tank when the cam-lock cap is in place, but the quill rod could be vented back to the tank vapor space. Based upon the definitions in the Flammable Gas JCO, this could be interpreted as dome intrusive work. Plastic cam-lock caps are judged to have a negligible potential for causing a flammable gas ignition under the applied conditions.

RISK ACCEPTANCE:

This is an item where worker safety must be balanced with negligible ignition source risk. Not using the caps would cease all PMCS and retained gas sampling. Steel caps were previously used, but were eliminated because they were a personnel safety hazard. Installation and removal of the caps is normally done at arm's length to minimize personnel exposure or contamination. The cap is held out and slowly raised up onto the quill rod and the cam-lock handles on the adapter moved to hold the cap in place. Handling of the heavy steel caps was difficult at arm's length, so the plastic caps were implemented. This has improved operations around the truck. In use, the caps are motionless. Thus, there is no mechanism for static charge buildup. Elimination of the plastic caps is not warranted from a cost, schedule, and worker safety standpoint, and is a more significant concern than the small risk of a flammable gas ignition event due to a spark from the plastic caps. The risk associated with continuing their use is managed by performing flammable gas monitoring, with safe shutdown controls, prior to and/or during use. This will include monitoring per method [A] as applicable for the core sampling step being performed. See definition of monitoring methods at the end of this section.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Would delay PMCS and retained gas sampling until different caps were obtained; increased personnel safety hazard.

Facility Group 2 Tanks-Would delay PMCS and retained gas sampling until different caps were obtained; increased personnel safety hazard.

Facility Group 3 or other Tanks-No Impact.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring control [A] as appropriate for use of plastic cam-lock caps in:

1) FG 1,2 dome intrusive regions (non-waste disturbing [NWD])

ITEM CLASSIFICATION: DE MINIMUS

ITEM NUMBER: 19

EQUIPMENT: Presence of extension cords

CATEGORY: Static Spark Potential

USE:

Used for providing power to electrical equipment.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #5	FG 1 ex-tank FG 2 ex-tank (GWD)

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

Electrical cords are used in some ex-tank regions. The cords meet equivalence with the Flammable Gas JCO from an electrical spark potential as long as power connections or disconnections are accomplished outside the area or when the ex-tank area does not exist. There is a negligible risk of a static spark potential from the plastic or rubber coated extension cords.

RISK ACCEPTANCE:

Continued use of this equipment will permit activities to continue that require temporary service electrical power to an ex-tank region. Calibration or maintenance of Technical Safety Requirements and Operating Specification Documents required instruments, Standard Hydrogen Monitoring System (SHMS) cabinets, leak detectors or other instruments is a more significant concern than the negligible risk of a flammable gas ignition event due to a static spark from one of these items. The risk associated with continuing to use the cords is managed by performing flammable gas monitoring, with safe shutdown controls, prior to installation and during use when personnel are present. This will include monitoring per method [A]. See definition of monitoring methods at the end of this section.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Will shut down a moderate amount of ex-tank region work.

Facility Group 2 Tanks-Same as above, except only during GWD.

Facility Group 3 or other Tanks-No Impact.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring control [A] for the presence of electrical cords in:

1) FG 1 ex-tank regions
2) FG 2 ex-tank regions (GWD)

ITEM CLASSIFICATION: DE MINIMUS

ITEM NUMBER: 20

EQUIPMENT: Closed Pit Work Related Equipment-Installation, Use and Removal of Low and High Pressure Pit Spray Whirlie and Operation of Valve Handles

CATEGORY: Mechanical Spark Potential

USE:

Used for washing down pits and operating valves in pits.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #1	FG 1 ex-tank FG 2 ex-tank (GWD) FG 1 dome intrusive FG 2 dome intrusive FG 3 dome intrusive (LWD, GWD)

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

The subject tools and equipment are normally made of carbon steel and were not procured to meet non-sparking criteria. The valve handle is used for operating valves in pits through holes in the cover blocks. The spray whirlie is inserted through an opening in the cover block and sprays solutions inside the pit for decontamination or temporarily fixing loose contamination. Most usage will be ex-tank related, but it may be required to use a valve handle or the whirlie in a pit during a time when it is designated as dome intrusive.

RISK ACCEPTANCE:

Valve handle operation has been evaluated to be low risk with regards to spark initiation. This is due to the low energies and small ranges of motion involved. The whirlie operation creates a high humidity environment within the pit which is not conducive to spark generation. Furthermore, these tools are either; a) not readily or economically available in a spark resistant version, or b) are only rarely used in areas requiring compliance with the Flammable Gas JCO controls, hence, the time at risk is low. The need to use these tools is a more significant concern than the small risk of a flammable gas ignition event due to a spark from one of them. The risk associated with continuing to use these tools and equipment is managed by performing flammable gas monitoring, with safe shutdown controls, prior to and/or during the work. The monitoring used is method [A] as appropriate. See definition of monitoring methods at the end of this section.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Will significantly increase contamination and exposure, and shut down all pit work and a minor amount of other ex-tank work until alternate equipment or means of isolating from the tank can be established. Will halt installation of most new equipment items into the tank.

Facility Group 2 Tanks-Will significantly restrict or shut down pit work during dome intrusive activities until alternate tools or means of isolating from the tank can be established. Will halt installation of most new equipment items into the pit. Will affect most all transfers. Will significantly increase exposure and spread of contamination.

Facility Group 3 or other Tanks-Will halt some transfers. Will significantly increase exposure and spread of contamination.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring controls [A] as appropriate for the above equipment:

1) FG 1 tank ex-tank regions.
2) FG 1 tank dome intrusive regions
3) FG 1 and 2 tanks dome intrusive regions (LWD, GWD).
4) FG 2 ex-tank regions GWD

ITEM CLASSIFICATION: DE MINIMUS

ITEM NUMBER: 21

EQUIPMENT: Fittings on openings less than or equal to 2.54 cm (1 in) inside diameter located on the boundary of intrusive locations.

CATEGORY: Static Spark Potential

USE:

Used for sealing tank ventilation system access points and fitting on instrument lines.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #2	During fitting removal during entry into intrusive locations and final installation upon exiting intrusive locations

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

Electrically conductive objects are bonded as per NFPA 77 (1993) during intrusive work, except removal and installation of fittings on lines that are less than 2.54-cm (1-in) in diameter. The 2.54-cm (1-in) diameter line is chosen to exclude most instrument tubing or small piping from bonding, but to include all gasketed flanges. This is justified because bonding is done to minimize static electrical buildup and discharge. The potential for static buildup on a screwed fittings is minimal as a resistance of less than 1 megohm (required by NFPA 77 (1993) for static bonding) between the nut and the tubing is realistic for small screwed fitting in the service seen in tanks farms. Any static charge buildup that might occur while the fitting is off will be discharged by touching the fitting against a ground point prior to installation.

RISK ACCEPTANCE:

Monitoring is not an appropriate control for removal of small fittings during intrusive location entry as the monitoring activity requires the availability of an intrusive location access point, which required the removal of a fitting. Per the above discussion, it is an acceptable risk to remove and install small fittings without bonding or monitoring for flammable gases during the entry and final fitting installation portion of an activity.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

All facilities within the scope of this JCO - Require additional bonding, grounding, and monitoring steps in work packages and procedures that remove or install these fittings.

REQUESTED APPROVAL FROM DOE:

Continued practice of removing and installing small fitting without bonding or monitoring in:

1) Entry into intrusive locations
2) Fitting installation during exiting from intrusive locations

ITEM CLASSIFICATION: NON DE MINIMUS

ITEM NUMBER: 22

EQUIPMENT: Use of Type 4 Vapor Sampling head

CATEGORY: Static Spark Potential

USE:

Used for obtaining Type 4 dome space vapor samples.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #3	FG 1 ex-tank FG 1,2 dome intrusive

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

Type 4 vapor sampling is the tank vapor sampling method currently used. It is a marked improvement over Type 3 sampling in both cost, schedule and sampling time. The sampling is done in situ, making the data more reliable than the Type 3 vapor sampling. Type 3 vapor sampling requires the removal of vapors from a tank through heated sampling tubes. Type 4 vapor sampling requires the insertion of a sampling head equipped with sampling media. Figure 4VS-1 is a sketch of the equipment inserted into the tank vapor space. Some of the items on the sampling head are made of different polymers. Encased within the acrylic tubing are approximately 1 foot of the plastic flexible tube bundle, the bulkhead top collar (ultra-high molecular weight plastic) and Teflon filter. The tube bundle, within the acrylic tubing, terminates with the stainless steel sample head (non-sparking) containing the exposed (to tank vapors) Teflon alignment guide. The remainder of the tube bundle above the acrylic tubing is wrapped in plastic sleeving.

The scope of this requested exception is limited to the Type 4 vapor sampling head items.

RISK ACCEPTANCE:

See risk acceptance writeup starting on next page.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Would halt Type 4 vapor sampling until alternate items were available.

Facility Group 2 Tanks-Would halt Type 4 vapor sampling until alternate items were available.

Facility Group 3 or other Tanks-No Impact.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring control [B] for above polymeric items during Type 4 vapor sampling in:

1) FG 1 ex-tank regions
2) FG 1,2 tanks during dome intrusive activities

Risk Acceptance for Type 4 vapor sampling head.

The Teflon and various plastic components in the Type 4 vapor sampling head were all specifically selected for use based upon their physical characteristics and because they were shown to cause minimal bias to the sampling operation from outgassing of organics. Alternate materials cannot be used for the Type 4 vapor sampling head without going through extensive testing. The sampling method is sufficiently sensitive that during early sampling with the Type 4 vapor sampler, it was found that the results were being biased by outgassing from the plasticizer used in the tape that attached the plastic sleeve to the sample head. This required revising the taping method normally used for sleeving objects inserted into tank risers to the one shown in Figure 4VS-1 which maintains a barrier between the tape and the vapor sampling head inlet. The ends of the sampling tubes are tightly pressed into the teflon end piece. There is no flow of tank vapors into the acrylic housing as there is no driving force to cause vapors to pass by the seal.

Static buildup is a function of the RH and physical factors that influence a charge such as mechanical friction. The Type 4 vapor sampling head is only in a tank vapor space for a few hours. The unit is stationary at that time while the tank vapors flow through the tubes. There is no work done to induce a static charge.

The RH has been measured at >50% in 95% of the non-exhausted tanks sampled (as of 7/96). This is to be expected since the concentration of water in air in a sealed chamber will eventually reach saturation, and be in equilibrium with the liquid phase. The remaining 5% of the non-exhausted tanks all measured approximately between 40 to 50% RH. The SX Farm exhausted tanks measured approximately between 20 to 40% RH, except one tank which was 65% RH. Tank 241-C-105 measured 40 to 60% RH, and Tank 241-C-106 measured 50 to 100% RH. Therefore, for non-exhausted tanks, plastics in dome intrusive regions are expected to be in compliance with the Flammable Gas JCO about 95% of the time. For exhausted tanks, Tanks 241-C-105 and 241-C-106 are approximately 50% RH. Most double-shell tanks would be expected to be the same due to the liquid or moist solid surfaces.

Concern is when a spark occurs coincident with a flammable gas mixture >100% lower flammability limit (LFL). Per Appendix A of this JCO, vapor space sample results for single-shell tanks indicate that 70 to 90% of the tanks show negligible or nondetectable flammable gas levels during non waste intrusive work. The remaining 10 to 30% of the tanks average 1.2 to 1.5% of the LFL. The highest CGM measurement (7%) recorded to date using the organic vapor monitor (OVM) samples equated to approximately 3.5% of the LFL. The highest vapor sample results obtained via Type B/Type 4 vapor sampling correlates to 2.51% of the LFL. One inactive miscellaneous underground storage tank (IMUST) sampled showed no flammable gas present. The highest recorded organic concentration, 3.8% of the LFL, was found in Tank 241-C-103. Tank 241-C-103 is the only waste tank known to have a significant floating organic layer. Since July 1996, one tank has shown a 10% of the LFL combustible gas meter (CGM) reading (5% of the LFL), and one showed a 13% LFL CGM reading (6.5% LFL) prior to intrusive activities. Actively ventilated tanks would be expected to have low flammable gas levels because of the constant dilution air passing through the tanks. No actively ventilated single-shell tanks have shown flammable gas levels above minimum detectible levels in either the Type 3 or 4 vapors samples or in the special OVM samples taken in these tanks.

Trapping of gases is not a concern with the Type 4 vapor sampling head as the top end of the external sleeving is open. The following list summarizes the points to be considered when evaluating the risk associated with using the Type 4 vapor sampling head:

1) The air flow in the sampler tubing is insufficient to induce a static charge.

2) There is a low potential for static buildup and subsequent discharge with the unit. There are no moving parts and the head is in the tank vapor space for only a few hours.

3) The RH in passively ventilated tanks or waste intruding equipment is expected to be high enough so that the majority of the time nonconductive plastic use in these areas is in compliance with the Flammable Gas JCO.

4) There is no liquid or wind exposure to the head to cause a static buildup.

5) Flammable gas levels have not been seen in excess of the LFL in the tank dome space for any tank except in pre-mitigated Tank 241-SY-101 during one or more gas release event (GREs). In about 80% of the single-shell tanks that have been sampled the LFL is below detectable. In the remaining 20% of the single-shell tanks the LFL is less than 2%, except for 2-3 specific readings which have ranged up to 6.5%. The presence of flammable gases in actively ventilated single-shell and double-shell tanks would be expected to be low most of the time because of the constant dilution air. Therefore, although the presence of flammable gas concentrations in dome intrusive areas above the LFL cannot be positively ruled out, they can be expected to be a rare occurrence.

Based upon the following, continued use of the Type 4 vapor sampling head in Tank Farms poses a low risk of causing a flammable gas ignition event; a) consideration of the small amount of time the Type 4 vapor sampling head is exposed to the tank vapor space, b) the low percentage of the time the Type 4 vapor sampling head will be used in a dome intrusive regions when the RH will be low enough that the head use would not meet the Flammable Gas JCO, c) the lack of any significant static generating mechanisms, and d) the small percent of the time that flammable gas levels might be above the LFL.

The risk with continuing use of the Type 4 vapor sampling head is further reduced by performing flammable gas monitoring of the work area prior to and during use. This will include monitoring per method [A]. See definition of monitoring methods at the end of this section.

When flammable gas levels reach 25% of the LFL, work ceases as required per the Flammable Gas JCO. The National Fire Protection Association (NFPA 30, 1988) recommends that processes be controlled so that flammable gas concentrations are <25 percent of the LFL, when relying upon vapor space flammability levels to preclude the possibility of an ignition. DOE Order 5480.4 requires Hanford waste tanks to be operated within NFPA guidelines. Thus, a control of <25% of the LFL has been established for performing activities in and around Tank Farm facilities. Because of the unpredictable nature of GREs, it is currently not possible to ensure that 25% of the LFL is never exceeded. Procedures and controls are thus in place to minimize the potential for a tank to exceed 25% of the LFL, and to cease work in areas common with the tank vapor space when the flammable gas concentration exceeds this value. This 25% limit is far below the actual limit at which flammability can occur, and is conservatively chosen to allow for potential measurement errors.

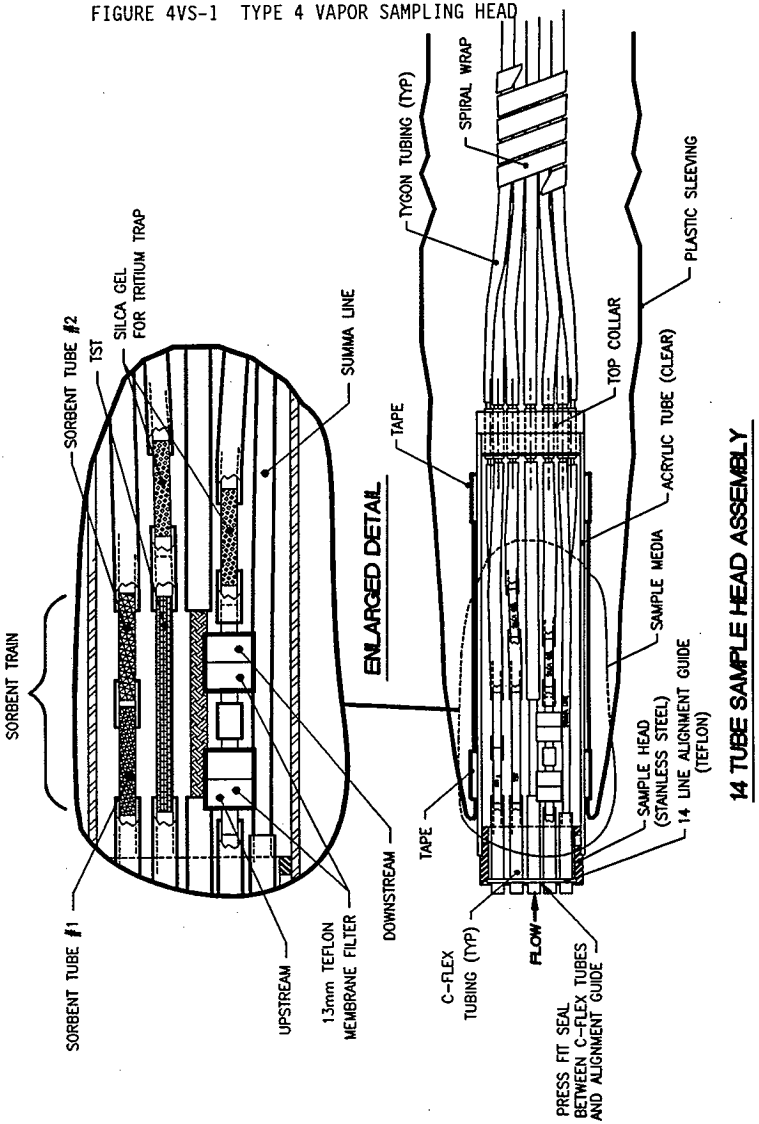
Monitoring is normally performed with a portable CGM. The CGM is calibrated with pentane and reads high by 100% when monitoring for hydrogen in air. For conservatism, no correction factor is applied in the field to the CGM reading when used for monitoring for personnel protection. Thus a 25% of the LFL reading on a CGM is actually 12.5% of the LFL for hydrogen in air, but is treated as if it were 25%. Depending upon the concentration of the flammable gas constituent and oxidants (ammonia, methane, carbon monoxide, nitrous oxide) a 25% LFL CGM reading will be indicative of 12.5% to approximately 20% of the LFL. The response time of a CGM to an increase in flammable gas concentration is not instantaneous. The CGM starts responding to an increase in flammable gas concentrations almost immediately upon the gas reaching the CGM internals. The internal response time for a CGM to reach a 10% of the LFL indication (5% LFL actual for hydrogen in air) when exposed to a 23% of the LFL pentane mixture (equivalent to a 11.5% of the LFL hydrogen in air mixture) ranged from 7-12 seconds in a number of informal tests. Time to reach the full 23% test gas indication took 20-40 seconds.

If the CGM is drawing a sample out of a tank dome space, the time for the tank vapors to reach the CGM is approximately 26 seconds, based upon the 500 cm^3/min CGM flow and the tubing currently used for flammable gas monitoring. Thus an instantaneous change from 0 to 12.5% of the LFL for hydrogen in air in a tank vapor space (an indicated 25% of the LFL) would not indicate any change at all on a CGM for about 26 seconds. At 26 seconds, the indicated LFL would begin to rise and 33-36 seconds after the step change the CGM would indicate about 10% of the LFL. The CGM would indicate 25% of the LFL approximately 45-65 seconds after the step change.

A CGM is an acceptable instrument to use for flammable gas monitoring in Dome Intrusive regions as long as work is halted upon significant increase in the indicated flammable gas levels. An instantaneous step increase in an entire tank dome vapor space concentration from 0 to 100% of the LFL is not realistic due to the large volume of gas which would be required to be released, although localized spots near the waste surface could show a quick step change to >100% of the LFL from relatively small releases of gases from below the waste surface. The risk is low that a gas stream would be released from the waste surface of a 75 foot diameter tank and enter the 2½ inch diameter sampling head directly above without the gas being partially diffused by tank vapors. The sampling head is not routinely used near the waste surface where there could be quick localized step changes in the flammable gas concentration. Were high gas concentrations present for a few seconds until noted by the CGM, there is still low risk of a static discharge as there are no moving parts to the Type 4 vapor sampling head and no major static discharge inducing activity.

The current polymeric materials used for vapor sampling were selected after a study which evaluated the effects of outgassing with a variety of compounds. Using other materials, even if they were available, would result in unnecessary expense and delays to the vapor sampling program. The impact on resolution of tank safety issues by halting Type 4 vapor sampling is a more significant concern than the low risk of a flammable gas ignition event due to a spark from these items.

FIGURE 4VS-1 TYPE 4 VAPOR SAMPLING HEAD



ITEM CLASSIFICATION: NON DE MINIMUS

ITEM NUMBER: 23

EQUIPMENT: Electric Impact Wrench

CATEGORY: Electrical Spark Potential, Mechanical Spark Potential

USE:

Used for loosening and tightening jumper heads in pits.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #1, #5	FG 1 ex-tank

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

The impact wrench is a large, 480 VAC electrical induction motor and socket. It is not designed to meet the ICS controls. The unit is used in tank farms for making jumper changes.

RISK ACCEPTANCE:

See risk acceptance writeup starting on next page.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Will shut down most pit work until an alternate wrench, administrative controls or means of isolating the pit from the tank vapor space can be derived.

Facility Group 2 Tanks-No impact.

Facility Group 3 or other Tanks-No impact.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring control [A] for the electric impact wrench:

1) FG 1 ex-tank regions (NWD, LWD)

Risk Acceptance for Electric Impact Wrench.

The electrical impact wrench is both an electrical spark source and a mechanical spark source. It is used for tightening and loosening horizontal and vertical jumper heads in pump pits, diversion boxes, valve pits and any location where the old design Hanford or newer PUREX jumper heads are present. No equipment is known to exist which can meet the Flammable Gas JCO controls from both electrical and mechanical spark source standpoints. Manual wrenches are not practical for the majority of the high torques required and would result in high personnel exposures.

Concern is when a spark occurs coincident with a flammable gas mixture >100% LFL. Per Appendix A of this Flammable Gas JCO, vapor space sample results for single-shell tanks indicate that approximately 70-90% of the tanks show negligible or nondetectable flammable gas levels during non waste intrusive work. The remaining 10-30% of the tanks average 1.2-1.5% of the LFL. The highest CGM measurement (7%) recorded to date using the OVM samples equated to approximately 3.5% of the LFL. The highest vapor sample results obtained via Type B/Type 4 vapor sampling correlates to 2.51% of the LFL. One IMUST tank sampled showed no flammable gas present. The highest recorded organic concentration, 3.8% of the LFL, was found in Tank 241-C-103. Tank 241-C-103 is the only waste tank known to have a significant floating organic layer. Since July 1996, one tank has shown a 10% of the LFL CGM reading (5% of the LFL), and one showed a 13% LFL CGM reading (6.5% LFL) prior to intrusive activities. Actively ventilated tanks would be expected to have low flammable gas levels because of the constant dilution air passing through the tanks. No actively ventilated single-shell tanks have shown flammable gas levels above minimum detectible levels in either the Type 3 or 4 vapors samples or in the special OVM samples taken in these tanks.

The following can be summarized concerning the risk associated with using the impact wrench:

1) Its use is required to make jumper changes or repairs.

2) Flammable gas levels have not been seen in excess of the LFL in the tank dome space for any tank except in pre-mitigated Tank 241-SY-101 during one or more GREs. In about 80% of the single-shell tanks that have been sampled the LFL is below detectable. In the remaining 20% of the single-shell tanks the LFL is less than 2%, except for 2-3 specific readings which have ranged up to 6.5%. The presence of flammable gases in actively ventilated single-shell and double-shell tanks would be expected to be low most of the time because of the constant dilution air. Therefore, although the presence of flammable gas concentrations in Dome Intrusive areas above the LFL cannot be positively ruled out, they can be expected to be a rare occurrence. The presence of flammable gases at concentrations >25% of the LFL in an Ex Tank area is expected to be even less likely.

Based upon the following, continued use of the impact wrench in Tank Farms poses a low risk of causing a flammable gas ignition event; a) the requirement to use the wrench if some transfers are to continue and b) the small percent of the time that flammable gas levels might be above the LFL in the Ex Tank pit area.

The risk associated with continuing use of the impact wrench is further reduced by performing flammable gas monitoring of the work area prior to and during use. This will include monitoring per method [A], which will require continuous monitoring of the tank dome space or the pit. See definition of monitoring methods at the end of this section.

When flammable gas levels reach 25% of the LFL, work ceases as required per the monitoring requirements of this Flammable Gas JCO. The National Fire Protection Association (NFPA 30, 1988) recommends that processes be controlled so that flammable gas concentrations are <25 percent of the LFL, when relying upon vapor space flammability levels to preclude the possibility of an ignition. DOE 5480.4 requires Hanford waste tanks to be operated within NFPA guidelines. Thus, a control of <25% of the LFL has been established for performing activities in and around Tank Farm facilities. Because of the unpredictable nature of GREs, it is currently not possible to ensure that 25% of the LFL is never exceeded. Procedures and controls are thus in place to minimize the potential for a tank to exceed 25% of the LFL, and to cease work in areas common with the tank vapor space when the flammable gas concentration exceeds this value. This 25% limit is far below the actual limit at which flammability can occur, and is conservatively chosen to allow for potential measurement errors.

Monitoring is normally performed with a portable CGM. The CGM is calibrated with pentane and reads high by 100% when monitoring for hydrogen in air. For conservatism, no correction factor is applied in the field to the CGM reading when used for monitoring for personnel protection. Thus a 25% of the LFL reading on a CGM is actually 12.5% of the LFL for hydrogen in air, but is treated as if it were 25%. Depending upon the concentration of the flammable gas constituent and oxidants (ammonia, methane, carbon monoxide, nitrous oxide) a 25% LFL CGM reading will be indicative of 12.5% to approximately 20% of the LFL. The response time of a CGM to an increase in flammable gas concentration is not instantaneous. The CGM starts responding to an increase in flammable gas concentrations almost immediately upon the gas reaching the CGM internals. The internal response time for a CGM to reach a 10% of the LFL indication (5% LFL actual for hydrogen in air) when exposed to a 23% of the LFL pentane mixture (equivalent to a 11.5% of the LFL hydrogen in air mixture) ranged from 7 to 12 seconds in a number of informal tests. Time to reach the full 23% test gas indication took 20 to 40 seconds.

If the CGM is drawing a sample out of a tank dome space, the time for the tank vapors to reach the CGM is approximately 26 seconds, based upon the 500 cm^3/min CGM flow and the tubing currently used for flammable gas monitoring. Thus an instantaneous change from 0 to 12.5% of the LFL for hydrogen in air in a tank vapor space (an indicated 25% of the LFL) would not indicate any change at all on a CGM for about 26 seconds. At 26 seconds, the indicated LFL would begin to rise and 33-36 seconds after the step change the CGM would indicate about 10% of the LFL. The CGM would indicate 25% of the LFL approximately 45 to 65 seconds after the step change.

If the CGM was being used to sample the immediate work area where an impact wrench was used the 26 second delay would not apply, the CGM would start to rise immediately and a reading of 10% of the LFL would be noted 7 to 12 seconds after sensing a 25% step increase in the LFL.

A CGM is an acceptable instrument to use for flammable gas monitoring in dome intrusive or ex-tank regions as long as work is halted upon significant increase in the indicated flammable gas levels. An instantaneous step increase in an entire tank dome vapor space concentration from 0 to 100% of the LFL is not realistic due to the large volume of gas which would be required to be released, although localized spots near the waste surface could show a quick step change to >100% of the LFL from relatively small releases of gases from below the waste surface. The risk is very low that a gas stream would be released from the waste surface of a 75 foot diameter tank and enter a 4 inch diameter pit drain directly above without the gas being partially diffused by tank vapors. Since monitoring for flammable gases is done both in the tank dome space and the pit while using the wrench, the current response time for CGMs is not a significant concern.

There does not appear to be a suitable substitute for an electric impact wrench which could adequately tighten and loosen jumper heads and, at the same time, create no potential for mechanical sparking. In its tank farm applications, the impact wrench is judged to present a low risk for ignition of flammable gas due to the combination of the location of its use and the relatively short duration of its use. Therefore, the benefits derived from the use of the impact wrench (e.g., enabling waste transfers and repairing jumper leaks) must be balanced with the low risk introduced by its potential for mechanical sparking.

ITEM CLASSIFICATION: NON DE MINIMUS

ITEM NUMBER: 24

EQUIPMENT: Type 4 Vapor Sampling Cart

CATEGORY: Electrical Spark Potential

USE:

Used for monitoring flows and providing suction for gas drawn through sampling tubes inserted in the tank.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #5	FG 1,2 dome intrusive

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

The electronic equipment on the Type 4 sampling cart consists of four mass flowmeters, four electronic totalizers, and a vacuum pump. The Type 4 vapor sampling cart establishes the vacuum, and monitors the flow of tank vapors from the Type 4 vapor sampling head. The information is not yet available to show whether the items on the cart meet the controls for dome intrusive electrical equipment for Facility Group 1 and 2 tanks. Although the definitions in the Flammable Gas JCO would imply the equipment is not required to meet Dome Intrusive criteria, a conservative assumption is that it should meet the requirements as filtered tank gases pass through the equipment and any flammable mixtures would be exposed to the electrical equipment internals. Type 4 vapor sampling is currently only performed on FG 2 and FG 3 tanks, plans are to sample at least one FG 1 tank in the future.

RISK ACCEPTANCE:

See risk acceptance writeup starting on next page.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-No impact unless sample FG 1 tanks. If FG 1 tanks are sampled, the impact would be the same as for FG 2 tanks.

Facility Group 2 Tanks-If the risk of continuing to use the current equipment is not accepted, all in-situ vapor sampling (Type 4) vapor sampling activities will be shutdown until different equipment is available or the existing equipment can be shown to meet the Flammable Gas JCO criteria.

Facility Group 3 or other Tanks-No Impact.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring control [A] for the current Type 4 vapor sampling cart:

1) FG 1,2 dome intrusive regions

Risk Acceptance for Type 4 vapor sampling cart.

The scope of this discussion is limited to potential electrical spark ignition events from the Type 4 sampling cart.

The Type 4 vapor sampling cart was developed to sample tank vapors to support resolution of tank safety issues. It replaces Type 3 vapor sampling which is more expensive and time consuming, and did not provide in situ sampling.

Concern is when a spark occurs coincident with a flammable gas mixture >100% of the LFL. Per Appendix A of this Flammable gas JCO, vapor space sample results for single-shell tanks indicate that approximately 70-90% of the tanks show negligible or nondetectable flammable gas levels during non waste intrusive work. The remaining 10-30% of the tanks average 1.2-1.5% of the LFL. The highest CGM measurement (7%) recorded to date using the OVM samples equated to approximately 3.5% of the LFL. The highest vapor sample results obtained via Type B/Type 4 vapor sampling correlates to 2.51% of the LFL. One IMUST tank sampled showed no flammable gas present. The highest recorded organic concentration, 3.8% of the LFL, was found in Tank 241-C-103. Tank 241-C-103 is the only waste tank known to have a significant floating organic layer. Since July 1996, one tank has shown a 10% of the LFL CGM reading (5% of the LFL), and one showed a 13% LFL CGM reading (6.5% LFL) prior to intrusive activities. Actively ventilated tanks would be expected to have low flammable gas levels because of the constant dilution air passing through the tanks. No actively ventilated single-shell tanks have shown flammable gas levels above minimum detectible levels in either the Type 3 or 4 vapors samples or in the special OVM samples taken in these tanks.

The following can be summarized concerning the actual risk from using the Type 4 vapor sampling cart:

1) Analytical data from Type 4 vapor sampling is used to support waste tank safety issue resolution.

2) Flammable gas levels have not been seen in excess of the LFL in the tank dome space for any tank except in Tank 241-SY-101 during one or more GREs. In about 80% of the single-shell tanks that have been sampled the LFL is below detectable. In the remaining 20% of the single-shell tanks the LFL is less than 2%, except for 2-3 specific readings which have ranged up to 6.5%. The presence of flammable gases in actively ventilated single-shell and double-shell tanks would be expected to be low most of the time because of the constant dilution air. Therefore, although the presence of flammable gas concentrations in Dome Intrusive areas above the LFL cannot be positively ruled out, they can be expected to be a rare occurrence.

Based upon the need for Type 4 vapor sampling and the small percent of the time that flammable gas levels might be above the LFL, continued use of the Type 4 vapor sampling cart poses a low risk of causing a flammable gas ignition event.

The risk associated with continued use of the Type 4 vapor sampling cart is further reduced by performing flammable gas monitoring of the work area and dome space prior to and during use. This will include monitoring per method [A]. See definition of monitoring methods at the end of this section.

When flammable gas levels reach 25% of the LFL, work ceases as required per the monitoring requirements this Flammable Gas JCO. The National Fire Protection Association (NFPA 30, 1988) recommends that processes be controlled so that flammable gas concentrations are <25 percent of the LFL, when relying upon vapor space flammability levels to preclude the possibility of an ignition. DOE Order 5480.4 requires Hanford waste tanks to be operated within NFPA guidelines. Thus, a control of <25% of the LFL has been established for performing activities in and around Tank Farm facilities. Because of the unpredictable nature of GREs, it is currently not possible to ensure that 25% of the LFL is never exceeded. Procedures and controls are thus in place to minimize the potential for a tank to exceed 25% of the LFL, and to cease work in areas common with the tank vapor space when the flammable gas concentration exceeds this value. This 25% limit is far below the actual limit at which flammability can occur, and is conservatively chosen to allow for potential measurement errors.

Monitoring is normally performed with a portable CGM. The CGM is calibrated with pentane and reads high by 100% when monitoring for hydrogen in air. For conservatism, no correction factor is applied in the field to the CGM reading when used for monitoring for personnel protection. Thus a 25% of the LEL reading on a CGM is actually 12.5% of the LFL for hydrogen in air, but is treated as if it were 25%. Depending upon the concentration of the flammable gas constituent and oxidants (ammonia, methane, carbon monoxide, nitrous oxide) a 25% LFL CGM reading will be indicative of 12.5% to approximately 20% of the LFL. The response time of a CGM to an increase in flammable gas concentration is not instantaneous. The CGM starts responding to an increase in flammable gas concentrations almost immediately upon the gas reaching the CGM internals. The internal response time for a CGM to reach a 10% of the LFL indication (5% LFL actual for hydrogen in air) when exposed to a 23% of the LFL pentane mixture (equivalent to a 11.5% of the LFL hydrogen in air mixture) ranged from 7 to 12 seconds in a number of informal tests. Time to reach the full 23% test gas indication took 20 to 40 seconds.

If the CGM is drawing a sample out of a tank dome space, the time for the tank vapors to reach the CGM is approximately 26 seconds, based upon the 500 cm^3/min CGM flow and the tubing currently used for flammable gas monitoring. Thus an instantaneous change from 0 to 12.5% of the LFL for hydrogen in air in a tank vapor space (an indicated 25% of the LFL) would not indicate any change at all on a CGM for about 26 seconds. At 26 seconds, the indicated LFL would begin to rise and 33 to 36 seconds after the step change the CGM would indicate about 10% of the LFL. The CGM would indicate 25% of the LFL approximately 45-65 seconds after the step change.

A CGM is an acceptable instrument to use for flammable gas monitoring in Dome Intrusive regions as long as work is halted upon significant increase in the indicated flammable gas levels. An instantaneous step increase in an entire tank dome vapor space concentration from 0 to 100% of the LFL is not realistic due to the large volume of gas which would be required to be released, although localized spots near the waste surface could show a quick step change to >100% of the LFL from relatively small releases of gases from below the waste surface. The risk is very low that a gas stream would be released from the waste surface of a 75 foot diameter tank and enter the 2½ inch diameter sampling head directly above without the gas being partially diffused by tank vapors. The sampling head is not routinely used near the waste surface where there could be quick localized step changes in the flammable gas concentration. Were high gas concentrations present for a few seconds until noted by the CGM, the CGM would indicate high flammable gas levels present before flammable gases approached the Type 4 vapor sampling cart, leaving adequate time for shutdown.

Continuous monitoring is performed during Type 4 vapor sampling using a CGM. Sampling is conducted through a tube within the flexible tube bundle that is lowered into the tank. Tank vapors flow faster through the tubing used for flammable gas monitoring than through the tubing used for sampling the tank gases. This is because the vapors are drawn through the flammable gas monitoring tube with the CGM while the tank vapors to be sampled are drawn through sampling tubes by the vacuum pump on the cart. The time for tank vapors to reach the CGM is approximately 26 seconds. Tank vapors being sampled by the cart take approximately 65 seconds to reach the in situ vapor sampling instrumentation on the cart. Therefore, with the current flammable gas monitoring arrangement, a significant change in the tank flammable gas concentration would be noticed within 33-38 seconds or less, assuming there were no other indications of a GRE. This still leaves approximately 30 seconds before the instrumentation on the cart would see the gas, which allows adequate time for personnel response to shut off the vacuum pump. This monitoring is continuous during Type 4 vapor sampling while the vacuum pump is running. Shutdown of the electrical equipment on the Type 4 cart is manual upon receipt of a CGM alarm or indication.

Additionally, given that vapor sampling is non waste disturbing, the activity would not induce a GRE.

ITEM CLASSIFICATION: NON DE MINIMUS

ITEM NUMBER: 25

EQUIPMENT: Open Pit Work Related Equipment (e.g., T-bar, chokers, shackles, bull hooks, pike poles, sockets; installation/removal of process blanks, vapor seals, jumpers and leak detectors)

CATEGORY: Mechanical Spark Potential

USE:

Used for handling items during installation or removal inside open pits

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #1	FG 1 ex-tank

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

The subject items are normally made of carbon steel and were not procured to meet non-sparking criteria.

RISK ACCEPTANCE:

See risk acceptance writeup starting on next page.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Will shut down all pit work. Will halt installation and removal of equipment in the waste tanks.

Facility Group 2 Tanks-No Impact.

Facility Group 3 or other Tanks-No Impact.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring controls [A] as appropriate for rigging equipment:

1) FG 1 during ex-tank activities.

Risk Acceptance for Open Pit Work Related Equipment.

These items are potential mechanical spark sources. They are used for moving and adjusting equipment or sealing lines in various pits. Due to their size and weight, replacement equipment which meets the Flammable Gas JCO requirements is not readily or economically available. Control is provided through the use of proper rigging controls and procedures. Tools and equipment in this exception request are either not readily or economically available in a spark resistant version or are only rarely used in areas which require the Flammable Gas JCO controls.

Concern is when a spark occurs coincident with a flammable gas mixture >100% of the LFL. Per Appendix A this Flammable Gas JCO, vapor space sample results for single-shell tanks indicate that approximately 70 to 90% of the tanks show negligible or nondetectable flammable gas levels during non waste intrusive work. The remaining 10 to 30% of the tanks average 1.2 to 1.5% of the LFL. The highest CGM measurement (7%) recorded to date using the OVM samples equated to approximately 3.5% of the LFL. The highest vapor sample results obtained via Type B/Type 4 vapor sampling correlates to 2.51% of the LFL. One IMUST tank sampled showed no flammable gas present. The highest recorded organic concentration, 3.8% of the LFL, was found in Tank 241-C-103. Tank 241-C-103 is the only waste tank known to have a significant floating organic layer. Since July 1996, one tank has shown a 10% of the LFL CGM reading (5% of the LFL), and one showed a 13% LFL CGM reading (6.5% LFL) prior to intrusive activities. Actively ventilated tanks would be expected to have low flammable gas levels because of the constant dilution air passing through the tanks. No actively ventilated single-shell tanks have shown flammable gas levels above minimum detectible levels in either the Type 3 or 4 vapors samples or in the special OVM samples taken in these tanks.

The following can be summarized concerning the risk associated with using these tools and equipment:

1) This equipment is required to accomplish pit work and to install and remove equipment in waste tanks.

2) Flammable gas levels have not been seen in excess of the LFL in the tank dome space for any tank except in Tank 241-SY-101 during one or more GREs. In about 80% of the single-shell tanks that have been sampled the LFL is below detectable. In the remaining 20% of the single-shell tanks the LFL is less than 2%, except for 2-3 specific readings which have ranged up to 6.5%. The presence of flammable gases in actively ventilated single-shell and double-shell tanks would be expected to be low most of the time because of the constant dilution air. Therefore, although the presence of flammable gas concentrations in dome intrusive areas above the LFL cannot be positively ruled out, they can be expected to be a rare occurrence. The presence of flammable gases at concentrations >25% of the LFL in an ex-tank area is therefore expected to be even less likely.

Based upon the following, continued use of these tools and equipment in Tank Farms poses a low risk of causing a flammable gas ignition event; a) the use of the tools and equipment is required if transfers are to continue and b) the small percent of the time that flammable gas levels might be above the LFL in the ex-tank pit area.

The risk associated with continuing use of the tools and equipment is further reduced by performing flammable gas monitoring of the work area prior to and during use. This will include monitoring per method [A]. See definition of monitoring methods at the end of this section.

When flammable gas levels reach 25% of the LFL, work ceases as required per the monitoring requirements of this Flammable Gas JCO. The National Fire Protection Association (NFPA 30, 1988) recommends that processes be controlled so that flammable gas concentrations are <25 percent of the LFL, when relying upon vapor space flammability levels to preclude the possibility of an ignition. DOE Order 5480.4 requires Hanford waste tanks to be operated within NFPA guidelines. Thus, a control of <25% of the LFL has been established for performing activities in and around Tank Farm facilities. Because of the unpredictable nature of GREs, it is currently not possible to ensure that 25% of the LFL is never exceeded. Procedures and controls are thus in place to minimize the potential for a tank to exceed 25% of the LFL, and to cease work in areas common with the tank vapor space when the flammable gas concentration exceeds this value. This 25% limit is far below the actual limit at which flammability can occur, and is conservatively chosen to allow for potential measurement errors.

Monitoring is normally performed with a portable CGM. The CGM is calibrated with pentane and reads high by 100% when monitoring for hydrogen in air. For conservatism, no correction factor is applied in the field to the CGM reading when used for monitoring for personnel protection. Thus a 25% of the LFL reading on a CGM is actually 12.5% of the LFL for hydrogen in air, but is treated as if it were 25%. Depending upon the concentration of the flammable gas constituent and oxidants (ammonia, methane, carbon monoxide, nitrous oxide) a 25% LFL CGM reading will be indicative of 12.5% to approximately 20% of the LFL. The response time of a CGM to an increase in flammable gas concentration is not instantaneous. The CGM starts responding to an increase in flammable gas concentrations almost immediately upon the gas reaching the CGM internals. The internal response time for a CGM to reach a 10% of the LFL indication (5% LFL actual for hydrogen in air) when exposed to a 23% of the LFL pentane mixture (equivalent to a 11.5% of the LFL hydrogen in air mixture) ranged from 7 to 12 seconds in a number of informal tests. Time to reach the full 23% test gas indication took 20 to 40 seconds.

If the CGM is drawing a sample out of a tank dome space, the time for the tank vapors to reach the CGM is approximately 26 seconds, based upon the 500 cm^3/min CGM flow and the tubing currently used for flammable gas monitoring. Thus an instantaneous change from 0 to 12.5% of the LFL for hydrogen in air in a tank vapor space (an indicated 25% of the LFL) would not indicate any change at all on a CGM for about 26 seconds. At 26 seconds, the indicated LFL would begin to rise and 33-36 seconds after the step change the CGM would indicate about 10% of the LFL. The CGM would indicate 25% of the LFL approximately 45-65 seconds after the step change.

If the CGM was being used to sample the ex-tank area where these tools are used the 26 second delay would not apply, the CGM would start to rise immediately and a reading of 10% of the LFL would be noted 7-12 seconds after sensing a 25% step increase in the LFL.

A CGM is an acceptable instrument to use for flammable gas monitoring in ex-tank and dome intrusive regions as long as work is halted upon significant increase in the indicated flammable gas levels. An instantaneous step increase in an entire tank dome vapor space concentration from 0 to 100% of the LFL is not realistic due to the large volume of gas which would be required to be released, although localized spots near the waste surface could show a quick step change to >100% of the LFL from relatively small releases of gases from below the waste surface. The risk is very low that a gas stream would be released from the waste surface of a 75 foot diameter tank and enter a 4 inch diameter pit drain directly above without the gas being partially diffused by tank vapors. Since monitoring for flammable gases is done in the pit while using the tools and equipment, the current response time for CGMs is not a significant concern.

ITEM CLASSIFICATION: NON DE MINIMUS

ITEM NUMBER: 26

EQUIPMENT: Closed Pit Work including the Installation and Removal of Valve Handles

CATEGORY: Mechanical Spark Potential

USE:

Used for operating valves in pits.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #1	FG 1 ex-tank FG 2 ex-tank (GWD)

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

Valve handles are made of carbon steel. They were not procured to meet non-sparking criteria. The valve handles are bulky and are a potential spark source during installation and removal. Valve operation is covered as a de minimus item.

RISK ACCEPTANCE:

See risk acceptance writeup starting on next page.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Will shut down transfers.

Facility Group 2 Tanks- May impact transfers.

Facility Group 3 or other Tanks-No Impact.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring control [A] for installation and removal of valve handles in:

1) FG 1 tank ex-tank regions.
2) FG 2 tank ex-tank regions (GWD) operations

Risk Acceptance for Closed Pit Work.

Valve handles are potential mechanical spark sources as they could be dropped during installation or removal due to their size and weight. Concern is when a spark occurs coincident with a flammable gas mixture >100% of the LFL. Per Appendix A of this Flammable Gas JCO, vapor space sample results for single-shell tanks indicate that approximately 70 to 90% of the tanks show negligible or nondetectable flammable gas levels during non waste intrusive work. The remaining 10 to 30% of the tanks average 1.2 to 1.5% of the LFL. The highest CGM measurement (7%) recorded to date using the OVM samples equated to approximately 3.5% of the LFL. The highest vapor sample correlates to 2.51% of the LFL. One IMUST tank sampled showed no flammable gas present. The highest recorded organic concentration, 3.8% of the LFL, was found in Tank 241-C-103. Tank 241-C-103 is the only waste tank known to have a significant floating organic layer. Since July 1996, one tank has shown a 10% of the LFL CGM reading (5% of the LFL), and one showed a 13% LFL CGM reading (6.5% LFL) prior to intrusive activities. Actively ventilated tanks would be expected to have low flammable gas levels because of the constant dilution air passing through the tanks. No actively ventilated single-shell tanks have shown flammable gas levels above minimum detectible levels in either the Type 3 or 4 vapors samples or in the special OVM samples taken in these tanks.

The following can be summarized concerning the risk associated with installing and removing valve handles,

1) Valve handles are required to perform transfers.

2) Flammable gas levels have not been seen in excess of the LFL in the tank dome space for any tank except in pre-mitigated Tank 241-SY-101 during one or more GREs. In about 80% of the single-shell tanks that have been sampled the LFL is below detectable. In the remaining 20% of the single-shell tanks the LFL is less than 2%, except for 2-3 specific readings which have ranged up to 6.5%. The presence of flammable gases in actively ventilated single-shell and double-shell tanks would be expected to be low most of the time because of the constant dilution air. Therefore, although the presence of flammable gas concentrations in dome intrusive areas above the LFL cannot be positively ruled out, they can be expected to be a rare occurrence. The presence of flammable gases at concentrations >25% of the LFL in an ex-tank area is therefore expected to be even less of a probability.

Based upon the need to install and remove valve handles if some transfers are to continue and the small percent of the time that flammable gas levels might be above the LFL in the ex-tank pit area, continued installation and removal of the valve handles poses a low risk of causing a flammable gas ignition event.

The risk associated with continuing installation and removal of valve handles is further reduced by performing flammable gas monitoring of the work area prior to and during the activity. This will include monitoring per method [A]. See definition of monitoring methods at the end of this section.

When flammable gas levels reach 25% of the LFL, work ceases as required per the monitoring requirements of this Flammable Gas JCO. The National Fire Protection Association (NFPA 30, 1988) recommends that processes be controlled so that flammable gas concentrations are <25 percent of the LFL, when relying upon vapor space flammability levels to preclude the possibility of an ignition. DOE Order 5480.4 requires Hanford waste tanks to be operated within NFPA guidelines. Thus, a control of <25% of the LFL has been established for performing activities in and around Tank Farm facilities. Because of the unpredictable nature of GREs, it is currently not possible to ensure that 25% of the LFL is never exceeded. Procedures and controls are thus in place to minimize the potential for a tank to exceed 25% of the LFL, and to cease work in areas common with the tank vapor space when the flammable gas concentration exceeds this value. This 25% limit is far below the actual limit at which flammability can occur, and is conservatively chosen to allow for potential measurement errors.

Monitoring is normally performed with a portable CGM. The CGM is calibrated with pentane and reads high by 100% when monitoring for hydrogen in air. For conservatism, no correction factor is applied in the field to the CGM reading when used for monitoring for personnel protection. Thus a 25% of the LFL reading on a CGM is actually 12.5% of the LFL for hydrogen in air, but is treated as if it were 25%. Depending upon the concentration of the flammable gas constituent and oxidants (ammonia, methane, carbon monoxide, nitrous oxide) a 25% LFL CGM reading will be indicative of 12.5% to approximately 20% of the LFL. The response time of a CGM to an increase in flammable gas concentration is not instantaneous. The CGM starts responding to an increase in flammable gas concentrations almost immediately upon the gas reaching the CGM internals. The internal response time for a CGM to reach a 10% of the LFL indication (5% LFL actual for hydrogen in air) when exposed to a 23% of the LFL pentane mixture (equivalent to a 11.5% of the LFL hydrogen in air mixture) ranged from 7 to 12 seconds in a number of informal tests. Time to reach the full 23% test gas indication took 20 to 40 seconds.

If the CGM is drawing a sample out of a tank dome space, the time for the tank vapors to reach the CGM is approximately 26 seconds, based upon the 500 cm^3/min CGM flow and the tubing currently used for flammable gas monitoring. Thus an instantaneous change from 0 to 12.5% of the LFL for hydrogen in air in a tank vapor space (an indicated 25% of the LFL) would not indicate any change at all on a CGM for about 26 seconds. At 26 seconds, the indicated LFL would begin to rise and 33 to 36 seconds after the step change the CGM would indicate about 10% of the LFL. The CGM would indicate 25% of the LFL approximately 45 to 65 seconds after the step change.

If the CGM were being used to sample the pit where these tools are used, the 26 second delay would be reduced to 3 to 6 seconds (due to shorter sample tube lengths and, thus, shorter transport times), and a reading of 10% of the LFL would be noted 10 to 18 seconds after sensing a 25% step increase in the LFL.

A CGM is an acceptable instrument to use for flammable gas monitoring in pits as long as work is halted upon significant increase in the indicated flammable gas levels. An instantaneous step increase in an entire tank dome vapor space concentration from 0 to 100% of the LFL is not realistic due to the large volume of gas which would be required to be released, although localized spots near the waste surface could show a quick step change to >100% of the LFL from relatively small releases of gases from below the waste surface. The risk is very low that a gas stream would be released from the waste surface of a 75 foot diameter tank and enter a 4 inch diameter pit drain directly above without the gas being partially diffused by tank vapors. Since monitoring for flammable gases is done in the pit before installation and removal of the valve handles, the current response time for CGMs is not a significant concern.

There is no readily available substitute for the valve handles. Therefore, the ability to install and remove the existing valve handles is essential for transferring of waste and other basic plant operations. The benefits of the ability to install and remove valve handles must be balanced against the small risk of igniting flammable gas via mechanical sparking.

ITEM CLASSIFICATION: NON DE MINIMUS

ITEM NUMBER: 27

EQUIPMENT: Cover blocks, riser flanges, shield plugs, and tank installed waste intrusive and non waste intrusive equipment items (e.g., thermocouple trees, steel LOWs, pumps, manual tapes, FICs, ENRAFs, radar gauges, heated vapor probes, multiple instrument trees (MITs), corrosion probes, velocity-density temperature trees (VDTTs), water lances, void fraction meter, core sampling drill string, salt well screens, dip tubes, cameras, lights, viscometer, auger sampler)

CATEGORY: Mechanical Spark Potential

USE:

Items are used for various purposes in risers and pits, or are equipment installed or removed in tanks to perform various functions.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #1	FG 1 ex-tank FG 1,2 dome intrusive FG 3 dome intrusive (LWD, GWD) FG 2 ex-tank (GWD) Waste Intrusive Regions

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

These are potential mechanical spark sources during seismic events, large GREs, and during installation, removal, or movement during use of various tools and equipment. Many are made of carbon steel. These items are inserted into or attached to the top of a riser or pit opening. Where required by the Flammable Gas JCO, these items are also bonded. Installation, removal, and use of these items are considered routine operations. The risk of mechanical sparks is minimized by use of practical measures such as controlling the rate of insertion or removal. Monitoring is done during installation, removal, and movement, and these are stopped if required by flammable gas levels.

RISK ACCEPTANCE:

See risk acceptance writeup starting on next page.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Will shut down most pit or riser installation work and halt installation of equipment into tanks.

Facility Group 2 Tanks-Will shut down most pit or riser installation work and halt installation of equipment into tanks.

Facility Group 3 or other Tanks-Will restrict or shut down all waste intrusive installations and removals.

REQUESTED APPROVAL FROM DOE:

Presence of non-spark resistent materials for installed equipment in locations and during activities as listed below. As this portion of the exception applies to the presence of installed equipment, no monitoring is required by this portion of the exception.

Installation and removal or movement during use of equipment fabricated from non-spark resistent materials when practical measures to control mechanical spark potential are applied and while performing flammable gas monitoring controls [A] as appropriate for the location and activity type in:

1) FG 1 tanks ex-tank activities
2) FG 1,2 tanks dome intrusive activities
3) FG 3 tanks dome intrusive (LWD, GWD)
4) FG 2 ex-tank regions (GWD)
5) Waste intrusive regions

Risk Acceptance for Cover Blocks, Flanges, Shield Plugs, Waste Intrusive and Non-Waste Disturbing Equipment.

These items are potential mechanical spark sources due their material. Fabrication of the items from non-sparking materials is not practical or cost effective.

Concern is when a spark occurs coincident with a flammable gas mixture >100% of the LFL. Per Appendix A of this Flammable Gas JCO, vapor space sample results for single-shell tanks indicate that approximately 70 to 90% of the tanks show negligible or nondetectable flammable gas levels during non waste intrusive work. The remaining 10 to 30% of the tanks average 1.2 to 1.5% of the LFL. The highest CGM measurement (7%) recorded to date using the OVM samples equated to approximately 3.5% of the LFL. The highest vapor sample correlates to 2.51% of the LFL. One IMUST tank sampled showed no flammable gas present. The highest recorded organic concentration, 3.8% of the LFL, was found in Tank 241-C-103. Tank 241-C-103 is the only waste tank known to have a significant floating organic layer. Since July 1996, one tank has shown a 10% of the LFL CGM reading (5% of the LFL), and one showed a 13% LFL CGM reading (6.5% LFL) prior to intrusive activities. Actively ventilated tanks would be expected to have low flammable gas levels because of the constant dilution air passing through the tanks. No actively ventilated single-shell tanks have shown flammable gas levels above minimum detectable levels in either the Type 3 or 4 vapors samples or in the special OVM samples taken in these tanks.

The following can be summarized concerning the risk and practical controls for the tools and equipment fabricated from non-spark resistent materials:

1) The use of this equipment is required to perform much of the work in Tank Farms. This includes temperature, pressure and level monitoring, transfers, sampling, and installation of equipment.

2) Flammable gas levels have not been measured in excess of the LFL in the tank dome for any tank except in pre-mitigated Tank 241-SY-101 during one or more GREs. In approximately 80% of the single-shell tanks that have been sampled the flammable gas is below detectable levels. In the remaining 20% of the single-shell tanks the flammable gas is less than 2% of the LFL, except for 2-3 specific readings which have ranged up to 6.5% of the LFL. The presence of flammable gas would only arise in the event of a GRE as steady state releases are managed by ventilation. The coincident occurrence of a spontaneous GRE and a mechanical spark is judged to be a low likelihood event. The likelihood of an induced GRE during waste disturbing operations is not fully quantified but is judged to be more likely than a spontaneous GRE. Flammable concentrations that might result from a small GRE are expected to persist for at most a short period of time as the gases are diluted with the air in the tank dome space.

3) Mechanical sparking is limited to situations where non-spark resistent materials are in motion such that sparks can be created by mechanical impacts or significant friction. These situations are described below.

   a. Motion of installed equipment in the ex-tank or dome intrusive locations might be caused by a seismic event. Specific controls to address a seismic event induced flammable gas deflagration are not included in this JCO. The risk and appropriate additional controls (if any) for this scenario are being addressed in the TWRS FSAR effort.

   b. Motion of equipment installed in waste intrusive locations might be caused by motion of the waste caused by seismic events, large spontaneous or induced GREs, or motion due to the effects of moving waste jets as in the case of operation of a waste mixer pump.

      Significant waste motion was observed during large GREs in Tank 241-SY-101 prior to mitigation. This waste motion caused long length installed equipment (e.g., T/C trees, air lances) to move about with significant velocity causing a concern for GRE induced mechanical sparks. Video surveillance of JCO FG 1 tanks indicates that significant waste and equipment motion does not occur during GREs in these tanks. Therefore, the risk of GRE induced mechanical sparks is judged to be low.

      For unmanned operations that might induce a GRE (e.g., waste transfers, operation of air lift circulators) gas monitoring is not practical. For manned activities, gas monitoring and safe shutdown are applied during the activity as required by this JCO.

      The risk and appropriate additional controls (if any) for the seismic event scenario are being addressed in the TWRS FSAR effort.

      The risks associated with gas releases and coincident mechanical sparks that might result from the operation of a large mixer pump are not yet fully evaluated. Therefore, this exception does not cover the presence of non-spark resistent materials in long length installed equipment that might be moved by the operation of a large mixer pump such that mechanical sparks might result.

c. Motion occurs during the installation of equipment (e.g., as it is lowered into the tank through a riser). Practical measures to reduce the likelihood of a mechanical spark during equipment installation shall be included in equipment design, work packages, or installation procedures when such movement has significant potential to cause mechanical sparks. This can include: limiting insertion speeds, water bathing of equipment, prevention of contact with other non-spark resistent materials by use of collars or bumpers, use of critical lift procedures where appropriate. Gas monitoring during these manned activities is performed as required by this JCO.

d. Motion occurs during the removal of equipment (e.g., as it is raised through a riser). Practical measures to reduce the likelihood of a mechanical spark during equipment removal shall be included in equipment design, work packages, or removal procedures when such movement has significant potential to cause mechanical sparks. This can include: limiting removal speeds, water bathing of equipment, prevention of contact with other non-spark resistent materials by use of collars or bumpers, use of critical lift procedures where appropriate. Gas monitoring during these manned activities is performed as required by this JCO.

e. Motion can occur as part of the operation of equipment (e.g., pushing a drill string/core barrel into the waste, [and through a riser], movement of waste characterization sampling devices such as retained gas samplers, void fraction meters, viscometer, auger sampler as they are moved through the waste). These operations are generally performed manually and are limited to low velocities by the nature of the operation. Practical measures to reduce the likelihood of a mechanical spark during equipment movement shall be included in the work packages and installation procedures when such movement has significant potential to cause mechanical sparks. This can include: limiting speeds, water bathing of equipment, prevention of contact with other non-spark resistent materials by use of collars or bumpers, use of critical lift procedures where appropriate. Gas monitoring during these manned activities is performed as required by this JCO.

The risk associated with continuing use of the tools and equipment is further reduced by performing flammable gas monitoring of the work area prior to and during use. This will include monitoring per method [A]. See definition of monitoring methods at the end of this section.

When flammable gas levels reach 25% of the LFL, work ceases as required per the monitoring requirements of this Flammable Gas JCO. The National Fire Protection Association (NFPA 30, 1988) recommends that processes be controlled so that flammable gas concentrations are <25% of the LFL, when relying upon vapor space flammability levels to preclude the possibility of an ignition. DOE 5480.4 requires Hanford waste tanks to be operated within NFPA guidelines. Thus, a control of <25% of the LFL has been established for performing activities in and around Tank Farm facilities. Because of the unpredictable nature of GREs, it is not possible to ensure that 25% of the LFL is never exceeded. Procedures and controls are thus in place to minimize the potential for a tank to exceed 25% of the LFL, and to cease work in areas common with the tank vapor space when the flammable gas concentration exceeds this value. This 25% limit is far below the actual limit at which flammability can occur, and is conservatively chosen to allow for potential measurement.

Monitoring is normally performed with a portable CGM. The CGM is calibrated with pentane and reads high by 100% when monitoring for hydrogen in air. For conservatism, no correction factor is applied in the field to the CGM reading when used for monitoring for personnel protection. Thus a 25% of the LFL reading on a CGM is actually 12.5% of the LFL for hydrogen in air, but is treated as if it were 25%. Depending upon the concentration of the flammable gas constituent and oxidants (ammonia, methane, carbon monoxide, nitrous oxide) a 25% LFL CGM reading will be indicative of 12.5% to approximately 20% flammable gas mixture. The response time of a CGM to an increase in flammable gas concentration is not instantaneous. The CGM starts responding to an increase in flammable gas concentrations almost immediately upon the gas reaching the CGM internals. The internal response time for a CGM to reach a 10% of the LFL indication (5% LFL actual for hydrogen in air) when exposed to a 23% of the LFL pentane mixture (equivalent to a 11.5% of the LFL hydrogen in air mixture) ranged from 7-12 seconds in a number of informal tests. Time to reach the full 23% test gas indication took 20-40 seconds.

If the CGM is drawing a sample out of a tank dome space, the time for the tank vapors to reach the CGM is approximately 26 seconds, based upon the 500 cm^3/min CGM flow and the tubing currently used for flammable gas monitoring. Thus an instantaneous change from 0 to 12.5% of the LFL for hydrogen in air in a tank vapor space (an indicated 25% of the LFL) would not indicate any change at all on a CGM for about 26 seconds. At 26 seconds, the indicated LFL would begin to rise and 33 to 36 seconds after the step change the CGM would indicate about 10% of the LFL. The CGM would indicate 25% of the LFL approximately 45 to 65 seconds after the step change.

If the CGM was being used to sample the immediate work area, the 26 second delay would not apply, the CGM would start to rise immediately and a reading of 10% of the LFL would be noted 7 to 12 seconds after sensing a 25% step increase in the LFL.

It is not realistic to have an instantaneous step change from 0% of the LFL to 100% of the LFL in an ex-tank area. Therefore, a CGM is an acceptable instrument to use for flammable gas monitoring in these areas as long as work is halted upon significant increase in the indicated flammable gas levels. An instantaneous step increase in an entire tank dome vapor space concentration from 0 to 100% of the LFL also is not realistic due to the large volume of gas which would be required to be released. However, localized spots near the waste surface could show a quick step change to >100% of the LFL from relatively small releases of gases from below the waste surface. The risk is very low that a gas stream would be released from the waste surface of a 75 foot diameter tank and enter a 4 inch diameter riser directly above without the gas being partially diffused by tank vapors. The response time for CGMs is not a concern when monitoring prior to or during use of this equipment.

It is necessary to balance the minimal time at risk and the risk of a mechanical sparking with the environmental and nuclear safety compliance enabled by the use of this equipment.

ITEM CLASSIFICATION: NON DE MINIMIS

ITEM NUMBER: 28, 29

EQUIPMENT: Pressure switches, limit switches and leak detector for salt well pumping Tanks 241-T-104 and 241-BY-109

CATEGORY: Electrical Spark Potential

USE:

Used to detect leaks, ensure proper valve positioning and provide pump pressure detection during salt well pumping.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #2	FG 3 dome intrusive (GWD)

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

The above equipment are items that are currently installed for salt well pumping Tanks 241-T-104 and 241-BY-109. These items are located in the salt well pump pit and although potential spark sources, they would only do so under the following conditions; 1) if the pump or jumper were to develop a leak, 2) a valve were to leak through or not seat properly, 3) high or low pressures were detected in the pump assembly, and 4) if valving were realigned during pumping. The exercising of these instruments results in a low time at risk for sparking. The Flammable Gas JCO ICS #2 requirements are only applicable for these pieces of equipment during salt well pumping or any global waste disturbing activity.

Tank 241-BY-109 is listed as a Facility Group 3 tank in this Flammable Gas JCO.

RISK ACCEPTANCE:

See risk acceptance writeup starting on next page.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-N/A

Facility Group 2 Tanks-N/A

Facility Group 3 or other Tanks-Will delay interim stabilization of Tank 241-T-104, potential impact to Tri-Party Agreement milestones and increased radiological exposure to personnel.

REQUESTED APPROVAL FROM DOE:

Continued use of the above equipment with pit monitoring with installed flammable gas monitor and monitoring per method [A] in:

1) Tank 241-T-104 (GWD).
2) Tank 241-BY-109, following approval of Facility Group 3 categorization (GWD).

Risk Acceptance for Tanks 241-T-104 and 241-BY-109 Salt Well Pumping Equipment.

The scope of this discussion is limited to potential electrical spark ignition events from the listed equipment in the Tanks 241-T-104 and 241-BY-109 pump pits. The pressure switches, limit switches and leak detector are installed.

Tank 241-T-104 has been pumped for 7 months prior to its shutdown. Continuous flammable gas monitoring of the pump pit has consistently indicated less than detectible levels of flammable gases (<3% LFL). It is estimated that pumping of this tank will be completed within three months of restart.

Tank 241-BY-109 has been pumped intermittently over the past several years. The highest flammable gas levels seen in the pump pit during the six weeks of pumping commencing September 10, 1996 was <10% of the LFL. During the previous pumping campaign in September 1995 the highest concentration shown in the tank dome space on the installed SHMS cabinet was 12% of the LFL for a two-hour period. The pump pit flammable gas monitor was installed after September 1995. The pump pit flammable gas monitor in Tank 241-BY-109 deenergizes equipment in the pit at 10% of the LFL. It is estimated that pumping of this tank will be completed within three months of restart.

Concern is when a spark occurs coincident with a flammable gas mixture >100% of the LFL. Per Appendix A of this Flammable Gas JCO, vapor space sample results for single-shell tanks indicate that approximately 70-90% of the tanks show negligible or nondetectable flammable gas levels during non waste intrusive work. The remaining 10-30% of the tanks average 1.2-1.5% of the LFL. The highest CGM measurement (7%) recorded using the OVM samples equated to approximately 3.5% of the LFL. The highest vapor sample results obtained via Type B/Type 4 vapor sampling correlates to 2.51% of the LFL. One IMUST tank sampled showed no flammable gas present. The highest recorded organic concentration, 3.8% of the LFL, was found in Tank 241-C-103. Tank 241-C-103 is the only waste tank known to have a significant floating organic layer. Since July 1996, one tank has shown a 10% of the LFL CGM reading (5% of the LFL), and one showed a 13% LFL CGM reading (6.5% LFL) prior to intrusive activities. Actively ventilated tanks would be expected to have low flammable gas levels because of the constant dilution air passing through the tanks. No actively ventilated single-shell tanks have shown flammable gas levels above minimum detectible levels in either the Type 3 or 4 vapors samples or in the special OVM samples taken in these tanks.

The following can be summarized concerning the risk with using the listed equipment:

1) The equipment is essential to the most cost effective and expeditious interim stabilization of Tanks 241-T-104 and 241-BY-109.

2) No flammable gas has been detected in the pump pit throughout the Tank 241-T-104 salt well pumping campaign.

3) Tank 241-T-104 has pumped for 7 months already, with three-months pumping estimated to remain. Flammable gas has been detected at 12% of the LFL in the Tank 241-BY-109 vapor space for a very short period in September 1995.

4) Flammable gas has not been detected above the 10% deenergizing setpoint in the pump pit. Since the pump pit flammable gas monitor was installed.

5) Tank 241-BY-109 has been pumped intermittently for several years, with one month pumping estimated to remain.

The risk associated with continuing use of the equipment is further reduced by continuous flammable gas monitoring of the pit area with the installed pit flammable gas monitor during pumping. In addition, this includes monitoring per method [A]. See definition of monitoring methods at the end of this section.

The design and configuration of the salt well pumping equipment in Tanks 241-T-104 and 241-BY-109 measures flammable gas levels in the pit area and deenergizes all electrical equipment in the pit upon detection of 10% LFL.

Stabilization of Tanks 241-T-104 and 241-BY-109 reduces the chance of an environmental release and is an M-41 Tri-Party Agreement milestone. These benefits must be balanced against the minimal risks of a flammable gas ignition event due to a spark from the pit equipment. The increased risk of using this existing equipment is judged to be minimal if not equivalent due to the short pumping time remaining (approximately three months for Tank 241-T-104 and one month for Tank 241-BY-109) and the use of the continuous flammable gas monitor with automatic deenergization of equipment on detection of 10% LFL. Additionally, modification of this equipment would increase the potential for radiological exposure to the maintenance and operation crews and the potential for a spread of contamination to the environment. It will take an estimated 20 man REM to modify equipment in the Tank 241-BY-109 pump pit to meet the Flammable Gas JCO if this exception is not approved.

ITEM CLASSIFICATION: NON DE MINIMUS

ITEM NUMBER: 30

EQUIPMENT: Fiberglass and Tefzel LOWs

Used for determining interstitial liquid levels.

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #3, ICS 1 #3	FG 2 dome intrusive FG 3 dome intrusive (LWD, GWD) FG 2,3 waste intruding equipment (failed LOWs only)

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

Liquid observation wells (LOWs) are hollow pipes sealed at the bottom that are inserted into many single-shell tanks for measuring the interstitial liquid level. Measurement is done by lowering a neutron source to the bottom of the LOW and measuring the observed neutron level as the probe is withdrawn. Fiberglass LOWs and Tefzel LOWs are judged to have a negligible potential for causing flammable gas ignition under the applied conditions.

Failed LOWs are waste intruding equipment because of the potential to trap waste gases. A failed LOW is one that has broken or cracked inside the tank and can let waste enter the pipe. Any work inside a known failed LOW requires flammable gas monitoring prior to the start.

RISK ACCEPTANCE:

See risk acceptance writeup starting on next page.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-No Impact.

Facility Group 2 Tanks-Removal of the LOWs would result in loss of leak detection capability and therefore cause environmental non-compliance. The risk of removing the LOWs is far greater from cost, ALARA, and lack of level monitoring standpoints, than the risk involved with leaving them in place.

Facility Group 3 or other Tanks-Same as for FG 2 tanks.

REQUESTED APPROVAL FROM DOE:

Continued presence and use of fiberglass and Tefzel LOWs in tanks without flammable gas monitoring:

1) FG 2,3 dome intrusive regions

Continued presence of failed fiberglass and Tefzel LOWs without flammable gas monitoring, or work in a failed fiberglass or Tefzel LOW following flammable gas monitoring control [8] for:

2) FG 2,3 tanks waste intruding equipment

Risk Acceptance for Fiberglass and Tefzel LOWs.

This is an item where environmental compliance must be balanced against the minimal risk associated with flammable gas ignition due to the presence and use of fiberglass or Tefzel LOWs. The LOWs are already installed in the tanks. The cost in personnel, time, waste disposal, and personnel exposure to remove the LOWs must be balanced with the low risk of a flammable gas ignition event due to a spark from a LOW. Steel LOWs can be installed as new ones are needed, but these are not compatible for all proposed LOW monitoring methods.

The RH has been measured to be >50% in 95% of the non-exhausted tanks sampled. This is to be expected since the concentration of water in air in a sealed chamber will eventually reach saturation, and be in equilibrium with the liquid phase. The remaining 5% of the non-exhausted tanks measured between 40-50% RH. The SX Farm exhausted tanks measured between 20-40% RH, except one tank which was 65% RH. Tank 241-C-105 measured between 40-60% RH, and Tank 241-C-106 measured between 50-100% RH. Therefore, for non-exhausted tanks, plastics in dome intrusive regions are expected to be in compliance with the Flammable Gas JCO about 95% of the time. Exhausted Tanks 241-C-105 and 241-C-106 are approximately 50% RH. For the inside of failed LOWs, any concentrated (i.e., non diluted by tank air) waste gases will be at 100% RH because the gases come from waste pockets surrounded by liquid waste. In such pockets the water vapor in the gas would be at equilibrium with the water in the liquid. The gas in failed LOWs will likely be partially mixed with tank vapors, but as most tank vapors have a high RH, the RH in the failed LOWs should be expected to be >50%. There is negligible air flow across LOWs in service to build up a static charge on them.

For use of intact LOWs, a swab is taken of each LOW prior to work inside the pipe; swabbing and monitoring is currently performed weekly. This is done by running a swab up and down the inside of the LOW and monitoring the swab for radioactivity. This is a much more accurate means of detecting a leaking LOW than using flammable gas monitoring. Work is rarely performed inside failed LOWs. The only activity in recent years was in confirming a failed LOW in Tank 241-SX-104. When required, monitoring is conducted per method [B].

The presence and use of fiberglass and Tefzel LOWs is of concern when the LOW has failed such that flammable gas may accumulate and be ignited due to static discharge upon removal of the nonconductive LOW cap. The time at risk is reduced to that time which is required to remove a cap. This time is on the order of seconds. Flammable gas monitoring is not an appropriate control for the routine presence of the LOWs in a tank vapor space as no response actions are available. It is an acceptable risk based upon experience for the LOWs to remain installed in the tanks without monitoring for flammable gases.

ITEM CLASSIFICATION: NON DE MINIMUS

ITEM NUMBER: 31

EQUIPMENT: Continuous Air Sampler (CAS) (SAIC Model #H-810 and H-809V1)

CATEGORY: Electrical Spark Potential

USE:

Used for monitoring for airborne radioactivity

APPLICABLE CONTROL NOT MET:	WHEN CONTROL NOT MET:
ICS 2 #5	FG 1 ex-tank FG 2 ex-tank (GWD)

DISCUSSION OF FLAMMABLE GAS JCO APPLICABILITY:

The CAS uses a 110v sparking motor to drive the vacuum pump which draws the air sample. The unit is not in compliance with the Flammable Gas JCO, as it does not meet the requirements of ICS 2 #2. In most applications, the sampler draws air from areas requiring ICS 2 controls. The unit will be located 18 opening diameters or 15 feet from the tank opening, whichever is less. Plastic hoses will be used to connect the sampler pump to the sampler head located in the worker's breathing space. Use of the plastic hoses is addressed in Item 1. Additionally, continuous monitoring for flammable gas while the unit is operating will be employed. If flammable gas concentration in excess of 10% of the LFL is detected, the unit will be immediately shut off.

RISK ACCEPTANCE:

See risk acceptance writeup starting on next page.

IMPACT OF NOT ACCEPTING RISK OF CONTINUED USE:

Facility Group 1 Tanks-Failure to accept the risk of continued use will shut down all tank intrusive work. All manned activity in ex-tank areas will be cancelled until qualified air samplers which meet requirements can be identified and procured. Essential ex-tank work may be performed only if workers are on breathing air.

Facility Group 2 Tanks-Failure to accept the risk of continued use will shut down all tank intrusive work during global waste disturbing operations. All manned activity in Ex Tank areas during GWD activities will be cancelled until qualified air samplers can be identified and procured. During GWD, essential ex-tank work may be performed only if workers are on breathing air.

Facility Group 3 or other Tanks-No Impact.

REQUESTED APPROVAL FROM DOE:

Continued use when performing flammable gas monitoring controls [A] for CASs in:

1) Ex-tank regions in FG 1 tanks.
2) Ex-tank regions in FG 2 tanks (GWD)

If flammable gas concentrations in excess of 10% of the LFL is detected, the unit will be immediately shut off.

Risk Acceptance for Continuous Air Sampler.

Use of CAS for personnel safety is standard in the nuclear industry. At Hanford, the HANFORD SITE RADIOLOGICAL CONTROL MANUAL, HSRC-1, requires air monitoring when appropriate as one of its basic tenets. Sections 125 and 136 both require evaluation of air spaces. Sections 551 and 555 give more specific requirements for this monitoring.

Concern is when a spark occurs coincident with a flammable gas mixture >100% of the LFL. Per Appendix A of this Flammable Gas JCO, vapor space sample results for single-shell tanks indicate that approximately 70-90% of the tanks show negligible or nondetectable flammable gas levels during non waste intrusive work. The remaining 10-30% of the tanks average 1.2-1.5% of the LFL. The highest CGM measurement (7%) recorded to date using OVM samples equated to approximately 3.5% of the LFL. The highest vapor sample results obtained via Type B/Type 4 vapor sampling correlates to 2.51% of the LFL. One IMUST tank sampled showed no flammable gas present. The highest recorded organic concentration, 3.8% of the LFL, was found in Tank 241-C-103. Tank 241-C-103 is the only waste tank known to have a significant floating organic layer. Since July 1996, one tank has shown a 10% of the LFL CGM reading (5% of the LFL), and one showed a 13% LFL CGM reading (6.5% LFL) prior to intrusive activities. Actively ventilated tanks would be expected to have low flammable gas levels because of the constant dilution air passing through the tanks. No actively ventilated single-shell tanks have shown flammable gas levels above minimum detectible levels in either the Type 3 or 4 vapors samples or in the special OVM samples taken in these tanks.

The following can be summarized concerning the actual risk with using the CAS:

1) Hanford Site radiological controls require use of a CAS for many of the operations in tank farms.

2) Flammable gas levels have not been seen in excess of the LFL in the tank dome space for any tank except in pre-mitigated Tank 241-SY-101 during one or more GREs. In about 80% of the single-shell tanks that have been sampled the LFL is below detectable. In the remaining 20% of the single-shell tanks the LFL is less than 2%, except for 2-3 specific readings which have ranged up to 6.5%. The presence of flammable gases in actively ventilated single-shell and double-shell tanks would be expected to be low most of the time because of the constant dilution air. Therefore, although the presence of flammable gas concentrations in Dome Intrusive areas above the LFL cannot be positively ruled out, they can be expected to be a rare occurrence. The presence of flammable gases at concentrations >25% of the LFL in an ex-tank area is therefore expected to be even less likely.

Based upon the requirement for remote placement of the CAS instrument during work in ex-tank areas, continuous monitoring and shutdown if flammable gas concentration exceeds 10% of the LFL, and the minimal potential for flammable gas concentrations above the LFL in the ex-tank area, the use of the CAS, with the compensatory measures prescribed poses an acceptable risk. This is especially relevant when balanced with the competing safety requirements for the protection of workers during these activities.

When flammable gas levels reach 25% of the LFL, work ceases as required per the monitoring requirements of this Flammable Gas JCO. The National Fire Protection Association (NFPA 30, 1988) recommends that processes be controlled so that flammable gas concentrations are <25 percent of the LFL, when relying upon vapor space flammability levels to preclude the possibility of an ignition. DOE 5480.4 requires Hanford waste tanks to be operated within NFPA guidelines. Thus, a control of <25% of the LFL has been established for performing activities in and around Tank Farm facilities. Because of the unpredictable nature of GREs, it is currently not possible to ensure that 25% of the LFL is never exceeded. Procedures and controls are thus in place to minimize the potential for a tank to exceed 25% of the LFL, and to cease work in areas common with the tank vapor space when the flammable gas concentration exceeds this value. This 25% limit is far below the actual limit at which flammability can occur, and is conservatively chosen to allow for potential measurement errors. For the CAS, the equipment shutdown limit is set more conservatively at 10% of the LFL.

Monitoring is normally performed with a portable CGM. The CGM is calibrated with pentane and reads high by 100% when monitoring for hydrogen in air. For conservatism, no correction factor is applied in the field to the CGM reading when used for monitoring for personnel protection. Thus a 25% of the LFL reading on a CGM is actually 12.5% of the LFL for hydrogen in air, but is treated as if it were 25%. Depending upon the concentration of the flammable gas constituent and oxidants (ammonia, methane, carbon monoxide, nitrous oxide) a 25% LFL CGM reading will be indicative of 12.5% to approximately 20% of the LFL. The response time of a CGM to an increase in flammable gas concentration is not instantaneous. The CGM starts responding to an increase in flammable gas concentrations almost immediately upon the gas reaching the CGM internals. The internal response time for a CGM to reach a 10% of the LFL indication (5% LFL actual for hydrogen in air) when exposed to a 23% of the LFL pentane mixture (equivalent to a 11.5% of the LFL hydrogen in air mixture) ranged from 7 to 12 seconds in a number of informal tests. Time to reach the full 23% test gas indication took 20 to 40 seconds.

If the CGM is drawing a sample out of a tank dome space, the time for the tank vapors to reach the CGM is approximately 26 seconds, based upon the 500 cm^3/min CGM flow and the tubing currently used for flammable gas monitoring. Thus an instantaneous change from 0 to 12.5% of the LFL for hydrogen in air in a tank vapor space (an indicated 25% of the LFL) would not indicate any change at all on a CGM for about 26 seconds. At 26 seconds, the indicated LFL would begin to rise and 33 to 36 seconds after the step change the CGM would indicate about 10% of the LFL. The CGM would indicate 25% of the LFL approximately 45 to 65 seconds after the step change.

If the CGM was being used to sample the immediate work area where a CAS is being used the 26 second delay would not apply, the CGM would start to rise immediately and a reading of 10% of the LFL would be noted 7 to 12 seconds after sensing a 25% step increase in the LFL.

A CGM is an acceptable instrument to use for flammable gas monitoring in dome intrusive or ex-tank regions as long as work is halted upon significant increase in the indicated flammable gas levels. An instantaneous step increase in an entire tank dome vapor space concentration from 0 to 100% of the LFL is not realistic due to the large volume of gas which would be required to be released, although localized spots near the waste surface could show a quick step change to >100% of the LFL from relatively small releases of gases from below the waste surface. The risk is very low that a gas stream would be released from the waste surface of a 75 foot diameter tank and enter a 4 inch diameter riser directly above without the gas being partially diffused by tank vapors. Since monitoring for flammable gases is done in the immediate area when using the CAS, the current response time for CGMs is not a significant concern.

The risk to personnel of internal exposure due to unmonitored airborne radioactivity is a more significant risk than that of a flammable gas ignition event due to a spark from the CAS motor. This competing safety concern requires the monitoring to be performed or the job will be shut down. No Site-approved CASs are currently available that meet the requirements of the Flammable Gas JCO, and initial attempts to identify an intrinsically safe air particulate sampler have failed to identify a substitute.

Monitoring definitions used in the previous sheets are:

[A] Standard monitoring requirements as described in Section 4.4 of this JCO are applicable. The monitoring requirements are graded based on when and where flammable conditions are postulated consistent with the Facility Group assignment, equipment or work locations, and activity or operation type.

[B] For waste intruding equipment activities, perform [A] above. Sampling during waste intrusive activities associated with handling waste intruding equipment is also as specified in [A] above. Monitoring associated with the waste intruding equipment shall include monitoring before any equipment item in the waste intruding equipment vapor space is energized, prior to (or during if necessary) connecting/disconnecting equipment, or prior to working with nonconductive plastic materials.

EXECUTIVE SUMMARY

ES.1 FACILITY BACKGROUND AND MISSION

Public Law 101-510, *National Defense Authorization Act for Fiscal Year 1991*, Section 3137, "Safety Measures for Waste Tanks at Hanford Nuclear Reservation" (known as the Wyden Amendment), mandates that the U.S. Department of Energy develop plans to respond to safety issues associated with the underground waste storage tanks on the Hanford Site. Tank 241-C-106 has been identified as having serious potential for release of high-level waste because of an uncontrolled temperature increase if active cooling is not maintained in the tank.

Ecology, EPA, and DOE, *Hanford Federal Facility Agreement and Consent Order*, is commonly referred to as the Tri-Party Agreement. Milestone M-45-03A of the agreement, "Initiate Sluicing Retrieval of 241-C-106," states "initiate sluicing retrieval of Tank 241-C-106 to resolve the high heat issue and demonstrate waste retrieval." The U.S Department of Energy is taking action to eliminate the safety concern regarding storage of the radiogenic high heat waste in Tank 241-C-106 and to demonstrate a single-shell tank waste retrieval technology.

The proposed action for eliminating the Tank 241-C-106 safety concern, designated as Project W-320, Tank 241-C-106 Sluicing, is the retrieval and transfer of waste from Tank 241-C-106 to double-shell Tank 241-AY-102. Tank 241-AY-102 is designed to safely store high heat wastes.

Project W-320, and related upgrades, subsequently referred to as the Waste Retrieval Sluicing System (WRSS), provides the design, procurement, installation, and testing of equipment as well as the preparation of documentation required to implement the proposed action. The scope of activities covered by this addendum includes presluicing waste transfers, startup support of the Project W-320, sluicing operations, activities through completion of the transfer of the wastes from Tank 241-C-106 to Tank 241-AY-102, and subsequent storage and monitoring of the waste in Tanks 241-AY-102 and 241-C-106.

Per requirements of DOE 5480.21, *Unreviewed Safety Questions*, an Unreviewed Safety Question evaluation (TF-95-0105, *Project W-320, C-106 Sluicing and Waste Retrieval for Storage in AY-102*) has been performed. The Unreviewed Safety Question evaluation determined that U.S. Department of Energy approval of this proposed action is required.

A safety analysis is required to demonstrate conclusively that a safety problem does not exist and to serve as the technical basis for a change to the Authorization Basis. The Waste Retrieval Sluicing System is an operation of limited complexity, limited scope (involving only two tanks), and of limited duration (six months to two years). To satisfy the requirements of documenting a safety analysis in accordance with DOE 5480.23, *Nuclear Safety Analysis Reports*, this safety analysis is prepared per DOE-STD-3009-94, *Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility*

Safety Analysis Reports, and is added as an addendum to the main text of HNF-SD-WM-BIO-001, *Tank Waste Remediation System Basis for Interim Operation* (BIO).

ES.2 FACILITY OVERVIEW

Tank 241-C-106, constructed during 1943 and 1944, is a 2.0 million L (530,000 gal) capacity single-shell tank, a high heat tank (greater than 11.7 kW [40,000 Btu/h]), and a watchlist tank that requires the addition of approximately 22,600 L (6000 gal) of cooling water per month to maintain safe storage temperatures.

Tank 241-AY-102, constructed in the late 1960's, has a rated capacity of 3.7 million L (980,000 gal), and is composed of a primary and secondary steel tank. The life-limiting conditions for Tank 241-AY-102, identified through life prediction models, suggest that Tank 241-AY-102 should not fail by through-wall pitting well beyond 2028. The primary tank wall is not expected to be breached until the year 2033 and the tank is not listed as a watchlist tank.

The major items of equipment provided by the WRSS are two nearly identical pump systems, one for delivery of the sluice stream or supernate to Tank 241-C-106 and the other for delivery of slurry to Tank 241-AY-102; a sluicer system; a slurry distributor; interfarm piping to complete a dedicated, closed-loop sluicing system; Tank 241-C-106 heating, ventilating, and air-conditioning system; and modifications to the Tank 241-AY-102 annulus ventilation system.

The WRSS uses the existing tank farm support systems, modified as required to support Project W-320 requirements. Backup for instrument air is not provided. Backup power is provided for the AY Farm and C Farm tank ventilation systems. Backup power for other systems will be provided as determined by the engineering analysis discussed in Section 4.2, "Requirements." Support services in the form of raw water, sanitary water, electrical power, telecommunications, and hoisting hardware are provided. The use of existing septic systems or portable facilities for sanitary sewage will be considered for the personnel using the control trailer.

ES.3 FACILITY HAZARD CLASSIFICATION

An evaluation to determine the WRSS hazard classification was performed. The WRSS is designated Hazard Category 2 as discussed in Section 3.3.2.1, "Hazard Classification."

ES.4 SAFETY ANALYSIS OVERVIEW

The types of events considered for the WRSS hazard analysis were internal events, external events, and natural phenomena events that can cause the uncontrolled release of radioactive or hazardous materials and affect the public, workers, or the environment. Single and multiple failures (i.e., as a

result of equipment and human errors) and common-cause failures were considered to be accident initiators. Sabotage and terrorism events were not considered. The results of the hazard evaluations and accident analyses were then used to identify a subset of hazardous conditions that bound the consequences and provide a quantitative basis for the identification of controls (e.g., structures, systems, and components and Technical Safety Requirements) required to protect the public, workers, and the environment. The list of bounding, representative hazardous conditions becomes the basis for the list of candidate accidents. As a check of the selection process, each hazardous condition is grouped under a candidate accident. If hazardous conditions that cannot be represented by existing candidate accidents remain, additional candidate accidents are identified. Results of the hazard analysis activities were recorded in a hazard analysis database.

The principal bases used for identifying safety structures, systems, and components and Technical Safety Requirements are risk guidelines. The objective is to identify safety structures, systems, and components and Technical Safety Requirements that result in satisfying the risk guidelines and providing Defense-in-Depth.

The results of an assessment of beyond evaluation basis accidents analyzed to provide a perspective of the residual risk associated with tank farm operations is provided in the BIO main text.

ES.5 ORGANIZATIONS

The Hanford Nuclear Facility near Richland, Washington, is managed by the Department of Energy and its contractors. The main text of the BIO contains the description of key Hanford and Tank Waste Remediation organizations and their responsibilities.

ES.6 SAFETY ANALYSIS CONCLUSIONS

The accident analysis reviewed the safety of new structures, systems, and components to ensure the protection of the public, onsite workers, facility workers, and the environment by preventing or mitigating the consequences of representative accidents. The accident analysis established the additional controls required to operate the Tank Waste Remediation System facility modification through preventive and mitigative requirements.

The hazards associated with normal and abnormal operation of the WRSS have been identified and examined in the preliminary hazard analysis. The preliminary hazards analysis provided a comprehensive list of the hazards related to this activity and its related systems and operations, which is contained in Appendix C, "Hazard Evaluation Results." The hazards analysis was performed in accordance with the methodology described in Section 5.2.1, "Methodology" of the BIO main text. Bounding accidents have been analyzed and equipment has been classified as necessary to protect the public, the onsite worker, facility worker, and the environment.

The safety analysis demonstrates that the Waste Retrieval Sluicing System design provides an adequate safety margin that is appropriate to proceed with operation. The correct design requirements have been established through the safety classification process based on the accident analyses. This addendum addresses the risk of WRSS operation and shows the risk to be acceptable.

ES.7 SAFETY ANALYSIS REPORT ORGANIZATION

This addendum is organized in accordance with current U.S. Department of Energy standards. For those chapters where information would be provided about site-wide programmatic controls, the chapters are abbreviated to reference only documents impacted by this modification. Because the details of existing site-wide programs can be found in the BIO main text, descriptions of those programs are omitted in this addendum.

Chapter 3.0, "Hazard Evaluations and Accident Analyses," describes the methodology and presents the results of the hazard and accident analyses performed for the Waste Retrieval Sluicing System components and operations described in Chapter 2.0, "Facility Description." Chapter 3.0 also includes information pertaining to the designation of the facility hazard classification.

Based on the results of the hazard and accident analyses, Safety-Class and Safety-Significant structures, systems, and components; Technical Safety Requirements; and additional Defense-in-Depth controls are identified for protection of the public, onsite workers, and facility workers. Chapter 4.0, "Safety Structures, Systems, and Components," provides details of the safety structures, systems, and components identified and Chapter 5.0, "Derivation of Technical Safety Requirements," provides the derivation basis of Technical Safety Requirements. Design and operational features required specifically to protect the environment from uncontrolled releases of radioactive and hazardous material are also identified in Chapter 5.0.

1.0 SITE CHARACTERISTICS

1.1 INTRODUCTION

The objective of this chapter is to describe the Hanford Site characteristics as applicable to the Project W-320, Tank 241-C-106 Sluicing activities at the Tank Waste Remediation System facilities. The Waste Retrieval Sluicing System (WRSS) is located in the 200 East Area of the Hanford Site.

1.2 REQUIREMENTS

The site characterization requirements for support of safety analysis and design applicable to WRSS are provided in DOE 4700.1, *Project Management System*, and Hanford Plant Standard HPS-SDC-4.1, *Standard Architectural-Civil Design Criteria: Design Loads for Facilities.*

1.3 SITE DESCRIPTION

This section addresses the site boundary and site location with respect to the WRSS. For site geography, general site description, and demography see Appendix C, Section C1.3 "Site Description," of HNF-SD-WM-BIO-001, *Tank Waste Remediation System Basis for Interim Operation* (BIO) main text.

The WRSS calculation of radiological and toxicological consequences to the maximum offsite individual assumes the maximum Site boundary at the near bank of the Columbia River at a distance of either 8,760 m (28,740 ft) to the north or 8,690 m (28,510 ft) to the north-northwest depending on the duration of the release.

1.4 ENVIRONMENTAL DESCRIPTION

The meteorological data used to calculate atmospheric dispersion coefficients for postulated WRSS accidents is nine-year averaged data (1983-1991) from the Hanford meteorology tower in the 200 Area. Calculation of atmospheric dispersion coefficients is detailed in WHC-SD-WM-SARR-016, *Tank Waste Compositions and Atmospheric Dispersion Coefficients for Use in Safety Analysis Consequence Assessments.* Meteorological data was not examined explicitly by the project.

1.5 NATURAL PHENOMENA THREATS

A natural phenomena threat is an act of nature that poses a threat to workers, the public, or the environment by having the potential to cause damage to systems, structures, or components. Evaluation of natural phenomena

effects to WRSS activities is based on work documented in Section 3.4.2.18, "Natural Phenomena" of this addendum. Natural phenomena threats considered potential WRSS accident initiators include the following:

- Earthquake
- High wind
- Dust storm
- Flooding
- Rain
- Snow
- Volcanic activity
- Lightning
- Range fire
- Extreme cold temperatures.

Natural phenomena were considered to initiate a sequence of events that could result in the release of hazardous materials from a tank ventilation system during WRSS operations.

1.6 EXTERNAL MAN-MADE THREATS

There are no unique external man-made threats for the WRSS. For a full discussion of this subject see Appendix C, Section 1.6, "External Manmade Threats," in the main text of the BIO.

1.7 NEARBY FACILITIES

Accidents attributed to nearby facilities are discussed in Appendix C, Section 1.7, "Nearby Facilities," in the main text of the BIO. There are no unique accidents from nearby facilities identified for the WRSS. The WRSS accidents with the potential to affect the maximum onsite individual are specifically limited to those discussed in Section 3.4.2, "Evaluation Basis Accident," of this addendum.

Tank 241-AY-102 is connected to other nearby tanks in the AY/AZ tank farm through a common connection to the ventilation system (either 241-A-702 or 241-AZ-702). The configuration of the ventilation system was considered in the analysis of accidents unique to the WRSS operations. Tank 241-AY-102 is also connected to other tanks through a common, existing transfer system. There were no accidents unique to WRSS identified with regard to this system.

Tank 241-C-106 is currently shares a ventilation system (296-P-16) with Tank 241-C-105 and an overflow cascade line also connects the two tanks. The new Tank 241-C-106 ventilation system (296-C-006) has no connection to other tanks. Existing configurations were considered in the analysis of accidents unique to WRSS operations.

1.8 VALIDITY OF EXISTING ENVIRONMENTAL ANALYSES

The existing environmental analyses for the WRSS is evaluated in DOE/EA-0933, *Environmental Assessment, Tank 241-C-106 Past-Practice Sluicing Waste Retrieval, Hanford Site, Richland, Washington.* No significant discrepancies have been identified between the WRSS assumptions herein and DOE/EA-0933.

2.0 FACILITY DESCRIPTION

2.1 INTRODUCTION

The purpose of this chapter is to provide a description of the Project W-320, Tank 241-C-106 Sluicing system facilities, equipment, instrumentation, operations and any changes to the description of the Tank Waste Remediation System (TWRS) facility provided in Appendix B, Section 2.0 of HNF-SD-WM-BIO-001, *Tank Waste Remediation System Basis for Interim Operations* (BIO). The sluicing system will be referred to as the Waste Retrieval Sluicing System (WRSS) in this document. Representative accidents unique to the WRSS and its operation as described in this chapter are analyzed in Chapter 3.0, "Hazard Evaluations and Accident Analysis." Defense-In-Depth and Safety-Class or Safety-Significant structures, systems, and components are addressed in Chapter 4.0, "Safety Structures, Systems and Components."

Tank 241-C-106, a 2.0 million-L (530,000-gal) capacity single-shell tank (SST), is a high heat tank [greater than 11.7 kW (40,000 Btu/h)] and a watchlist tank (HNF-EP-0182-120, *Waste Tank Summary Report for Month Ending March 31, 1998*) requiring the addition of up to approximately 22,600 L (6000 gal) of cooling water per month to maintain safe storage temperatures. A significant safety issue has been generated by the need to continue water additions until about the year 2045 when the radiogenic heat of decay will be less than 11.7 kW (40,000 Btu/h), the high heat tank criteria. If a tank leak occurs, it would be desirable to stop water additions to the tank to limit the leakage to the environment. However, if cooling water additions were interrupted, the sludge temperatures would exceed established limits and could cause structural damage to the tank concrete that would allow high-level waste (HLW) to be released from the tank. Should water additions continue into a leaking tank, the leakage would further contaminate the soil column.

Public Law 101-510, *National Defense Authorization Act for Fiscal Year 1991*, Section 3137, "Safety Measures for Waste Tanks at Hanford Nuclear Reservation" (known as the Wyden Amendment), mandates that the U.S. Department of Energy (DOE) develop plans to respond to safety issues associated with the underground waste storage tanks on the Hanford Site and to report progress on implementing those plans to Congress. Tank 241-C-106 has been identified (in accordance with the Wyden Amendment) as having serious potential for release of HLW because of an uncontrolled high-temperature increase if active cooling is not maintained in the tank. According to WHC-SP-0697, *A Plan to Implement Remediation of Waste Tank Safety Issues at the Hanford Site*, Tank 241-C-106 is one of four Priority 1 waste tank safety issues.

Ecology, EPA, and DOE, *Hanford Federal Facility Agreement and Consent Order*, known as the Tri-Party Agreement, Milestone M-45-03A, "Initiate Sluicing Retrieval of 241-C-106," requires RL to "initiate sluicing retrieval of Tank 241-C-106 to resolve the high heat issue and demonstrate waste retrieval." Based on the needs and criteria detailed in WHC-EP-0586, *Tank Selection Criteria and Retrieval Recommendation for Tri-Party Agreement Milestone M-07*, Tank 241-C-106 has been identified as the retrieval demonstration tank by DOE, and the Washington State Department of Ecology, (Ecology) has concurred in this selection.

2.1.1 Safety Issues Background

DOE is taking action to eliminate the safety concern regarding storage of the radiogenic high heat waste in Tank 241-C-106 and to demonstrate a SST waste retrieval technology.

The proposed action is the retrieval and transfer of waste from Tank 241-C-106 to double-shell tank (DST) 241-AY-102. Tank 241-C-106, constructed during 1943 and 1944 is well past its design life, since the original design life of the Hanford single shell tanks was on the order of 20 years. Of the 48 tanks of this type built in this time frame (B, C, T, and U tank farms) 21 are known to be leaking. The life-limiting conditions for Tank 241-AY-102 were identified through WHC-SD-WM-ER-585, *DST Remaining Useful Life Estimates*, the development of life prediction models. The results of this model suggest that this DST should not fail by through-wall pitting until well beyond 2028. The primary tank wall is not expected to be breached until the year 2033. The waste retrieval technology to be demonstrated will employ enhanced past-practice sluicing methods which were successfully employed in retrieving roughly 7.57 million L (2.0 millon gal) of waste solids from 53 SSTs during uranium, cesium, and strontium recovery campaigns in the 1950's, 1960's, and 1970's. Past-practice methods have been enhanced by the addition of a more modern control system, improved pump designs, flow and pressure monitoring instrumentation, routine in tank imaging (CCTV), and transfer line flushing capability.

Project W-320, Tank 241-C-106 Waste Retrieval Sluicing System (WRSS), which represents the proposed action, provides for the design, procurement, installation, and testing of equipment as well as the preparation of documentation required to implement the proposed action. The equipment includes sluice and slurry pumping systems; dedicated (closed-loop) transfer lines; heating, ventilation, and air-conditioning systems; support systems; and modifications to existing tanks and their associated support systems. Documentation includes an Environmental Assessment (DOE\EA-0933, *Environmental Assessment, Tank 241-C-106 Past Practice Sluicing Waste Retrieval, Hanford Site, Richland, Washington*), functional design criteria (HNF-SD-W320-FDC-001, *Functional Design Criteria for Tank 241-C-106 Waste Retrieval, Project W-320*), a safety equipment list (WHC-SD-WM-SEL-033, *Tank 241-C-106 Sluicing Preliminary Safety Equipment List*), a preliminary safety evaluation (WHC-SD-WM-PSE-010, *Preliminary Safety Evaluation for the 241-C-106 Waste Retrieval, Project W-320*), and the BIO.

The scope of this proposed action includes operations activities in support of WRSS such as pre-sluicing waste transfers and startup support, sluicing operation, and storage and monitoring of the waste in Tanks 241-C-106 and 241-AY-102. The proposed action includes activities through completion of the transfer of the wastes from Tank 241-C-106 to Tank 241-AY-102 and subsequent monitoring of Tanks 241-AY-102 and 241-C-106.

2.1.2 Change to Facility Authorization Basis

The WRSS is considered a change to an existing facility Authorization Basis requiring an Unreviewed Safety Question (USQ) evaluation per the

requirements of DOE 5480.21, *Unreviewed Safety Questions*. A USQ evaluation, TF-95-0105, *Project W-320, C-106 Sluicing and Waste Retrieval for Storage in AY-102*, has been performed. The USQ evaluation determined that DOE approval of this proposed action is required.

A safety analysis is required before operations can proceed, in accordance with DOE 5480.21, to determine conclusively what controls and engineered features are required and serves as the technical basis for a change to the Authorization Basis which specifically authorizes WRSS activities. DOE 5480.23, *Nuclear Safety Analysis Reports*, requires safety analysis reports for DOE nuclear facilities. The WRSS is an operation of limited complexity, limited scope (involving only two tanks), and of limited duration (six months to two years). To satisfy the requirements to document the safety analysis of the WRSS in accordance with DOE 5480.23, the safety analysis is prepared according to DOE-STD-3009-94, *Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports*.

2.2 REQUIREMENTS

See Appendix B, Section 2.2, "Requirements," of the BIO main text for descriptions of design codes, standards, regulations, and DOE orders relevant to TWRS. Design requirements for WRSS are presented in HNF-SD-W320-FDC-001.

2.3 FACILITY OVERVIEW

The major pieces of equipment necessary for the WRSS are summarized below. The major equipment items include: two nearly identical pump systems, one for delivery of the sluice stream or supernate to Tank 241-C-106 and a second for delivery of slurry to Tank 241-AY-102; a sluicer system; a slurry distributor; and interfarm piping to complete a dedicated, closed-loop sluicing system (Figures 2-1 and 2-2). Other major equipment items are the Tank 241-C-106 ventilation system and modifications to the Tank 241-AY-102 annulus ventilation system.

2.3.1 Sluice and Slurry Pump Systems

The sluice and slurry pump systems are each made up of two pumps in series (a submersible pump and a booster pump). The booster pump raises the transfer fluid pressure to the level necessary to move the slurry between the two tanks.

2.3.2 Sluicer System

One sluicer is provided to mobilize the Tank 241-C-106 sludge in preparation for transferring the slurry to Tank 241-AY-102. The sluicer will operate in the Tank 241-C-06C sluice pit. The sluicer is vertically articulated with its articulation point located at a fixed elevation (4.7 m [15.5 ft] above the bottom center of the tank) as high as practical in the tank.

2.3.3 Slurry Distributor (Tank 241-AY-102)

The slurry from Tank 241-C-106 is discharged into Tank 241-AY-102 through a slurry distributor. The slurry distributor is a straight 4-in. pipe with four 2-in. diameter horizontal nozzles spaced at 90° intervals that are located at a fixed 3.8 m (12.5 ft) elevation in the tank. The slurry lines, and slurry distributor will be routinely flushed during WRSS operations to ensure that solids build-up in the system does not occur. Uniformity of the distributed layer of sludge in Tank 241-AY-102 will be determined at each sluicing increment through temperature data in combination with the ENRAF densitometer measurement.

A high capacity drain is incorporated into the slurry distributor head assembly installed at Pit 241-AY-02A, Riser 6. The high capacity drain is sized to drain all liquid from within the pit in the event a transfer line break were to occur during maximum flow. Liquid accumulating within the pit which overcomes the existing pit floor drain is channeled through the high capacity drain, down the respective riser, and into the tank. A drain plug is provided to seal the high capacity drain when pit cover blocks are removed.

2.3.4 Interfarm Piping

The waste is transferred through two encased pipelines, one for delivery of sluicing media (Tank 241-AY-102 supernate) to Tank 241-C-106 and the other for transporting slurry to Tank 241-AY-102. These pipelines are approximately 0.5 km (0.3 mi) each in length. The primary lines are designed to withstand a maximum pressure of 2.2 MPa (320 psig). This provides a conservative margin to the maximum expected WRSS operations pressure range of 0.7 - 1.4 MPa (105 - 200 psig) at the nominal 1325 L/min (350 gal/min) flow rate. They are provided with leak detection, either buried or covered with an earthen berm to limit personnel dose to tank farm workers in accordance with As Low As Reasonably Achievable (ALARA) practices, and have a seismic trip switch to shut off the pumps in case of an earthquake.

2.3.5 Tank 241-C-106 Sluicing Ventilation System

The Tank 241-C-106 ventilation system (296-C-006) serves to: (1) cool the tank, (2) maintain the tank at a negative pressure relative to atmosphere, which discharges a decontaminated ventilation stream to the atmosphere and (3) dilute the flammable gasses generated in the tank. The system is a combination recirculation and exhaust system. The recirculation portion of the system is used to provide the needed cooling. The exhaust portion of the system maintains the required negative pressure in the tank and flammable gas dilution. The 296-C-006 ventilation system is the only ventilation system that will be in operation on Tank 241-C-106 during active sluicing operations. Figure 2-5 provides a diagram of the 296-C-006 system. The 296-C-006 process building inlet duct includes a flushing feature to allow the duct to be washed down internally to reduce operator exposure. This feature would be used in the event that internal contamination levels produce radiation levels in the area around the ducting which do not meet ALARA guidelines.

An older ventilation system (296-P-16), the Tank 241-C-105/106 ventilation system also serves Tank 241-C-106. It will be maintained in an operational standby status as a backup system for cooling Tank 241-C-106, but will only be used to cool the tank before sluicing and during monitoring or maintenance periods. However, the main function of the older ventilation system will be to cool the Tank 241-C-106 waste before initiation of sluicing to reduce the potential for a steam release event during the retrieval activity and to provide a high-flow exhaust system to support Tank 241-C-106 open-riser maintenance activities.

2.3.6 Tank 241-AY-102 Ventilation System

The Tank 241-AY-102 primary ventilation system, 241-A-702, (1) cools the tank, (2) maintains the tank at a negative pressure while discharging a decontaminated ventilation stream to the atmosphere and (3) dilutes the flammable gases generated in the tank. Figure 2-7 provides a diagram of the 241-A-702 system. A new ventilation system, 241-AZ-702, was installed by Project W-030 and is available for use by the WRSS.

The 241-AZ-702 ventilation system uses separate systems for cooling and/or confinement and for exhausting. However, 241-AZ-702 and the existing ventilation system, 241-A-702, both rely on evaporative cooling to maintain waste temperatures. The exhaust system contains HEPA filtration and stacks similar to the existing design. A separate recirculating system is added for cooling and confinement. This additional system greatly reduces the amount of air vented out the stack. The 241-AZ-702 system will have three operating modes available: recirculation, high heat, and by-pass. It is planned that the WRSS will utilize the 241-AZ-702 system which is currently being installed. This safety assessment bounds the filtration, flow, and cooling capacity of the 241-AZ-702 system and the 241-A-702 system (which may be used as a contingency). Figure 2-9 provides a diagram of the 241-AZ-702 system.

The annulus space in Tank 241-AY-102 is provided with a dedicated, independent ventilation system. Figure 2-8 provides a diagram of the annulus ventilation system. The cooling capacity of the annulus ventilation system has been upgraded to increase the underfloor flow rate and increase the vacuum capacity. Both conservative and best estimate calculations have been developed for the required annulus cooling parameters as a function of the incremental waste volume that is transferred from Tank 241-C-106 to Tank 241-AY-102 (HNF-SD-W320-ER-004, *Project W-320 SAR and Process Control Thermal Analysis*). The best estimate calculations show that all of the sludge in Tank 241-C-106 can be accommodated in Tank 241-AY-102 without further modification to the ventilation system. Conversely, when conservative values for waste fluffing factor, heat load, and heat distribution are selected, these calculations indicate that additional cooling capacity may be required (i.e., additional blowers and/or a chiller may need to be installed). However, even the conservative calculations show that a transfer of 2 feet (0.61 m) of sludge to Tank 241-AY-102 can be cooled with the current ventilation system. Thus, the initial sluicing campaign will be limited to 2 feet (0.61 m) (or less) of sludge. Following the transfer of the initial (and each subsequent) increment, an evaluation of the system will be performed to determine its ability to maintain the waste at 30 °F below local saturation

temperature as required by Technical Safety Requirements (TSR) controls (Administrative Control [AC] 5.12.2 and AC 5.25.2). If this evaluation (i.e., thermal monitoring and modeling) indicates that 30 °F subcooling cannot be maintained for further waste additions, then the Tank 241-AY-102 ventilation system will be modified, with the addition of blowers or a combination of blowers and chillers, before transferring additional waste. It is important to note that this safety assessment analyzes the entire 6-ft waste transfer to provide bounding accident consequences.

2.3.7 Seismic Shutdown System

Seismic shutdown systems are provided as part of the Tank 241-C-106 and the 241-AY-102 WRSS electrical systems. Each seismic shutdown system consists of two seismic triggers connected in series. Each of the triggers are housed in separate environmental enclosures which protect the triggers and provide a controlled internal temperature of approximately 50 °F to 85 °F.

Both the Tank 241-C-106 and the Tank 241-AY-102 seismic systems are essentially identical. The seismic systems serve to shutdown waste transfer operations by interrupting electrical power to the submersible pumps, the booster pumps, and other WRSS components in the event a seismic event occurs which results in a ground acceleration above the trigger set point value. The individual seismic triggers open the control circuits of a contact when a seismic event occurs. The contacts remain open during and after the seismic event.

2.4 FACILITY STRUCTURES

2.4.1 Systems Descriptions

The major equipment provided by WRSS is described in detail in this section. The transfer system that consists of the sluice pumps, slurry pumps, winch assemblies and encased transfer lines which include anti-syphon and cathodic protection systems are described. Other major pieces of equipment provided specifically for Tank 241-C-106 include the sluicer system, the sluicing ventilation system, the air inlet chiller and an in-tank imaging system. The major pieces of equipment provided for Tank 241-AY-102 are the slurry distributor and the sluicer pumps. A portable in-pit imaging system is used, as necessary, at pits over both tanks.

2.4.1.1 Tank 241-C-106.

2.4.1.1.1 Tank Configuration. Tank 241-C-106 is beyond its design life as it was constructed during 1943 and 1944. It has a rated capacity of approximately 2.0 million L (530,000 gal), at a vacuum less than 1.3 m (50 in) of water. The tank is 23 m (75 ft) in diameter, and is fabricated of reinforced concrete with a carbon steel liner on the bottom and sides. The tank has a 31 cm (12 in) deep, dished bottom and a useable waste depth of about 4.9 m (16 ft) at the sidewall. The bottom of the tank is 15 cm (6 in) thick reinforced concrete covered with a 5 cm (2 in) layer of asphalt

composition material, placed between the steel liner and the reinforced concrete during construction to seal the outer surface of the steel liner and to provide a moisture barrier, and a 1 cm (3/8 in) steel plate liner. The knuckle (the transition section from bottom to sidewall) is a 1 cm (3/8 in) thick steel plate. The tank walls are 33 cm (13 in) thick reinforced concrete; the steel liner extends 5.5 m (18 ft) up the straight side of the tank, varying in thickness from 0.6 to 1 cm (1/4 to 3/8 in). The top of the steel liner is covered with lead flashing to prevent moisture from entering any spaces between the liner and concrete wall. The dome of the tank is constructed of 38 cm (15 in) thick reinforced concrete. No liner is provided for the concrete dome. The tank is shown in plan and elevation in Figure 2-3 and in pictorial cross-section in Figure 2-4.

Tank 241-C-106 contains 746,000 L (197,000 gal) (about 1.75 m [69 in.]) of sludge with a total heat load estimated at 38.8 kW (132,400 Btu/h) as of June 1994 (HNF-SD-W320-ER-004). The total heat load and, in part, the heat load distribution determine the peak temperature in the sludge. If this peak sludge temperature exceeds the local saturation temperature, a bump can occur. Tank 241-C-106 is on the High Heat Watch List and must receive periodic water additions to maintain the waste temperatures within allowable limits. The waste temperatures are maintained with evaporative cooling by means of active ventilation.

2.4.1.1.2 Ventilation. The Tank 241-C-106 ventilation system (296-P-16) serves to: (1) cool the tank, (2) maintain the tank at a negative pressure relative to atmosphere while discharging a thoroughly decontaminated ventilation stream to the atmosphere and (3) dilute the flammable gases generated in the tank. The system provides a nominal flow rate of 67.9 m^3/min (2400 ft^3/min) and has multiple capabilities, combining the functions of pressure, temperature, and humidity control. It includes equipment to limit the release of hazardous aerosols and a ventilation exhaust radiation monitoring system to confirm the effectiveness of the ventilation system to maintain emissions of radionuclides ALARA in compliance with Washington Administrative Code, WAC 173-480, "Air Pollution Control Regulations."

The project has installed a ventilation system chiller in combination with an inlet filter cooling coil on the 296-P-16 ventilation system, designed to cool the tank contents. This provides a constant 4.4 °C (40 °F) inlet air flow, which is adequate on a long-term basis to preclude the existence of a steam bubble in the waste (NAI-940708-3, *GOTH Tank C-106 Thermal Hydraulics Analysis Related to the 1995 Process Test*). However, even with the chiller and inlet filter cooling system, reduced water additions will continue until an adequate volume of high heat waste is removed from the tank.

In addition to the chiller and filter cooling coil, a new ventilation system (296-C-006) for Tank 241-C-106 is installed as part of WRSS and provides a nominal exhaust flow rate of 6.5 m^3/min (230 ft^3/min) with a recirculation flow rate of up to 24 m^3/min (860 ft^3/min) (Figure 2-5). The recirculation portion of the system is used to provide the needed cooling. The exhaust portion of the system maintains the required negative pressure in the tank and flammable gas dilution. There is a cascade line between

Tanks 241-C-105 and 241-C-106 which is assumed to be open in the HVAC system design. Major pieces of ventilation equipment are mounted on transportable skids (WHC-SD-W320-TI-002, *Project W-320 Tank 241-C-106 Sluicing Process*).

The ventilation system has been designed to:

- Maintain a negative tank pressure
- Remove heat from the tank and dehumidify recirculating air
- Remove aerosols from ventilation emissions
- Monitor the exhaust ventilation emissions stream through the exhaust stack to the atmosphere
- Use the existing ventilation system for active ventilation for extended maintenance or additional tank cooling (before or during the sluicing retrieval activity)
- Reduce formation of fog in the tank vapor space by recirculating de-humidified air into the tank to improve visibility for the remote viewing cameras in accordance with WHC-SD-W320-TI-002 (fog formation is not eliminated under all anticipated conditions)
- Dilute the flammable gases generated in the tank.

To minimize releases to the atmosphere from the ventilation system on Tank 241-C-106, a high-efficiency particulate air (HEPA) filtration system is installed on Tank 241-C-106. A high-efficiency mist eliminator (HEME) and a high-efficiency metal filter (HEMF) are also included in this system.

Instrumentation to monitor the condenser (HX-1361) air stream differential pressure, air stream inlet temperature, air stream outlet temperature, heating coil (HC-1361) outlet temperature, recirculation fan (FN-1361) differential pressure, and motor current is provided. Instruments to monitor HEME (HME-1361) and HEMF (HMF-1361) differential pressures and HEME outlet temperature are also provided. Position switches indicate the HEMF flush water and/or blowdown air inlet valve and drain valve positions to the control station operator.

New exhaust ducts have been designed and installed to discharge through the new filtration system. The old ventilation system and ducts will remain in place and operational for Tank 241-C-105 and Tank 241-C-106 major maintenance operations. During these infrequent major maintenance operations, an air flow of approximately 85 m^3/min (3000 ft^3/min) would be discharged through this ventilation system.

A HEME and HEMF unit is installed upstream from the HEPA filtration units, which would catch the majority of the contaminants before they reach the HEPA filters. The HEME and HEMF are included to meet ALARA requirements, which are designed to minimize worker exposure to the greatest extent possible. Because the HEME and HEMF are flushable, little or no solid waste

is expected to be generated by the entire air filtration system. At the conclusion of the waste retrieval activities, the disposable part of these filter units would be disposed of at the Hanford Site.

To control the temperature and humidity of the Tank 241-C-106 vapor space during sluicing, a recirculation line in the ventilation system was installed. This recirculation line consists of a condenser, a mist eliminator, a heater and a recirculation fan. The condenser provides a means of removing excess heat from the tank to allow sluicing to proceed safely and efficiently. If it is determined by thermal modeling (HNF-SD-W320-ER-004) that a higher cooling rate is needed, this cooling may be accomplished by activating the original high-capacity ventilation system to allow the inlet air chiller to be used. This cooling approach can only be used during periods when sluicing is not operating.

The 296-P-16 HVAC system will be used to ventilate Tank 241-C-106 during large riser (12 and 36 inch diameter risers) opening maintenance activities to maintain inflow rates at capture velocities. It may also be used during maintenance outages of the 296-C-006 HVAC system depending on their duration. The added air flow provided by the existing ventilation system may also be required periodically during the life of the project to maintain waste temperatures (i.e., ensure a continued adequate margin below any steam void formations). Air is drawn through the headspace using the existing Tank 241-C-105/106 exhauster (296-P-16).

2.4.1.1.3 Existing Instrumentation. Table 2-1 lists the existing instrumentation, prior to WRSS, for Tank 241-C-106. The signals are used to provide alarms as well as to provide data input for logging and trend analysis.

2.4.1.2 Tank 241-AY-102.

2.4.1.2.1 Tank Configuration. Tank 241-AY-102 was constructed in the late 1960's and has a rated capacity of 3.7 million L (980,000 gal). It is an underground, carbon steel, radioactive waste tank encased in a concrete shell. Tank 241-AY-102 consists of a primary steel tank with an inner diameter of 22.9 m (75 ft) and a secondary concrete, steel-lined tank with an inner diameter of 24.4 m (80 ft). The free-standing height of the primary tank is 14.3 m (46.9 ft) to the top of the dome. The thickness of the carbon steel tank bottom varies from 1 to 2.54 cm (3/8 to 1 in). The wall thickness varies from 1 to 1.9 cm (3/8 to 3/4 in), with the thicker plates at the bottom. The maximum liquid level is about 11 m (35 ft) from the bottom. There are 22 airlift circulators located in Tank 241-AY-102: one at the tank's center axis, 8 equally spaced at a radius of about 4.4 m (14.5 ft), and the remainder equally spaced at a radius of about 8.2 m (27 ft).

The tank-in-tank concept ensures that any leakage from the primary tank will be contained in the annulus between the tank walls, allowing transfer of the contents to another tank. The second barrier meets the requirement of DOE 6430.1A, *General Design Criteria*, Sections 1300-3.3 and 1323, that a single failure not result in a loss of safety function.

The tank is connected to other tanks through a network of underground transfer piping, diversion boxes, diverter stations, and valve pits. Tank 241-AY-102 is shown in an elevation view in Figure 2-2 and in a pictorial cross section in Figure 2-6.

Tank 241-AY-102, a double-shell tank, contains 121,000 L (32,000 gal) (about 305 mm [12 in.]) of sludge and 3.1 million L (812,000 gal) of supernate for a total waste depth of about 9 m (30 ft). The estimated heat load of Tank 241-AY-102 is 13.2 kW (45,000 Btu/h) (HNF-SD-W320-ER-004).

2.4.1.2.2 Ventilation. The 241-A-702 primary, and available backup ventilation systems, (1) cools the tank, (2) maintains the tank at a negative pressure and (3) dilutes the flammable gases generated in the tank (Figure 2-7, sheets 1 and 2). The annulus ventilation system ventilates and provides filtered air to the tank annulus (Figure 2-8). The 241-A-702 primary ventilation system exhausts the Aging Waste Facility (AWF) tanks (241-AY-101, 241-AY-102, 241-AZ-101, and 241-AZ-102), two catch tanks (241-AZ-151 and 241-AZ-154), and the 241-AX-152 diverter station. Two 113 m^3/min (4000 ft^3/min) exhausters operate, one at a time, to draw the gases through an extensive particulate and condensate removal system before discharging to the atmosphere via the 296-A-17 stack. This design has a heat removal capacity of 4 million Btu/h per tank (16 million Btu/h for the AWF) assuming the heat generating materials are maintained in suspension, thus enabling convective cooling.

The 241-A-702 backup ventilation system is a skid-mounted 113 m^3/min (4000 ft^3/min) exhauster. It provides containment of radioactivity should the primary exhaust fans fail during testing and maintenance of the 241-A-702 primary system, and during chemical flushing or upper pad water flushing of the K1-5-2A deentrainer. The backup exhaust fan starts automatically upon failure of both primary exhaust fans. This system uses the deentrainers and condensers of the 241-A-702 primary system but has its own preheater, HEPA filters, and ventilation fan.

The Project W-030 ventilation system (241-AZ-702) replaces the 241-A-702 and uses separate systems for cooling and/or confinement and for exhausting (Figure 2-9). However, 241-AZ-702 and the existing ventilation system, 241-A-702, both rely on evaporative cooling to maintain waste temperatures. The exhaust system contains HEPA filtration and stacks similar to the existing design. A separate recirculating system is added for cooling and confinement. This additional system greatly reduces the amount of air vented out the stack. Because of this reduced flow rate, Tank 241-AY-102 inleakage pathways will be sealed to the maximum extent practical to maintain negative pressure in the tank.

Project W-030 has three operating modes available: recirculation, high heat, and by-pass. Operation of the 241-AZ-702 system in the recirculation mode will have flow rates of 14.2 m^3/min (500 ft^3/min) with 11.3 m^3/min (400 ft^3/min) recirculated and only 2.8 m^3/min (100 ft^3/min) exhausted through the stack. In the high heat mode, the system can provide 14.2 m^3/min (500 ft^3/min), single-pass ventilating to one of the AWF tanks. The normal mode provides 2.8 m^3/min (100 ft^3/min), single-pass ventilation per AWF tank. The new design will have one recirculating system per tank while sharing a

common exhaust stack. The new design also will contain some additional components such as a high-efficiency gas absorber and a high-efficiency mist eliminator.

The annulus ventilation system provides filtered air to the annulus area on Tank 241-AY-102 to monitor for primary tank leaks; minimize moisture accumulation; remove a major portion of the heat generated in the primary tank; and ventilate the leak detection pits. The annulus ventilation system supplies air through two routes: (1) a direct supply to the annulus via eight tank drop legs, of which four 14.7 cm (6 in) lines deliver air at approximately midpoint and four 10.2 cm (4 in) lines deliver air to the underfloor distribution plenum at the center of the tank; and (2) an underfloor air distribution grid work system. The underfloor flow is approximately 4.3 m^3/min (150 ft^3/min). To direct cooling flow to the floor of the tank, the annulus system upgrade will be performed to block the flow to the four 14.7 cm (6 in) annulus supply lines and to operate at a higher vacuum and exhaust flow rate. As described in Section 2.3.6, "Tank 241-AY-102 Ventilation System," an inlet system blower, or an inlet system blower and chiller can be installed to maintain the waste at 30 °F below local saturation temperature. These upgrades will enhance the cooling capacity of the annulus ventilation system to meet the cooling capacity needs of the tank based on thermal analysis of observed waste conditions (volume, fluffing factor, and tank temperature response). This evaluation is performed following each sluicing increment according to the control (AC 5.25) specified in Section 3.4.2.11, "Tank Bump."

2.4.1.3 Pump Systems. The pump systems (located in the 241-AY-02E pit and the 241-C-06A pit, respectively) each include two pumps in series. The first is a centrifugal, 40-hp submersible pump mounted on a winch system that allows its height to be adjusted. The submersible pump feeds a 250-hp, variable speed centrifugal booster pump located in the pump pit above the submersible pump. The booster pump raises the transfer fluid pressure to the level necessary to transit the distance between the two tanks at the nominal 1325 L/min (350 gal/min) flow rate and 2.7 m/s (8.7 ft/s). The booster pump variable speed drive allows fine-flow adjustments to control the tank liquid level. The submersible in-tank pumps are equipped with winches that adjust height of the pump to control the liquid level, enhance sluicing efficiency, and allow adjustment of the pump height to meet net positive suction head requirements as the liquid level changes.

The slurried waste in Tank 241-C-106 is transferred using a submersible slurry pump (P-1361) in series with a centrifugal slurry booster pump installed in pump pit 241-C-06A. The submersible slurry pump is a direct-drive, end-suction, 40-hp submersible pump installed in the 91 cm (36 in), R-9 riser in pump pit 241-C-06A. The slurried waste pressure is then increased by the centrifugal slurry booster pump, which is a 250-hp, vertical direct drive, variable-speed pump that will deliver the slurried waste to Tank 241-AY-102. Together the submersible slurry pump and slurry booster pump are rated to deliver 1325 L/min (350 gal/min) or 2.7 m/s (8.7 ft/s) at 195 m (640 ft), operating at a temperature of 49 °C (120 °F), and have a structural design temperature of 82 °C (180 °F). The temperature of the slurry in the transfer system at the beginning of sluicing operations is anticipated to be between 80 and 90 °F. The slurry temperature will increase slowly during the

active sluicing operations as the result of the energy inputs of the pumps. The resulting heating of the pumped fluids was evaluated (TR-W-320-126, *Project W-320, Tank 241-C-106 Sluicing - An Analysis of Energy and Temperature Effects for Tank AY-102*) and after 30 days of nearly continuous pumping operations the temperature was estimated to increased to approximately 120 °F.

Because sluicing operations will be intermittent (short period of sluicing followed by longer periods of observation), it is not anticipated that the 120 °F limit will be reached during sluicing operations.

The planned manner of control of the liquid level in Tank 241-C-106 is adjustment of the Tank 241-AY-102 booster pump speed. The speed of the slurry booster pump will be adjusted to give a 1325 L/min (350 gal/min) flow rate with zero solids loading, after which the speed will remain constant for the most part. This will result in a nominal flow rate of 1174 L/min (310 gal/min) at 10% solids loading based on pump run-in curves adjusted for the specific gravity and viscosity of the 10% slurry. This information is included in the WRSS Process Control Plan (PCP). The PCP will include pump performance information for a range of pump speed settings and solids loading. The 350 gpm pump flow rate is a nominal value, not a limiting operational value. Operations accidents have been analyzed for flow rates up to 450 gpm and pumping operations may be conducted down to flow rates as low as 250 gpm. Therefore, the pump flow rate for a 10% slurry loading with the booster pump speed set to provide 350 gpm with zero percent solids is not significant from a safety standpoint.

The main purpose for having a variable-speed slurry booster pump is to help maintain an optimum liquid heel in the tank. This will allow positive control while monitoring parameters such as level, temperature, and slurry concentration.

Operating experience gained from operation of the WRSS will be applied to future sluicing campaigns in other tanks, since one of the objectives of this activity is sluicing technology demonstration.

Local controls and indications for the Tank 241-C-106 submersible slurry pump (P-1361) and the variable-speed-drive slurry booster pump (P-1362) are provided at the motor control center and the variable-speed-drive cabinet located in the C Tank Farm's electrical equipment skid. In addition, remote controls and indications for the two pumps including suction and discharge pressure and volumetric flow rate, winch position control, and pump start/stop control, are provided locally. The slurry booster pump's motor speed and voltage, as well as motor current, bearing, and stator temperatures for both pumps are furnished at the electrical equipment skid. Alarms, via the panel-mounted annunciators, alert the operator to abnormal conditions. The control of the pump will be addressed in the process control plan and WRSS operating procedures.

The submersible slurry pump suction inlet has been designed to minimize vortexing and is protected by a heavy gauge, 0.6 cm (1/4 in) mesh screen that will prevent the entrainment of large sludge conglomerations. This mesh screen can also be backflushed during shutdown periods by flushing from Tank 241-AY-102.

The base plate of each winch assembly includes a 6-inch diameter high capacity drain. The high capacity drains are sized to drain all liquid from within the pit in the event a guillotine line break were to occur during maximum flow. Liquid accumulating within the pit which overcomes the existing pit floor drain is channeled through the 6-inch drain hole, down the respective riser, and into the tank. A drain plug is provided to seal the high capacity drain when pit cover blocks are removed.

2.4.1.4 Sluicer System. One sluicer is provided to mobilize the Tank 241-C-106 sludge in preparation for transferring the slurry to Tank 241-AY-102. The sluicer operates in the Tank 241-C-06C sluice pit. The sluicer is a remotely articulated design with a fixed-elevation articulation point located as high as practical in the tank to maximize impact point control of the sluice stream. The sluicer design prevents the sluice stream from being aimed above the tank liner. A control system has been provided to control the aiming of the sluicing stream from the sluicer (S-1361). During the early stages of sluicing the sluice stream will not be aimed directly at the tank walls. The perimeter of the tank will be sluiced last to minimize the amount of material that could potentially leak through the tank wall as a result of sluicer impingement on areas weakened by corrosion. The sluicer is equipped with a 2.5 cm (1 in) nozzle that is designed for a pressure drop of 1.24 kPa (180 psig). A sluicer arrangement diagram is provided in Figure 2-10. Aiming of the sluicer nozzle is accomplished by using a self-contained hydraulic system in which hydraulic cylinders provide the azimuth and rotational control. The sluicer positioning control system has two control modes: Manual and Semi-Automatic. The selection of the mode to be used depends on the operational needs, the situation in the tank, and operational experience gained during the startup phase of the project.

Clarified supernate (Sanders 1995, *Project 93L-EWW-320, Tank 241-C-106 Sluicing-Sluicing Fluid Baseline Change to Corrosion Inhibited Water*) is delivered to the sluicer nozzle in Tank 241-C-106 via a submersible sluice pump (P-0621) in series with a sluice booster pump (P-0622) installed in sluice pit 241-AY-02E. The submersible and booster sluice pumps are identical to the counterpart slurry pumps. Only minor jumper and winch assembly differences required by the pit arrangements differentiate the two pumping systems. The submersible pump is installed in the 86 cm (34 in) R-10C riser with the booster installed in the sluice pit 241-AY-02E above. The sluice pump system has the same capacity, pressure, and temperature characteristics as the slurry pump system.

The speed control of the sluice booster pump (adjusted through a variable frequency drive) is used to control the flow rate of the pumped waste. Local controls and indicators for the submersible sluice pump (P-0621) and the variable speed drive sluice booster pump (P-0622) are provided at the 241-AY Tank Farm operator station located in the 241-AY-51 Tank Farm electrical equipment skid. Pump discharge pressure and volumetric flow, booster pump motor speed and voltage, motor current, bearing, and stator temperatures for both pumps are also provided for operator information.

The slurry concentration is controlled by a combination of sluicer aiming and slurry pump suction height adjustment. The submersible sluice pump's suction height is regulated by a remotely adjustable winch from the control

station to minimize the solids loading in the sluice stream and maintain the required net positive suction head. With the exception of the painted carbon steel motor casings and the two pump liquid level detector housings, all wetted surfaces of the pumps are constructed of 300 Series stainless steel. The suction inlet of the submersible sluice pump has been designed to minimize vortexing and is protected by a heavy gauge, 0.6 cm (1/4 in) mesh screen that prevents the entrainment of large sludge conglomerations, and is capable of being backflushed, if necessary, through the sluice line flushing connection at Tank 241-AY-102. There are no provisions for reducing particle size below the inlet screen size and that attained by vigorous agitation from the sluice stream. The schedule 40 stainless steel pipeline has sufficient wall thickness to support the anticipated erosion for the less than 1000 hours of planned slurry transfer.

A high capacity drain is incorporated into the sluicer assembly installed at Pit 241-C-06C, Riser 3. The high capacity drain is sized to drain all liquid from within the pit in the event a guillotine line break were to occur during maximum flow. Liquid accumulating within the pit which overcomes the existing pit floor drain is channeled through the high capacity drain, down the respective riser, and into the tank. A drain plug is provided to seal the high capacity drain when pit cover blocks are removed.

2.4.1.5 Existing Instrumentation. Table 2-2 lists the Tank 241-AY-102 existing instrumentation (prior to WRSS) for tank liquid-level monitoring (using ENRAF and manual tapes), temperature monitoring, pressure and vacuum monitoring, and leak detection systems. The signals are used to provide alarms as well as to provide data input for logging and trend analysis.

2.4.1.6 Leak Detection. Any leaks from primary Tank 241-AY-102 would be contained in the annulus between the primary and secondary tanks. The annulus is designed to collect and transport released waste to a common point within the annulus for detection and transfer. Leak detection is also provided in the pits located on the tank dome.

The supernate and slurry transfer piping encasements are provided with a leak detection system at pump pit 241-C-06A. The fluid that is collected in the encasement piping drains by gravity to the respective pit connected to the piping and returns to Tank 241-C-106. A manual valve, with an extended valve handle operator, is located at the low point in the encasement drain line to permit the operator to isolate the piping leakage from the pit and/or to pressure test the encasement piping.

An existing dry well monitoring system coupled with the ENRAF provides limited leak detection surveillance for Tank 241-C-106. The wells are open-bottomed, either 15 or 20 cm (6 or 8 in) diameter mild steel casings, with depths ranging from 25 to 33 m (75 to 100 ft). On a monthly to quarterly schedule radiation probes determine the radiation profile in the well.

2.4.1.7 Primary Transfer Pipes. There are two primary transfer lines, with the following major features:

Clarified supernate line

- From a functional standpoint, solids content must be less than 10 wt% per the project functional design criteria (HNF-SD-W320-FDC-001). Solids loading in the slurry line is periodically verified by performing material balance calculations during the hold periods between sluicing activities. Grab samples will be taken periodically to validate the material balance. Because of the volume of supernate in Tank 241-AY-102, 10% solids loading is not considered possible unless nearly all solids from Tank 241-C-106 remain in suspension.

  The 10% solids loading in the supernatant line is not a rapidly changing parameter due to the large volume (greater than 500,000 gallons) of supernatant liquid in Tank 241-AY-102. The combination of relatively high solids settling estimates (based on core sample particle size distributions) and intermittent sluicing operations make achieving the 10% figure virtually impossible. The solids loading in Tank 241-AY-102 is monitored by a combination of the Tank 241-AY-102 ENRAF densitometer and grab samples.

- Maximum viscosity of the supernate at a 10 wt% solids loading is 20 centipoise (cP). Viscosity is not directly measured. It is controlled indirectly by the same methods used to control solids loading.

- The line is made of 10 cm (4 in), welded, schedule 40, 304L stainless steel. Design and performance attributes of the piping system are addressed in HNF-SD-W320-TI-008, *Tank 241-C-106 Sluicing Project W-320 Integrity Assessment Report*.

- The pipeline length is 0.5 km (0.3 mi).

- The line delivers supernate from Tank 241-AY-102 to the sluicer in Tank 241-C-106.

- Flow velocity in the pipes is nominally 2.7 m/s (8.7 ft/s) and the flow is nominally 1325 L/min (350 gal/min).

Slurried waste line

- Solids content is to be limited to 30 wt% per the project functional design criteria (HNF-SD-W320-FDC-001). Solids loading is measured during sluicing by mass flow meter, and periodically verified during the hold periods between sluicing activities.

- Maximum viscosity of the slurry at 30 wt% solids loading is 100 cP. Viscosity is not directly measured. It is controlled indirectly by the same methods used to control solids loading.

- The line is made of 10 cm (4 in), welded, schedule 40, 304L stainless steel. Design and performance attributes of the piping system are addressed in HNF-SD-W320-TI-008.
- The pipeline length is 0.5 km (0.3 mi).
- The line delivers slurry from Tank 241-C-106 to Tank 241-AY-102 via the slurry distributor.
- Flow velocity in the pipes is nominally 2.7 m/s (8.7 ft/s) and the flow is nominally 1325 L/min (350 gal/min).

Both of the primary transfer lines will meet the design, fabrication, installation, and testing requirements of normal service fluid (ANSI/ASME B31.3-1993, *Chemical Plant and Petroleum Refinery Piping*). As needed, thermal expansion elbows are placed for stress reduction and to follow topography (minimum bend radius 1 m [3.3 ft]). Stainless steel was chosen for corrosion resistance and for ease of decontamination in preparation for disposal following project completion.

2.4.1.8 Secondary Transfer Pipes. The secondary (encasement or outer) transfer pipes are of welded 15.2 cm (6-in.), schedule 40, carbon steel. The primary pipe is installed within the secondary pipe. The two secondary transfer (encasement or outer) pipes provide secondary confinement for the two primary transfer pipes. Both secondary transfer lines have provisions for leak detection at their low points. Additional leak detectors are provided within pump pit 241-C-06A, and sluice pit 241-C-06C. Any leakage collected at the transfer piping encasement low points or at the pits will be returned to Tank 241-C-106. Leaks to pump pit 241-AY-02A and sluice pit 241-AY-02E are monitored by existing leak detectors that alarm locally. The 241-AY-02A pit leak detector also alarms via the Computerized-Automated Surveillance System. Any leakage collected in these pits is returned to Tank 241-AY-102 by the respective pit drains.

The two pipe-in-pipe transfer lines are buried or bermed (a minimum of 0.9 m [3 ft] of earth cover between farms and 0.6 m [2 ft] of earth cover in farms) for freeze protection and to maintain personnel radiation exposure ALARA. This berm is an earth backfill and is covered with an aggregate stabilizer to prevent wind erosion. Each transfer line will be about 0.5 km (0.3 mi) in length and has been designed to slope continuously from 0.003 ft/ft to 0.10 ft/ft from Tank 241-AY-102 to Tank 241-C-106 to facilitate self-draining. This prevents any liquid stagnation in the lines during system shutdown. All transfer piping has a design operating temperature limit of 82 °C (180 °F) (WHC-SD-W320-TI-002).

2.4.1.9 Cathodic Protection System. A cathodic protection system is provided for the transfer lines to mitigate the effects of external corrosion.

2.4.1.10 Transfer Pits. The WRSS provides for new and modified waste transfer piping, pumps, flanges, jumpers, connectors, and instruments to be in the pits. The supernate is transferred directly to sluice pit 241-C-06C from Tank 241-AY-102. The 241-C-06A pit contains the slurry pump (P-1361), the slurry booster pump (P-1362), the slurry pump winch, and the slurry header

flow and pressure-measuring instrumentation. At the C Tank Farm, the sluicing pits 241-C-06A and 241-C-06C are used as transfer pits. At the AY Tank Farm, pump pit 241-AY-02A and sluice pit 241-AY-02E are used as transfer pits.

The sluicer winch assemblies, sluicer, and slurry distributor assembly have drains that are designed to accept the additional flow rate from a failure of slurry and/or supernate transfer lines and to drain the liquid to the associated tank. Leak detection instruments are provided to detect leakage inside the pits.

2.4.1.11 Syphon Protection. Syphon protection is required on the transfer piping because of an elevation difference of about 10.7 m (35 ft) between Tanks 241-C-106 and 241-AY-102. Properly sized anti-syphon holes (W320-27-045, *Pipe Drain Flow and Anti-Siphon Sizing for Transfer Lines*) are provided on the slurry distributor and the submersible sluice pump discharge line within Tank 241-AY-102 to prevent establishing a syphon when the slurry pumps or the sluice pumps are shut down. On the slurry distributor, two 1.3 cm (1/2 in) holes are provided to prevent syphoning of the slurry line, and two 0.6 cm (1/4 in) holes are provided on the discharge from the sluice pump. The larger-size holes are necessary on the slurry line since the likelihood of solids entrainment is greater there (pump suction screens out particles larger than 0.6 cm [1/4 in]). A syphon, if established, could drain back from Tank 241-AY-102 to 241-C-106 and could result in overfilling Tank 241-C-106 or, in the event of a failure of the transfer piping, a release of radioactive waste to the soil column.

2.4.1.12 Instrumentation and Control. Additional instrumentation (over and above that existing prior to WRSS) is required in both tanks, in the transfer lines between the tanks, and on the ventilation systems associated with both tanks. Also, communications between the control rooms at Tanks 241-AY-102 and 241-C-106 are required to ensure that shutdown functions are accomplished.

Tank 241-C-106 has instrumentation that monitors tank pressure to minimize the release of hazardous airborne particulates or gaseous material. Monitoring for tank vapor hydrogen concentration is also provided.

Leak detection is provided for the new transfer lines and the pump pits. Seismic shutdown switches are provided to reduce the volume of a spill from rupture of both transfer lines that could be caused by a design-basis earthquake. Mass flow rate, slurry density, and total mass flow are measured on the Tank 241-C-106 to Tank 241-AY-102 transfer line. Volumetric flow rate and pressure are measured at the discharge of the booster pumps on both transfer lines.

Temperature monitoring for Tank 241-AY-102 includes the capability to measure temperature at multiple elevations in the waste and the operation of existing thermocouples. A level gauge and a densitometer provide the capability to determine waste depth, sludge depth, and density of the fluid portion of the waste. Flow rate, temperature, and humidity monitoring on the 241-AZ-702 primary ventilation system is provided, and flow rate and temperature monitoring is provided on the annulus ventilation system. Hydrogen monitoring is provided for the Tank 241-AY-102 dome space.

2.4.1.13 In-Pit Closed Circuit Television Imaging System. A portable in-pit closed circuit television (CCTV) imaging system is provided to periodically monitor the interior of the process pits through access holes in the pit cover blocks. The system is used for determining pit conditions before opening for maintenance, leak verification, or inspection of equipment conditions.

2.4.1.14 In-Tank Imaging System. An in-tank imaging system, composed of a CCTV camera, mast assembly, a pan and tilt unit, and a shield/mounting plug, is provided within Tank 241-C-106 to locate the tank sludge accumulations during the sluicing operations and to ensure wastes are not exposed. The imaging panel contains the controls for positioning and illuminating the field-of-view for the in-tank CCTV system, as well as the cathode ray tube (CRT) displaying the in-tank view. This system also enables operators to aim the sluicer at the remaining waste sludge while minimizing the liquid level after the initial solids-removal increments.

2.4.1.15 Chemical Additions and Tank Sampling. Tank 241-AY-102 is accessible through riser number 15-O for chemical additions and for tank sampling. Chemicals (typically sodium hydroxide to adjust PH), are added through the riser as needed to enhance the compatibility of the waste in Tank 241-C-106 with that of the waste in Tank 241-AY-102. Chemicals added to Tank 241-AY-102 supernate are dispersed throughout the WRSS by normal operation of the pumping systems. Bulk chemical additions to Tank 241-AY-102 may be necessary to maintain tank chemistry within specified limits for corrosion control. Note that the addition of corrosion inhibitor (NaOH) is compatible with the need to maintain the alkalinity of the waste in order to avoid the potential for plutonium segregation. This is further described in Section 2.5.5.

2.4.1.16 Process Building Skid. The process building skid is located within Process Building 241-C-91. This skid consists of a condenser, a moisture separator, a heating coil, a recirculation fan, a HEME, and a HEMF. Gases from the Tank 241-C-106 headspace enter the ventilation system through a 25 cm (10 in) duct and are cooled by a propylene glycol/water mixture circulating through the condenser. Part of the flow is directed to the exhaust skid and the balance circulated through the moisture separator and heating coil before returning to Tank 241-C-106 through a 20 cm (8 in) duct to cool the tank. The exhaust gases are prefiltered through the HEME and HEMF. A 20 cm (8 in) valved connection is provided between the moisture separator and the heating coil on the recirculation line to allow a portable exhauster hookup for ventilation system outages.

Compressed air and raw water supply systems are provided to support operation of the ventilation system, such as backwashing the HEME and flushing the HEMF. A seal pot is provided to collect liquids from the condenser and from other equipment drains within the process building.

2.4.1.16.1 Condenser. The condenser (HX-1361) is a shell and tube type, designed to meet the requirements of ASME *Boiler and Pressure Vessel Code*, Section VIII, Division 1. The ventilation air stream, circulating on the shell side, normally is cooled to about 4.4 °C (40 °F) by the chilled-water cooling system, which circulates a 46% propylene glycol solution on the tube side. The condenser shell side has been designed for an air flow of 34.5 m^3/min (1220 ft^3/min), an inlet temperature range of 10 to 82 °C (50 to

180 °F), an outlet temperature range of 0.6 to 82 °C (33 to 180 °F), and an operating pressure range of -15 to -0.8 cm (-5.9 to -0.3 in) w.g. The condenser tube side has been designed for a coolant flow of 416 L/min (110 gal/min), an inlet temperature range of -0.6 to 32 °C (31 to 90 °F), and an outlet temperature range of 2 to 32 °C (36 to 90 °F).

2.4.1.16.2 Moisture Separator. The moisture separator (MS-1361) is a centrifugal mist eliminator that removes moisture droplets from the recirculation air stream by centrifugal force and gravity. Drains from the moisture separator are routed to the seal pot in the process building for return to Tank 241-C-106. Water droplet removal efficiency as a function of droplet size has been evaluated for the WRSS expected conditions and is documented in W320-H-015, *Sizing of Moisture Separator*. The moisture separator will remove 99.9% of all droplets greater than 10 microns and 60% of all droplets in the range of 2-10 microns.

2.4.1.16.3 Recirculation Heating Coil. The heating coil (HC-1361) is used to reduce the relative humidity of recirculating air and protect the recirculation fan from erosion by liquid aerosols. This equipment serves to reduce any fog formations in the tank vapor space to enhance visibility for the in-tank camera system. If fog formation does not occur, this coil would not be used, since some uncertainties exist regarding potential buildup of particulates in the tank vapor space with its use. The heating capacity is approximately 25 to 30 kW (85,303 to 102,360 Btu/h). Liquid drains from the heating coil and is routed to the process building seal pot for return to Tank 241-C-106.

2.4.1.16.4 Recirculation Fan. The recirculation fan (FN-1361) has a rated capacity of 27.6 m^3/min (996 ft^3/min) at a 40.6 cm (16 in) w.g. pressure differential. Drains from the recirculation fan are routed to the process building seal pot for return to Tank 241-C-106.

2.4.1.16.5 High-Efficiency Mist Eliminator. The HEME (HME-1361) is a cartridge-type moisture eliminator with a monofilament fiberglass filter bed designed for an air flow of 10.2 m^3/min (360 ft^3/min) at a face velocity of 9 m/min (30 ft/min), a temperature of 4.4 °C (40 °F), and a pressure of 98 kPa (14.2 psig). The removal efficiency rating of the HEME is 99.5% for particles 0.5 μm and larger, which removes any moisture carryover from the condenser. The filter housing is constructed of type 304L stainless steel and designed to meet the requirements of ASME *Boiler and Pressure Vessel Code*, Section VIII, Division 1. The HEME has provisions for periodic backwashing with filtered raw water to increase its efficiency; retained particulate material is returned to Tank 241-C-106 via the process building seal pot. The control for backwashing the HEME is designed to be either manual (controlled by an operator) or automatic (controlled by a timer). The HEME is provided with a bypass to allow for maintenance. This bypass cannot be used during operation since these valves are only accessible from inside the ventilation building.

2.4.1.16.6 High-Efficiency Metal Filter. The HEMF (HMF-1361) has several sintered metal fiber-type filters arranged cylindrically within a vessel and is designed for an airflow of 10.2 m^3/min (360 ft^3/min) at a temperature of 4.4 °C (40 °F) and a pressure of 95.8 kPa (13.9 psig). The HEMF acts as a prefilter for the HEPA filter (in the exhaust stream) and

removes at least 99.97% of 0.3 μm particles and greater. The filter housing is constructed of 304L stainless steel and is designed to meet the requirements of ASME *Boiler and Pressure Vessel Code*, Section VIII, Division 1. The HEMF has provisions for backflushing, using filtered raw water followed by a compressed air blowdown and drying of the filter media. Backflushing of the HEMF is manually initiated by the operator, as required, at a predetermined radiation level sensed by a local detector. The filtered water used for backflushing, and any particulate material removed, are returned to Tank 241-C-106 via a dedicated encased drain line through the 10 cm (4 in) R-4 riser. The HEMF is provided with a bypass to allow for maintenance. As with the HEME above, this bypass is not used for the backflushing. The liquid is returned to the tank by gravity.

2.4.1.17 Recirculation System. The 296-C-006 recirculation system removes heat from the Tank 241-C-106 vapor space, promotes visibility, and dehumidifies the recirculating air. The recirculation fan (FN-1361) provides air flow (including gases in the vapor space of the tank) in the recirculation path. The condenser (HX-1361) cools the air, condenses moisture in the airstream, and the condensate is returned to the tank. The moisture separator (MS-1361) removes moisture from the air stream. A recirculation system heating coil (HC-1361) is used to reheat the air to about 25 °C (77 °F) to decrease the relative humidity of the air stream and to provide some fog suppression before returning the recirculating air to the tank.

Air, at flow rates of 34.5 m^3/min (1220 ft^3/min), flows from Tank 241-C-106 through a 25 cm (10 in) combined recirculation and exhaust flow duct, circulates through the condenser, and returns to Tank 241-C-106 through a 20 cm (8 in) duct. The discharge of the recirculation fan splits into a 20 cm (8 in) recirculation pipe, with a flow rate of 24 m^3/min (860 ft^3/min), and a 15 cm (6 in) exhaust pipe, with a flow rate of 10.2 m^3/min (360 ft^3/min), 304L stainless steel. Ventilation system ducts are constructed from schedule 10, 304L stainless steel.

2.4.1.18 Process Building Drain and Seal Pot. A seal pot is provided on the process building drain line. It serves as a common collection point and seal for the condenser and other ventilation system equipment drains while preventing Tank 241-C-106 from venting into the process building. The overflow from the seal pot, which includes the HEME backwash waste water, is returned to Tank 241-C-106 via a dedicated encased drain line through the 10 cm (4 in), R-4 riser.

2.4.1.19 Chiller Skid. The chiller skid contains an air-cooled chiller and a chilled-water cooling system. The chilled-water cooling system consists of a makeup storage tank, an air separator, circulation pumps, an expansion tank, and instruments for monitoring the closed-loop cooling system. The circulating fluid (chilled water) is a 46% propylene glycol solution mixed with water circulated between the chiller and the recirculation system condenser. Chilled water may also be provided to the intake air cooling coil (CC-1361). The chilled water cooling system removes heat and dehumidifies the recirculating tank vapor by reducing the temperature of the vapor from about 35 to 4.4 °C (95 to 40 °F). In its alternate use with the existing ventilation system, it cools the bulk solid waste in Tank 241-C-106 to reduce

(before sluicing initiation) or maintain (during intermittent sluicing outages) waste temperatures below local saturation. The chiller skid is located outside the fenced area of the C Tank Farm.

2.4.1.19.1 Air-Cooled Chiller. An air-cooled chiller (R-1361) is used to remove heat that the chilled-water system gained from the recirculation ventilation system condenser, or with the existing ventilation system, from cooling ambient inlet air to 4.4 °C (40 °F) in the intake air cooling coil (CC-1361). The chiller is a complete factory assembled package, rated at 40 tons, with reciprocating compressors, condenser, refrigerant circuits, cooler, and controls. The chiller reduces the temperature of the chilled water returning from the recirculation condenser by about 2.7 °C (5 °F).

2.4.1.19.2 Makeup Storage Tank. The makeup storage tank (TK-1361) is pressurized by compressed air to provide the suction head required by the chilled-water circulation pumps and supplies makeup glycol solution for the chilled-water circulation system.

2.4.1.19.3 Air Separator. An air separator (TK-1363) is provided to remove air from the chilled-water circulation system. Air is automatically expelled from the air separator through a float-type air vent.

2.4.1.19.4 Circulation Pumps. Two 416 L/min (110 gal/min) centrifugal pumps are provided to circulate chilled water through the condenser or intake air-cooling coil (CC-1361) and the air-cooled chiller. One pump (P-1364) is designated the primary pump and the other (P-1365) the standby pump. Following failure of the primary pump, the standby starts. Each pump is provided with normally open isolation valves that allow pump maintenance while minimizing any effect on system operations.

2.4.1.19.5 Expansion Tank. The expansion tank (TK-1362) provides space for expansion and contraction of chilled water system fluid as the fluid temperature varies.

2.4.1.19.6 Circulation Piping. The 8 cm (3 in) circulation piping routes the chilled water to and from the condenser, located in the process building, or the intake-air cooling coil (CC-1361) on the existing ventilation system (valving change required) and the air-cooled chiller. The buried and insulated piping is Schedule 40 carbon steel with welded fittings.

2.4.1.20 Exhaust Skid. This skid directs exhaust through a heating coil, two HEPA filters with a test section for each filter, and an exhaust fan. This skid also includes an exhaust stack and exhaust-monitoring instruments. The exhaust ventilation system controls the pressure of the Tank 241-C-106 vapor space. The exhaust skid is located immediately east of the recirculation skid.

Air in-leakage, to make up for the exhausted volume, flows into Tank 241-C-106 from two pathways: (1) between pits and pit cover blocks into pits and then through pit drains into Tank 241-C-106 and (2) through the existing 8 cm (3 in) cascade line connecting Tank 241-C-105 to Tank 241-C-106.

2.4.1.20.1 Exhaust Heating Coil. A heating coil (HC-1362), located upstream of the HEPA filter train, has been designed to heat the saturated air and prevent condensation on the HEPA filters. The heating capacity is about 2 kW (6820 Btu/h). During normal operations the heating coil raises the air stream temperature from 4.4 °C to 21 °C (40 °F to 53 °F) and maintains a relative humidity of 60%.

2.4.1.20.2 High-Efficiency Particulate Air Filters. The HEPA filters are the bag-in/bag-out type, designed for a particulate removal mass efficiency basis of 99.97% of 0.3 μm particles and greater. This is achieved by using two HEPA filters (HEP-1361 and HEP-1362) in series. Each filtration stage has provisions for in-place testing while in use. A HEPA filter is required to be changed out whenever the pressure differential across the filter exceeds allowables or when the radiation measurement on the filter housing is about 2.0 mSv/h (200 mrem/h).

2.4.1.21 Exhaust Fan. The 296-C-006 exhaust fan is direct driven by a variable frequency, drive-controlled, 7.5-hp electric motor with a flow capacity of 10.2 m^3/min (360 ft^3/min) at 101.6 cm (40 in) w.g. Fan speed is modulated as required to control the vapor space pressure in Tank 241-C-106.

2.4.1.22 Exhaust Stack. The 15 cm (6 in) diameter exhaust stack extends to a height of about 5.2 m (16 ft) above the exhaust skid's concrete pad. The exhaust stack provides the point of discharge for the tank ventilation system. The primary exhaust air stream is sampled for radioactive particulate and monitored for radioactivity before discharge via the stack. The exhausted air stream is also monitored for flow.

2.4.2 Support Systems

The WRSS uses the existing tank farm support systems, modified as required to support Project W-320 requirements. Backup for the instrument air system is not provided. Backup power is provided for the AY Farm and the 241-A-702 and 4,000 cfm backup exhauster tank ventilation systems. Backup power for other systems will be provided, based on their safety function, as determined by the engineering analysis discussed in Section 4.2, "Requirements," of this addendum. Support services in the form of raw water, electrical power, telecommunications, and hoisting hardware, are provided. The use of portable facilities for sanitary sewage will be provided for the personnel using the control trailer.

2.4.2.1 Electrical Systems. Electrical power systems include AC power for Tank 241-C-106, Tank 241-AY-102, and Control Facility MO-211. All electrical equipment and components are selected, or protected, to resist the adverse effects of the environment in which they are installed. Electrical enclosures and junction boxes of the proper National Electrical Manufacturers Association rating and material are used to protect internal components from the corrosive effects of moisture and chemicals.

Power from the Hanford Site power grid is provided for Tank 241-C-106 by a 480 Vac, portable, skid-mounted substation on a concrete slab outside the fence near the 241-C Tank Farm. The existing 13.8 kV pole line (C8-L6) is

extended from the pole line on the north side of the 241-C Tank Farm to the east side of the 241-C Tank Farm. The new substation includes a transformer, switchgear, and a motor control center.

The sluice pump located in Tank 241-AY-102 is supplied with 480 Vac power from the existing 13.8 kV pole line (C8-L6). This line is tapped to supply a new 13.8 kV to 480 V transformer. The motor control center and variable speed drive are located on a skid-mounted (241-AY-51) enclosure outside the 241-AY Tank Farm.

2.4.2.2 Air Supply Systems. The existing compressed air system serving 241-C Farm will not be used by the WRSS. The compressed air system provided by WRSS distributes air at various pressures, providing a source of dry instrument-quality air to various components of WRSS. Compressed air for the WRSS is provided by a compressor and receiver unit (C-1361) rated at 0.8 m^3/min (27.5 ft^3/min) and 690 kPa (100 psig). Moisture is removed from the system by an air dryer (D-1361) that will lower the dew point to -40 °C (-40 °F). The compressor unit and dryer are located in Air and Water Service Building 241-C-73. Pneumatically operated valves are supplied with either 550 kPa or 690 kPa (80 or 100 psig) as required. Blowdown and drying air to the HEMF are provided at 690 kPa (100 psig) via a 113.6-L (30-gal) air accumulator (TK-1361) located in Process Building 241-C-91. Additionally, purge air is provided at 140 kPa (20 psig) for Tank 241-C-106 level and pressure instrumentation. Backup systems are readily available in the form of either portable or stationary compressor units.

2.4.2.3 Water Supply Systems. All water for the 200 East Area is supplied from the Hanford Site Export Water System. Water is distributed throughout the area by two separate systems: the raw water system and the sanitary water system. Raw water is untreated, unchlorinated water used primarily for cooling, flushing, and dilution systems. Sanitary water is treated (filtered, purified) and used for drinking and sanitary facilities.

The WRSS has been designed to have flushing capability using raw water for all components. Raw water is provided from an existing 30 cm (12 in) fire water line through a new 5 cm (2 in) supply line into Air and Water Service Building 241-C-73 where it passes through a 20 mesh duplex strainer (F-1363). Two backflow preventers in series minimize the potential for contamination. These backflow preventers (BP-1361 and BP-1362) are located in Air and Water Service Building 241-C-73 and Process Building 241-C-91. Raw water, used for either backwashing the HEME or flushing the HEMF, is passed through two stages of filtration to remove any particulate material. The first stage is a nominal 30 μm filter (F-1361) followed by a second stage 0.5 sum absolute filter (F-1362). Between these two filters is a line used for flushing or rinsing the intake imaging system.

Pump pits 241-AY-02E and 241-AY-02A provide for water flushing of the primary transfer piping (inner pipe). Backflow prevention is provided in the flush jumper system. This flushing water is supplied by tanker truck.

During an emergency, cooling water for the condensers in the AWF ventilation system, 241-A-702, is provided by the emergency cooling water system. This system consists of a cold water sump and a warm water sump, each

with two pumps, and an induced draft cooling tower, all located outside of the restricted area east of the 241-A-401 Condenser Building. Makeup water for the cold water sump is obtained from well 299-E25-6 located about 268 m (880 ft) north of the 241-A-CT-400 cooling tower. The deep well pump and emergency cooling water equipment has standby power from a backup diesel generator.

2.4.2.4 WRSS Control Station. The WRSS control station, located just outside the 241-C Farm fence on the North East side of the farm, is in a 3.7- by 3.7-m (12- by 12-ft) room and contains control consoles for the WRSS. One console is for the CCTV (CP02), one console is for controlling C Tank Farm pumps, winches, and the sluicer (CB-01), and one console is for annunciation and indication of process variables. The control station is designed for one operator.

2.4.2.5 241-AY-02E Pit Chiller. A pit chiller is provided at the 241-AY-02E Pit to remove the heat generated by the operation of the Booster pump and control the pit air temperature within equipment operating limits. The chiller is a split system consisting of a fan coil unit mounted within the pit (FC-0621) and a packaged outdoor air cooled water chiller (R-0621). The outdoor unit provides a chilled 46% propylene glycol/water solution to the fan coil unit and includes fan controls and other system instrumentation. A similar system is not required at the C-farm pump pit due to the larger size of the pit.

2.4.2.6 Standard Hydrogen Monitoring System. Standard Hydrogen Monitoring Systems (SHMS) are provided at both Tanks 241-C-106 and 241-AY-102. The SHMS are used to continuously monitor the gas composition of the tank vapor space. Gas samples are collected from the tank dome space at Tank 241-AY-102 and from the ventilation ducting at Tank 241-C-106.

The SHMS are provided with dual range electrochemical cells for measurement of hydrogen concentrations in the range of a few hundred ppm-volume to above the flammable limit of 4%-volume. The SHMS also include sensitive gas chromotographs to measure concentrations of hydrogen and other gases in the range of a few ppm to above the lower flammability limit. Sample ports are provided at the SHMS Cabinets to facilitate grab sampling. The SHMS provides alarms and indications at both TMACS and the W-320 control rooms.

2.4.2.7 Tank 241-C-106 Pit Sump Pumps. Sump pumps are provided at both of the Tank 241-C-106 transfer pits. Sump Pump P-1363 is located in the 241-C-06A pit and Sump Pump P-1368 is located in the 241-C-06C Pit. The sump pumps provide a means to evacuate liquid accumulated with the transfer pits following detection of a leak. When a leak is detected an operator manually energizes the sump pump. The sump pump transfers the collected liquid from the pit floor back into the tank via the high capacity drain.

2.5 PROCESS DESCRIPTION

The following section describes the WRSS operation plans and the process control plan. The text of Section 2.5 commits to a prescribed process control plan (PCP) and summarizes the content of the PCP. The PCP, in turn,

implements processes and controls that are contained in the flammable gas, thermal, and chemistry topical reports. TSRs and Defense-In-Depth controls are implemented by the PCP and are summarized in Sections 3.4.2.8 and 3.4.2.11 of this addendum for flammable gas and thermal issues. This includes controls for monitoring and for contingencies such as supernate removal.

The section contains four subsections. The first subsection, Sluicing Preparations, discusses the activities that will be accomplished in advance of the first sluicing operations to prepare the tank for sluicing and to acquire information needed for process control.

The second subsection, WRSS Operations, discusses the Sluicing Campaign Plan and the integration of all associated process monitoring instrumentation and controls. The various operating modes of the WRSS system and contingency plans are also discussed in this section.

The third subsection, Supporting Operations, discusses the non-WRSS operations activities that support the operations of the WRSS, chemical additions and sampling.

The fourth subsection, Past Practice Sluicing Lessons Learned, outlines historical problems and equipment sensitivities associated with past practice sluicing activities at Hanford's 200 Area.

2.5.1 Sluicing Preparations

The presluicing operations activities needed to acquire information necessary for process control and to prepare the tank for sluicing are discussed below.

2.5.1.1 Tank 241-C-106 Ventilation Waste Subcooling. As documented in HNF-SD-W320-ER-002, *Project W-320 Thermal Evaluation*, the sludge in Tank 241-C-106 will be subcooled (the temperature reduced to below the local saturation temperature) to prevent a steam release event from occurring. This subcooling is accomplished by operation of the existing Tank 241-C-106 exhauster (296-P-16) in combination with the inlet filter cooling coil and chiller system provided by the WRSS. The cooling coil cools the air entering C-106 to approximately 4 °C (40 °F). This cooled inlet air helps to reverse or prevent the increase of tank waste temperatures resulting from higher temperatures in summer.

2.5.1.2 WRSS Supernate Temperature Equalization. A number of small supernate liquid transfers will be required between the two tanks to equalize the temperatures in the tank liquids. The number and volume of transfers to accomplish the equalization will be dependent on the initial liquid volume in Tank 241-C-106 and its initial temperature. This equalization procedure will be performed only before start of WRSS operations or after extended delay periods between sluicing increments, if the temperature differential between the tanks would result in exceeding existing control limits. Normal WRSS operations will provide temperature equalization during sluicing.

2.5.1.3 WRSS Temperature/Thermal Data Baselines. To establish the startup thermal baseline for Tanks 241-AY-102 and 241-C-106, the temperatures in both tanks will be monitored for a period of not less than one month in advance of the start of sluicing operations. This thermal baseline will be compared to the project thermal analysis before the start of sluicing to ensure that the baseline is within the assumptions envelope of the analysis.

2.5.1.4 WRSS Flammable Gas Generation and Composition Baselines. The flammable gas concentrations will be monitored in Tanks 241-AY-102 and 241-C-106 for a period of not less than four weeks before the start of sluicing to establish the flammable gas baselines. The baseline will also include the flammable gas compositions for the tanks based on vapor space sampling results.

2.5.1.5 Tank 241-AY-102 Supernate Level Adjustment Transfer. Using the existing 241-AY-02D pit transfer pump, the waste level in Tank 241-AY-102 will be reduced before the start of sluicing to approximately 4.3 m (14 ft) by a transfer of supernate to a double shell receiver tank through the existing transfer system. This level includes the existing sludge in the tank.

2.5.2 WRSS Operations

2.5.2.1 WRSS Sluicing Campaign Plan Overview. The planned approach to remove the sludge from Tank 241-C-106 is discussed in the following section.

The following definitions are used to describe the planned sluicing operations:

- Campaign—Refers to the combination of sluicing increments. Each increment requires one or more sluicing batches which remove a given volume of sludge from Tank 241-C-106. The nominal volume of sludge transferred in each of the first and second campaigns is approximately 250 m^3 (66,000 gal). The third campaign is intended to remove all of the remaining sluicable sludge in Tank 241-C-106, but the volume of this campaign is expected to be less than 250 m^3 (66,000 gal).

- Increment—The sluicing increment refers to the 125 m^3 (33,000 gal) increments of sludge. The volume in a sluicing increment is equivalent to nominally 0.3 m (1 ft) of tank level. Therefore, two sluicing increments represent a transferred sludge volume equivalent to a nominal sluicing campaign. The increment size was selected based on estimates of the magnitude of "worst case" thermal conditions or flammable gas releases which could be accommodated in a single transfer.

- Batch—The sluicing batch is the smallest sluicing element. It is a single continuous or nearly continuous sluicing operation, the duration of which is controlled by either the accumulated volume of transferred sludge reaching the desired value, or the maximum sluicing batch time limit being reached, whichever occurs first. If the sluicing process can operate at the optimum efficiency, only one

sluicing batch is required to transfer one sluicing increment. Under less optimal conditions, two or more sluicing batches may be required to complete one sluicing increment.

2.5.2.1.1 First Sluicing Campaign. The first sluicing campaign retrieval operation is characterized by a requirement to maintain a specified liquid cover over the sludge in Tank 241-C-106 and the requirement to limit the amount of material transferred (HNF-SD-W320-ER-004). The liquid cover requirement is needed only during the first campaign to maintain saturation temperature suppression by hydraulic head (HNF-SD-W320-ER-004).

Completion of the first retrieval campaign is estimated to eliminate the need to add water to Tank 241-C-106 to maintain temperature control (HNF-SD-W320-ER-004). However, active ventilation will still be required to maintain the tank within its required temperature limits. It is, therefore, projected that completion of the first campaign will result in the removal of enough heat generating waste to resolve the Tank 241-C-106 high heat safety issue.

Sluicing Increments. The first sluicing campaign is projected to include two, approximately 124,900 L (33,000 gal) sluicing increments. The 124,900 L (33,000 gal) increment size was selected for two reasons. The first reason for establishing the 124,900 L (33,000 gal) sluicing increment is to achieve conservatism in the Tank 241-AY-102 temperature process control. HNF-SD-W320-ER-004 predicts that Tank 241-AY-102 will remain within temperature limits without the need for tank annulus ventilation, even if the heat load and waste fluffing in the initial 124,900 L (33,000 gal) of transferred sludge are greater than the range of probable values. The second reason is based on past practice sluicing experience that showed the maximum liquid cover through which sluicing could be effectively achieved was 22.9 to 30.5 cm (9 to 12 in).

After waiting the required period for analyses to show that adequate subcooling has occurred, the minimum liquid level/sludge cover control level will be reduced for each succeeding sluicing increment.

Sluicing Batches. Each of the above sluicing increments will be made up of several sluicing batches. The sluicing batch operational approach is used to provide assurance that inadvertent transfer of an excessive amount of heat-generating material (greater than the 124,900 L [33,000 gal] increment volume) into Tank 241-AY-102 does not occur.

The sluicing batch durations will be limited by two parameters: (1) the total sludge transferred as determined by the mass flow meter and (2) a maximum sluicing duration based on mass flow meter instrument uncertainty. These two values will be specified in the process control plan. The values may be subsequently modified based on WRSS operational experience.

2.5.2.1.2 Monitoring During and After the First Sluicing Campaign (Increment and Batch). Following the completion of the first sluicing campaign, a period of monitoring will be instituted prior to initiating any following sluicing operations. The monitoring period durations and requirements are discussed below. If a sluicing batch or increment completion

is concurrent with the next large-sized sluicing element, then the more extensive monitoring requirements from each will take precedence. Parameters to be monitored between sluicing batches include:

- Gas release rates (SHMS)
- Waste levels (ENRAF)
- Sludge level (ENRAF Densitometer)
- Waste temperatures (TC trees, Multifunction Instrument Tree, Air Lift Circulator TC's, and under-tank TC's)
- Annulus ventilation flow rate and inlet and outlet temperatures
- Dome space ventilation flow rate, inlet and outlet temperatures, relative humidity, and chiller performance

Specific monitoring requirements are contained in the process control plan and are summarized in the following paragraphs.

Post-Batch Monitoring. The post-batch monitoring period will extend for a minimum of three days following each batch. The batch monitoring durations are established by the solids-settling velocity reported in HNF-SD-WM-TI-756, *Chemical and Chemically Related Considerations Associated with Sluicing Tank C-106 Waste to Tank AY-102*, which is such that the initial settling period will be completed and a distinct sludge-supernate interface will have formed in Tank 241-AY-102.

During the monitoring period, the volume of Tank 241-C-106 sludge transferred to Tank 241-AY-102 will be calculated using ENRAF densitometer density profile data and Tank 241-AY-102 grab samples analysis results. This estimate will be compared with the mass flow meter totalizer readings. The monitoring period duration may also be extended until adequate confidence is established in the estimated sludge volume/heat load transferred. For example, if sludge settling takes longer than expected, a longer monitoring period will be required to establish volume and heat load values since these values are highly dependent on sludge depth.

Post-Increment Monitoring. The post increment monitoring period will extend for a minimum of seven days following the completion of each increment. The increment monitoring durations are established in the WRSS process control plan.

At the completion of each sluicing increment, an updated thermal baseline for both the tanks is established prior to proceeding with further sluicing. All of these considerations have some bearing on how subsequent retrieval actions will be performed, perhaps determining if they can be performed at all.

During the increment monitoring period, the sludge volume will be calculated as discussed above. In addition, tank thermal data will be

collected and reviewed to verify that anticipated thermal responses are occurring. Deviations from the anticipated responses will be evaluated.

Post-First Sluicing Campaign Monitoring. The post-first sluicing campaign monitoring period will extend for a minimum of two weeks following the completion of the campaign. The increment monitoring durations are established by LA-UR-97-1330. Both thermal and flammable gas process parameters will be monitored during this period.

2.5.2.1.3 Second Sluicing Campaign. This sluicing campaign will be identical to that described in Section 2.5.2.1.1, except that there is no requirement to maintain a minimum hydraulic head on Tank 241-C-106 sludge by means of a minimum liquid cover. This will permit operation of both the sluicer and slurry submersible pump in the optimum position to maximize sluicing efficiency.

Both temperatures and gas retention in Tank 241-AY-102 depend on the vertical distribution of heat generating isotopes after the waste transfers. This vertical distribution, in turn, depends on the degree of isotope stratification in Tank 241-C-106, and the degree of mixing created by the sluicing jet in Tank 241-C-106. The waste in Tank 241-C-106 may be highly stratified. For example, grab samples collected during 1996 show a fairly low and relatively uniform isotopic heat content in the upper approximate 4 ft of waste, with one interpretation being that most of the heat generating isotopes may be in the lower 2 ft (HNF-SD-WM-TI-756). However, process data from when the tank was filled show two relatively high isotopic layers, one at approximately 0-2 ft from the top and one at approximately 1-3 ft from the bottom of the tank (HNF-SD-W320-ER-004).

The sluicing strategy of the second sluicing campaign will be planned to minimize Tank 241-AY-102 waste temperatures and gas retention during subsequent waste transfers. For example, higher temperatures would occur if the heat generating isotopes were in a stratified layer at mid-depth in the sludge of Tank 241-AY-102, than if they were at the top or mixed throughout (HNF-SD-W320-ER-004).

Based on monitoring results of the quantity of heat generating materials transferred to Tank 241-AY-102 and remaining in Tank 241-C-106 after the first sluicing campaign, and model predictions, the depth of localized sluice jet penetration in Tank 241-C-106 will be adjusted to the extent practicable to optimize the subsequent waste transfers. This can be done by either excavating deeper in one area of the tank, or conversely, by removing a layer of more uniform thickness from the surface of the sludge.

2.5.2.1.4 Post-Second Sluicing Campaign Monitoring. The monitoring during this period will be identical to that discussed in Section 2.5.2.1.3, with the exception that Tank 241-C-106 will no longer require special thermal evaluation because the potential two phase zone in the tank will have been eliminated by the removal of two feet of waste.

2.5.2.1.5 Final Sluicing Campaign. This sluicing campaign will be identical to that described in Section 2.5.2.1.3.

2.5.2.1.6 Long-Term Monitoring. The waste in Tank 241-AY-102 is monitored to ensure that the waste remains within the tank's operating specifications and applicable Technical Safety Requirements (TSRs) for waste storage. Monitoring is specified through the process control plan which describes the requirements for the incremental transfer and monitoring.

The WRSS equipment has a design life of two years, although actual sluicing operations should take about one year to complete. The life of the in-tank pumping systems have been reevaluated with a preliminary result of approximately 4 years (with flushing of the transfer system). After the retrieval operation is complete, equipment installed in the tanks for WRSS operations and the waste transfer lines remain in place until decommissioning by a follow-on project, or disposal activities remove them. Other project waste would be disposed of in a properly sited landfill or hazardous waste facility in accordance with all applicable state and federal guidelines.

2.5.2.2 WRSS Sluicing Operation Control. The following discussion provides details on the sluicing operation control considerations and the associated bases that are implemented in the above discussion of the sluicing campaigns and associated monitoring.

2.5.2.2.1 Slurry Solids Loading Process Control. The solids loading in the slurry line is monitored using two real-time process control instruments discussed below.

The principal solids loading process control instrument is the 241-AY-02A pit mass flow meter. This instrument provides a direct indication of the slurry loading in the slurry line at the receiver tank end of the transfer line by measuring the density of the slurry. Knowledge of the solution density (obtained from either the ENRAF densitometer or grab samples) is required to support determining the slurry solids loading.

An additional indication of slurry solids loading is provided by the slurry flow rate measured by the mag-flow meter installed in the 241-C-06A pit. This instrument provides an indirect measure of the solids loading. The utilization of the slurry flow rate will require fixing the slurry booster pump speed setting as follows.

The slurry booster pump speed is set for a flow of 1325 L/min (350 gal/min) assuming a 0% solids loading. As the solids loading increases, the slurry flow rate is estimated to decrease approximately 4 gal/min for each 1% solids loading change. The sluicing operator will monitor this flow rate to determine the effectiveness of the sluicing operations. To assist the operator in controlling the slurry loading at a level that will not potentially allow transfer lines solids settling, the flow rate for a 20 wt% solids loading will cause an alarm to sound. The response to this alarm will be to take action to avoid a future solids loading increase or to reduce the solids loading to below 20%. The following process control actions to reduce the solids loading would be implemented incrementally in the listed order to the extent required to reduce the solids loading to below 20%:

(1) Raise the submersible slurry pump level.

(2) Direct the sluice stream to the area of the submersible slurry pump intake to dilute the solids entering the pump.

(3) Increase the pump speed to achieve a 1700 l/min (450 gal/min) flow rate until the higher solids content slurry clears the system. Note: This action would have to be reversed as soon as the higher slurry content stream cleared the transfer line to reestablish the slurry loading process control pump speed setting.

2.5.2.2.2 Sludge Volume/Heat Load Transfer Process Control. The sludge volume transferred from Tank 241-C-106 to Tank 241-AY-102 is monitored in real time using the mass flow meter located in the 241-AY-02A. The solids volume transferred is used to estimate the approximate heat load transferred between the two tanks.

After the sludge transfer, a material balance is performed using the monitoring data from both tanks (i.e., levels, temperatures, ventilation flow, temperature, and humidity data) to refine the thermal analysis baseline (HNF-SD-W320-ER-004) and verify that subsequent sluicing operations can be accomplished safely.

2.5.2.2.3 Flammable Gas Process Control. The phenomena related to flammable gas generation, retention, and release have been evaluated for transfer of the Tank 241-C-106 sludge to Tank 241-AY-102 (LA-UR-97-1330, *Discussion of Flammable Gas Issue for Project W-320*). A presluicing flammable gas baseline with a four-week monitoring period, using the Standard Hydrogen Monitoring Systems (SHMS) instrumentation installed on the tanks, will be established for Tanks 241-AY-102 and 241-C-106. The flammable gas baselines will include flammable gas release rates, flammable gas compositions, and rate projections for these rates at key points in the planned sluicing operations. Data evaluations include the following:

- Gas concentrations and ventilation rates in both tanks
- An accurate accounting of all materials introduced into or removed from the tanks
- Video monitoring of the Tank 241-AY-102 waste surface for indications of foaming or crust formation during the initial sluicing operations
- Headspace grab sampling at Tank 241-AY-102
- Liquid level monitoring in both tanks (Tank 241-C-106 monitoring is limited to nonsluicing periods)
- Tank 241-AY-102 sludge settling monitoring (densitometer and/or multi-functional instrument tree)
- Evaporation rate determined by ventilation flow rate and relative humidity.

Subsequent flammable gas monitoring will continue throughout the WRSS operations. Data from this monitoring will be compared to projections and significant deviations will be evaluated to determine if mitigative actions are warranted.

Process monitoring during the period between sluicing batches, increments, and campaigns will be the same as discussed under baseline development above. The data relating to gas retention in the Tank 241-AY-102 sludge will be carefully evaluated during the hold periods between sluicing increments and campaigns. If this evaluation identifies a potentially unacceptable flammable gas buildup, then the void fraction measurement instrument would be deployed as described in section 2.5.2.3.8. If the void fraction instrument confirms the flammable gas buildup condition, the tank excess supernate removal contingency plan would be implemented. As discussed in LA-UR-97-1330, the primary mitigation option selected is the removal of the Tank 241-AY-102 supernate. A summary of the process control for flammable gas is contained in the following discussions.

Assuming that the transfer-induced degassing stops immediately after the transfer, the gas concentrations in the headspace of Tank 241-C-106 should exhibit exponential decay. Because the gas generation in Tank 241-C-106 is reduced by sludge transfer, the headspace gas concentration in this tank will exponentially decay below the baseline concentration established before sluicing.

Waste (tank) level and flammable gas concentration are monitored in Tank 241-AY-102. The waste level and background hydrogen concentrations will equilibrate within two to four weeks. The void fraction of the sludge can be estimated by comparing the background hydrogen concentration transient with the steady state concentrations using the level rise. During this time, barometric pressure evaluation (BPE) may also be deployed to obtain additional data. Sludge density measurements using the ENRAF densitometer and the sludge thickness measurements using the same instrument along with the multi-functional instrument tree validation probe will also be required.

Using the gas inventory data from Tank 241-AY-102, a decision will be made to either transfer more waste or spend additional time evaluating the situation. Sluicing in the presence of a gas inventory indicating a buoyancy instability requires implementation of a mitigation plan to remove the excess supernate from the tank. If the gas inventory estimates contain large uncertainties (as defined in the WRSS process control plan), the void fraction instrument must be deployed to measure the gas inventory at a few locations in Tank 241-AY-102. If a level swell of more than 10 cm (4 in), corrected for evaporation, is detected and high voids are indicated by the void fraction instrument, the supernate in Tank 241-AY-102 will be removed. The decision to remove the supernate will be based on the calculated potential for a buoyancy induced rollover. Such a calculation will include the total data gathered such as gas release rates, level growth, barometric pressure evaluations, void fraction measurements. The measurements are described in reports LA-UR-97-1330 and PNNL-11627, *Monitoring Gas Retention and Slurry Transport During the Transfer of Waste from C-106 to AY-102*, and will be implemented in the PCP.

2.5.2.2.4 Liquid Level Process Control. Until the steam bump accident concern is eliminated, the liquid level in Tank 241-C-106 will have to be controlled at or above a set level to avoid affecting the subcooling provided by the hydraulic head of the liquid in the tank. The minimum liquid level is established to maintain the measured temperature of the waste at all locations below the local saturation temperature. The minimum liquid level to maintain safe operations is maintained through a TSR level control (AC 5.26).

The liquid level in 241-C-106 can not be monitored using the ENRAF liquid level instrument because this instrument will be shut down during sluicing operations to avoid damage by the sluice stream. Therefore, this measurement will be made using the lower liquid level sensor on the submersible slurry pump. As a backup to the above level control, the liquid level in Tank 241-AY-102 will also be controlled using the ENRAF liquid level instrument from that tank and the variable speed sluice booster pump.

The minimum liquid cover/hydraulic head control requirement will be eliminated after the first sluicing campaign as discussed in WHC-SD-WM-ER-588.

2.5.2.2.5 Leak Prevention/Minimization Process Control. The routine sluicing operations remove the sludge from Tank 241-C-106 while minimizing the potential for leakage during these operations. Leak potential is minimized in two ways.

The first planned leak prevention/minimization method is to limit the standing liquid volume in Tank 241-C-106 during sluicing operations to the extent possible, given thermal concerns and related process control limitations. The limiting of the standing liquid volume in Tank 241-C-106 will be accomplished using operating procedures which administratively control sluicing operations to the minimum practical liquid level consistent with 1) the minimum liquid level required to maintain subcooling (applicable during the removal of the first 0.6 m [2 ft] of sludge) and 2) protection of the pump from cavitation. Liquid level control is as specified in Section 2.5.2.2.4 above.

The second leak prevention/minimization methodology is to avoid directing the sluice stream toward the tank walls during the early stages of sluicing. The perimeter of the tank will be sluiced last to minimize the amount of material that could leak through the tank wall as a result of sluicer impingement.

2.5.2.2.6 Temperature and Thermal Process Control. The process control methodology is based on thermal considerations in both Tanks 241-C-106 and 241-AY-102. The conclusions of the WRSS Thermal Evaluations (HNF-SD-W320-ER-004) follow.

- The minimum WRSS objective of retrieving 0.6 m (2 ft) of waste from Tank 241-C-106 does not require operation of the Tank 241-AY-102 annulus ventilation system.
- Accumulation of the equivalent of 0.6 m (2 ft) of Tank 241-C-106 sludge in Tank 241-AY-102 is possible without modifications to the annulus ventilation system of Tank 241-AY-102. However, as a

Defense-In-Depth precaution, annulus blocking has been implemented. The capability to draw a high annulus vacuum along with annulus blocking will be provided, to provide margin for waste transfers beyond the first 0.6 m (2 ft) (such as could be needed if a leak were to develop in 241-C-106 during the initial sluicing increment). Additionally modifications to the secondary ventilation system (air inlet blower and/or chiller) may be implemented depending on the tank thermal behavior resulting from the first 0.6 m (2 ft) of sludge transfer. (Section 2.3.6.)

- Incremental sluicing with real-time mass control and monitoring will limit the thermal response caused by the heat-generating material added to Tank 241-AY-102.

- By evaluating the monitoring data with a transient thermal analysis, the steady state equilibrium temperatures can be predicted. Based on this prediction, sluicing can proceed without delays required to reach thermal equilibrium.

- Adequate subcooling can be maintained in Tank 241-C-106 with presluice chilling of the waste and incremental sluicing with hold periods for subsequent cooling before removing the hydrostatic head. The hold periods for cooling were established by thermal modeling.

2.5.2.2.7 Submersible Pump Elevation Process Control. Controls for the Tank 241-C-106 slurry pump system are provided at the MO-211 sluicing control room operators control panel. This panel has the controls for the pumps and pump winches, and indicates pump operational status and positions. The submersible slurry pump winch also has a lockout feature for its "lower" function which will be used in combination with pump shutdown interlock for the lower liquid level sensor mounted on the body of the submersible slurry pump to ensure that the liquid head on the sludge in the tank is not lowered during the first sluicing campaign.

2.5.2.2.8 Sluicer Aiming Process Control. A sluicer is provided for mobilizing the sludge in Tank 241-C-106 to transfer it as a slurry to Tank 241-AY-102. The sluicer will operate in sluice pit 241-C-06C through the 30 cm (12 in) riser R-3.

The sluicer has two control modes: manual and semiautomatic. The control system is based on nozzle position information obtained from magnetostrictive actuator position indicators. In the manual mode, the operator moves the joystick to position the nozzle in elevation (tilt) and azimuth (pan). In semiautomatic mode, the pan position constantly cycles between two set points on the meter relay. Tilt is set by the joystick, and then the joystick is administratively disabled. The pan cycle is limited to ±97°. The meter relay and related set point adjustments are limited to ±95° to avoid affecting the mechanical motion limits. The vertical motion is physically limited to +115° from 0° (straight down). Procedural controls avoid affecting the physical limits of tilt.

The sluicer will be used to direct waste to the suction of the slurry pump. It is anticipated that the tank wall adjacent to the submersible slurry pump will be exposed as a result of the slurry flowing into the pump intake.

The MO-211 control room features a main instrumentation control console, and consoles for the data acquisition system (DACS). The main instrumentation console is built around a sluicing panel, which contains the controls necessary to position the sluicer spray impact location within Tank 241-C-106. These controls feature a keyboard and a joystick controller for the positioning of the operating sluicer. The position of the impacting sluice stream will be indicated by a sluicer positioning device.

2.5.2.2.9 In-Tank Imaging System Monitoring. The MO-211 control room features an imaging panel containing the controls for positioning and illuminating the field-of-view for the in-tank CCTV system, as well as the CRT displaying the in-tank view from the CCTV imaging system. The in-tank CCTV imaging system that provides near real-time pictures or waste-surface-contour depictions during sluicing operations will be used to help control and direct the sluicing operations. It consists of a remotely controlled television camera and illumination source mounted in riser R-7 of Tank 241-C-106. Although it is not absolutely necessary for sluicing operations, the CCTV system is intended to locate any sludge accumulations, and allow for optimum sluicer aiming while minimizing the volume of liquid resident in Tank 241-C-106. Sluicer operation is mainly guided by azimuthal and vertical directional controls.

The in-tank CCTV system is composed of a TV camera, mast assembly, a pan and tilt unit, and a shield/mounting plug. The mast assembly includes a pressure-regulated supply of instrument air/nitrogen and associated enclosure control valves, a pressurized filtered raw water enclosure and associated enclosure control valves, and video processing electronics and associated wiring. The mast assembly is constructed of 304L Series stainless steel and includes a pan and tilt unit, a charge coupled device (CCD) camera, and high-efficiency metal halide focused-beam lamps, and will fit into a 30 cm (12 in) riser. The pan and tilt unit provides for a 360° field of view with a -90°/+30° elevation. The purge gas supply provides instrument cooling and condensation removal. The water supply provides camera lens and mast cleaning.

2.5.2.2.10 Modifications to Process Controls. The uncertainty in the characterization and dynamic behavior of the wastes contained in the WRSS is such that operational experience may show some deviation from predicted system behavior. Because of this, a performance baseline must be reestablished following every sluicing increment and the predictive models used for the WRSS must be modified to reflect the observed behavior. All anticipated conditions related to the WRSS operations have been included in this analysis.

2.5.2.3 WRSS Operating Modes and Contingency Plans. The following sections include discussions of the major operating modes of the WRSS and several contingency plans which have been developed to ensure the WRSS operations are prepared to respond to the identified off-normal operations.

2.5.2.3.1 Sluicing Startup. During the start of sluicing operations, the slurry pump is used to decant the supernate in Tank 241-C-106, to Tank 241-AY-102, so that the supernate level is 183 cm (72 in). The slurry pump is then positioned so that its low-level detector is located at 178 cm (70 in). The sluice pump is started and the sluice stream is aimed to agitate the area around the slurry pump intake. This startup mode of operation ensures that an acceptably low solids content (estimated at 10% or less) is present in the solution around the slurry pump intake when it is started.

Next, the slurry pump will be started and the associated slurry flow rate and pressure instrumentation continuously monitored until a stable slurry loading is achieved. The solids level in the slurry line is monitored using the mass flow meter installed in the AY Farm end of the slurry line. As a backup, the slurry pump discharge pressure and volumetric flow rate can be used as a gross indication of excessive solids loading in the slurry transfer line. This would be evidenced by either the flow rate decreasing towards the limiting low value, or the pump discharge pressure increasing towards the limiting high value expected for the slurry. The response would be to reposition the sluicer to impact at a less efficient location for slurry formation, and the slurry booster pump could be raised to a less efficient elevation. For follow-on sluicing campaigns where the liquid level is not constrained in Tank 241-C-106, the ENRAF level gauge in Tank 241-AY-102 can be used as a gross volumetric estimate of the sludge transferred. Nominally, a given volume of sludge transferred from Tank 241-C-106 will displace the same volume of supernate in Tank 241-AY-102. However, factors such as waste fluffing and settling rate will affect this assumption. The relationship between solids percentages and viscosity has been defined for this application by the project functional design criteria (HNF-SD-W320-FDC-001).

At a constant slurry velocity, as the solids percentage increases, the flow rate will decrease approximately 15 L/min (4 gal/min) per 1% solids loading change and the pump discharge pressure will increase. Changes in the slurry composition sufficient to effect a noticeable change in the pump parameters should also be indicated by the slurry mass flow meter and associated net flow computer (NFC). Therefore, the slurry line mass flow meter is the primary online process control tool. The mass flow meter may be backed up by the slurry line volumetric flow meters, the ENRAF level gauge in Tank 241-AY-102, and the discharge pressure and low-limit detector of the slurry pump suction, depending upon the applicable thermal-hydraulic constraints currently in effect.

These procedures do not apply to the solids level in the sluice stream, since a rapid buildup of high solids loadings cannot occur in the large volume of Tank 241-AY-102 supernate. The sluice pump flow rate is adjusted, as needed to maintain the desired liquid levels in the two tanks.

As sluicing operations proceed, most of the solids transferred into the Tank 241-AY-102 are anticipated to settle out, adding to the solids heel. Uniformity of the distributed slurry layer in Tank 241-AY-102 will be verified by monitoring the thermocouple readings. The finer solids may remain suspended in the bulk solution long enough to be recirculated back to Tank 241-C-106 in the sluice stream.

Once the tank conditions have been established to start sluicing operations, the WRSS pumps will be operated to adjust the liquid level in Tank 241-C-106. During sluicing operations, the operator will maintain the resulting liquid level in Tank 241-AY-102, taking into account the effect of the volumes required to fill the transfer lines. The sluice pumps will be started first, and to prevent the possibility that the low-level alarm on the slurry booster pump may be activated by loss of the liquid volume required to fill the slurry transfer line, the slurry pumps will not be started until sluicer flow is verified in Tank 241-C-106. The 241-C Tank Farm operator will set the slurry pump flow rate to a representative value that will ensure no solids settling occurs in the slurry transfer line. The minimum allowed flow rate is 946 L/min (250 gal/min). The nominal flow rate will, however, be 1325 L/min (350 gal/min). The AY-Farm operator strives to maintain the resulting supernate level in Tank 241-AY-102 by controlling the sluice pump speed.

2.5.2.3.2 Routine Sluicing. During the run-hold cycle, the pumps are allowed to run for a period defined by both mass transfer and time limits, which will be provided by Process Engineering. The sluice batch time limit is determined from the uncertainties in the waste characterization and the measurement accuracy of the coriolis mass flowmeter. The interpretation of the time limit is that solid particles could be transferred at a rate equal to 30.48 cm (1 ft) of Tank 241-C-106 sludge over the defined time period, even if the mass flow meter indicated no solids were being transferred. Any indication of particulate solids transfer then reduces the remaining allowed amount of pump run time proportional to the ratio of the measured particulate solids transfer to the particulate solids transfer limit.

At the end of the sluicing batch, the hold period begins to allow data collection and analysis. One primary goal of the hold period is to obtain verification of the mass of solids transferred to Tank 241-AY-102. Three days are allowed to pass so that a clean interface can be established between the settling solids and the supernate in Tank 241-AY-102. The three-day period is chosen to ensure that a clean sludge/supernate interface has formed in Tank 241-AY-102. The ENRAF densitometer in Tank 241-AY-102 is used to obtain two key pieces of information: the density of the clarified supernate and the level of the settled solids (sludge)/supernate interface. If a settled solids bed with sufficient mechanical strength or density to support the ENRAF displacer has not formed, the density of the settling slurry can be measured, and this information can also be used to help estimate the mass of sludge transferred. Thereafter, the depth of the interface, or the density of the settling slurry, can be measured at a desired frequency to see if the waste solids continue to settle. The frequency will have to balance the need for information with the concern of excavating a depression in the solids bed, thus compromising the accuracy of the interface measurement (HNF-SD-WM-RPT-293, *Repository of Not Readily Available Documents for Project W-320*).

During sluicing operations, the sluicer can be controlled either semi-automatically or manually to reduce the solids level throughout the tank as evenly as possible, except for a 1.52 m (5 ft) wide ring of solids against the tank wall. The retrieval activities are accomplished in a series of 0.3 m (1 ft) waste increments. The first two retrieval increments will be

accomplished while maintaining a constant liquid level over the Tank 241-C-106 sludge to minimize the potential for a steam release event that might occur because of any abrupt reductions in hydrostatic pressure on the hotter waste deep in the sludge. The sluicer is used to wash the solids toward the slurry pump suction.

After completion of the first sluicing campaign, when the initial two feet of sludge are removed and the hold periods are satisfied, the volume of supernate in Tank 241-C-106 is minimized for tank leakage considerations and to maximize sluicing efficiency. This is controlled by using submersible slurry pump position indication and the integral level detectors on the pump. The in-tank imaging system may also be used to monitor liquid volume present in the tank. Operation of the sluicer is based on nozzle position information obtained from the sluicer drive position indication system. If fogging does not restrict viewing, the in-tank imaging system is used to help control the sluicer, thereby enhancing sluicing efficiency. During sluicing shutdown periods after the initial two feet of solids removal, the in-tank imaging system is used to identify zones of solids that need to be sluiced.

The duration of the sluicing batch will be limited to provide assurance that excess solids are not unintentionally transferred to Tank 241-AY-102. In addition, measurements on tank temperatures and liquid levels are obtained to determine the amount of sludge transferred. Process control information needs are addressed in the process control plan.

In the event that a solids level reduction assessment can not be accomplished using the in-tank CCTV system in a real-time mode, more frequent (potentially once a shift) temporary shutdowns may be used to allow defogging of the tank to support visual progress assessments.

If pieces of solids (broken-up crust or hard pan materials) too large to pass through the slurry pump inlet screen accumulate at the slurry pump inlet partially or completely plugging the inlet screen, the slurry pump can be temporarily shut down, and the chunks can be sluiced away from the pump intake by directing the sluice stream to agitate this area. In addition, line drainage through the submersible slurry pump will also tend to flush material away from the inlet screen.

2.5.2.3.3 Sluicing Shutdown. For controlled sluicing shutdown operations, the shutdown will be controlled to produce the desired liquid level in Tank 241-C-106. In addition, the pump height or sluicer aiming will be adjusted to reduce the solids loading in the slurry line when the pump is shut down.

To shut down the WRSS, it is desired to minimize the slurry concentration in the slurry transfer line, thus minimizing the amount of solids that may settle out in the line. The sluicer and slurry booster pump will be positioned to control the slurry concentration so that when the transfer lines drain following WRSS shutdowns, only a minimal amount of solids will have settled in the pipe. Water flushing is needed only if the shutdown is known to be of significant duration, such as at the completion of the transfer of a 30.48 cm (1-ft) sluicing increment. Water flushing will not normally be required following shutdown of the system at the completion of a sluicing

batch, because a water flushing operation would take longer than a verification of the mass of sludge transferred during that batch. In this case, the small amount of sludge that settles out in the pipes should be resuspended when the system starts back up because the shutdown duration is not long enough for the settled solids to dry out or cause a significant flammable gas concentration to build up in the pipe.

Flushing water is tapped into the slurry and supernate transfer lines via jumpers in pit 241-AY-02A at Tank 241-AY-102. After flushing, the water remaining in the transfer lines drains back through the lines to 241-C-106 by gravity.

2.5.2.3.4 Tank 241-C-106 Sluicing Completion Evaluation and Post-Sluicing Operations. Determination of the end point for the sluicing operation would depend on performance of a thermal analysis to verify the amount of heat generating material remaining in Tank 241-C-106. An evaluation of whether enough heat generating material has been removed from Tank 241-C-106 is performed in either of the following cases.

CASE 1: The maximum feasible waste recovery has been achieved.

CASE 2: Sluicing operations are stopped for an extended period after the material balance procedure indicates that an adequate volume of heat-generating solids have been removed from the tank to allow it to be stabilized (i.e., less than 18,900 L [5000 gal] supernate and less than 189,000 L [50,000 gal] interstitial liquid).

The evaluation involves maintaining the remaining waste in a wet condition while monitoring the in-tank temperature trends. The temperature data thus generated would then be used to develop an estimate of the remaining heat load in the tank.

This project is designed to lower the heat output of the remaining waste to less than 11.7 kW (40,000 Btu/h), and if required to meet temperature limits to remove as much waste as possible beyond that to demonstrate a waste retrieval technology. The volume of waste removed from the tank may have to be limited for either thermal or flammable gas considerations applicable to the receiving tank. At the end of sluicing operations, however, a 0.3 to 0.6 m (1 to 2 ft) layer of hardened waste may remain. This hardened layer, if not removed during the sluicing operation, would be removed by a different technology which is under development as part of a separate project. In the interim, between the conclusion of the proposed action and the initiation of this future retrieval action, the hardened layer would be monitored and treated (removing any potential excess heat by using air chillers and sprinkler systems), if necessary depending on the heat load, to prevent overheating the tank or keep the waste from drying out.

2.5.2.3.5 Tank AY-102 Supernate Removal Contingency Plan. If implemented, the supernate removal contingency pumping plan uses the existing Tank 241-AY-102 sluice pump system and Tank 241-C-106 slurry pump system in combination to transfer excess Tank 241-AY-102 supernate first into Tank 241-C-106 and subsequently on to the selected receiver tank. Tanks 241-AP-104, 241-AP-106 or 241-AP-107 have been identified as candidate

receivers. A jumper connecting the U11 nozzle (SL100) slurry line to the U3 (SL-503) transfer line in the 02A pit will be available for installation, if required, to support this contingency transfer plan (LA-UR-97-1330).

2.5.2.3.6 Tank 241-C-106 Tank Leak Contingency Plan. In the event of a leak (confirmed through verification of material balance calculations) in Tank 241-C-106 at or above the minimum detectable level of 30,000 L (8000 gal), the following actions would be taken to place the tank in the safest possible condition while follow-on actions are determined in consultation with the U.S. Department of Energy, Richland Operations Office (DOE-RL) and Ecology.

- Stop sluicing retrieval, pending consultation with DOE-RL and Ecology.
- Minimize liquid level within liquid level limitations.
- Maintain evaporative cooling by wetting the waste surface, pending a thermal determination of the need to continue this practice.
- Determine if leak has stopped (by liquid level monitoring).

If the leak has stopped, estimate the amount of leakage from the tank, evaluate consequences of the leaked volume, make appropriate reports, consult with DOE-RL and Ecology to make recommendations to continue the retrieval, and maintain the liquid level below that of the leak site if possible.

If the leak has not stopped, perform periodic wetting of the sludge using the sluicer or other means deemed as appropriate (maintaining minimum liquid inventory in Tank 241-C-106 to keep the sludge wet), evaluate consequences of the leaked volume, make appropriate reports, and perform a thermal analysis to support a decision to continue or stop sluicing retrieval in consultation with DOE-RL and Ecology. It is desirable from an overall risk perspective to remove as much material as possible from Tank 241-C-106 to maintain the post-sluicing temperatures below saturation. Depending on the temperature conditions in the tank, the 296-P-16 exhauster and inlet chiller (subcooling system) may also be reactivated.

2.5.2.3.7 Transfer Line Unplugging Contingency Plan. In the unlikely event that the design features and operating process controls do not prevent a line plug, the following graded approach will be used until the plug is relieved. Design features which minimize the potential for plugging have been incorporated and include 1) a robust pumping system able to maintain turbulent flow, 2) use of long-radius elbows in the buried transfer lines, 3) a transfer line flushing system, and 4) free draining process piping.

1. At the Tank 241-AY-102 end the cover block plug over the flush connection nozzle will be removed and the flush adapter installed. Pressurized hot water (within the lines, allowable pressure is 2206 kPa [320 psig]) is used to remove the plug.

2. If Step 1 is unsuccessful, the Tank 241-C-106 end pit is opened and the associated jumper is removed. A pressure test jumper is connected to the

plugged transfer line and pressurized hot water (transfer line pressure limit: 2206 kPa [320 psig]) is used to remove the plug. Operational experience with the cross site transfer line has shown this method to be effective in plug removal.

3. If Step 2 is unsuccessful, a commercially available hydrolase system is employed to remove the plug. The hydrolase systems are special, moderate- to high-pressure spray heads attached to a flexible hose. These systems are inserted into the pipeline until the spray head is in contact with the plug material. Water is then forced through the spray head to dislodge and flush the plug solids from the transfer line. Because of the free-draining nature of the hydrolasing process, hydrostatic pressure is built up to the allowable pressure of 2206 kPa (320 psig). The transfer line plugging experience at Hanford has been that plugging develops over time and adequate time is available to take corrective measures to stop the buildup of solids before the line completely plugs.

4. In the event Steps 1 through 3 fail to unplug the line and the line must be replaced, ALARA considerations are assessed. The obstruction is located by performing a gamma assay of the pipeline, and confinement barriers are placed around the area. ALARA and waste containment considerations are assessed again before excavating the berm, cutting and removing the pipeline, and replacing and welding the new pipe section.

To maintain a conservative design basis the project has incorporated features to provide a robust pumping system, monitoring capabilities, and operating plans that can be used to ensure that any solids buildup potentially leading to the plugging of either the slurry or sluice transfer lines is detected in time to allow for corrective action such as process solution flushing. These features are discussed in the following paragraphs.

Transfer Pumps. The first such feature provided by the project is a robust transfer pump having the capability to transfer up to 50 wt% solids and maintain turbulent/transition flow (which minimizes solids settling.

Monitoring Instrumentation. The second plugging-prevention design feature is instrumentation to monitor the pump discharge pressure, flow rate, mass transfer rate, and speed setting (the tandem pump system booster pump has a variable speed drive to support flexibility in responding to varying sluicing operating conditions).

The past slurry transfer operations have shown that the combination of pump discharge pressure and flow rate are the best indicators of impending plugging problems. Monitoring these two parameters during sluicing operations is the primary means of detecting changes that indicate a solids plug is beginning to develop. If these two parameters indicate a solids plug is beginning to develop, proactive corrective actions (such as flushing or increased pump flow rates) may be initiated.

Operating Procedures. The third plugging prevention element consists of the operating procedures for the Tank 241-C-106 tandem slurry pump system which avoid excessive solids loading in the slurry pipeline. This element is

not considered necessary for the Tank 241-AY-102 sluice pump because of the lower solids loading in the sluicing stream. During the startup of the Tank 241-C-106 slurry pump, the following three steps are used to ensure excessive solids are not pumped into the slurry transfer line.

1. The submersible pump is raised so that it pumps from the upper layer of liquid in the tank.

2. The sluice stream entering the tank from Tank 241-AY-102 is directed to stir the area around the submersible pump's intake, thereby diluting the solids entering the pump's intake and ensuring that a high (above 30%) solids level solution is not present at the pump intake.

3. When the tandem pumping system is started or the running submersible pump is lowered (after the first sluicing campaign) to improve solids recovery, the pump discharge pressure and flow rate is continuously monitored until steady conditions have been established. Monitoring is continued periodically after this point throughout the WRSS operation.

Transfer Line Flushing. Process supernate flushing of the slurry line is used on a routine basis to prevent the buildup of solids in the slurry line. In addition, should process monitoring identify the beginning of a solids-buildup problem, one of the two following flushing operations would be undertaken to correct the problem.

Routine Process Solution Flushing. During sluicing operations, whenever a slurry pump shutdown is planned, the submersible slurry pump is raised and the sluicer is aimed to minimize the solids entering the pump intake. Approximately 1325 L/min (350 gal/min) of relatively solids free supernate will then be used to flush out the slurry transfer line. After at least one and a half line volumes of relatively solids-free solution have been transferred, the pumps are shut down.

If the transfer pump shuts down unexpectedly, disallowing the use of process solution flushing, the system is flushed by this same process as soon as the pump can be restarted, generally within the next one to eight hours.

Water Flushing. This flushing option would be used when process data indicate the need for flushing and the routine process solution flush is not possible. It would also be used when jumper change operations are planned and it is necessary to decontaminate the process jumpers to the maximum extent practicable for ALARA reasons.

Both the sluice and slurry transfer lines can be water-flushed from the Tank 241-AY-102 end using flush connections in the sluicing system jumpers located in the 02A (slurry distributor) pit and 02E (sluice pump) pit. A cover block shielding plug is removed from the AY pit cover block using a crane. This allows access to the flushing port blank. The blank is removed and a flushing adapter jumper is attached in its place. Water from a tank

truck is then pumped through the transfer line to achieve the required flush. This nonroutine flushing operation can generally be accomplished within one to two weeks of the identification of the need.

2.5.2.3.8 Tank 241-AY-102 Void Fraction Monitoring Contingency Plan. LA-UR-97-1330 identifies the need for a contingency plan to add void fraction monitoring to Tank 241-AY-102 within two weeks of the identification of the flammable gas buildup that would warrant this monitoring enhancement.

2.5.3 Supporting Operations

2.5.3.1 Sampling. Liquid grab sampling is planned during sluicing operations to provide necessary process control characterization data. This sampling will generally be accomplished through an existing above grade riser at Tank 241-AY-102 using existing sampling procedures.

After every batch sluicing transfer, a liquid grab sample will be taken from Tank 241-AY-102. The following items will be analyzed and reported: bulk density, gravity settled solids density, liquid density, gravity settled solids volume percent, plutonium, hydroxide, nitrates, and nitrites. Thermo-gravimetric analysis, inductively coupled plasma analysis, and radioisotope analysis for Sr-90 and CS-137 results may also be performed. (It should be noted that C-106 solids dissolution by dilute Tank 241-AY-102 supernate may affect the source term. The samples that will be collected and assessed will indicate any such effects. This should have no impact on accident consequences, because a ratio of 33% solids and 67% liquids is used in the spray leak accident analysis.)

Additional sampling requirements may be specified by East Tank Farms Engineering, Environmental Permit/Policy, and Process Engineering.

2.5.3.2 Chemical Additions. The addition of nitrates and/or nitrites maintains tank corrosion specifications. This can be accomplished via additions from a tank truck to either tank or by routing the chemicals into Tank 241-AY-102 through waste transfer lines from the 204-AR Waste Unloading Facility. The supernate in Tank 241-AY-102 will be adjusted to meet double shell tank corrosion specifications before starting sluicing operations (HNF-SD-WM-TI-756).

2.5.3.3 Maintenance and Replacement of Long Length Equipment. The WRSS has been designed and arranged for efficient, cost-effective operation and maintenance, with personnel radiation exposure meeting ALARA principles. Remote maintenance capabilities are provided where required and justified. System designs provide for the safety of maintenance personnel.

2.5.4 Past Practice Sluicing Lessons Learned

Because sluicing was conducted in two distinct phases at separate times in Hanford's history, this discussion of lessons learned is broken down into

1950's and 1970's sections. Lessons learned in the 1950's were incorporated in sluicing operations in the 1970's. The lessons learned during the 1970's have been addressed by design features added to the WRSS.

WHC-SD-WM-TI-302, *Hanford Waste Tank Sluicing History*, discusses the past practice sluicing operations conducted in the 1950's and 1970's. It is the source document for the following summary of lessons learned.

2.5.4.1 1950's Past Practice Sluicing Lessons Learned. As discussed in WHC-SD-WM-TI-302, the problem areas encountered during the 1950's phase of past practice sluicing fell in three areas: 1) multiple pump failures, 2) multiple sluicer hose failures, and 3) a plugged transfer line. Each of these is discussed below.

2.5.4.1.1 Pump Failures. Failures of Nagel sludge pumps occurred frequently during the 1950's campaigns, including C Farm sluicing operations. Fifteen Nagel sludge pumps failed during the sluicing of Tanks 241-C-101 through 241-C-106. Twelve of these failures, however, occurred during the sluicing of the first tank, 241-C-101, indicating that a significant learning curve was achieved on the subsequent sluicing operations.

No specifics were provided on the cause of these pump failures in WHC-SD-WM-TI-302. However, possible causes include the inadequacy of the basic cantilevered pump design employed by the Nagel pumps for slurry service, and operations of the pumps at a too low net positive suction head, potentially causing cavitation and short pump life. Operation of the pumps at low submergence levels would have been used to maximize the sludge recovery.

The fact that the sludge pump design was changed for 1970's sluicing operations and a lack of similar problems during those operations infers that the problem was corrected, though a specific reference is not available. The 1970's slurry pumps were either straight-stick centrifugal or vertical-turbine pumps incorporating long drive shafts between the pump motor located in the process pits on top of the tanks and the impellers located down in the waste in the tanks. The drive shafts were supported by multiple intermediate bearings. This design approach provided a much more robust slurry pump, but did complicate the task of adjusting the height of the pumps. The Nagel pumps had been suspended inside the tank vapor space from chains or flat cables which allowed the height of the intake to be adjusted remotely.

The WRSS slurry and sluice pump systems were specified to ensure a robust design that would withstand the rigors of challenging slurry service conditions. The pump specification, HWS-9090, for the most successful of the 1970's slurry pumps, the P-200 Barrett, Haentjens & Co. slurry pump, was used as a starting point for the project WRSS slurry and sluice pump specification. Most of the applicable design requirements of the 1970's sluice and slurry pumps have been retained for the new sluice/slurry pump systems.
A submersible pump was specified to allow use of the remote height adjustment feature used in the 1950's. The new pump systems are more complex than either the 1950's or 1970's systems because of the need for a higher pump pressure caused by the longer transfer routes, necessitating the need for a booster pump in each system.

2.5.4.1.2 Sluicer Failures. A single sluicer hose failure was reported during the 1950's C Farm sluicing operations. A number of similar failures were also reported for sluicing in other farms during the 1950's. WHC-SD-WM-TI-302 indicates that this was corrected by installing a hose rated for a higher operating pressure.

2.5.4.1.3 Line Plugging. Transfer line plugging has been identified as a potential operational concern. Slurry pumping experience over the years at the Hanford Site indicates that a transfer line plug during sluicing operations is very unlikely. This experience includes the sluicing of 53 SSTs using past practice sluicing technology. Only a single line-plugging event was recorded during these operations, and the line involved was a sluice line, not the higher-solids slurry line.

However, to provide a robust sluicing system, design features have been incorporated into the WRSS to minimize the potential for line plugging and to allow for flushing of both the transfer lines. Design features which minimize the potential for plugging include 1) a robust pumping system able to maintain turbulent flow, 2) use of long-radius elbows in the buried transfer lines, 3) a transfer line flushing system, and 4) free draining process piping.

2.5.4.2 1970's Past Practice Sluicing Lessons Learned. WHC-SD-WM-TI-302 also discusses the sluicing operations conducted in the late 1960's and 1970's (referred to here collectively as 1970's sluicing). The problem areas encountered during these sluicing operations included: (1) sluicer hose failures, (2) extended sluicing status evaluation times, and (3) slurry pump height adjustment delays. Each of these problem areas is discussed below.

2.5.4.2.1 Sluicer Hose Failures. Sluicer hose failures were again encountered during the early parts of the 1970's sluicing operations. One or more alternative hoses were tested in operations and the final selection, Gates 18MB air drill (wire braid) hose, proved satisfactory in overcoming these problems. The new sluicer is an improved stainless steel version of the 1970's sluicers. It also uses a high-pressure rated hose 5515.81 kPa (800 psi).

The hose selected for use in the WRSS is the Gates Food Master (Specification 3132C). This hose is made of radiation-tolerant materials capable of handling radiation doses far above those anticipated during the operational life of the WRSS. The working pressure rating for this hose is well above the sluicing system operating pressure and its bend radius characteristics are superior to those of the Gates 18MB hose used in the successful 1970's sluicers.

2.5.4.2.2 Extended Sluicing Status Evaluation Time. Evaluation of the progress and completion status of sluicing operations took much too long to effectively support the operations of processing programs that depended on the sluicing program for feed stock (i.e., B Plant Strontium recovery operations).

The evaluation of sluicing progress status was accomplished by pumping the sluice tank to minimum liquid level and assuming the liquid level rise in

the receiver tank was the result of transferred solids. This technique provided no information useful in determining where next to direct the sluice stream in the tank.

Two additional techniques were available to process engineering to help provide information to direct subsequent sluicing operations. The first was gamma monitoring instrumentation installed on the slurry transfer line. Higher gamma reading from this instrumentation was used to indicate that sludge recovery was occurring. This technique had two drawbacks. The first and most obvious was that it provided only after-the-fact information, i.e., it couldn't be used to determine in advance where to sluice to achieve effective solids recovery. The second drawback was that no correlation between the radiation reading and the actual volumes of sludge being recovered existed.

The second and most informative of the sluicing progress assessment techniques was in-tank photographs. Use of this technique was, however, minimized because of its impact on the sluicing schedule and increased cost.

The process of taking photographs in the tank began by increasing the air flow through the tank by opening a riser on the tank to be photographed. This was necessary to remove fog and sluicing-generated vapors that would have otherwise obscured details in any photos taken inside the tank. The duration of the venting of the tank varied greatly depending on the time of year. In hot or warm weather, fog could be cleared in a day or two. In cold weather, as much as a week or more was required.

The photographs were then taken and developed overnight. The resulting group of 24 photographs was then hand assembled into a mosaic of the tank's interior to support interpretation of the sluicing progress status. This normally took approximately one half day.

The overall process, therefore, took between three days and a week and a half. This duration was frequently affected by unacceptably hazy photographic results, i.e., it was sometimes difficult to determine by looking down a tank riser if the tank had adequately defogged.

Because some of these sluicing operations supported and were closely coupled to the much more costly strontium recovery operations at B Plant, the duration uncertainties associated with these progress evaluations received a great deal of management attention and were considered an area in which the sluicing program needed to improve its performance. The CCTV system is designed to operate successfully in the misty, dirty tank vapor environment anticipated to be present in Tank 241-C-106 during sluicing operations. It includes provision for gas purging of the CCTV viewing lens and water flushing of both the viewing and light element lenses. The water-flushing feature was added to the system based on the results of one-quarter scale simulant testing conducted for project WRSS by the Pacific Northwest National Laboratory. The Tank 241-C-106 HVAC system also includes a provision to support in-tank viewing CCTV system. This feature is an air-recirculation loop heater designed to reheat the air being returned to the tank to avoid fogging that would obscure the tank interior.

The addition of the in-tank imaging capability to Tank 241-C-106 by the WRSS is intended to resolve this shortcoming in past practice sluicing. The design also resolved the pump height adjustment delays experienced in the 1970's sluicing program by allowing remote pump intake level height adjustments. The adjustable height design draws heavily from the successful 1950's sluicing adjustable height pump design.

2.5.4.2.3 Slurry Pump Height Adjustment Delays. The use of straight-stick pumps rather than adjustable-length pumps resulted in the need to occasionally adjust the height of the pump intake. To accomplish this adjustment, sluicing had to be stopped, thereby affecting the duration of sluicing operations.

During the initial installation of the slurry pumps, the pumps were backflushed into the waste solids in the tank until the downward movement of the pumps stopped. This usually occurred before the pump mounting flange had mated with the associated riser flange. The distance between the flanges was measured and a two-part spool piece, slightly taller than this measurement, was fabricated on a priority basis. The pump was then raised with a crane, the halves of the spool piece were slipped into place, the pump was set on the spool, and the pump discharge jumper installed. This process required a minimum of two days and up to a week or more depending on the wind conditions present (open pit operations could not be conducted with wind speeds above 12 mph at that time). Because the wind was the major contributor to the duration uncertainty, the duration could not be accurately predicted in advance.

Because some of these sluicing operations supported and were close-coupled to the much more costly strontium recovery operations at B Plant, the duration uncertainties associated with pump height adjustments received a great deal of attention and were considered a point where the sluicing program needed to improve its performance. The sluice/slurry pump system resolved the pump height adjustment delays experienced in the 1970's sluicing program by allowing remote pump intake level height adjustments. The adjustable height design draws heavily from the successful 1950's sluicing adjustable height pump design.

2.5.5 Chemical Compatibility

In addition to completing the compatibility evaluations required by TWRS operating procedures, additional laboratory work was performed. In the experimental procedure described in HNF-SD-WM-TI-756, a sample of Tank 241-AY-102 supernate was mixed with a sample of Tank 241-C-106 sludge. No unusual behaviors were noted; and most importantly no exotherm was noted for the combined solution, indicating that the energetics of the mixture are not reactive. This result is consistent with the expectations based on the chemical composition of the sludge in Tank 241-C-106 and the supernate in Tank 241-AY-102. The major chemical species in the solid phase of the Tank 241-C-106 sludge are sodium aluminum silicates, iron hydroxide, sodium bicarbonate and carbonate, sodium oxalate and aluminum hydroxide (HNF-SD-WM-TI-756, Table 8-1). Of these species, only the sodium bicarbonate/carbonate is anticipated to dissolve in the Tank 241-AY-102

supernate and the dissolution releases a small amount of energy in comparison to the heat capacity of the water present (HNF-SD-WM-TI-756, Appendix A.10). In another experimental procedure described in PNNL-11381, *Washing and Caustic Leaching of Hanford Tank C-106 Sludge*, a sludge sample from Tank 241-C-106 was subjected to washing and caustic leaching. During the washing tests, approximately 25% by weight of the solid was dissolved, while in the more aggressive leaching tests 38% by weight of the solid dissolved. The strontium showed no tendency to dissolve in either test while cesium dissolution ranged from 40 to 60%. The transuranic elements showed no tendency to dissolve in either the 0.01 M NaOH wash or the 3 M NaOH leach. These experiments confirmed the chemical behavior described in the criticality safety evaluation for the project (HNF-SD-W320-CSA-001, *Criticality Safety Assessment for Tank 241-C-106 Remediation*), which concluded that plutonium will remain bound with the neutron absorbers in a predominantly agglomerated form, provided the pH remains alkaline.

2.6 SAFETY SUPPORT SYSTEMS

This section provides detailed descriptions of the relevant Tank 241-C-106 and Tank 241-AY-102 safety support systems and equipment in their respective tank farms. These safety support systems consist of indicators, controls/control systems and interlocks.

2.6.1 Fire Protection Systems

A fire protection system includes detection, alarm, and suppression elements. Most of the hydrants are fed from raw water systems. Portable fire extinguishers are in each of the tank farm control stations located at the edge of each tank farm.

2.6.2 Ventilation Exhaust Radiation Monitoring System

The ventilation exhaust radiation monitoring system consists of a continuous air monitor and a record sampler that provides continuous radiation monitoring of the ventilation exhaust. The ventilation exhaust radiation monitoring systems are able to detect and limit a radioactive aerosol leak, resulting from an unfiltered release of the exhaust gases to the environment, by initiating a shutdown of the exhaust system.

Continuous stack air monitors sample and monitor air for the presence of radionuclides in areas of potential airborne radioactivity. The continuous air monitors are located on the exhaust stacks of the primary and alternate/backup ventilation systems for both Tanks 241-AY-102 and 241-C-106.

2.6.3 WRSS System Interlocks

The interlocks utilized by the WRSS are listed in Tables 2-3 through 2-7.

2.6.4 System Controller and Interlocks

The ventilation system controller provides and performs the following functions:

- Differential pressure indication and alarm for process-related HEPA filtration units
- Tank vacuum monitoring and control system capable of fan speed adjustments and/or ventilation system shutdown upon tank ventilation system failure
- Isokinetic monitoring station at ventilation exhaust stack to monitor radiation emissions
- Emissions monitoring at ventilation exhaust stack to meet the requirements of 40 CFR 61, Subpart H, "National Emission Standards for Emissions of Radionuclides Other than Radon from Department of Energy Facilities."

Interlocks shut down the exhaust fan or prevent its operation when an exhaust high-radiation condition is detected by the ventilation exhaust radiation monitoring system (Table 2-4).

2.7 UTILITY DISTRIBUTION SYSTEMS

Tank 241-AY-102 is supported by buildings, systems, and components located in the AY Tank Farm, and served by utility systems that provide electrical power, process and instrument air, and cooling water.

Tank 241-C-106 is supported by trailers, systems, and components located in the C Tank Farm and served by utility systems that provide electrical power, 241-raw water, compressed air, and sanitary facilities.

2.7.1 Process and Instrument Air

The Tank 241-AY-102 compressed air system supplies instrument air to the primary tank and annulus ventilation systems and to the ALCs, which will not be operated during the retrieval activities. There are 22 independently controlled ALCs installed in Tank 241-AY-102.

2.7.2 Electrical Power

Power from the Hanford Site power grid is provided from existing 13.8 kV pole line C8-L6 (See Section 2.4.2.1 for a more complete discussion).

2.7.3 Water Supply

All water for the 200 East Area is supplied from the Hanford Site export water system and is distributed throughout the area in the raw water system and the sanitary water system. This treated water is supplied from the 200 Area power plants and is transported by tanker truck.

2.7.4 Compressed Air System

The compressed air system installed as part of the Project W-320 WRSS at the 241-C Tank Farm will be used. A dedicated compressed air system is provided (see Section 2.4.2.2 for a more complete discussion).

2.8 AUXILIARY SYSTEMS AND SUPPORT FACILITIES

No systems or facilities other than those described in the previous sections were identified as requiring descriptions in this document.

X = Indicates application or use.
DACS = Digital Alarm Control System.

Table 2-3. C-Farm Ventilation System Interlocks.

Event	Sensing device	Interlock action
High differential pressure across both exhaust HEPA filters, HEP-1361 and HEP-1362	1) PDISH-13620 & KY-13620 (30 second timer)	1) High Differential Pressure (-5 W.C.) Across HEPAs HEP-1361 & HEP-1362 starts timer KY-13620, 30 seconds later Exhaust Fan (FN-1362) is shut down.
High Radiation	2) RSH-1363 (KY-13531A), High Radiation	2) High radiation in the exhaust stack Air Monitor system shuts down Exhaust Fan (FN-1362).
Excess Tank Dome space Vacuum	3) PSH-1361, Excess Vacuum	3) Excess vacuum shuts down Exhaust Fan (FN-1362).
Exhaust Fan (FN-1362) not operating	4) Fan Motor Contactor Auxiliary Contact	4) Exhaust Fan (FN-1362) is interlocked with Stack Air Monitor Vacuum Pumps. An auxiliary contact on the Fan contactor interlocks the fan with the vacuum pumps. The Exhaust Fan must be operating before Air Monitor Vacuum pumps can be turned on.
Exhaust Fan (FN-1362) not operating	5) Fan Motor Contactor Auxiliary Contact	5) Exhaust Fan (FN-1362) is interlocked with Exhaust Heater (HC-1362). An auxiliary contact on the Fan contactor interlocks the fan with the heater.
Recirculating Fan (FN-1361)	1) Fan Motor Contactor Auxiliary Contact	1) Recirculating Fan (FN-1361) is interlocked with Recirculating Heater (HC-1361). An auxiliary contact on the Fan contactor interlocks the fan with the heater.
Primary Chilled Water Circulation Pump (P-1364)	Pressure Switch PSL-13610	Low pressure shuts down primary pump (P-1364) and starts stand by pump (P-1365).
Chiller System	Flow Switch FSLL-1364	Chiller system shuts down on low flow.

HEPA = high-efficiency particulate air (filter).
HVAC = heating, ventilating, and air conditioning.
VERMS = Ventilation Exhaust Radiation Monitoring System

Table 2-4. C-Farm Submersible Pump Shutdown Interlocks.

Event	Sensing device	Interlock action
Submersible Slurry Pump Stator Winding Temperature High	TISHH-13615	Shuts down Submersible Slurry pump.
Submersible Slurry Pump Bearing Temperature #1 High	TISH-13614A	Shuts down Submersible Slurry pump.
Submersible Slurry Pump Bearing Temperature #2 High	TISH-13614B	Shuts down Submersible Slurry pump.
Submersible Slurry Pump Level Detection (Low), 1 Minute Time delay	KY-13645	Shuts down Submersible Slurry pump.
Seismic Sensor Contactor Cabinet, Unit 1361, Temperature High	TSHH-13636	High Temperature opens the contactor supplying power to the Submersible Slurry pump.
Seismic Sensor Contactor Cabinet, Unit 1362, Temperature High	TSHH-13637	High Temperature opens the contactor supplying power to the Submersible Slurry pump.
Seismic Event Sensor (Unit 1361)	ASH-1361A (Transverse) ASH-1361B (Horz.Long.) ASH-1361C (Vertical)	Seismic event opens the contactor supplying power to the Submersible Slurry pump.
Seismic Event Sensor (Unit 1362)	ASH-1362A (Transverse) ASH-1362B (Horz.Long.) ASH-1362C (Vertical)	Seismic event opens the contactor supplying power to the Submersible Slurry pump.

Table 2-5. C-Farm Booster Pump Shutdown Interlocks.

Event	Sensing device	Interlock action
Pump Bearing #1 Temperature High	TSH-1363A	Shuts down Slurry Booster pump.
Pump Bearing #2 Temperature High	TSH-1363B	Shuts down Slurry Booster pump.
Stator Winding Temperature High	TSHH-1364	Shuts down Slurry Booster pump.
Pump Suction Pressure Low	PISL-1363/KY-13632	Low pressure starts timing relay KY-13632, after a time delay, (1-60 seconds) the Slurry Booster Pump shuts down.
Seismic Sensor Contactor Cabinet, Unit 1361, Temperature High	TSHH-13636	High Temperature opens the contactor supplying power to the Slurry Booster pump.
Seismic Sensor Contactor Cabinet, Unit 1362, Temperature High	TSHH-13637	High Temperature opens the contactor supplying power to the Slurry Booster pump.
Seismic Event Sensor (Unit 1361)	ASH-1361A (Transverse) ASH-1361B (Horz.Long.) ASH-1361C (Vertical)	Seismic event opens the contactor supplying power to the Slurry Booster pump.
Seismic Event Sensor (Unit 1362)	ASH-1362A (Transverse) ASH-1362B (Horz.Long.) ASH-1362C (Vertical)	Seismic event opens the contactor supplying power to the Slurry Booster pump.

Table 2-6. AY-Farm Submersible Pump Shutdown Interlocks.

Event	Sensing device	Interlock action
Submersible Sluice Pump Stator Winding Temperature High	TISHH-0621	Shuts down Submersible Sluice pump.
Submersible Sluice Pump Bearing Temperature #1 High	TISH-0622A	Shuts down Submersible Sluice pump.
Seismic Sensor Contactor Cabinet, Unit 0621, Temperature High	TSHH-06211	High Temperature opens the contactor supplying power to the Submersible Sluice pump.
Seismic Sensor Contactor Cabinet, Unit 0622, Temperature High	TSHH-06212	High Temperature opens the contactor supplying power to the Submersible Sluice pump.
Seismic Event Sensor (Unit 0621)	ASH-0621A (Transverse) ASH-0621B (Horz.Long.) ASH-0621C (Vertical)	Seismic event opens the contactor supplying power to the Submersible Sluice pump.
Seismic Event Sensor (Unit 0622)	ASH-0622A (Transverse) ASH-0622B (Horz.Long.) ASH-0622C (Vertical)	Seismic event opens the contactor supplying power to the Submersible Sluice pump.

Table 2-7. AY-Farm Booster Pump Shutdown Interlocks.

Event	Sensing device	Interlock action
Pump Bearing Temperature #1 High	TSH-06210A	Shuts down Sluice Booster pump.
Pump Bearing Temperature #2 High	TSH-06210B	Shuts down Sluice Booster pump.
Stator Winding Temperature High	TSHH-0629	Shuts down Sluice Booster pump.
Pump Suction Pressure Low	PISL-0621/KY-0621	Low pressure starts timing relay KY-0621, after a time delay, (1-60 seconds) the Sluice Booster Pump shuts down.
Seismic Sensor Contactor Cabinet, Unit 0621, Temperature High	TSHH-06211	High Temperature opens the contactor supplying power to the Sluice Booster pump.
Seismic Sensor Contactor Cabinet, Unit 0622, Temperature High	TSHH-06212	High Temperature opens the contactor supplying power to the Sluice Booster pump.
Seismic Event Sensor (Unit 0621)	ASH-0621A (Transverse) ASH-0621B (Horz.Long.) ASH-0621C (Vertical)	Seismic event opens the contactor supplying power to the Sluice Booster pump.
Seismic Event Sensor (Unit 0622)	ASH-0622A (Transverse) ASH-0622B (Horz.Long.) ASH-0622C (Vertical)	Seismic event opens the contactor supplying power to the Sluice Booster pump.

3.0 HAZARD EVALUATIONS AND ACCIDENT ANALYSES

3.1 INTRODUCTION

This chapter describes the methodology and presents the results of the hazard and accident analyses performed for WRSS components and operations described in Chapter 2.0, "Facility Description." This chapter also includes the facility hazard classification for WRSS. Based on the results of the hazard and accident analyses, Safety-Class and Safety-Significant structures, systems, and components (SSCs); Technical Safety Requirements (TSRs); and additional Defense-in-Depth controls are identified for protection of the public, onsite workers, and facility workers. This chapter also identifies design and operational features required specifically to protect the environment from uncontrolled releases of radioactive and hazardous material. Chapter 4.0 provides details of the safety structures, systems, and components identified herein. Chapter 5.0 provides the derivation basis of Technical Safety Requirements necessary to support the separate Technical Safety Requirement document required by DOE 5480.22, *Technical Safety Requirements*.

This page intentionally left blank.

3.2 REQUIREMENTS

The U.S. Department of Energy orders and standards that provide requirements and guidance for performing hazard and accident analyses to establish the safety basis of nuclear facilities are as follows:

- DOE 5480.23, *Nuclear Safety Analysis Reports*, Change 1 (1994)
- DOE-STD-1027-92, *Hazard Categorization and Accident Analysis Techniques for Compliance with DOE Order 5480.23, Nuclear Safety Analysis Reports* (1992)
- DOE-STD-3009-94, *Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports* (1994).

Additional design codes, standards, regulations, and U.S. Department of Energy orders relevant to specific hazards are identified as required in other sections of this addendum.

Risk evaluation guidelines to be used in this Addendum are contained in Tables 5.3-2 and 5.3-3 of the main text of the BIO.

This page intentionally left blank.

3.3 HAZARD ANALYSIS

This section contains the methodology and results of the hazards analysis conducted for the WRSS facilities and operations. The types of events considered in the WRSS hazards analysis are internal events, external events, and natural phenomena that can cause the uncontrolled release of radioactive or hazardous materials and affect the public, workers, or the environment. Sabotage and terrorism are not considered.

3.3.1 Methodology

The methodology used to perform the WRSS hazards analysis is the same as that described in Section 5.2.1 and Section D2.0 (Appendix D) of the BIO main text. Details of the hazards analysis, as related to the WRSS, are presented below.

3.3.1.1 Hazard Identification. The hazards analysis includes identification of the hazards associated with the WRSS design, processes, and operations. The same methodology described in Section 5.2.1.1 and Section D2.1 (Appendix D) of the BIO was used for the WRSS. The hazard identification form and related checklist used for the WRSS evaluation are the same as those shown in Tables D2.1-1 and D2.1-2 (Appendix D) of the BIO.

It should be noted that the WRSS material at risk assumptions are based on the following:

- **Chemical Inventory** — The source for the WRSS maximum hazardous chemical inventory is WHC-SD-WM-SARR-011, *Toxic Chemical Considerations for Tank Farm Releases*. This document contains the bounding limits for chemical-unit-liter concentrations of the waste to be transported through the WRSS.

- **Radiological Inventory** — The WRSS worst-dose radiological inventory is based on WHC-SD-WM-SARR-016, *Tank Waste Composition and Atmospheric Dispersion Coefficients for Use in Safety Analysis Consequence Assessments*, and WHC-SD-WM-SARR-037, *Development of Radiological Concentrations and Unit Liter Doses for TWRS FSAR Radiological Consequence Calculations*. These documents contain bounding unit-liter doses for the tanks within the TWRS facility.

3.3.1.2 Hazard Topography. The TWRS hazard topography is described in Section D2.2 (Appendix D) of the BIO. The hazardous conditions identified for the components and activities of the WRSS were mapped into this topography.

3.3.1.3 Hazard Evaluation. Detailed discussions of hazard evaluation techniques are presented in Section 5.2.1.2 and Section D2.3 (Appendix D) of the BIO. The methodology described in these sections was applied to the hazard evaluation of the WRSS. A hazards and operability (HAZOP) study was performed by a team of cognizant Project, Operations, and Engineering personnel; safety analysts familiar with the WRSS; and technical experts in specialty areas for the WRSS. The results of the WRSS hazard evaluation are contained in Appendixes A through C of this addendum.

3.3.1.4 Candidate Accident Selection. The methodology for candidate accident selection is described in Section 5.2.1.3 and Section D.2.4 (Appendix D) of the BIO. This methodology was applied to accident selection for the WRSS. The initial list of accident groupings (bins) was based on the list of candidate accidents developed for the BIO.

3.3.1.5 Controls Identification. The methodology for controls identification is described in Section 5.2.1.4 and Section D.2.5 (Appendix D) of the BIO. This BIO methodology was also applied to controls identification for the WRSS.

3.3.2 Hazard Analysis Results

This section summarizes the results of the hazards analysis activities, control decision process, and accident analysis for onsite consequences. This includes results of the hazard identification and evaluation, accident selection, and control identification activities. Section 3.4 describes the accident analysis and consequences. Details of the hazard analysis are provided in the following appendices of this addendum:

- Appendix A, "Hazard Topography"
- Appendix B, "Representative Analyzed Accidents"
- Appendix C, "Hazard Evaluation Results"
- Appendix D, "Control Allocation Tables."

3.3.2.1 Hazard Classification. DOE 5480.23 requires the hazard classification of nuclear facilities and operations. Guidelines for hazard classifications that meet the requirements of DOE 5480.23 are provided in DOE-STD-1027-92. DOE-STD-1027-92 classifies a facility as either Hazard Category 1, 2, or 3 depending on the quantities of radioactive material in the facility. Hazard Category 2 and 3 facilities contain quantities of radioactive material in excess of the threshold values in Table A.1 of DOE-STD-1027-92. A facility that does not exceed the DOE-STD-1027-92 Hazard Category 3 threshold for radioactive material, but possesses some radioactive material, is considered a radiological facility.

Waste retrieval operations were specifically excluded from the current BIO; the WRSS safety documentation is intended to augment the current BIO for retrieval of the Tank 241-C-106 waste via sluicing. The WRSS operations involve different mixtures of waste types than covered in the BIO. WRSS operations involve higher pressures and flow rates than analyzed in the BIO. In addition, new ventilation systems are considered. The results of the hazard evaluation done specifically for WRSS operations are summarized in Table 3.3.2-1. Table 3.3.2-2 provides a tabulation of some of the differences between WRSS operations and those covered in the BIO.

WRSS will transfer waste from Tank 241-C-106 to the double-shell Tank 241-AY-102, both of which are part of the Tank Waste Remediation System (TWRS). The TWRS has a Hazard Category 2 designation as described in the BIO main text. WRSS will not have any waste associated with it other than the waste it is transferring from one tank to the other. It is not a separate facility, but is physically attached to TWRS. Based on these factors, it is recommended that WRSS be given a Hazard Category 2 designation.

3.3.2.2 Hazard Evaluation. The hazard evaluation activity for the WRSS (documented in LA-UR-97-1581, *Preliminary Hazard Analysis for Project W-320*) determined a set of potential hazardous conditions that could result in the uncontrolled release of radioactive and/or hazardous material. The results of the accident selection, frequency/consequence assessment, and control allocation are given in Appendixes B, C, and D, respectively of this addendum.

The hazard evaluations support the selection of accidents for more detailed analysis and the identification of safety controls. The controls for the safe operation of WRSS are identified based on both the accident and the hazard analysis results. This section addresses the accident selection and identification of controls. It covers controls for offsite, onsite, worker, and environmental consequences. Section 3.4 describes the details of the accident consequence analysis.

3.3.2.2.1 Accident Selection. Hazardous conditions identified by the hazard evaluation, specifically conducted for WRSS operations, were used to select accidents for analysis and evaluation (LA-UR-97-1581). The design characteristics and configuration of the WRSS equipment was considered in determining the hazards. The hazards specific to WRSS operations are summarized in Table 3.3.2-1 and were compared with those identified for the BIO. This comparison resulted in the grouping of the identified hazards into groups (or bins) for further evaluation which corresponded to the groups established for analysis in the main text of the BIO. The groups of hazards are represented in the accident analysis by representative and bounding accidents. The titles of the representative accidents were changed to match the terminology of the BIO main text, as reflected in Table 3.3.2-2. Further evaluation was then performed to determine if the analysis in the main text of the BIO was bounding or if the WRSS operations required specific analyses. Table 3.3.2-3 identifies each analyzed accident and provides a reference to the appropriate section of the addendum and the main text of the BIO.

It is important to note that all the hazardous conditions represented by the same accident analysis are not the same in every respect. Each unique hazard represented by a specific analysis can have different initiating events, which can result in different controls being applied to prevent or mitigate the hazard.

Appendix B of this addendum lists the analyzed (representative) accidents as developed in the hazards evaluation, as well as the hazardous conditions represented by each accident.

For each hazardous condition listed in Appendix B of this addendum, the following information is provided:

- The accident release category that identifies hazardous conditions that could result in common accident release attributes
- A specific and unique identification number associated with each hazardous condition
- The material at risk
- The hazardous condition that defines a release (information is provided on the location of the release and whether the material is hazardous or toxic)
- The cause of the hazardous condition

- The initial frequency and consequence assessment for an accident associated with a particular hazardous condition (this assessment assumes no controls or active systems were in place)
- A cause group identifier
- A representative accident number that is assigned to a hazardous condition grouping (bin).

3.3.2.2.2 Defense-in-Depth. The hazardous conditions identified for the WRSS are shown in Appendix C of this addendum and are arranged according to consequence category. Where applicable, Defense-in-Depth controls have been allocated to hazardous conditions. In addition, Defense-in-Depth controls have been allocated to the hazardous conditions with significant facility worker consequences. For each accident analyzed, a summary of the structures, systems, and components and Technical Safety Requirements along with the Defense-in-Depth controls are shown in Table 3.3.2-4.

3.3.2.2.3 Facility Worker Protection. In the course of the WRSS hazards analysis process, a number of potential hazardous conditions only affecting the facility worker were identified. These hazardous conditions were divided into radiation protection and occupational safety concerns.

Radiation Protection. This section discusses only potential facility worker radiation exposure not related to the loss of containment of radioactive material. As a result of the hazards analysis performed for WRSS, four potential facility worker radiation exposure concerns specifically associated with WRSS were identified. These potential facility worker radiation exposure hazardous conditions, along with their identifiers and causes, are presented in Table C-5 of Appendix C of this addendum. All WRSS-specific radiation protection issues are currently covered under the Hanford Site radiation protection program.

Occupational Safety. The hazards analysis performed on WRSS and its physical interfaces with other facilities also identified a number of potential facility worker occupational safety concerns. Potential facility worker occupational safety hazardous conditions, along with their identifiers and causes, are presented in Appendix C, Table C-6 of this addendum. All of the identified occupational hazards identified for WRSS are covered under the Hanford Site occupational safety program and are addressed in HNF-SD-WM-HSP-002, *Tank Farms Health and Safety Plan*.

3.3.2.2.4 Environmental Protection. The hazard evaluation included a qualitative assessment of the environmental impact of hazardous conditions that could potentially result in an uncontrolled release of radioactive or hazardous material. The results of this assessment are given in Appendix C, Table C-4 of this addendum. Hazardous conditions with significant environmental consequences (E2 or E3) are identified in the hazard analysis conducted for the WRSS (Table C-4 in Appendix C of this addendum). Section 5.4.4 of the main text of the BIO provides discussion and additional required controls to protect the environment.

The impacts of tank waste leaking to the soil are covered in DOE/EIS-0189, *Final Environmental Impact Statement for the Tank Waste Remediation System*, and in WHC-SD-WM-ES-218, *Engineering Study of Tank Leaks Related to Hydraulic Retrieval of Sludge from Tank 241-C-106*. Multiple options, including the no action which postulates all the waste from 177 tanks leaks to the ground, are reported in DOE/EIS-0189. Appendix F, Table F.2.2.13 of DOE/EIS-0189 gives duration of the contaminant release as occurring over a time period of 2.85 to 158 years. The waste reaches the interface between the vadose zone and the groundwater 140 to 250 years later (DOE/EIS-0189). A postulated 151,400 L (40,000 gal) during sluicing operations is assumed in WHC-SD-WM-ES-218. Travel time to the aquifer is estimated to be 60 years (WHC-SD-WM-ES-218). The effect of the leak to the soil (including previous leaks and spills in the tank farms) may require some form of soil remediation. This will cause future clean up costs to be increased. However, both these studies indicate that there is no short-term risk (1 year or less) to the onsite receptor located at 100 m (328 ft) or the offsite receptor.

Table 3.3.2-1. Project W-320 Hazards Identification.[a]

Energy Classification	Accident Number[b]	
	PT	PE
Corrosive	2,4,5	1,2,4,5
Explosive/pyrophoric	6,7,8	6,7,8
Nuclear criticality	15,16	15
Flammable materials	11,13,14	11,13,14
Thermal radiation	5	N/A
Chemical reactions	1	N/A
Friction	3,5	1,2,3,5
Electrical	3,4,5,6,9,10,11,14,16	3,4,5,6,7,8,9,10,11,12,14,16,18
Kinetic-rotational	2,3,4	2,3,4,7
Kinetic-linear	1,5,7	1,4,5,7
Mass, gravity, height	3,5,11,15,16	2,3,5,10,11,15,16
Pressure-volume	7,9,11	5,6,8,9,11,12
Thermal (except radiant)	N/A	3,6

[a] The hazards identification represents the hazards that could potentially cause an uncontrolled release of radioactive or hazardous materials only. Hazards only resulting in personnel injury are not included.

[b] The numbers correspond to a section number, 3.4.2.x, for example the number "3" refers to Section 3.4.2.3.

N/A = not applicable.
PT = potentially present in the facility.
PE = potentially present elsewhere in/adjacent to facility.

Table 3.3.2-2. Candidate Accidents Versus Analyzed Accidents Used for WRSS Analysis. (2 sheets)

Difference between Representative Accidents and Analyzed Accidents		
Representative Accidents	Analyzed Accidents	Comments
1. Pump Vortices Criticality in Tank	1. Nuclear Criticality	WRSS-specific analysis performed
2. Release through Failed HEPA Filter due to a Tank Bump	2. HEPA Filter Failure - high temperature - high pressure	WRSS-specific analysis performed - source term for WRSS operations different from BIO analysis
3. Ventilation Ducting Breach/Unfiltered Release	3. HEPA Filter Failure - high temperature - high pressure	Consequences bounded by accident 2, above
4. Flammable Gas Ignition in Pit	4. Fuel Fire in Contaminated Area	BIO analysis found to be bounding
5. Caustic Spray Leak	5. Caustic Spray Leak	BIO analysis found to be bounding
6. Tank Failure due to Flooding Dome Load	6. Tank Failure due to Excessive Loads	WRSS-specific analysis performed - analyzed using AWF solids
7. Tank Failure due to Excessive Vacuum	7. Tank Failure due to Excessive Loads	Consequences bounded by accident 6, above
8. Flammable Gas Release Event with Ignition	8. Flammable Gas Deflagrations	BIO analysis (qualitative) adopted
9. Organic Layer Formation and Subsequent Organic Fire	9. Organic Solvent Fire - Pool Fires - Puddle Fires - Wick Stabilized Fires	WRSS-specific analysis performed, analyzed different organic solvent than the BIO
10. In-Tank Propylene Glycol Fire	10. In-Tank Fuel Fire/Deflagrations	Consequences bounded by accident 9, above
11. Steam Bump	11. Tank Bump	WRSS-specific analysis performed - unique to WRSS activities
12. Liner Breach due to Steam between Steel Liner and Concrete Shell in C-106	12. Liner Breach due to Steam between Steel Liner and Concrete Shell in C-106	WRSS-specific analysis performed - accident scenario not part of the BIO
13. Transfer Line Develops Leak and Secondary Casing is Defective	13. Subsurface Leak remaining Subsurface	WRSS-specific analysis performed - transfer line configuration different than that analyzed in the BIO
14. Local Flooding during Transfer/Line Uncovered and Breached	14. Subsurface Leak Resulting in Pool	WRSS-specific analysis performed - higher flow rate/pressure and ULDs than analyzed in the BIO
15. Pipe Break or Leak in Pit, Drain Cover On, Pit Fills and Overflows	15. Surface Leak Resulting in Pool	WRSS-specific analysis performed - higher flow rate/pressure and ULDs than analyzed in the BIO
16. Spray Leak from Flushing Connection in AY-102 Pit during Sluicing Transfer	16. Spray Leak from Structure	WRSS-specific analysis performed - unique WRSS configuration
17. Spray Leak from Waste Transfer Line	17. Spray Leak from an Underground Waste Transfer Line	WRSS-specific analysis performed - higher flow rate/pressure and ULDs than analyzed in the BIO

Table 3.3.2-2. Candidate Accidents Versus Analyzed Accidents Used for WRSS Analysis. (2 sheets)

Difference between Representative Accidents and Analyzed Accidents		
Representative Accidents	Analyzed Accidents	Comments
18. Natural Phenomena - high wind - dust devil - flood - range fire - ash fall - lightning - seismic	18. Natural Phenomena (Note: Not analyzed)	No specific analyses Natural Phenomena were performed. They were considered as potential initiators for the accidents listed above

AWF = Aging Waste Facility.
HEPA = High-efficiency particulate air (filter).
ULD = Unit-liter dose.
WRSS = Waste retrieval sluicing system.

Table 3.3.2-3. Accident Analysis Sections.

Section which addresses analyzed accident			
Number	Analyzed accidents	Addendum Section	Main Text Section
1	Criticality	3.4.2.1	5.3.2.1
2	HEPA Filter Failure Due to Exposure to High Pressure or High Temperature	3.4.2.2	5.3.2.2
3	Unfiltered Release	3.4.2.3	5.3.2.2

3.4 ACCIDENT ANALYSIS

The following sections describe the results of the analyses of the potential accidents identified in Section 3.3.2. The consequence calculation methods common to the analyses are summarized in Section 5.3.1 of the BIO main text, including a discussion of receptor locations and exposure pathways, radionuclide and hazardous chemical inventories and associated unit liter dose (ULD) and sum-of-fraction values, atmospheric dispersion, and the equations used to calculate downwind radiological and toxicological consequences. Section 3.4.1 describes how the WRSS-unique ULD and sum-of-fraction values were selected.

Results of the evaluation basis accident analyses that are unique to WRSS are presented in Section 3.4.2. Evaluation basis accidents are analyzed to identify the set of Safety-Class and Safety-Significant structures, systems, and components and TSRs. These are identified by performing an analysis in which no credit is taken for preventive or mitigative controls. The results of the analyses without controls are compared to risk guidelines. If the guidelines are exceeded, safety structures, systems, and components and TSRs that reduce the event frequency or consequences are added. Analyses with controls (that assume the identified controls are functioning as intended) are then performed.

This page intentionally left blank.

3.4.1 Methodology

This section summarizes the general calculation methods used to quantify the radiological and toxicological consequences of postulated accidents. The individual analyses, presented in Section 3.4.2, summarize the consequence calculation methods specific to individual postulated accidents. Accidents involving the transfer lines, such as the spray leaks and pool leaks, were evaluated at a flow rate of 28.4 L/s[1] (450 gpm) for normal flow and 41.0 L/s (650 gpm) for flow without restriction. The project requested that the accident analysis use these values to provide a conservative envelope for the anticipated flow rate of approximately 22.1 L/s (350 gpm). In addition, the source term is expected to change over the course of the transfer operations because of factors like dissolution of solids and liquid/solid fractions. To account for these, conservative assumptions have been made (below). Samples will be periodically taken to ascertain that the project is remaining within the analyzed envelope.

3.4.1.1 Radiological Consequence Calculation Methodology.

3.4.1.1.1 Radionuclide Inventory. WHC-SD-WM-SARR-037 discusses in detail the development of the radionuclide inventory. Table 3.4.1-1 lists the radionuclide constituents that make up the individual ULDs that were used in the accident analysis for WRSS operations.

3.4.1.1.2 Exposure Pathways. Two potential radiological exposure pathways (i.e., internal and external) are associated with releases of radioactive materials. The total effective dose equivalent calculated for an individual is equal to the sum of the dose contributions from these two exposure pathways. See Section 5.3.1 of the BIO for more detail.

3.4.1.1.3 Dose Calculation Methods. WHC-SD-WM-SARR-016 presents an overview of (1) the method used to calculate the inhalation dose to the maximum onsite individual, and (2) the inhalation, ingestion, and resuspension dose to the maximum offsite individual. WHC-SD-WM-SARR-037 presents a detailed description of the derivation of ULD values. This section develops the application of specific ULDs and liquid/solid ratios for the WRSS.

Liquid/Solid Ratios. Table 3.4.1-2 lists the liquid/solid waste ratios used in the WRSS analysis. The basis for the 67/33 ratio in Tank 241-C-106 and the slurry line is the expected maximum solids loading during sluicing. It is anticipated that 33% solids in the slurry will be bounding. The same ratio is assumed for the Tank 241-C-106 headspace and HEPA filters because the contamination in these areas originates from the Tank 241-C-106 aqueous phase.

---

[1]Most of the units involved in this project are measured in English units. For example, the flow rate is 450 gpm. The metric conversion for this is 28.4 L/s, that is, this is a "hard" conversion. The values are reported with enough decimal places so that conversion back to the original units results in little if any error. For example, rounding 28.4 L/s to 28 L/s and converting back to English units would give 443.8 gpm; obviously not the correct value. Therefore, to reduce conversion errors, this practice is followed throughout this document.

This is obviously conservative, because loading the headspace and the HEPA filters would take considerable time at 67/33 and the sluicing operation is of limited duration.

The basis for the 90/10 ratio in Tank 241-AY-102 and the sluice line is the same as the 67/33 ratio assumed for Tank 241-C-106. The reduced solids content is assumed because of the large layer of supernate in Tank 241-AY-102 (approximately 9.14 m [30 ft]), and the operational intention to draw the sluice stream from the top of the tank and inject the slurry stream into the bottom of the tank using a slurry distributor. A lower entrainment of solids in the sluice line (i.e., supernate of Tank 241-AY-102) is needed for the sluicing to be successful.

Composite Unit Liter Doses for Liquids and Solids. DOE-STD-3009-94 requires the Evaluation Basis Accidents to be analyzed in an unmitigated format (without administrative controls and active systems) and, if necessary, a mitigated format (taking control strategies into consideration). As part of this approach, two cases were chosen for waste transfer-related accident scenarios to provide ULDs for the liquids and solids. The first is a bounding case intended to provide a conservative estimate of ULDs. The second is a reasonable case that assumes minimal mixing of Tank 241-AY-102 solids, more representative of conditions expected in the controlled incremental sluicing activity of the WRSS. The terms "bounding" and "reasonable" were chosen based upon radiological considerations, not toxicological.

Bounding Case. For the bounding case (or the case without controls), the liquids ULD is assumed to be composed of 100% Aging Waste Facility (AWF) tank liquids, and the solids ULD is assumed to be composed of 100% AWF tank solids (the AWF ULDs are in Table 3.4.1-3). These ULDs are then used with the liquid/solid ratios found in Table 3.4.1-2 to arrive at the composite ULDs used in the unmitigated transfer accident scenarios (the columns labeled "inhalation bounding case" and "ingestion bounding case" in Table 3.4.1-4). The bounding ULDs used in the accident analysis are comprised entirely of AWF solids and AWF liquids. The ULD for the SST liquids is larger than the ULD for AWF liquids. However, the SST liquids ULD is bounded by the composite ULDs used for this project (Table 3.4.1-4). Since Tank 241-C-106 contains mostly sludge, there is very little SST liquid actually available to contribute to the source term. If the SST liquids ULD is used instead of the AWF liquids in the "bounding" case, the results are within 5%. This would not result in any meaningful changes when comparing to guidelines, setting safety structures, systems and components, or developing controls.

Reasonable Case. For the accident consequences with controls a more reasonable source term assumption was used which is more representative of conditions expected in the controlled incremental sluicing activity of the WRSS. It is assumed that the slurry distributor does not significantly mobilize the aging waste solids. This source term assumption will be confirmed during sluicing by calculating the total solids loading transferred after each batch of 12 hours maximum duration. For the reasonable case (or the case with controls), the liquids ULD is modeled as having a composition consisting of 10% SST liquids and 90% AWF tank liquids. This mixture of ULDs accounts for some of the SST liquids to be entrained during sluicing; however, the vast majority of liquids will be from Tank 241-AY-102, which provides the

sluice stream. The solids ULD for the mitigated accident scenarios is modeled as having a composition consisting of 10% AWF solids and 90% SST solids. This is a reasonable mixture, considering the nature of the operations: SST solids (Tank 241-C-106) are to be sluiced and pumped on top of AWF tank solids (Tank 241-AY-102) in a manner that minimizes mixing and disturbance of the Tank 241-AY-102 solids.

Assuming that 10% of the solids entrained in the sluicing operation are AWF tank solids is considered a reasonable upper bound for selection of ULDs. The representation of Tank 241-AY-102 solids by the AWF solids source term is conservative. The solids in Tank 241-AY-102 are much more benign than the AWF solids source term, which is based on a maximized isotopic distribution from sample data representing all four AWF tanks. For example, the significant inhalation dose contributor to the AWF source term dose is ^{241}Am, which represents 76% of the total inhalation dose. The concentration of ^{241}Am from Table 3.4.1-1 is 1.1 E+10 Bq/L. Data from 241-AY-102 (WHC-SD-WM-ER-454) indicate a ^{241}Am concentration of 9.3 E+08 Bq/L. Because of the conservatism in this term, it is only necessary to confirm the total solids loading after each batch during WRSS operations. Confirmation of a total solids loading in the slurry line of less than 33% will provide reasonable assurance that conditions in the field are bounded by the analysis. Historical data from past sluicing indicates that the actual solids loading in the slurry line will normally be below 10%. As a result, a much lower concentration of solids in the sluice line is necessary for sluicing to be successful.

The ULDs from Table 3.4.1-3 multiplied by the ratios discussed above and weighted by the liquid/solid ratios from Table 3.4.1-2 result in the composite ULDs that are used when reasonable accident consequences are estimated (the columns labeled "inhalation reasonable case" and "ingestion reasonable case" in Table 3.4.1-4). Other controls would also be credited at this time to form the total "mitigated" accident consequences.

3.4.1.2 Toxicological Consequence Calculation Methodology.

3.4.1.2.1 Chemical Inventory.

Gases, Liquids and Solids. The chemical composition of tank waste has been determined based on an evaluation of currently available data that characterizes the tank waste. Similar to the approach used for radionuclides, scatter plots for each of the 24 analytes were generated for both solid and liquid single-shell and double-shell tank samples, and the concentrations were reviewed by an expert panel to determine the maximum valid concentration. The scatter plots, along with the supporting data, procedures, and assumptions are documented in WHC-SD-WM-ER-400, *Tank Waste Source Term Inventory Validation.* WHC-SD-WM-SARR-011 presents a detailed discussion of the development of the chemical inventory. Table 3.4.1-5 provides the chemical constituents used to develop the liquid and solid sum-of-fraction of risk guidelines. Table 3.4.1-6 provides the chemical constituents in the released slurry gases used for the gaseous sum-of-fractions of risk guidelines.

3.4.1.2.2 Exposure Pathways. The toxicological source terms resulting from TWRS accidents comprise liquid and solid particulates and gases. The effects of chemical exposure are evaluated based on the airborne pathway only,

because the toxicological risk guidelines are based on the chemical concentration at the location of the maximum onsite and offsite individuals. Inhalation of chemicals, and exposure to the skin and eyes, were considered in developing the risk guidelines.

3.4.1.2.3 Exposure Calculation Methods. The basic sums-of-fractions used in the analysis are taken from WHC-SD-WM-SARR-011. The application of specific sums-of-fractions for the WRSS is developed in this section.

Following the information provided earlier on the liquid/solid ratios and the bounding and reasonable composites, sums-of-fractions were developed for each frequency category and for the case of a continuous release or a puff release. Table 3.4.1-7 provides the values used in this document. As discussed earlier, the terms "bounding" and "reasonable" were chosen based upon radiological considerations, not toxicological. Even though the toxicological sum-of-fractions labeled "bounding" is less than the sum-of-fractions labeled "reasonable," both were used in the calculations and compared against the risk guidelines. The derivation of unit release sum-of-fraction values are discussed in more detail in WHC-SD-WM-SARR-011.

3.4.2 Evaluation Basis Accidents

This section presents analyses of evaluation basis accidents identified in Table 3.3.2-1. The evaluation basis accidents are analyzed to identify Safety-Class and Safety-Significant SSCs and TSRs.

The first step in the analytical process is to quantify the consequences and frequency of a postulated accident, assuming the absence of existing preventive or mitigative features. As stated in DOE-STD-3009-94 assuming the absence of preventive or mitigative features "does not require denying the physical design of facility structures, systems, and components." Accordingly, credit is taken for certain design features, primarily those that are passive (e.g., in a waste transfer analysis, it is assumed that a waste transfer line is encased).

Understanding that an "analysis without controls" is an evaluation of a hypothetical condition and not an evaluation of the current operational configuration of a subject facility is important. The purpose of performing the analysis without controls is to establish a baseline risk (i.e., a consequence and frequency) that can be compared to the risk guidelines. This comparison puts the relative importance of the need for controls into perspective and defines the need for further analysis.

Consequences for analyses without controls are calculated by not taking credit for mitigative features (e.g., filtered ventilation pathways) during source term development. Frequencies are based on the absence of controls, not the failure of controls at a defined rate, and are therefore equal to the initiating event frequencies. Based on this approach, the frequency of accidents without controls typically falls in the anticipated category (i.e., $>1 \times 10^{-2}$ to $\leq 1 \times 10^{0}$ per year). This should not be misinterpreted to mean that the consequences of an accident without controls can actually occur at a TWRS facility at an anticipated frequency. As already stated, these are evaluations of hypothetical conditions performed to establish a baseline risk.

Once determined, the consequences and frequency of the accident without controls are compared to the risk guidelines. If the consequences are within both the onsite and offsite guidelines at the applicable frequency, no further quantitative analysis is performed to define controls. In such cases, existing controls are typically defined as providing Defense-in-Depth.

If the risk guidelines are exceeded, additional analysis is required to identify Safety-Class or Safety-Significant SSCs and TSRs. In accordance with WHC-CM-4-46[2], *Safety Analysis Manual*, Safety-Class SSCs are required if the offsite guidelines are exceeded. Safety-Significant SSCs are required if the onsite radiological or toxicological guidelines are exceeded.

---

[2]Refer to Appendix F, "Site-wide Controlled Manual Cross Reference Table," of the BIO for the cross-walk between sitewide controlled manuals (e.g., WHC-CM-X-XX) superseded by FDH procedures (e.g., HNF-PRO-XXX).

Consistent with DOE-STD-3009-94, safety SSCs and TSRs are selected using an iterative process in which credit for preferentially selected controls is taken incrementally and the results are compared with the risk guidelines. The result is an "analysis with controls." In these analyses, consequences and frequencies are determined, assuming that the identified controls function as intended. If the controls are mitigative, the accident frequency remains unchanged relative to the analysis without controls, but consequences are reduced. If the controls are preventative, the means by which the controls prevent the accident (or serve to reduce its frequency) are described, but no consequences are calculated. Although these analyses make the assumption that the controls function as intended, it is recognized that each identified SSC and TSR has an associated failure rate.

Controls were selected using the process and control decision criteria discussed in the BIO main text, Section 5.3.2. When comparing the results of analyses with and without controls to the guidelines, consideration was given to the margin by which the guidelines were met and the reliability of the selected controls. For cases in which the margin was small, the need for additional controls was evaluated. In these evaluations, the degree of conservatism in the consequence calculation was considered. Controls known to be of low reliability were not selected. For cases in which the degree of reliability was uncertain, the need for additional controls was evaluated.

The following sections summarize the findings of the evaluation basis accident analyses. A scenario, source term, consequence analysis, and comparison with guidelines are presented for each evaluation basis accident, both without and with controls. Selected safety structures, systems, and components; TSRs; and Defense-in-Depth controls are identified and defined. Each scenario describes the accident progression that links initiating events with other contributing phenomena and, for the analyses with controls, selected preventive or mitigative controls. For operational accidents, the scenario frequencies were developed from TWRS operating history and applicable equipment failure rates and human error probabilities. The frequencies were developed to a level of detail sufficient to place the event in a two-order of magnitude category as defined by the risk guidelines (i.e., 10^{-4} to 10^{-2}/yr).

Source terms and consequences of the postulated accidents were calculated using the method described in Section 3.4.1. The calculations are deterministic. Realistic, yet conservative, values were selected for each parameter used in the source term calculations. The ULDs, sum-of-fractions, and adverse meteorological conditions used in the consequence calculations also add conservatism. Such a compounding of conservatisms results in consequence values which when combined with the event frequency, can overstate the actual risk. This conservatism, however, is relied on to ensure that associated uncertainties are bounded. The sensitivities of key assumptions used in the consequence calculations are presented following the comparison with guidelines.

3.4.2.1 Criticality. The WRSS criticality accident is an internally initiated operational accident.

3.4.2.1.1 Scenario Development. WHC-SD-W320-CSA-001, *Criticality Safety Assessment of the Tank 241-C-106 Remediation*, concludes that an inadvertent criticality as a result of the activities associated with WRSS is not considered possible for the plutonium concentration determined to be in tank waste and the WRSS process to be applied to the tank waste (WHC-SD-W320-CSA-001). The criticality safety evaluation considered the potential settling behavior of the sludge in both tanks, the behavior of the sludge in pumps used in both tanks, and the resultant mixture of sludges in the receiver tank. The following paragraphs summarize the information found in WHC-SD-W320-CSA-001.

Tank 241-C-106 stores a total mass of plutonium that may be higher than in any other waste storage tank on the Hanford Site. For this reason, Tank 241-C-106 has the potential for a higher localized concentration of plutonium than any other waste tank. The best estimate of the highest concentration of plutonium that could be drawn into the transfer pump was identified, and the impact of discharging the fissile material bearing solids into Tank 241-AY-102 was determined.

Because core samples are mixed and homogenized before analysis, the analysis will not detect high plutonium concentration layers in the sludge. If a high plutonium concentration layer is formed and drawn into the discharge pump housing, the possibility exists that a more favorable geometry with respect to criticality might be achieved. Because the composition of the waste currently stored in Tank 241-C-106 and Tank 241-AY-102 cannot be observed, the estimate of the highest concentration of plutonium that may exist was determined largely by comparing historical records, transfer data, sample data, and computer modeling. Worst-case scenarios were chosen to investigate the concentrating mechanisms and the mass/geometry consequences of distributing the solids in both tanks.

Existing documents agree that waste in Tank 241-C-106 consists of four major waste layers. The plutonium concentration in each layer was estimated from a combination of flowsheet and sample information documented in WHC-MR-0132, *A History of the 200 Area Tank Farms*; LA-UR-94-2657, *Hanford Defined Wastes: Chemical and Radionuclide Compositions*; LA-UR-96-3860, *Hanford Tank Chemical and Radionuclide Inventories of HDW Model Rev. 4*; and WHC-EP-0793, *Estimation of Plutonium in Hanford Site Waste Tanks Based on Historical Records*. A review of sample data stored in the waste characterization data files supported the estimated composition of the waste layers.

A value for the highest plutonium concentration that may exist in a layer in the major waste types was based on a study of more than 260 waste transfers from the Plutonium-Uranium Extraction (PUREX) Plant to Tank 241-AZ-101 (HNF-SD-W151-CSA-001, *CSER 96-014: Criticality Safety of Project W-151, 241-AZ-101 Retrieval System Process Test*). Quantified uncertainties about the analogy between Tank 241-C-106 and Tank 241-AY-102 were not attempted, because empirical data on the plutonium concentrations of thin layers of waste in either tank are not available. The information from Tank 241-AZ-101 was used

because both tanks received plutonium-bearing waste in small batches, the waste in each batch was made alkaline before discharge, the plutonium-bearing solids settled out in layers, and the plutonium precipitate is expected to exhibit the same chemical and physical characteristics in both tanks. The highest plutonium concentration in the solid phase of a transfer from PUREX was estimated to be as much as six times greater than the average concentration of a waste layer. However, the layer of solids from a single transfer is estimated to be only a millimeter thick and will be diluted in the sluicing process.

For Hanford Site waste, the plutonium concentration must be at least 2.6 g Pu/L before criticality becomes possible, even in an unlimited volume of waste. This value is based on a uniform mixture of plutonium and other materials. The waste solids are conservatively assumed to match the Rogers Waste Model (WHC-SD-SQA-CSA-20356, *CSER 92-009: An Analytical Model for Evaluating Subcritical Limits for Waste in Hanford Site Storage Tanks*), which defines a minimum neutron absorber composition, assumes a solids density of 1.2 g/cc, and assumes the water content is optimized. This subcritical limit is set for k_∞ not exceeding 0.95 at a 95% confidence level. After considering the uncertainty, the calculated k_∞ is 0.935.

Potential segregation of plutonium-bearing solid particles is a primary concern with the activities associated with WRSS. Computer simulations estimated the segregation of various particle sizes in the pump well in Tank 241-C-106 and in layers settling in Tank 241-AY-102. The segregation of plutonium was evaluated by extrapolating the data from the models with the assumption that the plutonium existed exclusively as one of the particle sizes modeled (5 to 10 μm, 25 to 35 μm, or 50 to 55 μm). The largest particles (50 to 55 μm) are expected to exhibit the greatest degree of particle segregation from the bottom of the hole (pump well) to the top. The finest particles (5 to 10 μm) are the most uniformly distributed; the medium-sized particles and the plutonium-bearing solids in the conservative representation are expected to exhibit only moderate segregation.

The composition of solids and liquids involved in the retrieval operation will affect the behavior of plutonium in the sludges. Both plutonium solubility and plutonium sorption/desorption on the sludge particles are affected by solid and liquid composition. In Tank 241-AY-102, the average concentration of plutonium in the sludge is a factor of 34 lower than the minimum critical concentration of 2.6 g/L. The mass ratios for Fe/Pu and Mn/Pu are 1070 and 147, respectively. The Fe/Pu and Mn/Pu mass ratios are much greater than the minimum critical mass ratios for these neutron absorbers of 160 and 32, respectively. To reach these minimum criticality limits, the average sludge material must undergo a chemical alteration that concentrates the plutonium 34 times and that separates plutonium from iron and manganese by factors of 6.7 and 4.6, respectively.

Any chemical mechanism for concentrating the plutonium in a waste tank would require transport of plutonium from the solid phase to the aqueous liquid phase, and then to a small volume solid phase. Hence, for the first step, sorbed plutonium must be desorbed into the aqueous phase of the waste mixture. Plutonium sorption on oxyhydroxides is known to be mostly irreversible unless the solution composition in contact with the plutonium is

dramatically altered. This would require (1) the addition of organic or inorganic plutonium complexants, (2) a change in the REDOX potential of the solution by adding oxidants, or (3) acidification of the solution. None of these dramatic changes are part of the scope of the WRSS. A primary parameter for ensuring criticality safety is the mass ratios of insoluble absorbers to plutonium, i.e., Fe and Mn. The transport of soluble solids from the solid phase to the sluicing supernate will not impact the mass ratios of Fe/Pu and Mn/Pu. Even though the plutonium concentration per liter of solids may increase, the mixture will be subcritical regardless of the moderation or quantity.

A hole (e.g., pump well) was sluiced into the Tank 241-C-106 waste so that the immersible pump could be installed. The estimated concentration of plutonium in the slurry inside the hole depends on the initial plutonium concentration and the assigned particle size. The concentration of plutonium in all the solids entering the hole was assigned the high concentration of 0.78 g Pu/L of solids. Even though the medium-sized particles (25 to 35 μm) are considered conservative, the plutonium was assigned the coarsest particle dimension to provide a bounding analysis. The plutonium concentration of the slurry was determined to be 0.55 g Pu/L near the bottom of the hole and 0.12 g Pu/L of slurry near the surface of the hole. The other particle sizes were also evaluated and, as predicted, the plutonium concentration is fairly uniform throughout the hole, ranging from 0.12 g Pu/L to 0.2 g Pu/L of slurry. These concentrations are highly subcritical regardless of the geometry, quantity, or moderation.

Assuming that plutonium exists as the largest particle size (50 to 55 μm), the increase in plutonium concentration caused by settling was investigated. The particle segregation predictions discussed in WHC-SD-WM-TI-757, *Fluid Dynamic Particulate Segregation, Chemical Process, and Natural Ore Analog Discussions that Relate to the Potential for Criticality in Hanford Tanks* indicate that, for the most realistic scenarios, the level of segregation of fissile material from neutron absorbers is roughly a factor of 2.5. To bound these conclusions, the plutonium concentration was assumed to be increased by a factor of three. This results in a plutonium concentration of settled solids at the bottom of the pumpout well of 2.34 g Pu/L. Since the quantity of neutron absorber materials present is over 10 times the amount necessary to preclude a criticality, it is concluded that the waste will remain subcritical.

An operational scenario that was evaluated consists of the slurry pump being shut down for a time sufficient enough to allow all the solids in the hole to settle. The assumed retrieval rate of the slurry pump for this scenario is 18.9 L/s (300 gpm), so the slurry entering the hole was assumed to be 18.9 L/s (300 gpm) with a 30 wt% solids, with a mean residence time in the hole of about 1.5 minutes. If the solids entering the hole have a plutonium concentration of 0.78 g Pu/L, then over 1.5 minutes the hole will contain 306.6 L of solids for a total mass plutonium of 239.1 g. Since the minimum critical mass of plutonium is 520 g in idealized plutonium-water conditions, the solids in the hole will be highly subcritical.

The impact of pulling the layer with the highest estimated plutonium concentration into the slurry pump and transferring it to Tank 241-AY-102 was

investigated. Tank 241-AY-102 currently contains some plutonium-bearing solids, but the solids from Tank 241-C-106 are expected to settle in a relatively flat slab across the top of these solids. This evaluation, which was based on the available data, input, and assumptions, did not identify a mechanism for concentrating or segregating plutonium particles into a concentration or geometry sufficient to allow a criticality accident. These results, together with the fact that the quantity of neutron absorber materials present in both tanks is over 10 times the amount necessary to preclude a criticality, establish a reasonable degree of assurance that a criticality will not occur.

3.4.2.1.2 Source Term Analysis. The postulated WRSS criticality accident is considered to be beyond extremely unlikely. Because the accident is considered beyond extremely unlikely, no source term analysis is performed.

3.4.2.1.3 Consequence Analysis. The postulated WRSS criticality accident is considered to be beyond extremely unlikely. Because the accident is considered beyond extremely unlikely, no consequence analysis is performed.

3.4.2.1.4 Comparison to Guidelines. Because the postulated WRSS criticality accident is considered to be beyond extremely unlikely, no comparison to guidelines is performed.

3.4.2.1.5 Summary of Safety Structures, Systems, and Components and Technical Safety Requirement Controls. Because the criticality accident is considered beyond extremely unlikely, no safety structures, systems, and components are required. A TSR control has been identified, however, to protect key assumptions made in the analysis (Table 3.4.2.1-1). These provide reasonable assurance that the waste will remain subcritical during WRSS operations. These criticality safety conclusions are supported by the following evaluations: WHC-SD-W320-SP-001, *Project W-320 Position Paper - Criticality Concern*, and WHC-SD-W320-CSA-001.

Table 3.4.2.1-1. Technical Safety Requirement Control for Nuclear Criticality Accident.

Control	Safety Function	Comments
Nuclear Criticality Safety Program Key Elements • Establish CPSs based on CSERs • Recovery actions if limits are exceeded • Criticality training program	Prevents the occurrence of a nuclear criticality	None

CPS = Criticality Prevention Specification.
CSER = Criticality Safety Evaluation Report.

3.4.2.2 High-Efficiency Particulate Air Filter Failure Due to Exposure to High Pressure or High Temperature. Active ventilation is maintained across single-shell Tank 241-C-106 and double-shell aging waste facility Tank 241-AY-102. Chapter 2.0 describes Tank 241-C-106 and Tank 241-AY-102 ventilation systems and facilities. Potential releases of radioactive and hazardous materials resulting from ventilation system failures are evaluated in the following sections. This differs from Section 5.3.2.2 of the main text of the BIO because the unit liter doses for the material at risk for the WRSS are larger.

In the following two sections, potential releases of radioactive and hazardous materials resulting from High-Efficiency Particulate Air (HEPA) filter failures are evaluated. Section 3.4.2.2.1 presents an accident analysis of HEPA filter failure caused by exposure to high temperatures. Section 3.4.2.2.2 presents a nonmechanistic consequence analysis of HEPA filter failure caused by exposure to high pressure. Section 3.4.2.3 presents the accident analysis for an unfiltered release.

3.4.2.2.1 HEPA Filter Failure - Exposure to High Temperature. High temperatures associated with an external fire (occurring in close proximity to the ventilation system) or the failure of an in-line heater (present in some ventilation systems) could degrade the ventilation system filters. If the integrity of the filters were compromised, the inventory on the filters could be released, followed by an unfiltered release from the tank vapor space if the exhaust fans continue to operate.

Scenario Development. The postulated scenario assumes that a fire occurs in or around a ventilation system, the heat from the fire degrades the filters, a fraction of the inventory of tank waste accumulated on HEPA filters and other ventilation system components is released, and an unfiltered release pathway is established. For actively ventilated systems, the exhaust fans continue to run. For one case, releases from the unfiltered pathway are assumed to continue for up to one year.

Table 3.4.2.2-1 includes the conversion factor for calculation of the one year dose. This duration is in contrast to other potential WRSS accidents that have relatively short-term durations (i.e., minutes or hours). The one-year unfiltered release consequences show the sensitivity of the analysis to assumptions regarding release duration, and were used in conjunction with 12- and 24-hour consequences to select the necessary and sufficient set of controls.

The event frequency for this high temperature accident scenario is anticipated ($> 10^{-2}$ yr^{-1} to $\leq 10^{0}$ yr^{-1}) based on the initiating event frequency for either a heater failure or an external fire. Heaters in the ventilation system have failed in the past, resulting in high temperatures in the exhaust air and some degradation of the filters. The failure of the heater to shut off could create an high temperature situation and cause the failure of the filters in the ventilation system. An external fire around the ventilation system would likely cause a filter degradation, as analyzed here. This event frequency is consistent with the analysis presented in Section 3.4.2.4 that evaluates the consequences of a fire in a contaminated area.

Source Term Analysis. The source term and the unit liter doses for the accident analysis are presented in Section 3.4.1. It is assumed that the contamination on the Tank 241-AY-102 ventilation system filters and in the Tank 241-AY-102 headspace air, during sluicing operations and afterwards, is composed of 90% liquids and 10% solids. The contamination on the Tank 241-C-106 filters and in the Tank 241-C-106 headspace air is composed of 67% liquids and 33% solids. For both tanks, the liquid portion of the aerosol is assumed to be a mix of 10% single-shell tank liquids and 90% aging waste facility liquids. The solid portion of the aerosol is assumed to be a mix of 90% single-shell tank solids and 10% aging waste facility solids. The aerosol in Tank 241-AY-102 has a unit liter dose equal to 3.9×10^{4} Sv/L (3.9×10^{6} rem/L). The aerosol in Tank 241-C-106 has a unit liter dose equal to 1.2×10^{5} Sv/L (1.2×10^{7} rem/L).

The material at risk on the HEPA filters was assumed to have a filter housing contact dose rate of less than or equal to 2 mSv/h (200 mrem/h). Because this is an assumption for filter loading, it requires a TSR control. This contact dose rate is based on operational history and bounds the contact dose rates historically used to replace HEPA filters in the tank farms. HNF-SD-WM-CN-099, *Radiological and Toxicological Analyses of Tank 241-AY-102 and Tank 241-C-106 Ventilation Systems*, uses the contact dose rate and conservative sluicing source term to back calculate the inventory on the filters.

The material at risk on the High-Efficiency Gas Adsorber (HEGA) in the 241-AZ-702 ventilation system is assumed to be 100% of the material that passes through the upstream HEPA filter. A TSR control is required to protect the HEGA filter loading assumption in the analysis. To limit the material that could potentially accumulate on the HEGA filter, it will be replaced before the upstream HEPA filter in the associated filter train has been replaced 20 times, or upon indication of degraded HEPA filter performance.

The High-Efficiency Mist Eliminator (HEME) and High-Efficiency Metal Filter (HEMF) on the 296-C-006 ventilation system were assumed to be flushed to limit the dose rate at the radiation detector to less than or equal to 1 mSv/h (100 mrem/h). The radiation detector is set to alarm at a dose rate of 0.2 mSv/h (20 mrem/h) for purposes of personnel radiation protection, independent of the accident analyses. Since the dose rate is an assumption for filter loading, it requires a TSR control. The HEME for the 241-AZ-702 ventilation system is located in a vault and is not subject to internal or external heat sources. The de-entrainers for the 241-AZ-702 and the 296-P-16 ventilation systems are located in caissons and are not subject to internal or external heat sources. Thus, the HEME and de-entrainers do not contribute to the source term for a high temperature or fire condition.

Based on information presented in DOE-HDBK-3010-94, *Airborne Release Fractions/Rates and Respirable Fractions for Non-reactor Nuclear Facilities*, the respirable release fraction for HEPA filters exposed to high temperature or fire is 1.0×10^{-4}. This release fraction is judged to be suitable for the HEME and HEMF for the 296-C-006 ventilation system. The HEGA contains activated carbon for the adsorption of gases in the tank ventilation airstream. It is assumed that 100% of the HEGA inventory may be released as respirable particulate in the event of a fire.

The unfiltered effective continuous release amount was based on the ventilation flow and calculated by multiplying the nominal volumetric flow rate by a partition factor to convert it to an equivalent outflow of radioactive contaminant. An "agitated tank" partition factor of 1.0×10^{-8} was used. The partition factor cited here is based on experiment results published in RHO-RE-SA-216, *Characterization of Airborne Radionuclide Particulates in Ventilated Liquid Waste Tanks*, for agitated (1.0×10^{-8}) and unagitated (1.0×10^{-10}) tanks under active and passive ventilation.

Consequence Analysis. Appropriate dispersion coefficients and breathing rates are applied to the release amounts to calculate the radiological consequences. These consequence calculations are presented in HNF-SD-WM-CN-099.

The total consequences of the HEPA filter failure event without controls are calculated by adding the consequences resulting from the amount of respirable material released during the HEPA filter failure and the subsequent continuous, unfiltered release following the filter failure. Consequences resulting from the unfiltered release pathway were calculated for 12 hours (onsite receptor) and 24 hours (offsite receptor).

Table 3.4.2.2-1 summarizes the onsite and offsite radiological and toxicological consequences, without controls for releases from failed ventilation system filters. The factor for determination of the one-year unfiltered release consequences is also shown in Table 3.4.2.2-1. The one-year consequences indicate the sensitivity of the analysis to assumptions regarding release duration. Table 3.4.2.2-2 presents the consequences with controls.

Comparison to Guidelines. Table 3.4.2.2-1 presents the radiological and toxicological consequences of the accident scenario without controls. The radiological onsite consequences are above the risk guidelines for each of the ventilation systems except for 296-P-16. Table 3.4.2.2-1 shows that, for the 24-hour unfiltered release, the offsite radiological risk guidelines are not exceeded. The onsite and offsite toxicological risk guidelines also are not exceeded. A control has been developed to lower the consequences of the onsite radiological dose. This TSR control requires the active ventilation to be shut off within 10 minutes of detecting an unfiltered release. The consequences summary in Table 3.4.2.2-2 shows that, in the case with controls, the onsite radiological dose is kept at or below the risk guideline. The offsite radiological dose is below the risk guidelines. Toxicological consequences are assumed to be related to peak concentration and the peak concentration occurs at filter failure, any reduction in unfiltered event duration has no effect on the calculated sum-of-fractions of the risk guidelines.

Summary of Safety Structures, Systems, and Components and Technical Safety Requirement Controls.

Safety Structures, Systems and Components. The radiological dose to the onsite receptor exceeds the risk guideline (see Table 3.4.2.2-1) for each system except the 296-P-16 ventilation system. The continuous air monitor interlocks that shut off the ventilation system within 10 minutes for each of

the ventilation systems on Tank 241-AY-102 and Tank 241-C-106 are selected as safety significant components. The continuous air monitor interlock was also identified as safety significant in Section 5.3.2.2 of the main text of the BIO.

Table 3.4.2.2-3 lists the safety structures, systems, and components selected to lower the consequences of HEPA filter failure. For each safety structure, system, and component the safety function is described and additional comments are provided as appropriate.

Technical Safety Requirement Controls. Table 3.4.2.2-4 lists the TSRs selected to lower the consequences of HEPA filter failure. The TSRs require the CAM to detect high radioactivity caused by HEPA filter failure and the interlock to shut down the ventilation system. The filter loading is protected by requiring periodic testing, monitoring, and filter change out criteria.

Defense-in-Depth. In addition to the identified safety structures, systems, and components and TSRs that are further described in Chapters 4.0 and 5.0, respectively, other engineering and administrative controls provide defense-in-depth protection for the public and workers against the risk of HEPA filter failure. The defense-in-depth controls are identified in Table 3.4.2.2-5. The function of the defense-in-depth controls and additional comments are also included in the table, as appropriate.

3.4.2.2.2 HEPA Filter Failure - Exposure to High Pressure. A pressure differential of 2.5 Kpa (0.36 lb/in^2 [10 in. water gauge]) can fail HEPA filters. Upon failure, the inventory on the filters could be released, followed by an unfiltered release from the tank vapor space. The purpose of this analysis is to provide a common set of reference values to be used in analyzing potential accidents that could raise tank pressures to greater than 2.5 Kpa. These accidents include the following: flammable gas deflagrations (Section 3.4.2.8), organic solvent fire (Section 3.4.2.9), in-tank fuel fire/deflagrations (Section 3.4.2.10), tank bump (Section 3.4.2.11) and liner breach in tank 241-C-106 (Section 3.4.2.12).

Scenario Development. An overpressurization event is postulated to occur within a waste tank. All filters in the ventilation system fail because of the pressure increase, a fraction of the inventory of tank waste accumulated on the filters plus the ventilation system ductwork is released, and an unfiltered release pathway is established. The exhaust fan continues to run, releasing aerosols from the tank headspace. The event frequency is based on the initiating event frequency (e.g., tank bump in-tank fuel fire, etc.). The frequencies associated with the initiating event are discussed in the accident analyses in the sections identified above.

Source Term Analysis. The source term and the unit liter doses for the accident analysis are presented in Section 3.4.1 and discussed in Section 3.4.2.2.1.

The dose rate on the HEME for the 241-AZ-702 ventilation system was assumed to be limited to 8 mSv/h (800 mrem/h). Since this dose rate is an assumption for filter loading, it requires a TSR control. The waste inventory
